DISCLAIMER
       Care has been taken to confirm the accuracy of the information present and to describe generally accepted practices. However, the authors, editors, and publisher are not responsible for errors or omissions or for any consequences from application of the information in this book and make no warranty, expressed or implied, with respect to the currency, completeness, or accuracy of the contents of the publication. Application of this information in a particular situation remains the professional responsibility of the practitioner; the clinical treatments described and recommended may not be considered absolute and universal recommendations.
       The authors, editors, and publisher have exerted every effort to ensure that drug selection and dosage set forth in this text are in accordance with the current recommendations and practice at the time of publication. However, in view of ongoing research, changes in government regulations, and the constant flow of information relating to drug therapy and drug reactions, the reader is urged to check the package insert for each drug for any change in indications and dosage and for added warnings and precautions. This is particularly important when the recommended agent is a new or infrequently employed drug.
       Some drugs and medical devices presented in this publication have Food and Drug Administration (FDA) clearance for limited use in restricted research settings. It is the responsibility of the health care provider to ascertain the FDA status of each drug or device planned for use in their clinical practice.
       To purchase additional copies of this book, call our customer service department at **(800) 638-3030** or fax orders to **(301) 223-2320**. International customers should call **(301) 223-2300**.
       Visit Lippincott Williams & Wilkins on the Internet: http://www.lww.com. Lippincott Williams & Wilkins customer service representatives are available from 8:30 a.m. to 6:00 p.m., EST.

Preface

This eighth edition of *Comprehensive Pharmacy Review* reflects the continuing evolution of pharmacy practice and educational requirements. The main objective of the book is to provide a comprehensive study guide for pharmacy students and other candidates who are preparing for the North American Pharmacist Licensure Examination (NAPLEX). This volume represents the contributions of more than 50 specialists who provide wide expertise in pharmaceutical science, pharmacy practice, and clinical pharmacy. Their contributions to *Comprehensive Pharmacy Review* assure that this review guide is accurate and current as well as written in a comprehensible manner for students, teachers, and practitioners alike. This review publication, along with the separate booklet of simulated NAPLEX exams (Comprehensive Pharmacy Review Practice Exams, 8th edition), provides both guidance and test practice for NAPLEX candidates.

The current pharmaceutical education provides greater career opportunities for pharmacists than ever before. Pharmaceutical education, including pharmaceutical science and practice, must prepare pharmacy practitioners for the future. Among the many career choices for pharmacists include work in academic pharmacy, community pharmacy, long-term care, and consulting pharmacy, including hospice and home care, pharmaceutical and health care distributors, pharmaceutical industry, professional trade organizations, uniformed (public health) services, federal and state governments, hospital and institutional practice settings, managed care pharmacy, and other settings. Moreover, pharmacists are actively involved in health care. Examples include counseling and medication therapy, disease state management, and screening programs such as diabetes, hypertension, and high cholesterol along with the more traditional role of dispensing medication and educating patients. Many students enroll in pharmaceutical education programs that are combined with a business (MBA), research (PhD), or law (JD) degree to provide opportunities in various pharmacy-related professions and other challenging fields.

Comprehensive Pharmacy Review is principally written for NAPLEX candidates. However, the book is also intended for a broader audience of pharmacy undergraduates and health professionals who seek detailed summaries of pharmacy subjects. A wide range of topics central to the study of pharmacy—chemistry, pharmaceutics, pharmacology, pharmacy practice, drug therapy—is organized to parallel the pharmacy curriculum and presented in outline form for easy use. The *Comprehensive Pharmacy Review* may be used as a quick review (or preview) of essential topics by a diverse group of readers, including

- **Matriculating pharmacy students.** The organization and topical coverage of *Comprehensive Pharmacy Review* are such that many pharmacy students will want to purchase it in their first professional year and use it throughout their pharmacy education to prepare for course examinations.
- **Instructors and preceptors.** *Comprehensive Pharmacy Review* also functions as an instructor's manual and a reference for teachers and tutors in pharmacy schools. Chapter outlines can be used to organize courses and to plan specific lectures.
- **Professional pharmacists.** *Comprehensive Pharmacy Review* offers practitioners a convenient handbook of pharmacy facts. It can be used as a course refresher and as a source of recent information on pharmacy practice. The appendices include prescription dispensing information, common prescription drugs, and general pharmacy references.
- **Foreign pharmacy graduates.** *Comprehensive Pharmacy Review* provides a source of current information on pharmaceutical science, pharmacy practice, and clinical pharmacy for foreign pharmacy graduates who may be candidates for the Foreign Pharmacy Graduate Equivalency Examination (FPGEE). The appendices include prescription dispensing information, common prescription drugs, and general pharmacy references.

WHAT'S NEW IN THIS EDITION

The continuing evolution of pharmacy practice is reflected by the licensure examinations developed by the National Association of Boards of Pharmacy (NABP) to assess the competence of pharmacy candidates. For this reason, we have requested and have been given permission by NABP to reproduce the competency statements for the NABP

examination (NAPLEX) in the front matter of this edition of *Comprehensive Pharmacy Review*.

Because of the significant advances in drug therapy since the publication of the last edition, this edition has been revised to reflect the current educational and competency requirements for a successful career in pharmacy. Many of the chapters have been revised to represent the latest understanding of disease and therapeutic management. New chapters, such as Pain Management Including Migraines, Hepatic Disorders, Pediatrics, Geriatrics, Women's Health have been added to reflect the needs of special populations. The addition of the chapter, Biostatistics and Medical Literature Evaluation provides a basis for the evaluation of new therapeutic moieties that will be marketed in the future.

ORGANIZATIONAL PHILOSOPHY AND CHAPTER STRUCTURE

The organization of the eight edition reflects the current undergraduate pharmacy curriculum. Pharmaceutical Sciences (Chapters 1–18), contains subject matter pertaining to the basic science of pharmacy. Pharmacy Practice (Chapters 19–64), contains subject matter for the practice of pharmacy with emphasis on pharmaceutical care. Each chapter of the book contains topic outlines and practice questions according to the pharmacy school curriculum.

At the front matter of this book, you'll find guidelines for taking a test and an introduction to the NAPLEX exam, including the actual NAPLEX blueprint. The appendices of this book are compilations of handy reference tables.

Contributors

S. Thomas Abraham, PhD
Associate Professor of Pharmacology and Toxicology
Department of Pharmaceutical Sciences
Campbell University College of Pharmacy and Health Sciences
Buies Creek, North Carolina

Michael L. Adams, PharmD, PhD
Assistant Professor of Medicinal Chemistry

Contents

Taking a Test

One of the least attractive aspects of pursuing an education is the necessity of being examined on the material that has been presented. Instructors do not like to prepare tests, and students do not like to take them.

However, students are required to take many examinations during their learning careers, and little, if any, time is spent acquainting them with the positive aspects of tests and with systematic and successful methods for approaching them. Students perceive tests as punitive and sometimes feel as if they were merely opportunities for the instructor to discover what the student has forgotten or has never learned. Students need to view tests as opportunities to display their knowledge and to use them as tools for developing prescriptions for further study and learning.

While preparing for any exam, class and board exams as well as practice exams, it is important that students learn as much as they can about the subject they will be tested and are prepared to discover just how much they may not know. Students should study to acquire knowledge, not just to prepare for tests. For the well-prepared student, the chances of passing far exceed the chances of failing.

MATERIALS NEEDED FOR TEST PREPARATION

In preparing for a test, most students collect far too much study material, only to find that they simply do not have time to go through all of it. They are defeated before they begin because either they cannot get through all the material, leaving areas unstudied, or they race through the material so quickly that they cannot benefit from the activity.

It is generally more efficient for the student to use materials already at hand—that is, class notes, one good outline to cover and strengthen all areas and to quickly review the whole topic, and one good text as a reference for complex material that requires further explanation.

Also, many students attempt to memorize far too much information, rather than learning and understanding less material and then relying on that learned information to determine the answers to questions at the time of the examination. Relying too heavily on memorized material causes anxiety, and the more anxious students become during a test, the less learned knowledge they are likely to use.

ATTITUDE AND APPROACH

A positive attitude and a realistic approach are essential to successful test taking. If the student concentrates on the negative aspects of tests or on the potential for failure, anxiety increases and performance decreases. A negative attitude generally develops if the student concentrates on "I must pass" rather than on "I can pass." "What if I fail?" becomes the major factor motivating the student to run from failure rather than toward success. This results from placing too much emphasis on scores. The score received is only one aspect of test performance. Test performance also indicates the student's ability to use differential reasoning.

In each question with five alternatives, of which one is correct, there are four alternatives that are incorrect. If deductive reasoning is used, the choices can be viewed as having possibilities of being correct. The elimination of wrong choices increases the odds that a student will be able to recognize the correct choice. Even if the correct choice does not become evident, the probability of guessing correctly increases. Eliminating incorrect choices on a test can result in choosing the correct answer.

Answering questions based on what is incorrect is difficult for many students because they have had nearly 20 years of experience taking tests with the implied assertion that knowledge can be displayed only by knowing what is correct. It must be remembered, however, that students can display knowledge by knowing something is wrong, just as they can display it by knowing something is right.

PREPARING FOR THE EXAMINATION

1. **Study for yourself.** Although some of the material may seem irrelevant, the more you learn now, the less you will have to learn later. Also, do not let the fear of the test rob you of an important part of your education. If you study to learn, the task is less distasteful than studying solely to pass a test.

2. **Review all areas.** You should not be selective by studying perceived weak areas and ignoring perceived strong areas. Cover all of the material, putting added emphasis on weak areas.

3. **Attempt to understand, not just to memorize, the material.** Ask yourself: To whom does the material apply? When does it apply? Where does it apply? How does it apply? Understanding the connections among these points allows for longer retention and aids in those situations when guessing strategies may be needed.

4. **Try to anticipate questions that might appear on the test.** Ask yourself how you might construct a question on a specific topic.

5. **Give yourself a couple days of rest before the test.** Studying up to the last moment will increase your anxiety and cause potential confusion.

TAKING THE EXAMINATION

1. Be sure to pace yourself to use the test time optimally. You should use all of your allotted time; if you finish too early, you probably did so by moving too quickly through the test.

2. Read each question and all the alternatives carefully before you begin to make decisions. Remember, the questions contain clues, as do the answer choices.

3. Read the directions for each question set carefully. You would be amazed at how many students make mistakes in tests simply because they have not paid close attention to the directions.

4. It is not advisable to leave blanks with the intention of coming back to answer questions later. If you feel that you must come back to a question, mark the best choice and place a note in the margin. Generally speaking, it is best not to change answers once you have made a decision. Your considered reaction and first response are correct more often than are changes made out of frustration or anxiety.

5. Do not let anxiety destroy your confidence. If you have prepared conscientiously, you know enough to pass. Use all that you have learned.

6. Do not try to determine how well you are doing as you proceed. You will not be able to make an objective assessment, and your anxiety will increase.

7. Do not become frustrated or angry about what appear to be bad or difficult questions. You simply do not know the answers; you cannot know everything.

SPECIFIC TEST-TAKING STRATEGIES

Read the entire question carefully, regardless of format. Test questions have multiple parts. Concentrate on picking out the pertinent key words that will help you problem-solve. Words such as *always, all, never, mostly, primarily*, and so forth play significant roles. In all types of questions, distractors with terms such as *always* or *never* most often are incorrect.

Adjectives and adverbs can completely change the meaning of questions—pay close attention to them. The knowledge and application of grammar often are key to dissecting questions.

MULTIPLE CHOICE QUESTIONS

Read the question and the choices carefully to become familiar with the data provided. Remember in multiple choice questions, there is one correct answer and there are four distractors, or incorrect answers. (Distractors are plausible and possibly correct, otherwise they would not be called distractors.) They are generally correct for part of the question but not for the entire question. Dissecting the question into parts helps eliminate distractors.

Many students think that they must always start at option A and make a decision before they move to option B, thus forcing decisions they are not ready to make. Your first decisions should be made on those choices you feel the most confident about.

Compare the choices with each part of the question. To be wrong, a choice needs to be incorrect for only part of the question. To be correct, it must be totally correct. If you believe a choice is partially incorrect, tentatively eliminate that choice. Make notes next to the choices regarding tentative decisions. One method is to place a minus sign next to the choices you are certain are incorrect and a plus sign next to those that potentially are correct. Finally, place a zero next to any choice you do not understand or need to come back to for further inspection. Do not feel that you must make final decisions until you have examined all choices carefully.

When you have eliminated as many choices as you can, decide which of those that remain has the highest probability of being correct. Above all, be honest with yourself. If you do not know the answer, eliminate as many choices as possible and choose reasonably.

Multiple choice questions are not as difficult as some students make them. There are two general types of multiple choice questions, including (1) the more traditional single answer type question in which the candidate must decide one of five choices (a, b, c, d, or e) and (2) the combined response ("K" type) multiple choice question, which is shown next. In this case, these are the questions for which you must select from the following choices:

A if **only I** is correct
B if **only III** is correct
C if **I and II** are correct
D if **II and III** are correct
E if **I, II, and III** are correct

Remember that the name for this type of question is *multiple true–false* and then use this concept. Become familiar with each choice and make notes. Then concentrate on the one choice you feel is definitely incorrect. If you can find one incorrect alternative, you can eliminate three choices immediately and be down to a 50–50 probability of guessing

the correct answer. If choice A is incorrect, so are choices C and E; if choice B is incorrect, so are choices D and E. Therefore, you are down to a 50–50 probability of guessing the correct answer.

After eliminating the choices you are sure are incorrect, concentrate on the choice that will make your final decision. For instance, if you discard choice I, you have eliminated alternatives A, C, and E. This leaves B (III) and D (II and III). Concentrate on choice II and decide if it is true or false. (Take the path of least resistance and concentrate on the smallest possible number of items while making a decision.) Obviously, if none of the choices is found to be incorrect, the answer is E (I, II, III).

GUESSING

Nothing takes the place of a firm knowledge base; but having little information to work with, you may find it necessary to guess at the correct answer. A few simple rules can help increase your guessing accuracy. Always guess consistently if you have no idea what is correct—that is, after eliminating all that you can, make the choice that agrees with your intuition or choose the option closest to the top of the list that has not been eliminated as a potential answer.

When guessing at questions that present with choices in numeric form, you will often find the choices listed in an ascending or descending order. It is generally not wise to guess the first or last alternative because these are usually extreme values and are most likely incorrect.

USING A PRACTICE EXAM TO LEARN

All too often, students do not take full advantage of practice exams. There is a tendency to complete the exam, score it, look up the correct answer to those questions missed, and then forget the entire thing.

In fact, great educational benefits could be derived if students would spend more time using practice tests as learning tools. As mentioned previously, incorrect choices in test questions are plausible and partially correct, otherwise they would not fulfill their purpose as distractors. This means that it is just as beneficial to look up the incorrect choices as the correct choices to discover specifically why they are incorrect. In this way, it is possible to learn better test-taking skills as the subtlety of question construction is uncovered.

In addition, it is advisable to go back and attempt to restructure each question to see if all the choices can be made correct by modifying the question. By doing this, you will learn four times as much. By all means, look up the right answer and explanation. Then, focus on each of the other choices, and ask yourself under what conditions, if any, they might be correct.

SUMMARY

Ideally, examinations are designed to determine how much material students have learned and how that material is used in the successful completion of the examination. Students will be successful if these suggestions are followed:

- Develop a positive attitude and maintain that attitude.
- Be realistic in determining the amount of material you attempt to master and in the score you hope to attain.
- Read the directions for each type of question and the questions themselves closely, and follow the directions carefully.
- Bring differential reasoning to each question in the examination.
- Guess intelligently and consistently when guessing strategies must be used.
- Use the test as an opportunity to display your knowledge and as a tool for developing prescriptions for further study and learning.

Board examinations are not easy. They may be almost impossible for those who have unrealistic expectations or for those who allow misinformation concerning the exams to produce anxiety out of proportion to the task at hand. Examinations are manageable if they are approached with a positive attitude and with consistent use of all of the information the student has learned.

Michael J. O'Donnell

Introduction to the NAPLEX

After graduation from an accredited pharmacy program, the prospective pharmacist must demonstrate the competency to practice pharmacy. The standards of competence for the practice of pharmacy are set by each state board of pharmacy. NAPLEX—The North American Pharmacist Licensure Examination—is the principal instrument used by the state board of pharmacy to assess the knowledge and proficiency necessary for a candidate to practice pharmacy. The National Association of Boards of Pharmacy (NABP) is an independent, international, and impartial association that assists member boards and jurisdictions in developing, implementing, and enforcing uniform standards for the purpose of protecting the public health. NABP develops examinations that enable boards of pharmacy to assess the competence of candidates seeking licensure to practice pharmacy. Each state board of pharmacy may impose additional examinations. The two major examinations developed by NABP are

- The North American Pharmacist Licensure Examination (NAPLEX)
- Multistate Pharmacy Jurisprudence Examination (MPJE)

Foreign pharmacy graduates must pass the Foreign Pharmacy Graduate Equivalency Examination (FPGEE) as part of the Foreign Pharmacy Graduate Equivalency Certification process. Foreign-educated pharmacists awarded FPGEC certification is considered to have partially fulfilled eligibility requirements for licensure in those states that accept the certification.

A description of these computerized examinations and registration information may be found on the NABP website online at http://www.nabp.net. Before submitting registration materials, the pharmacy candidate should contact the board of pharmacy for additional information regarding procedures, deadline dates, and required documentation.

The NAPLEX is a computer-adaptive test. These questions measure *the prospective pharmacist's ability to measure pharmacotherapy and therapeutic outcomes, prepare and dispense medications, and implement and evaluate information for optimal health care*. The computer adaptive exam tests a candidate's knowledge and ability by assessing the answers before presenting the next test question. If the answer is correct, the computer will select a more difficult question from the test item pool in an appropriate content area; if the answer is incorrect, an easier question will be selected by the computer. The NAPLEX score is based on the difficulty level of the questions answered correctly.

NAPLEX consists of 185 multiple choice test questions. In the past, 150 questions were used to calculate the test score. The remaining 35 items served as pretest questions and do not affect the NAPLEX score. Pretest questions are administered to evaluate the item's difficulty level for possible inclusion as a scored question in future exams. These pretest questions are dispersed throughout the exam and cannot be identified by the candidate.

A majority of the questions on the NAPLEX are asked in a scenario-based format (i.e., patient profiles with accompanying test questions). To properly analyze and answer the questions presented, the candidate must refer to the information provided in the patient profile. Some questions appear in a stand-alone format and should be answered solely from the information provided in the question.

NAPLEX Blueprint

THE NAPLEX COMPETENCY STATEMENTS

All NAPLEX questions are based on competency statements that are reviewed and revised periodically. The NAPLEX Competency Statements describe the knowledge, judgment, and skills that the candidate is expected to demonstrate as an entry-level pharmacist. A complete description of the NAPLEX Competency Statements is published on the NABP website and is reproduced, with permission of NABP. A strong understanding of the Competency Statements will aid in your preparation to take the examination.

Area 1 Assess Pharmacotherapy to Assure Safe and Effective Therapeutic Outcomes (Approximately 56% of Test)

- **1.1.0** Identify, interpret, and evaluate patient information to determine the presence of a disease or medical condition, assess the need for treatment and/or referral, and identify patient-specific factors that affect health, pharmacotherapy, and/or disease management.
- **1.1.1** Identify and assess patient information including medication, laboratory, and disease state histories.
- **1.1.2** Identify patient-specific assessment and diagnostic methods, instruments, and techniques and interpret their results.
- **1.1.3** Identify and define the etiology, terminology, signs, and symptoms associated with diseases and medical conditions and their causes and determine if medical referral is necessary.
- **1.1.4** Identify and evaluate patient genetic, biosocial factors, and concurrent drug therapy relevant to the maintenance of wellness and the prevention or treatment of a disease or medical condition.
- **1.2.0** Evaluate information about pharmacoeconomic factors, dosing regimen, dosage forms, delivery systems and routes of administration to identify and select optimal pharmacotherapeutic agents for patients.

- **1.2.1** Identify specific uses and indications for drug products and recommend drugs of choice for specific diseases or medical conditions.
- **1.2.2** Identify the chemical/pharmacologic classes of therapeutic agents and describe their known or postulated sites and mechanisms of action.
- **1.2.3** Evaluate drug therapy for the presence of pharmacotherapeutic duplications and interactions with other drugs, food, and diagnostic tests.
- **1.2.4** Identify and evaluate potential contraindications and provide information about warnings and precautions associated with a drug product's active and inactive ingredients.
- **1.2.5** Identify physicochemical properties of drug substances that affect their solubility, pharmacodynamic and pharmacokinetic properties, pharmacologic actions, and stability.
- **1.2.6** Evaluate and interpret pharmacodynamic and pharmacokinetic principles to calculate and determine appropriate drug dosing regimens.
- **1.2.7** Identify appropriate routes of administration, dosage forms, and pharmaceutical characteristics of drug dosage forms and delivery systems to assure bioavailability and enhance therapeutic efficacy.
- **1.3.0** Evaluate and manage drug regimens by monitoring and assessing the patient and/or patient information, collaborating with other health care professionals, and providing patient education to enhance safe, effective, and economic patient outcomes.
- **1.3.1** Identify pharmacotherapeutic outcomes and end points.
- **1.3.2** Evaluate patient signs and symptoms and the findings of monitoring tests and procedures to determine the safety and effectiveness of pharmacotherapy. Recommend needed follow-up evaluations or tests when appropriate.
- **1.3.3** Identify, describe, and provide information regarding the mechanism of adverse reactions, allergies, side effects, iatrogenic, and drug-induced illness, including their management and prevention.

- **1.3.4** Identify, prevent, and address methods to remedy medication nonadherence, misuse, or abuse.
- **1.3.5** Evaluate current drug regimens and recommend pharmacotherapeutic alternatives or modifications.

Area 2 Assess Safe and Accurate Preparation and Dispensing of Medications (Approximately 33% of Test)

- **2.1.0** Demonstrate the ability to perform calculations required to compound, dispense, and administer medication.
- **2.1.1** Calculate the quantity of medication to be compounded or dispensed; reduce and enlarge formulation quantities and calculate the quantity or ingredients needed to compound the proper amount of the preparation.
- **2.1.2** Calculate nutritional needs and the caloric content of nutrient sources.
- **2.1.3** Calculate the rate of drug administration.
- **2.1.4** Calculate or convert drug concentrations, ratio strengths, and/or extent of ionization.
- **2.2.0** Demonstrate the ability to select and dispense medications in a manner that promotes safe and effective use.
- **2.2.1** Identify drug products by their generic, brand, and/or common names.
- **2.2.2** Identify whether a particular drug dosage strength or dosage form is commercially available and whether it is available on a nonprescription basis.
- **2.2.3** Identify commercially available drug products by their characteristic physical attributes.
- **2.2.4** Assess pharmacokinetic parameters and quality assurance data to determine equivalence among manufactured drug products, and identify products for which documented evidence of inequivalence exists.
- **2.2.5** Identify and provide information regarding appropriate packaging, storage, handling, administration, and disposal of medications.
- **2.2.6** Identify and provide information regarding the appropriate use of equipment and apparatus required to administer medications.
- **2.3.0** Demonstrate the knowledge to prepare and compound extemporaneous preparations and sterile products.
- **2.3.1** Identify techniques, procedures, and equipment related to drug preparation, compounding, and quality assurance.
- **2.3.2** Identify the important physicochemical properties of a preparation's active and inactive ingredients.

- **2.3.3** Identify the mechanism of and evidence for the incompatibility or degradation of a product or preparation and methods for achieving its stability.

Area 3 Assess, Recommend, and Provide Health Care Information that Promotes Public Health (Approximately 11% of Test)

- **3.1.0** Identify, evaluate, and apply information to promote optimal health care.
- **3.1.1** Identify the typical content of specific sources of drug and health information for both health care providers and consumers, and recommend appropriate resources to address questions or needs.
- **3.1.2** Evaluate the suitability, accuracy, and reliability of clinical and pharmacoeconomic data by analyzing experimental design, statistical tests, interpreting results, and formulating conclusions.
- **3.2.0** Recommend and provide information to educate the public and health care professionals regarding medical conditions, wellness, dietary supplements, and medical devices.
- **3.2.1** Recommend and provide health care information regarding the prevention and treatment of diseases and medical conditions, including emergency patient care and vaccinations.
- **3.2.2** Recommend and provide health care information regarding nutrition, lifestyle, and other nondrug measures that promote health or prevent the progression of a disease or medical condition.
- **3.2.3** Recommend and provide information regarding the documented uses, adverse effects, and toxicities of dietary supplements.
- **3.2.4** Recommend and provide information regarding the selection, use, and care of medical/surgical appliances and devices, self-care products, and durable medical equipment, as well as products and techniques for self-monitoring of health status and medical conditions.

NABP offers candidates who are preparing for the NAPLEX—the Pre-NAPLEX, which is similar to the actual NAPLEX and allows candidates to gain experience in answering questions before examination day. The Pre-NAPLEX can be accessed via the Internet at the following website: http://www.nabp.net/prenaplex/. For foreign pharmacy graduates, the FPGEE Study Guide is available from NABP and includes information about the blueprint of the FPGEE, sample questions, and a list of textbooks commonly used in United States pharmacy schools.

Pharmaceutical Calculations

ROBERT B. GREENWOOD

I. FUNDAMENTALS OF MEASUREMENT AND CALCULATION.

The pharmacist is often required to perform or evaluate a variety of calculations. Many of these calculations involve the use of direct or inverse proportions. **Dimensional** (or **unit**) **analysis** and **approximation** can be useful in solving these problems. In dimensional analysis, dimensions (or units) are included with each number used in the calculation. Units common to the numerator and denominator may be canceled and the remaining units provide the units for the final answer. In approximation, each number used in the calculation is rounded to a single significant digit. Factors common to the numerator and denominator may be canceled, and the answer to this approximation should be reasonably close to the final exact answer.

A. Ratio and proportion

1. **Ratio**. The relative magnitude of two like quantities is a ratio, which is expressed as a fraction. Certain basic principles apply to the ratio, as they do to all fractions.

    a. When the two terms of a ratio are multiplied or divided by the same number, the value of the ratio is unchanged.

    $$\frac{1}{3} \times \frac{2}{2} = \frac{2}{6} = \frac{1}{3}$$

    b. Two ratios with the same value are equivalent. Equivalent ratios have equal cross products and equal reciprocals. For example:

    $$\frac{1}{3} = \frac{2}{6}$$

    and

    $$1 \times 6 = 3 \times 2 = 6$$

    If two ratios are equal, then their reciprocals are equal:

    $$\text{if } \frac{1}{3} = \frac{2}{6}, \text{ then } \frac{3}{1} = \frac{6}{2}$$

2. **Proportion**. The expression of the equality of two ratios is a proportion. The product of the extremes is equal to the product of the means for any proportion. The way to express this, from the example cited, would be 1:3 = 2:6, where the means are 3 and 2, and the extremes are 1 and 6. Furthermore, the numerator of the one fraction equals the product of its denominator and the other fraction (i.e., one missing term can always be found given the other three terms). Most pharmaceutical calculations can be performed by use of proportion.

    a. **Proper ratios**. Some pharmacists use proper ratios (in which similar units are used in the numerator and denominator of each ratio) in their proportion calculations. Several examples follow:

    (1) If 240 mL of a cough syrup contains 480 mg of dextromethorphan hydrobromide, then what mass of drug is contained in a child's dose, 1 teaspoon (5 mL) of syrup?

    $$\frac{240 \text{ mL}}{5 \text{ mL}} = \frac{480 \text{ mg}}{x \text{ mg}}$$

    $$x = \frac{480 \times 5}{240} = 10 \text{ mg}$$

(2) If a child's dose (5 mL) of a cough syrup contains 10 mg of dextromethorphan hydrobromide, what mass of drug is contained in 240 mL?

$$\frac{240 \text{ mL}}{5 \text{ mL}} = \frac{x \text{ mg}}{10 \text{ mg}}$$

$$x = \frac{240 \times 10}{5} = 480 \text{ mg}$$

(3) If the amount of dextromethorphan hydrobromide in 240 mL of cough syrup is 480 mg, what would be the volume required for a child's dose of 10 mg?

$$\frac{x \text{ mL}}{240 \text{ mL}} = \frac{10 \text{ mg}}{480 \text{ mg}}$$

$$x = \frac{10 \times 240}{480} = 5\text{mL}$$

(4) How many milligrams of dextromethorphan base (molecular weight = 271.4) are equivalent to 10 mg of dextromethorphan hydrobromide (molecular weight = 352.3)?

$$\frac{x \text{ mg}}{10 \text{ mg}} = \frac{271.4}{352.3}$$

$$x = 10 \times \frac{271.4}{352.3} = 7.7 \text{ mg}$$

b. **Mixed ratios**. Some pharmacists use mixed ratios (in which dissimilar units are used in the numerator and denominator of each ratio) in their proportion calculations. Such computations generally give correct answers, providing the conditions in which mixed ratios cannot be used are known. A later example shows mixed ratios leading to failure in the case of dilution, when inverse proportions are required. For **inverse proportions**, similar units must be used in the numerator and denominator of each ratio. Following is an example of a mixed ratio calculation using the previous problem.

$$\frac{480 \text{ mg}}{10 \text{ mL}} = \frac{240 \text{ mg}}{x \text{ mL}}$$

$$x = 240 \times \frac{10}{480} = 5 \text{ mL}$$

The **same answer** is obtained in this example whether we use proper ratios, with similar units in numerator and denominator, or mixed ratios. This is not the case when dealing with inverse proportions.

3. **Inverse proportion**. The most common example of the need for inverse proportion for the pharmacist is the case of **dilution**. Whereas in the previous examples of proportion the relationships involved direct proportion, the case of dilution calls for an inverse proportion (i.e., as volume increases, concentration decreases). The necessity of using inverse proportions for dilution problems is shown in this example.

If 120 mL of a 10% stock solution is diluted to 240 mL, what is the final concentration? Using inverse proportion,

$$\frac{120 \text{ mL}}{240 \text{ mL}} = \frac{x\%}{10\%}$$

$$120 \times \frac{10}{240} = 5\%$$

As expected, the final concentration is one-half of the original concentration because the volume is doubled. However, if the pharmacist attempts to use direct proportion and neglects to estimate an appropriate answer, the resulting calculation would provide an answer of 20%, which is twice the actual concentration.

$$\frac{120 \text{ mL}}{240 \text{ mL}} = \frac{10\%}{x\%}$$

$$240 \times \frac{10}{120} = 20\% \text{ (incorrect answer)}$$

Likewise, the pharmacist using mixed ratios fails in this case

$$\frac{120 \text{ mL}}{10\%} = \frac{240 \text{ mL}}{x\%}$$

and

$$10 \times \frac{240}{120} = 20\% \text{ (again, incorrect answer)}$$

B. **Aliquot**. A pharmacist requires the aliquot method of measurement when the **sensitivity** (the smallest quantity that can be measured with the required accuracy and precision) of the measuring device is not great enough for the required measurement. Aliquot calculations can be used for measurement of solids or liquids, allowing the pharmacist to realize the required precision through a process of measuring a multiple of the desired amount, followed by dilution, and finally selection and measurement of an aliquot part that contains the desired amount of material. This example problem involves weighing by the aliquot method, using a prescription balance.

A prescription balance has a sensitivity requirement of 6 mg. How would you weigh 10 mg of drug with an accuracy of $\pm$ 5% using a suitable diluent?

1. First, calculate the least weighable quantity for the balance with a sensitivity requirement of 6 mg, assuming $\pm$ 5% accuracy is required.

$$\frac{6 \text{ mg}}{x \text{ mg}} = \frac{5\%}{100\%}; x = 120 \text{ mg (least weighable quantity for our balance)}$$

2. Now it is obvious that an aliquot calculation is required because 10 mg of drug is required, whereas the least weighable quantity is 120 mg to achieve the required percentage of error. Using the least weighable quantity method of aliquot measurement, use the smallest quantity weighable on the balance at each step to preserve materials.
   a. Weigh 12×10 mg = 120 mg of drug.
   b. Dilute the 120 mg of drug (from step **a**) with a suitable diluent by geometrical dilution to achieve a mixture that will provide 10 mg of drug in each 120-mg aliquot. The amount of diluent to be used can be determined through **proportion**.

$$\frac{120 \text{ mg drug}}{10 \text{ mg drug}} = \frac{x \text{ mg total mixture}}{120 \text{ mg aliquot mixture}}$$

$$x = 1440 \text{ mg total mixture}$$

$$1440 \text{ mg total} - 120 \text{ mg drug} = 1320 \text{ mg diluent}$$

   c. Weigh 120 mg (1/12) of the total mixture of 1440 mg that will contain the required 10 mg of drug, which is 1/12 of the 120 mg.

II. SYSTEMS OF MEASURE. The pharmacist must be familiar with **three systems** of measure: the **metric system** and two common systems of measure (the **avoirdupois** and **apothecaries'** systems). The primary system of measure in pharmacy and medicine is the metric system. Most students find it easiest to convert measurements in the common systems to metric units. A table of conversion equivalents is provided and should be memorized by the pharmacist (see Appendix B). The metric system, because of its universal acceptance and broad use, will not be reviewed here.

A. **Apothecaries' system of fluid measure.** The apothecaries' system of fluid measure is summarized in Appendix B.

B. **Apothecaries' system for measuring weight.** The apothecaries' system for measuring weight includes units of grains, scruples, drams, ounces, and pounds (see Appendix B).

C. **Avoirdupois system of measuring weight.** The avoirdupois (AV) system of measuring weight includes the grain, ounce, and pound. The grain is a unit common with the apothecaries' system and allows for easy conversion between the systems. The avoirdupois pound, however, is 16 AV ounces in contrast to the apothecaries' pound that is 12 apothecaries' ounces (see Appendix B).

D. **Conversion equivalents.** See Appendix B.

III. REDUCING AND ENLARGING FORMULAS. The pharmacist is often required to reduce or enlarge a recipe. Problems of this type are solved through proportion or by multiplication or division by the appropriate factor to obtain the required amount of each ingredient that will give the desired total mass or volume of the formula. Formulas can be provided in amounts or in parts.

A. **Formulas that indicate parts.** When dealing with formulas that specify parts, parts by weight will require the determination of weights of ingredients, whereas parts by volume warrant the calculation of volumes of ingredients. Always find the total number of parts indicated in the formula and equate that total with the total mass or volume of the desired formula in order to set up a proportion. Such a proportion will allow calculation of the mass or volume of each ingredient in units common to the total mass or volume.

What quantities should be used to prepare 100 g of "Diaper paste" from the following formula?

R_x	mineral oil	6 parts
	nystatin powder	1 part
	hydrocortisone powder	2 parts
	zinc oxide ointment	200 parts

Label:	diaper paste, maximum 1 year expiration

Total number of parts = 200 + 2 + 1 + 6 = 209 parts
For each of the ingredients, the ratio is then set up, such as

$$\frac{6 \text{ parts}}{209 \text{ parts}} = \frac{x \text{ g}}{100 \text{ g}}, \text{ with } x = 2.87 \text{ g for mineral oil or}$$

$$\frac{1 \text{ part}}{209 \text{ parts}} = \frac{y \text{ g}}{100 \text{ g}}, \text{ with } y = 0.48 \text{ g for nystatin powder}$$

B. **Formulas that indicate quantities.** The following prescription for cold cream provides a 100-g quantity.

What mass of each ingredient is required to provide 1 lb (AV) of cream?

R_x	white wax	12.5 g
	mineral oil	60.0 g
	lanolin	2.5 g
	sodium borate	1.0 g
	rose water	24.0 g

1 lb = 454 g

$\frac{454}{100}$ = 4.54 (multiplication factor to use in calculating the quantities of each ingredient)

12.5 g × 4.54 = 56.8 g of white wax
60.0 g × 4.54 = 272 g of mineral oil
2.5 g × 4.54 = 11.4 g of lanolin
1.0 g × 4.54 = 4.54 g of sodium borate
24.0 g × 4.54 = 109 g of rose water

IV. CALCULATING DOSES. Calculation of doses generally can be performed with dimensional analysis. **Problems** encountered in the pharmacy include calculation of the number of doses, quantities in a dose or total mass/volume, amount of active or inactive ingredients, and size of dose. Calculation of **children's doses** is commonly performed by the pharmacist. Dosage is optimally calculated by using the child's body weight or mass and the appropriate dose in milligrams per kilogram (mg/kg). Without these data, the following formulas based on an adult dose can be used.

A. **Fried's rule for infants**

$$\frac{\text{age (in months)} \times \text{adult dose}}{150} = \text{dose for infant}$$

B. Clark's rule

$$\frac{\text{weight (lb)} \times \text{adult dose}}{150 \text{ lb (avg wt of adult)}} = \text{dose for child}$$

C. Child's dosage based on body surface area (BSA)

$$\frac{\text{BSA of child (m}^2) \times \text{adult dose}}{1.73 \text{ m}^2 \text{ (avg adult BSA)}} = \text{approximate dose for child}$$

D. Young's rule for children 2 years old or older

$$\frac{\text{age (in years)}}{\text{age (in years)} + 12} \times \text{adult dose} = \text{dose for child}$$

E. Constant rate intravenous infusions. Some drugs are administered intravenously at a constant (zero-order) rate by using a continuous-drip infusion set or a constant-rate infusion pump. The flow rate (volume per unit time) required can be calculated from the volume to be administered and the duration of the infusion. The rate of drug administration can be calculated from the concentration of drug in the infused solution and the flow rate of the infusion set or pump. Conversion factors may be required to obtain the final answer in the correct units (drops per minute or milliliters per hour).

A vancomycin solution containing 1000 mg of vancomycin hydrochloride diluted to 250 mL with D_5W is to be infused at a constant rate with a continuous-drip intravenous infusion set that delivers 25 drops/mL. **What flow rate (drops per minute) should be used to infuse all 250 mL of the vancomycin hydrochloride solution in 2 hrs?**

$$\frac{250 \text{ mL}}{2 \text{ hrs}} \times \frac{1 \text{ hr}}{60 \text{ mins}} \times \frac{25 \text{ drops}}{1 \text{ mL}} = 52 \text{ drops/min}$$

V. PERCENTAGE, RATIO STRENGTH, AND OTHER CONCENTRATION EXPRESSIONS

A. Percentage weight in volume (w/v)

1. **Definition.** Percentage, indicating parts per hundred, is an important means of expressing concentration in pharmacy practice. Percentage w/v indicates the number of grams of a constituent per 100 mL of solution or liquid formulation. The pharmacist may be required to perform **three types** of calculations: determine the **weight** of active ingredient in a certain volume when given the percentage strength, determine the **percentage w/v** when the weight of substance and volume of liquid formulation are known, and determine the **volume** of liquid mixture when the percentage strength and amount of substance are known.

2. **Tolu balsam syrup (from the National Formulary).** Tolu balsam tincture contains 20% w/v tolu balsam.

   What is the percentage concentration of tolu balsam in the syrup from the formula shown in the following?

tolu balsam tincture	50 mL
magnesium carbonate	10 g
sucrose	820 g
purified water, q.s. a.d.	1000 mL

   a. First, determine what the amount of tolu balsam is contained in the 50 mL quantity of tincture used for the syrup. Then, by proportion, calculate the concentration of tolu balsam in the syrup.

   $$\text{tolu balsam tincture} = 50 \text{ mL} \times \frac{20 \text{ g}}{100 \text{ mL}} = 10 \text{ g tolu balsam}$$

   $$\frac{10 \text{ g}}{1000 \text{ mL}} = \frac{x \text{ g}}{100 \text{ mL}} ; x = \frac{1 \text{ g}}{100 \text{ mL}} = 1\% \text{ tolu balsam in the syrup}$$

In answering this one question, the first two types of problems listed beforehand have been solved, while exhibiting two methods of solving percentage problems—namely, by **dimensional analysis** and **proportion**.

b. For an example of the **third type** of percentage w/v problem, determine what volume of syrup could be prepared if we had only 8 g of magnesium carbonate. Use proportion to find the total volume of syrup that can be made using only 8 g of magnesium carbonate. If we have 10 g of magnesium carbonate in 1000 mL of solution, then, according to the recipe, 800 mL of solution can be prepared using all 8 g of the drug.

$$\frac{10 \text{ g}}{1000 \text{ mL}} = \frac{8 \text{ g}}{x \text{ mL}}; x = 800 \text{ mL}$$

B. Percentage volume in volume (v/v). Percentage v/v indicates the number of milliliters of a constituent in 100 mL of liquid formulation. The percentage strength of mixtures of liquids in liquids is indicated by percentage v/v, which indicates the parts by volume of a substance in 100 parts of the liquid preparation. The **three types** of problems that are encountered involve calculating **percentage strength**, calculating **volume of ingredient**, and calculating **volume of the liquid preparation**. Using the same tolu balsam syrup formula from earlier, we'll now work a percentage v/v problem.

What is the percentage strength v/v of the tolu balsam tincture in the syrup preparation? By proportion, we can solve the problem in one step.

$$\frac{50 \text{ mL tolu balsam tincture}}{x \text{ mL tolu balsam tincture}} = \frac{1000 \text{ mL syrup}}{100 \text{ mL syrup}}; x = 5\%$$

C. Percentage weight in weight (w/w). Percentage w/w indicates the number of grams of a constituent per 100 g of formulation (solid or liquid). Solution of problems involving percentage w/w is straightforward when the total mass of the mixture is available or when the total mass can be determined from the available data. In calculations similar to those for percentage w/v and v/v, the pharmacist might need to solve several types of problems, including determination of the weight of a constituent, the total weight of a mixture, or the percentage w/w.

1. How many grams of drug substance should be used to prepare 240 g of a 5% w/w solution in water?

a. The first step in any percentage w/w problem is to attempt identification of the total mass of the mixture. In this problem, the total mass is, obviously, provided (240 g).

b. The problem can be easily solved through **dimensional analysis**.

$$240 \text{ g mixture} \times \frac{5.0 \text{ g drug}}{100 \text{ g drug}} = 12 \text{ g}$$

2. When the total mass of the mixture is unavailable or cannot be determined, an **extra step** is required in the calculations. Because it is usually impossible to know how much volume is displaced by a solid material, the pharmacist is unable to prepare a specified volume of a solution given the percentage w/w.

How much drug should be added to 30 mL of water to make a 10% w/w solution? The volume of water that is displaced by the drug is unknown, so the final volume is unknown. Likewise, even though the mass of solvent is known (30 mL × 1 g/mL = 30 g), it is not known how much drug is needed, so the total mass is unknown. The water represents 100% − 10% = 90% of the total mixture. Then, by proportion, the mass of drug to be used can be identified.

$$\frac{30 \text{ g of mixture (water)}}{x \text{ g of mixture (drug)}} = \frac{90\%}{10\%}; x = 3.33 \text{ g of drug required to make a solution}$$

The **common error** that many students make in solving problems of this type is to assume that 30 g is the total mass of the mixture. Solving the problem with that assumption gives the following incorrect answer.

$$\frac{x \text{ g drug}}{10 \text{ g drug}} = \frac{30 \text{ g mixture}}{100 \text{ g mixture}}; x = 3 \text{ g of drug (incorrect answer)}$$

D. Ratio strength. Solid or liquid formulations that contain low concentrations of active ingredients will often have concentration expressed in **ratio strength**. Ratio strength, as the name implies, is the

expression of concentration by means of a ratio. The numerator and denominator of the ratio indicate grams (g) or milliliters (mL) of a solid or liquid constituent in the total mass (g) or volume (mL) of a solid or liquid preparation. Because **percentage strength** is essentially a ratio of parts per hundred, conversion between ratio strength and percentage strength is easily accomplished by proportion.

1. **Express 0.1% w/v as a ratio strength.**
   a. Ratio strengths are by convention expressed in reduced form, so in setting up our proportion to solve for ratio strength, use the numeral 1 in the numerator of the right-hand ratio as shown:

   $$\frac{0.1 \text{ g}}{100 \text{ mL}} = \frac{1 \text{ part}}{x \text{ parts}}; = 1000 \text{ parts, for ratio strength of 1:1000}$$

   b. Likewise, conversion from ratio strength to percentage strength by proportion is easy, as seen in the following example. Keep in mind the definition of percentage strength (parts per hundred) when setting up the proportion.

2. **Express 1:2500 as a percentage strength.**

   $$\frac{1 \text{ part}}{2500 \text{ parts}} = \frac{x \text{ parts}}{100 \text{ parts}}; x = 0.04, \text{ indicating } 0.04\%$$

E. **Other concentration expressions**
   1. **Molarity** (M) is the expression of the number of moles of solute dissolved per liter of solution. It is calculated by dividing the moles of solute by the volume of solution in liters.

   $$M_A = \frac{n_A}{\text{solution (L)}}$$

   2. **Normality.** A convenient way of dealing with acids, bases, and electrolytes involves the use of equivalents. One equivalent of an acid is the quantity of that acid that supplies or donates 1 mole of H^+ ions. One equivalent of a base is the quantity that furnishes 1 mole of OH^- ions. One equivalent of acid reacts with one equivalent of base. Equivalent weight can be calculated for atoms or molecules.

   $$\text{Equivalent weight} = \frac{\text{atomic weight or molecular weight}}{\text{valence}}$$

   The **normality** (N) of a solution is the number of gram-equivalent weights (equivalents) of solute per liter of solution. Normality is analogous to molarity; however, it is defined in terms of equivalents rather than moles.

   $$\text{Normality} = \frac{\text{\# equivalents of solute}}{\text{\# liters of solution}}$$

   3. **Molality** (m) is the moles of solute dissolved per kilogram of solvent. Molality is calculated by dividing the number of moles of solute by the number of kilograms of solvent. Molality offers an advantage over molarity because it is based on solvent weight and avoids problems associated with volume expansion or contraction owing to the addition of solutes or from a change in temperature.

   $$m_A = \frac{n_A}{\text{mass}_{\text{solvent (kg)}}}$$

   4. **Mole fraction** (X) is the ratio of the number of moles of one component to the total moles of a mixture or solution.

   $$X_A = \frac{n_A}{n_A, n_B, n_C \ldots}, \text{ where } X_A + X_B + X_C + \ldots = 1$$

VI. DILUTION AND CONCENTRATION.
If the amount of drug remains constant in a dilution or concentration, then any change in the mass or volume of a mixture is inversely proportional to the concentration.

A. **Dilution and concentration problems can be solved by the following:**
   1. Inverse proportion (as mentioned earlier)
   2. The equation quantity$_1$ × concentration$_1$ = quantity$_2$ × concentration$_2$

3. Determining the amount of active ingredient present in the initial mixture and, with the assumption that the initial quantity does not change, calculating the final concentration of the new total mass or volume
4. **Alligation medial.** A method for calculating the average concentration of a mixture of two or more substances
5. **Alligation alternate.** A method for calculating the number of parts of two or more components of known concentration to be mixed when the final desired concentration is known

B. **Dilution of alcohols and acids**
   1. **Dilution of alcohols.** When alcohol and water are mixed, a contraction of volume occurs. As a result, the final volume of solution cannot be determined accurately, nor can the volume of water needed to dilute to a certain percentage v/v be identified. Accordingly, percentage w/w is often used for solutions of alcohol.
   2. The **percentage strength** of concentrated acids is expressed as percentage w/w. The concentration of diluted acids is expressed as percentage w/v. Determining the volume of concentrated acid to be used in preparing a diluted acid requires the specific gravity of the concentrated acid.

C. **Dilution and concentration of liquids and solids.** Dilution and concentration problems are solved by identifying the amount of drug involved followed by use of an appropriate proportion.
   1. **How many milliliters of a 1:50 stock solution of ephedrine sulfate should be used in compounding the following prescription?**

   <div align="center">

Rx	ephedrine sulfate	0.25%
	rose water, a.d.	30 mL

   </div>

   $$\frac{0.25 \text{ g}}{100 \text{ mL}} \times 30 \text{ mL} = 0.075 \text{ g drug required}$$

   $$\frac{50 \text{ mL}}{1 \text{ g}} = \frac{x \text{ mL}}{0.075 \text{ g}};$$

   $$x = 3.75 \text{ mL of stock solution required for prescription}$$

   2. **How many milliliters of a 15% w/v concentrate of benzalkonium chloride should be used in preparing 300 mL of a stock solution such that 15 mL diluted to 1 L will yield a 1:5000 solution?**
      a. First, determine the amount of drug in 1 L of a 1:5000 solution.

      $$\frac{5000 \text{ mL}}{1000 \text{ mL}} = \frac{1 \text{ g}}{x \text{ g}}; = 0.2 \text{ g of benzalkonium chloride in the final solution}$$

      b. Now, because 15 mL of the stock solution is being diluted to 1 L, a stock solution is needed in which 15 mL contain 0.2 g of drug. The amount of drug required to make 300 mL of the stock solution is found by proportion.

      $$\frac{0.2 \text{ g}}{x \text{ g}} = \frac{15 \text{ mL}}{300 \text{ mL}}; x = 4 \text{ g of drug required to make 300 mL of solution}$$

      c. Finally, to determine the amount of 15% concentrate required.

      $$\frac{15 \text{ g}}{4 \text{ g}} \times \frac{100 \text{ mL}}{x \text{ mL}}; x = 26.7 \text{ mL of 15% solution required to obtain necessary drug}$$

   3. When the relative amount of components must be determined for preparation of a mixture of a desired concentration, the problem can be solved using alligation alternate.

   How many grams of 2.5% hydrocortisone cream should be mixed with 360 g of 0.25% cream to make a 1% hydrocortisone cream?

2.5%		0.75 parts of 2.5% cream	= 1 part	0.75/2.25 = 1/3
	1%	1.5 parts of 0.25% cream	= 2 parts	
0.25%		2.25 parts total	= 3 parts	1.5/2.25 = 2/3

   The relative amounts of the 2.5% and 1% creams are 1 to 2, respectively. By proportion, the mass of 2.5% cream to use can be determined. **If 2 parts of 0.25% cream is represented by 360 g, then the total mass (3 parts) is represented by what mass?**

$$\frac{2 \text{ parts}}{3 \text{ parts}} = \frac{360 \text{ g}}{x \text{ g}}; x = 540 \text{ g total}$$

With the total mass known, the amount of 2.5% cream can be identified. If 3 parts represent the total mass of 540 g, then 1 part represents the mass of 2.5% cream ($x \text{ g} = 180 \text{ g}$).

$$\frac{1 \text{ part}}{3 \text{ parts}} = \frac{x \text{ g}}{540 \text{ g}}; x = 180 \text{ g of 2.5% cream}$$

VII. ELECTROLYTE SOLUTIONS.
Electrolyte solutions contain species (electrolytes) that dissociate into ions. The **milliequivalent** (mEq) is the unit most frequently used to express the concentration of electrolytes in solution. *Table 1-1* exhibits some physiologically important ions and their properties.

A. **Milliequivalents.** The milliequivalent is the amount, in milligrams, of a solute equal to 1/1000 of its gram-equivalent weight. Conversion of concentrations in the form of milliequivalent to concentrations in percentage strength, milligrams per milliliter (mg/mL) or any other terms, begins with calculation of the number of milliequivalents of drug. The following examples demonstrate the computation of milliequivalents and manipulation of data from *Table 1-1* to perform the required calculations for preparing electrolyte solutions.

What is the concentration, in percent w/v, of a solution containing 2 mEq of potassium chloride per milliliter?

Calculations involving milliequivalents are easily solved if the practitioner follows a predefined procedure to determine the milliequivalent weight. This involves three steps.

1. Find the molecular weight (mol wt).

$$\text{Atomic wt K} = 39$$
$$\text{Atomic wt Cl} = 35.5$$
$$39 + 35.5 = 74.5 \text{ g} = \text{mol wt of KCl}$$

| Table 1-1 | VALENCES, ATOMIC WEIGHTS, AND MILLIEQUIVALENT WEIGHTS OF SELECTED IONS |

Ion	Formula	Valence	Atomic/Formula Weight	Milliequivalent Weight (mg)
Aluminum	Al^{+++}	3	27	9
Ammonium	NH_4^+	1	18	18
Calcium	Ca^{++}	2	40	20
Ferric	Fe^{+++}	3	56	18.7
Ferrous	Fe^{++}	2	56	28
Lithium	Li^+	1	7	7
Magnesium	Mg^{++}	2	24	12
Bicarbonate	HCO_3^-	1	61	61
Carbonate	CO_3^-	1	60	30
Chloride	Cl^-	1	35.5	35.5
Citrate	$C_6H_5O_7^{---}$	3	189	63
Gluconate	$C_6H_{11}O_7^-$	1	195	195
Lactate	$C_3H_5O_3^-$	1	89	89
Phosphate	$H_2PO_4^-$	1	97	97
Sulfate	SO_4^{--}	2	96	48
Potassium	K^+	1	29	39
Sodium	Na^+	1	23	23
Acetate	$C_2H_3O_2^-$	1	59	59

2. Calculate the equivalent weight (Eq wt) of KCl.

$$\text{Eq wt} = \frac{\text{mol wt}}{\text{valence}} = \frac{74.5}{1} = 74.5 \text{ g}$$

3. Determine the milliequivalent weight, which is 1/1000 of the equivalent weight.

$$\text{mEq wt} = 74.5 \text{ g}/1000 = 0.745 \text{ g or } 74.5 \text{ mg}$$

Now that we know the milliequivalent weight, we can calculate by dimensional analysis and proportion the concentration in percentage in a fourth step.

4. 0.0745 g/mEq × 2 mEq = 0.149 g of drug

$$\frac{0.149 \text{ g drug}}{1 \text{ mL}} = \frac{x \text{ g drug}}{100 \text{ mL}}; x = 14.9 \text{ g}/100 \text{ mL} = 14.9\%$$

How many milliequivalents of Na$^+$ would be contained in a 15-mL volume of the following buffer?

Na$_2$HPO$_4$·7H$_2$O		180 g
NaH$_2$PO$_4$·H$_2$O		480 g
Purified water	a.d.	1000 mL

For each salt, the mass (and milliequivalents) must be found in a 15-mL dose.

$$\text{mol wt Na}_2\text{HPO}_4\text{·7H}_2\text{O (disodium hydrogen phosphate)} = 268 \text{ g}$$
$$\text{Eq wt} = 268/2 = 134 \text{ g}$$
$$1 \text{ mEq} = 0.134 \text{ g or } 134 \text{ mg}$$

$$\frac{180 \text{ g}}{x \text{ g}} = \frac{1000 \text{ mL}}{15 \text{ mL}}; x = 2.7 \text{ g of disodium hydrogen phosphate in each 15 mL}$$

$$2.7 \text{ g} \times \frac{1 \text{ mEq}}{0.134 \text{ g}} = 20.1 \text{ mEq of disodium hydrogen phosphate}$$

$$\text{mol wt NaH}_2\text{PO}_4\text{·H}_2\text{O (sodium biphosphate)} = 138 \text{ g}$$
$$\text{Eq wt} = 138 \text{ g}$$
$$1 \text{ mEq} = 0.138 \text{ g}$$

$$\frac{480 \text{ g}}{x \text{ g}} = \frac{1000 \text{ mL}}{15 \text{ mL}}; x = 7.2 \text{ g of sodium biphosphate in each 15 mL}$$

$$7.2 \text{ g} \times \frac{1 \text{ mEq}}{0.138 \text{ g}} = 52.2 \text{ mEq of sodium biphosphate}$$

$$20.1 \text{ mEq} + 52.2 \text{ mEq} = 72.3 \text{ mEq of sodium in each 15 mL of solution}$$

B. Milliosmoles (mOsmol). Osmotic pressure is directly proportional to the total number of particles in solution. The milliosmole is the unit of measure for osmotic concentration. For nonelectrolytes, 1 millimole represents 1 mOsmol. However, for electrolytes, the total number of particles in a solution is determined by the number of particles produced in a solution and influenced by the degree of dissociation. Assuming complete dissociation, 1 millimole of KCl represents 2 mOsmol of total particles, 1 millimole of CaCl$_2$ represents 3 mOsmol of total particles, etc. The ideal osmolar concentration can be calculated with the following equation.

$$\text{mOsmol/L} = \frac{\text{wt of substance in g/L}}{\text{mol wt in g}} \times \text{number of species} \times 1000$$

The pharmacist should recognize the difference between **ideal** osmolar concentration and **actual** osmolarity. As the concentration of solute increases, interaction between dissolved particles increases, resulting in a reduction of the actual osmolar values.

C. Isotonic solutions. An **isotonic** solution is one that has the same osmotic pressure as body fluids. **Isosmotic** fluids are fluids with the same osmotic pressure. Solutions to be administered to

patients should be isosmotic with body fluids. A **hypotonic** solution is one with a lower osmotic pressure than body fluids, whereas a **hypertonic** solution has an osmotic pressure that is greater than body fluids.

1. **Preparation of isotonic solutions.** Colligative properties, including freezing point depression, are representative of the number of particles in a solution and are considered in preparation of isotonic solutions.

    a. When 1 g mol wt of any nonelectrolyte is dissolved in 1000 g of water, the freezing point of the solution is depressed by 1.86°C. By proportion, the weight of any nonelectrolyte needed to make the solution isotonic with body fluid can be calculated.

    b. Boric acid (H_3BO_3) has a mol wt of 61.8 g. Thus, 61.8 g of H_3BO_3 in 1000 g of water should produce a freezing point of 1.86°C. Therefore, knowing that the freezing point depression of body fluids is −0.52°C,

$$\frac{-1.86°C}{-0.52°C} = \frac{61.8 \text{ g}}{x \text{ g}}; x = 17.3 \text{ g}$$

    and 17.3 g of H_3BO_3 in 1000 g of water provides a solution that is **isotonic**.

    c. The degree of dissociation of electrolytes must be taken into account in such calculations. For example, NaCl is approximately 80% dissociated in weak solutions, yielding 180 particles in a solution for each 100 molecules of NaCl. Therefore,

$$\frac{-1.86°C \times 1.8}{-0.52°C} = \frac{58 \text{ g}}{x \text{ g}}; x = 9.09 \text{ g}$$

    indicating that 9.09 g of NaCl in 1000 g of water (0.9% w/v) should make a solution isotonic. Lacking any information on the degree of dissociation of an electrolyte, the following **dissociation values** (i) may be used:

    (1) Substances that dissociate into two ions: 1.8

    (2) Substances that dissociate into three ions: 2.6

    (3) Substances that dissociate into four ions: 3.4

    (4) Substances that dissociate into five ions: 4.2

2. **Sodium chloride equivalents.** The pharmacist will often be required to prepare an isotonic solution by adding an appropriate amount of another substance (drug or inert electrolyte or nonelectrolyte). Considering that isotonic fluids contain the equivalent of 0.9% NaCl, the question arises, how much of the added ingredient is required to make the solution isotonic? A **common method** for computing the amount of added ingredient to use for reaching isotonicity involves the use of **sodium chloride equivalents**.

    a. **Definition.** The sodium chloride equivalent represents the amount of NaCl that is equivalent to the amount of particular drug in question. For every substance, there is one quantity that should have a constant tonic effect when dissolved in 1000 g of water. This is 1 g mol wt of the substance divided by its dissociation value (i).

    b. **Examples**

    (1) Considering H_3BO_3, from the last section, 17.3 g of H_3BO_3 is equivalent to 0.52 g of NaCl in tonicity. Therefore, the relative quantity of NaCl that is equivalent to H_3BO_3 in tonicity effects is determined as follows:

$$\frac{\text{mol wt of NaCl}/i \text{ value}}{\text{mol wt of } H_3BO_3/i \text{ value}} = \frac{58.5/1.8}{61.8/1.0}$$

    Applying this method to atropine sulfate, recall that the molecular weight of NaCl and the molecular weight of atropine sulfate are 58.5 and 695 g, respectively, and their i values are 1.8 and 2.6, respectively. Calculate the mass of NaCl represented by 1 g of atropine sulfate (*Table 1-2*).

$$\frac{695 \times 1.8}{58.5 \times 2.6} = \frac{1 \text{ g}}{x \text{ g}}; x = 0.12 \text{ g NaCl represented by 1 g of atropine sulfate}$$

Table 1-2	SODIUM CHLORIDE (NaCl) EQUIVALENTS

Substance	NaCl Equivalent
Atropine sulfate (H_2O)	0.12
Boric acid	0.52
Chlorobutanol	0.24
Dextrose (anhydrous)	0.18
Ephedrine hydrochloride	0.29
Phenacaine hydrochloride	0.20
Potassium chloride	0.78

(2) An example of the practical use of sodium chloride equivalents is seen in the following problem:

How many grams of boric acid should be used in compounding the following prescription?

Rx	phenacaine hydrochloride	1%
	chlorobutanol	0.5%
	boric acid	q.s.
	purified water, a.d.	60.0 mL
	make isotonic solution	

The prescription calls for 0.3 g of chlorobutanol and 0.6 g of phenacaine. How much boric acid is required to prepare this prescription? The question is best answered in four steps:

(a) Find the mass of sodium chloride represented by all ingredients.

$0.20 \times 0.6 = 0.120$ g of sodium choloride represented by phenacaine hydrochloride

$0.24 \times 0.3 = \underline{0.072}$ g of sodium chloride represented by chlorobutanol

0.192 g of sodium chloride represented by the two active ingredients

(b) Find the mass of sodium chloride required to prepare an equal volume of isotonic solution.

$$\frac{0.9 \text{ g NaCl}}{100 \text{ mL}} = \frac{x \text{ g NaCL}}{60 \text{ mL}}; x = 0.540 \text{ g of sodium chloride}$$

in 60 mL of an isotonic sodium chloride solution

(c) Calculate, by subtraction, the amount of NaCl required to make the solution isotonic.

0.540 g NaCl required for isotonicity

$\underline{0.192}$ g NaCl represented by ingredients

0.348 g NaCl required to make isotonic solution

(d) Because the prescription calls for boric acid to be used, one last step is required

$$\frac{0.348 \text{ g}}{0.52} \text{ (sodium chloride equivalent for boric acid)} = 0.669 \text{ g of boric acid}$$
to be used

Study Questions

Directions for questions 1–30: Each question, statement, or incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. If a vitamin solution contains 0.5 mg of fluoride ion in each milliliter, then how many milligrams of fluoride ion would be provided by a dropper that delivers 0.6 mL?

   (A) 0.30 mg
   (B) 0.10 mg
   (C) 1.00 mg
   (D) 0.83 mg

2. How many chloramphenicol capsules, each containing 250 mg, are needed to provide 25 mg/kg/d for 7 days for a person weighing 200 lb?

   (A) 90 capsules
   (B) 64 capsules
   (C) 13 capsules
   (D) 25 capsules

3. If 3.17 kg of a drug is used to make 50000 tablets, how many milligrams will 30 tablets contain?

   (A) 1.9 mg
   (B) 1900 mg
   (C) 0.0019 mg
   (D) 3.2 mg

4. A capsule contains ⅛ gr of ephedrine sulfate, ¼ gr of theophylline, and ¹⁄₁₆ gr of phenobarbital. What is the total mass of the active ingredients in milligrams?

   (A) 20 mg
   (B) 8 mg
   (C) 28 mg
   (D) 4 mg

5. If 1 fluid ounce of a cough syrup contains 10 gr of sodium citrate, how many milligrams are contained in 10 mL?

   (A) 650 mg
   (B) 65 mg
   (C) 217 mg
   (D) 20 mg

6. How many capsules, each containing ¼ gr of phenobarbital, can be manufactured if a bottle containing 2 avoirdupois ounces of phenobarbital is available?

   (A) 771 capsules
   (B) 350 capsules
   (C) 3500 capsules
   (D) 1250 capsules

7. Using the formula for calamine lotion, determine the amount of calamine (in grams) necessary to prepare 240 mL of lotion.

calamine	80 g
zinc oxide	80 g
glycerin	20 mL
bentonite magma	250 mL
calcium hydroxide	sufficient quantity to
topical solution	make 1000 mL

   (A) 19.2 g
   (B) 140.0 g
   (C) 100.0 g
   (D) 24.0 g

8. From the following formula, calculate the amount of white wax required to make 1 lb of cold cream. Determine the mass in grams.

cetyl esters wax	12.5 parts
white wax	12.0 parts
mineral oil	56.0 parts
sodium borate	0.5 parts
purified water	19.0 parts

   (A) 56.75 g
   (B) 254.24 g
   (C) 54.48 g
   (D) 86.26 g

9. How many grams of aspirin should be used to prepare 1.255 kg of the powder?

Aspirin	6 parts
phenacetin	3 parts
caffeine	1 part

   (A) 125 g
   (B) 750 g
   (C) 175 g
   (D) 360 g

10. A solution contains 1.25 mg of a drug per milliliter. At what rate should the solution be infused (drops per minute) if the drug is to be administered at a rate of 80 mg/hr? (1 mL = 30 drops)

   (A) 64.00 drops/min
   (B) 1.06 drops/min
   (C) 32.00 drops/min
   (D) 20.00 drops/min

11. The recommended maintenance dose of aminophylline for children is 1.0 mg/kg/hr by injection. If 10 mL of a 25-mg/mL solution of aminophylline is added to a 100-mL bottle of 5% dextrose, what should be the rate of delivery in mL/hr for a 40-lb child?

(A) 2.30 mL/hr
(B) 8.00 mL/hr
(C) 18.90 mL/hr
(D) 18.20 mL/hr

12. For children, streptomycin is to be administered at a dose of 30 mg/kg of body weight daily in divided doses every 6 to 12 hrs. The dry powder is dissolved by adding water for injection, in an amount to yield the desired concentration as indicated in the following table (for a 1-g vial).

Approximate

Concentration (mg/mL)	Volume (mL)
200	4.2
250	3.2
400	1.8

Reconstituting at the lowest possible concentration, what volume (in mL) would be withdrawn to obtain a day's dose for a 50-lb child?

(A) 3.40 mL
(B) 22.73 mL
(C) 2.50 mL
(D) 2.27 mL

13. The atropine sulfate is available only in the form of 1/150 gr tablets. How many atropine sulfate tablets would you use to compound the following prescription?

atropine sulfate	1/200 gr
codeine phosphate	¼ gr
aspirin	5 gr
d.t.d.	#24 capsules
Sig:	1 capsule p.r.n.

(A) 3 tablets
(B) 6 tablets
(C) 12 tablets
(D) 18 tablets

14. In 25.0 mL of a solution for injection, there are 4.00 mg of the drug. If the dose to be administered to a patient is 200 μg, what quantity (in mL) of this solution should be used?

(A) 1.25 mL
(B) 125.00 mL
(C) 12.00 mL
(D) None of the above

15. How many milligrams of papaverine will the patient receive each day?

R_x papaverine hcl	1.0 g
aqua	30.0 mL
syrup tolu, q.s. a.d.	90.0 mL
Sig:	1 teaspoon t.i.d.

(A) 56.0 mg
(B) 5.6 mg
(C) 166.0 mg
(D) 2.5 mg

16. Considering the following formula, how many grams of sodium bromide should be used in filling this prescription?

R_x sodium bromide	1.2 g
syrup tolu	2.0 mL
syrup wild cherry, q.s. a.d.	5.0 mL
d.t.d.	#24

(A) 1.2 g
(B) 1200.0 g
(C) 28.8 g
(D) 220.0 g

17. How many milliliters of a 7.5% stock solution of $KMnO_4$ should be used to obtain the KMnO needed?

$KMnO_4$, q.s.
Distilled water, a.d. 1000 mL
Sig: 2 teaspoons diluted to 500 mL yield a 1:5000 solution

(A) 267.0 mL
(B) 133.0 mL
(C) 26.7 mL
(D) 13.3 mL

18. The formula for Ringer's solution follows. How much sodium chloride is needed to make 120 mL?

R_x sodium chloride	8.60 g
potassium chloride	0.30 g
calcium chloride	0.33 g
water for injection, q.s. a.d.	1000 mL

(A) 120.00 g
(B) 1.03 g
(C) 0.12 g
(D) 103.00 g

19. How many grams of talc should be added to 1 lb of a powder containing 20 g of zinc undecylenate per 100 g to reduce the concentration of zinc undecylenate to 3%?

(A) 3026.7 g
(B) 2572.7 g
(C) 17.0 g
(D) 257.0 g

20. How many milliliters of a 0.9% aqueous solution can be made from 20.0 g of sodium chloride?

    (A) 2222 mL
    (B) 100 mL
    (C) 222 mL
    (D) 122 mL

21. The blood of a reckless driver contains 0.1% alcohol. Express the concentration of alcohol in parts per million.

    (A) 100 ppm
    (B) 1000 ppm
    (C) 1 ppm
    (D) 250 ppm

22. Syrup is an 85% w/v solution of sucrose in water. It has a density of 1.313 g/mL. How many milliliters of water should be used to make 125 mL of syrup?

    (A) 106.25 mL
    (B) 164.10 mL
    (C) 57.90 mL
    (D) 25.00 mL

23. How many grams of benzethonium chloride should be used in preparing 5 gal of a 0.025% w/v solution?

    (A) 189.25 g
    (B) 18.90 g
    (C) 4.73 g
    (D) 35.00 g

24. How many grams of menthol should be used to prepare this prescription?

R_x	menthol	0.8%
	alcohol, q.s. a.d.	60.0 mL

    (A) 0.48 g
    (B) 0.80 g
    (C) 4.80 g
    (D) 1.48 g

25. How many milliliters of a 1:1500 solution can be made by dissolving 4.8 g of cetylpyridinium chloride in water?

    (A) 7200.0 mL
    (B) 7.2 mL
    (C) 48.0 mL
    (D) 4.8 mL

26. The manufacturer specifies that one Domeboro tablet dissolved in 1 pint of water makes a modified Burow's solution approximately equivalent to a 1:40 dilution. How many tablets should be used in preparing ½ gal of a 1:10 dilution?

    (A) 16 tablets
    (B) 189 tablets
    (C) 12 tablets
    (D) 45 tablets

27. How many milliosmoles of calcium chloride ($CaCl_2 \cdot 2H_2O$ − mol wt = 147) are represented in 147 mL of a 10% w/v calcium chloride solution?

    (A) 100 mOsmol
    (B) 200 mOsmol
    (C) 300 mOsmol
    (D) 3 mOsmol

28. How many grams of boric acid should be used in compounding the following prescription?

Phenacaine HCl 1.0% (NaCl eq = 0.17)
Chlorobutanol 0.5% (NaCl eq = 0.18)
Boric acid, q.s. (NaCl eq = 0.52)
Purified H_2O, a.d. 30 mL
Make isotonic solution
Sig: 1 drop in each eye

    (A) 0.37 g
    (B) 0.74 g
    (C) 0.27 g
    (D) 0.47 g

29. A pharmacist prepares 1 gal of KCl solution by mixing 565 g of KCl (valence = 1) in an appropriate vehicle. How many milliequivalents of K^+ are in 15 mL of this solution? (atomic weights: K = 39; Cl = 35.5)

    (A) 7.5 mEq
    (B) 10.0 mEq
    (C) 20.0 mEq
    (D) 30.0 mEq
    (E) 40.0 mEq

30. A vancomycin solution containing 1000 mg of vancomycin hydrochloride diluted to 250 mL with D_5W is to be infused at a constant rate with an infusion pump in 2 hrs. What is the rate of drug administration?

    (A) 2.08 mg/min
    (B) 8.33 mg/min
    (C) 4.17 mg/min
    (D) 16.70 mg/min
    (E) 5.21 mg/min

Answers and Explanations

1. **The answer is A** *[see I.A.2].*

2. **The answer is B** *[see II].*

3. **The answer is B** *[see II].*

4. **The answer is C** *[see II].*

5. **The answer is C** *[see I.A.2].*

6. **The answer is C** *[see II].*

7. **The answer is A** *[see III].*

8. **The answer is C** *[see II; III.A].*
   The formula tells the pharmacist that white wax (W.W.) represents 12 parts out of the total 100 parts in the prescription. What we wish to determine is the mass of white wax required to prepare 454 g (1 lb) of the recipe. This can be easily solved by proportion:

   $$\frac{12 \text{ parts W.W.}}{100 \text{ parts total}} = \frac{x}{454 \text{ parts (grams)}}; x = 54.48 \text{ g}$$

9. **The answer is B** *[see III.A].*

10. **The answer is C** *[see IV.E].*

11. **The answer is B** *[see II; IV].*

12. **The answer is A** *[see IV].*

13. **The answer is D** *[see II; III.B].*

14. **The answer is A** *[see I.A.2; II].*
    Dimensional analysis is often useful for calculating doses. Considering that 4 mg of the drug is present in each 25 mL of solution, we can easily calculate the number of milliliters to be used to give a dose of 0.200 mg (200 µg). Always include units in your calculations.

    $$\frac{25 \text{ mL}}{4 \text{ mg}} \times 0.200 \text{ mg} = 1.25 \text{ mL}$$

15. **The answer is C** *[see III.B].*

16. **The answer is C** *[see III.B].*

17. **The answer is B** *[see V.A; VI].*
    First, determine the mass of drug in the final diluted solution.

    $$\frac{1 \text{ part}}{5000 \text{ parts}} = \frac{x \text{ g}}{500 \text{ g}}; x = 0.1 \text{ g}$$

    Now, if 0.1 g of drug is present in 500 mL of 1:5000 solution, 2 teaspoons (10 mL) of the prescription contains the same amount of drug (0.1 g) before dilution. From this, the amount of drug in 1000 mL (the total volume) of the prescription can be determined:

    $$\frac{0.1 \text{ g}}{10 \text{ mL}} = \frac{x \text{ g}}{1000 \text{ mL}}; x = 10 \text{ g}$$

Finally, to obtain the correct amount of drug to formulate the prescription (10 g), we are to use a 7.5% stock solution. Recalling the definition of percentage strength w/v

$$\frac{100 \text{ mL}}{7.5 \text{ g}} \times 10 \text{ g} = 133.3 \text{ mL or } 133 \text{ mL}$$

18. **The answer is B** *[see III.B].*

19. **The answer is B** *[see V.C; VI.C].*

20. **The answer is A** *[see I.A.2; V.A].*
    Using dimensional analysis

    $$\frac{20 \text{ g} \times 100 \text{ mL}}{0.9 \text{ g}} = 2222 \text{ mL}$$

21. **The answer is B** *[see V.D.1].*

22. **The answer is C** *[see I.A; V.A.1].*
    Using the density, the weight of 125 mL of syrup can be calculated:

    $$125 \text{ mL} \times 1.313 \text{ g/mL} = 164.125 \text{ g}$$

    Using proportion and the sucrose concentration in w/v, the weight of sucrose in 125 mL of syrup can be calculated:

    $$\frac{100 \text{ mL}}{125 \text{ mL}} = \frac{85 \text{ g}}{x \text{ g}}; x = 106.25 \text{ g}$$

    Finally, the weight of water in 125 mL of syrup can be calculated:

    $$164.125 \text{ g} - 106.25 \text{ g} = 57.875 \text{ g}$$

    which has a volume of 57.90 mL.

23. **The answer is C** *[see I; II; V].*

24. **The answer is A** *[see I; V].*

25. **The answer is A** *[see I; V].*
    The problem is easily solved by proportion. The question to be answered is if 1 g of drug is present in 1500 mL of a solution, what volume can be made with 4.8 g of drug?

    $$\frac{1 \text{ g}}{4.8 \text{ g}} = \frac{1500 \text{ mL}}{x \text{ mL}}; x = 7200.0 \text{ mL}$$

    (the volume of 1 to 1500 solution that can be prepared from 4.8 g of drug)

26. **The answer is A** *[see I; V].*

27. The answer is C *[see VII.B].*
Recalling the expression for ideal osmolar concentration:

$$\text{mOsmol/L} = \frac{100 \text{ g/L}}{147 \text{ g/mol}} \times 3 \times 1000$$

$$= \text{mOsmol/L} \times 0.147 \text{ L}$$
$$= 300 \text{ mOsmol}$$

28. The answer is A *[see VII.C].*

29. The answer is D *[see VII.A].*

30. The answer is B *[see IV.E].*
Using dimensional analysis:

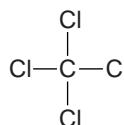
$$\frac{1000 \text{ mg}}{250 \text{ mL}} \times \frac{250 \text{ mL}}{2 \text{ hr}} \times \frac{1 \text{ hr}}{60 \text{ min}} = 8.33 \text{ mg/min}$$

2 Pharmaceutical Principles and Drug Dosage Forms

LAWRENCE H. BLOCK

I. INTRODUCTION. Pharmaceutical principles are the underlying physicochemical principles that allow a drug to be incorporated into a pharmaceutical **dosage form** (e.g., solution, capsule). These principles apply whether the drug is extemporaneously compounded by the pharmacist or manufactured for commercial distribution as a **drug product**.

   A. The finished **dosage form** contains the active drug ingredient in association with nondrug (usually inert) ingredients (**excipients**) that make up the **vehicle**, or **formulation matrix**.

   B. The **drug delivery system** concept, which has evolved since the 1960s, is a more holistic concept. It embraces not only the drug (or prodrug) and its formulation matrix, but also the dynamic interactions among the drug, its formulation matrix, its container, and the physiologic milieux of the patient. These dynamic interactions are the subject of **biopharmaceutics** (see Chapter 3).


II. INTERMOLECULAR FORCES OF ATTRACTION

   A. Introduction. The application of pharmaceutical principles to drug dosage forms is illustrated when drug dosage forms are **categorized** according to their **physical state**, **degree of heterogeneity**, and **chemical composition**. The usual relevant states of matter are **gases**, **liquids**, and **solids**. Intermolecular forces of attraction are weakest in gases and strongest in solids. Conversions from one physical state to another can involve simply overcoming intermolecular forces of attraction by adding energy (heat). Chemical composition can have a dramatic effect on physicochemical properties and behavior. For this reason, it is necessary to distinguish between **polymers**, or **macromolecules**, and more conventional (i.e., smaller) molecules, or **micromolecules**.

   B. Intermolecular forces of attraction. Because atoms vary in their electronegativity, electron sharing between different atoms is likely to be unequal. This asymmetric electron distribution causes a shift in the overall electron cloud in the molecule. As a result, the molecule tends to behave as a **dipole** (i.e., as if it had a positive and a negative pole). The dipole associated with each covalent bond has a corresponding **dipole moment** (μ) defined as the product of the distance of charge separation (d) and the charge (q):

$$\mu = q \times d$$

The molecular dipole moment may be viewed as the vector sum of the individual bond moments.

   1. Nonpolar molecules that have **perfect symmetry** (e.g., carbon tetrachloride) have dipole moments of zero (*Figure 2-1*).

Figure 2-1. The carbon tetrachloride molecule.

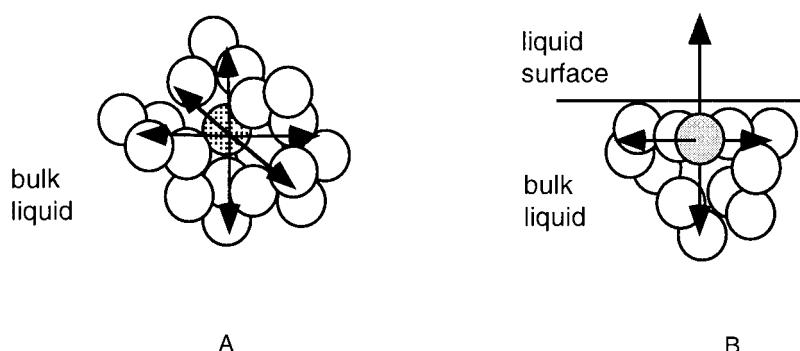
2. **Polar** molecules are **asymmetric** and have nonzero dipole moments.
3. When **dipolar** molecules approach one another close enough—"positive to positive" or "negative to negative"—so that their electron clouds interpenetrate, **intermolecular repulsive forces** arise. When these dipolar molecules approach one another so that the positive pole of one is close to the negative pole of the other, molecular **attraction** occurs (**dipole–dipole interaction**). When the identically charged poles of the two molecules are closer, **repulsion** occurs.

C. **Types of intermolecular forces of attraction** include the following:
1. Nonpolar molecules do not have permanent dipoles. However, the instantaneous electron distribution in a molecule can be asymmetric. The resultant transient dipole moment can induce a dipole in an adjacent molecule. This **induced dipole-induced dipole interaction** (**London dispersion force**), with a force of 0.5 to 1 kcal/mol, is sufficient to facilitate order in a molecular array. These relatively weak electrostatic forces are responsible for the liquefaction of nonpolar gases.
2. The transient dipole induced by a permanent dipole, or **dipole-induced dipole interaction** (**Debye induction force**), is a stronger interaction, with a force of 1 to 3 kcal/mol.
3. **Permanent dipole interactions** (**Keesom orientation forces**), with a force of 1 to 7 kcal/mol, together with Debye and London forces, constitute **van der Waals forces**. Collectively, they are responsible for the more substantive structure and molecular ordering found in liquids.
4. **Hydrogen bonds**. Because they are small and have a large electrostatic field, hydrogen atoms can approach highly electronegative atoms (e.g., fluorine, oxygen, nitrogen, chlorine, sulfur) and interact electrostatically to form a hydrogen bond. Depending on the electronegativity of the second atom and the molecular environment in which hydrogen bonding occurs, hydrogen bond energy varies from approximately 1 to 8 kcal/mol.
5. **Ion–ion**, **ion–dipole**, and **ion-induced dipole forces**. **Positive–negative ion interactions** in the solid state involve forces of 100 to 200 kcal/mol. Ionic interactions are reduced considerably in liquid systems in the presence of other electrolytes. **Ion–dipole** interaction, or **dipole induction by an ion**, can also affect molecular aggregation, or ordering, in a system.

III. STATES OF MATTER

A. **Gases**. Molecules in the gaseous state can be pictured as moving along straight paths, in all directions and at high velocities (e.g., mean velocity for H_2O vapor: 587 m/sec; for O_2: 440 m/sec), until they collide with other molecules. As a result of these random collisions, molecular velocities and paths change, and the molecules continue to collide with other molecules and with the boundaries of the system (e.g., the walls of a container holding the gas). This process, repeated incessantly, is responsible for the **pressure** exhibited within the confines of the system.
1. The interrelation among **volume** (**V**), **pressure** (**P**), and the **absolute temperature** (**T**) is given by the **ideal gas law**, which is the equation of state for an ideal gas:

$$PV = nRT$$
$$PV = (g/M)RT$$

where n is the number of moles of gas—equivalent to the number of grams (g) of gas divided by the molecular weight of the gas (M)—and R is the **molar gas constant** (0.08205 L atm/mole deg).
2. Pharmaceutical gases include the **anesthetic gases** (e.g., nitrous oxide, halothane). **Compressed gases** include oxygen (for therapy), nitrogen, and carbon dioxide. **Liquefiable gases**, including certain **halohydrocarbons** and **hydrocarbons**, are used as propellants in **aerosol products** (**pressurized packaging**), as are compressed gases, such as nitrous oxide, nitrogen, and carbon dioxide. Ethylene oxide is a gas used to sterilize or disinfect heat-labile objects.
3. In general, as the temperature of a substance increases, its **heat content**, or **enthalpy**, increases as well.
   a. Substances can undergo a change of state, or phase change, from the solid to the liquid state (**melting**) or from the liquid to the gaseous state (**vaporization**).
   b. **Volatile liquids** (e.g., ether, halothane, methoxyflurane) are used as inhalation anesthetics. Amyl nitrite is a volatile liquid that is inhaled for its vasodilating effect in acute angina.
   c. **Sublimation** occurs when a solid is heated directly to the gaseous, or vapor, state without passing through the liquid state (e.g., camphor, iodine). Ice sublimes at pressures below 3 torr. The process of **freeze-drying**, or **lyophilization**, is a form of vacuum drying in which water is


removed by sublimation from the frozen product. It is an especially useful process for drying aqueous solutions or dispersions of heat- or oxygen-sensitive drugs and biologicals (e.g., proteins, peptides).

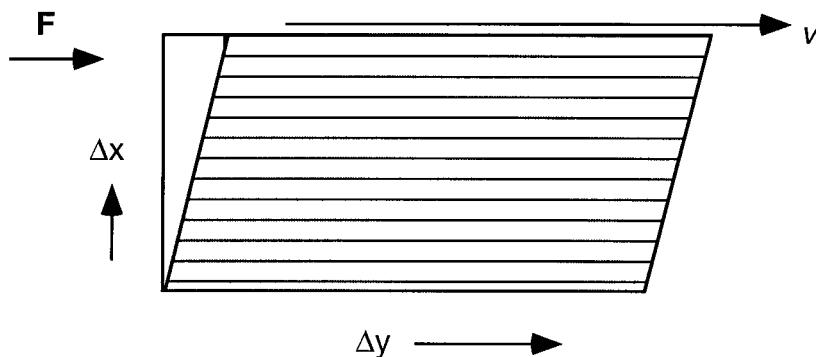
d. The reverse process (i.e., direct transition from the vapor state to the solid state) is also referred to as sublimation, but the preferred term is **deposition**. Some forms of sulfur and colloidal silicon dioxide are prepared in this way.

4. The intermolecular forces of attraction in gases are virtually nonexistent at room temperature. Gases display little or no ordering.

B. **Liquids**. The intermolecular forces of attraction in liquids (**van der Waals forces**) are sufficient to impose some ordering, or regular arrangement, among the molecules. **Hydrogen bonding** increases the likelihood of cohesion in liquids and further affects their physicochemical behavior. However, these forces are much weaker than **covalent** or **ionic** forces. Therefore, liquids tend to display short-range rather than long-range order. Hypothetically, although molecules of a liquid would tend to aggregate in localized clusters, no defined structuring would be evident.

1. **Surface and interfacial tension**

a. Molecules in the bulk phase of a liquid are surrounded by other molecules of the same kind (*Figure 2-2A*). Molecules at the surface of a liquid are not completely surrounded by like molecules (*Figure 2-2B*). As a result, molecules at or near the surface of a liquid experience a net inward pull from molecules in the interior of the liquid. Because of this net inward intermolecular attraction, the liquid surface tends to spontaneously contract. Thus, liquids tend to assume a spherical shape (i.e., a volume with the minimum surface area). This configuration has the least free energy.

b. Any expansion of the surface increases the free energy of the system. Thus, **surface free energy** can be defined by the work required to increase the surface area A of the liquid by 1 area unit. This value is expressed as the number of millinewtons (mN) needed to expand a 1-m^2 surface by 1 unit:


$$\text{work} = \gamma \times \Delta A$$

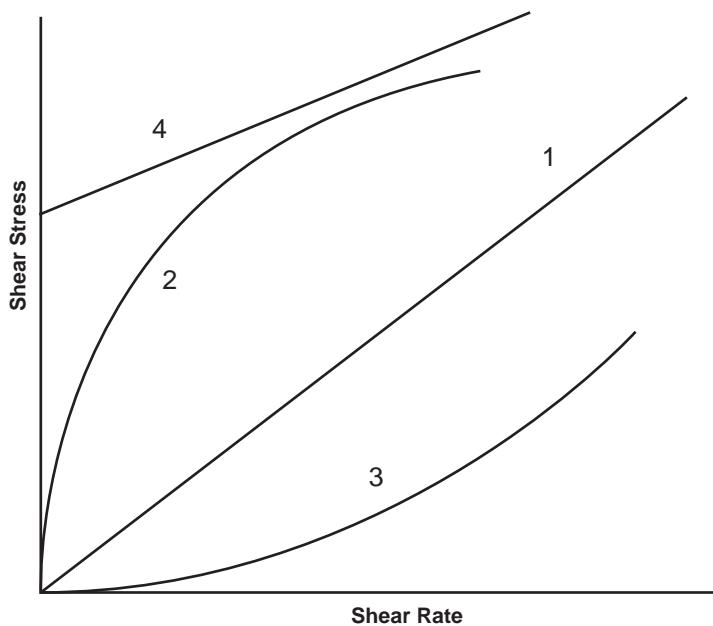
where ΔA is the increase in surface area and γ is the **surface tension**, or **surface free energy**, in mN m^{-1}—equivalent to centimeter-gram-second (CGS) units of dynes cm^{-1}. At 20°C, water has a surface tension of 72 mN m^{-1}, whereas *n*-octanol has a surface tension of 27 mN m^{-1}. Thus more work must be expended to expand the surface of water than to expand the surface of *n*-octanol (i.e., to proceed from a given volume of bulk liquid to the corresponding volume of small droplets).

c. At the **boundary**, or **interface**, between two immiscible liquids that are in contact with one another, the corresponding **interfacial tension** (i.e., free energy or work required to expand the interfacial area) reflects the extent of the intermolecular forces of attraction and repulsion at the interface. When the interface is between two liquids, substantial molecular interaction occurs across the interface between the two phases. This interaction reduces the imbalance in forces of attraction within each phase. The interfacial tension between *n*-octanol and water is reduced to 8.5 mN m^{-1} from 72 mN m^{-1} (γ air/water). This reduction indicates, in part, the interfacial interaction between *n*-octanol and water.

A   B

Figure 2-2. A. Molecules in the bulk phase. **B.** Molecules at the surface of a liquid.

Figure 2-3. Liquid flow.

2. The flow of a liquid across a solid surface can be examined in terms of the **velocity**, or rate of movement, of the liquid relative to the surface across which it flows. More insight can be gained by visualizing the flow of liquid as involving the movement of numerous parallel layers of liquid between an upper, movable plate and a lower, fixed plate (*Figure 2-3*). The application of a constant force (*F*) to the upper plate causes both this plate and the uppermost layer of liquid in contact with it to move with a velocity $\Delta y/\Delta x$. The interaction between the fixed bottom plate and the liquid layer closest to it prevents the movement of the bottom layer of liquid. The **velocity** (*v*) of the remaining layers of liquid between the two plates is proportional to their distance from the immovable plate (i.e., $\Delta y/\Delta x$). The **velocity gradient** leads to deformation of the liquid with time. This deformation is the **rate of shear**, dv/dx, or *D*. **Newton** defined flow in terms of the ratio of the force *F* applied to a plate of area *A*—**shear stress** (τ)—divided by the velocity gradient (*D*) induced by τ:


$$\frac{F}{A} = \eta \frac{dv}{dx}$$

or

$$\frac{\tau}{D} = \eta$$

The proportionality constant η is the coefficient of **viscosity**. It indicates the resistance to flow of adjacent layers of fluid. The reciprocal of η is **fluidity**. Units of viscosity in the CGS system are dynes $cm^{-2}s^{-1}$, or poise. In the SI system, the units are Newtons $m^{-2}s^{-1}$, which corresponds to 10 poise. The viscosity of water at 20°C is approximately 0.01 poise, or 1 centipoise (cps), which corresponds to 1 mN $m^{-2}s^{-1}$ or 1 mPa · s (milliPascal second).

  a. Substances that flow in accordance with the equation in III.B.2 (Newton's law) are known as **Newtonian substances**. Liquids that consist of simple molecules and dilute dispersions tend to be **Newtonian**. For a Newtonian fluid, a plot of shear stress as a function of shear rate (a **flow curve** or **rheogram**) yields a straight line with a slope of η (*Figure 2-4, Curve 1*).

  b. **Non-Newtonian substances** do not obey Newton's equation of flow. These substances tend to exhibit **shear-dependent** or **time-dependent viscosity**. In either case, viscosity is more aptly termed **apparent viscosity** because Newton's law is not strictly obeyed. Heterogeneous liquids and solids are most likely non-Newtonian.

   (1) **Shear-dependent viscosity** involves either an *increase* in apparent viscosity (i.e., **shear thickening** or **dilatancy**) (*Figure 2-4, Curve 3*) or a *decrease* in apparent viscosity (i.e., **shear thinning** or **pseudoplasticity**) (*Figure 2-4, Curve 2*) with an increase in the rate of shear. Shear thickening is displayed by suspensions that have a high solid content of small, deflocculated particles. Shear thinning is displayed by polymer or macromolecule solutions. **Plastic**, or **Bingham body**, behavior (*Figure 2-4, Curve 4*) is exemplified by flocculated particles in concentrated suspensions that show no apparent response to low-level stress. Flow begins only after a limiting yield stress (**yield value**) is exceeded.

   (2) **Time-dependent viscosity**

      (a) The yield value of **plastic** systems may be time dependent (i.e., may depend on the time scale involved in the application of force). **Thixotropic** systems display shear-thinning behavior but do not immediately recover their higher apparent viscosity

Figure 2-4. Non-Newtonian flow curves.

when the rate of shear is lowered. In a thixotropic system, structural recovery is relatively slow compared with structural breakdown.
    (b) Thixotropy occurs with heterogeneous systems that involve a three-dimensional structure or network. When such a system is at rest, it appears to have a relatively rigid consistency. Under shear, the structure breaks down and fluidity increases (i.e., **gel–sol** transformation).

    (c) Rheopexy (**negative thixotropy**, **or antithixotropy**) occurs when the apparent viscosity of the system continues to increase with continued application of shear up to some equilibrium value at a given shear rate. These systems display a **sol–gel** transformation. One explanation for antithixotropic behavior is that continued shear increases the frequency of particle or macromolecule interactions and leads to increased structure in the system.

C. Solids. Intermolecular forces of attraction are stronger in solids than in liquids or gases. Molecular arrangements in solids may be characterized as either crystalline or amorphous.

    1. Crystalline solids have the following attributes:

        a. Fixed **molecular order** (i.e., molecules occupy set positions in a specific array)

        b. A distinct melting point

        c. Anisotropicity (i.e., their properties are not the same in all directions), with the exception of cubic crystals

    2. Amorphous solids have the following attributes:

        a. Randomly arranged molecules with the short-range order typical of liquids

        b. No melting points

        c. Isotropicity (i.e., properties are the same in all directions)

        d. Less thermodynamic stability than the corresponding crystalline solid and therefore more apt to exhibit chemical and physical instability, increased dissolution rate, etc.

    3. Polymorphism is the condition wherein substances can exist in more than one crystalline form. These **polymorphs** have different molecular arrangements or crystal lattice structures. As a result, the different polymorphs of a drug solid can have different properties. For example, the melting point, solubility, dissolution rate, density, and stability can differ considerably among the polymorphic forms of a drug. Many drugs exhibit polymorphic behavior. Fatty (triglyceride) excipients (e.g., theobroma oil, cocoa butter) are recognized for their polymorphic behavior.

    4. The incorporation of solvent molecules into the crystal lattice of a solid results in a molecular adduct known as a **solvate** or **hydrate** (the latter term is used when water is the solvent). In general, solvates or hydrates exhibit different solubilities and dissolution rates than their unsolvated/anhydrous counterparts.

5. **Melting point and heat of fusion**. The melting point of a solid is the temperature at which the solid is transformed to a liquid. When 1 g of a solid is heated and melts, the heat absorbed in the process is referred to as the **latent heat of fusion**.

D. **Phase diagrams and phase equilibria**. A **phase diagram** represents the states of matter (i.e., solid, liquid, and gas) that exist as temperature and pressure are varied (*Figure 2-5*). The data arrays separating the phases in *Figure 2-5* delineate the temperatures and pressures at which the phases can coexist. Thus, gas (or vapor) and liquid coexist along "curve" *BC*, solid and liquid coexist along "curve" *AB*, and solid and gas (or vapor) coexist along "curve" *DB*. Depending on the change in temperature and pressure, **evaporation** or **condensation** occur along curve *BC*, **fusion** or **melting** along curve *AB*, and **sublimation** or **deposition** along curve *DB*. The three "curves" intersect at point *B*. Only at this unique temperature and pressure, known as the **triple point**, do all three phases exist in equilibrium. (The triple point for water is 0.01°C and 6.04×10^{-3} atm) Continuing along curve *BC*, to higher temperatures and pressures, one ultimately reaches point *C*, known as the **critical point**, above which there is no distinction between the liquid and the gas phases. Substances that exist above this critical point are known as **supercritical fluids**. Supercritical fluids such as carbon dioxide (critical point, 30.98°C and 73.8 atm) often exhibit markedly altered physicochemical properties (e.g., density, diffusivity, or solubility characteristics) that render them useful as solvents and processing aids in the production of pharmaceuticals and drug delivery systems.

Figure 2-5. Phase diagram for CO_2 showing the variation of the state of matter as pressure and temperature are varied. The solid state exists in the region *ABD*; the liquid state, in the region *ABC*; and the gas state, in the region to the right of curve *CD*. *B* corresponds to the triple point, the pressure and temperature at which all three phases coexist. *C* corresponds to the critical point, the pressure and temperature above which the liquid and gas phases are indistinguishable.

IV. PHYSICOCHEMICAL BEHAVIOR

A. Homogeneous systems

1. A **solution** is a homogeneous system in which a **solute** is molecularly dispersed, or dissolved, in a **solvent**. The solvent is the predominant species. **Saturated solutions** are solutions that, at a given temperature and pressure, contain the maximum amount of solute that can be accommodated by the solvent. If the saturation, or solubility, limit is exceeded, a fraction of the solute can separate from the solution and exist in equilibrium with it.

   a. **Solutes** can be gases, liquids, or solids, and nonelectrolytes or electrolytes.

      (1) **Nonelectrolytes** are substances that **do not form ions** when dissolved in water. Examples are estradiol, glycerin, urea, and sucrose. Their aqueous solutions do not conduct electric current.

      (2) **Electrolytes** are substances that **do form ions** in solution. Examples are sodium chloride, hydrochloric acid, and atropine. As a result, their aqueous solutions conduct electric current. Electrolytes are characterized as **strong** or **weak**. Strong electrolytes (e.g., sodium chloride, hydrochloric acid) are **completely ionized** in water at all concentrations. Weak electrolytes (e.g., aspirin, atropine) are **partially ionized** in water.

   b. The **colligative properties of a solution** depend on the total **number of ionic and nonionic solute molecules in the solution**. These properties depend on ionization but are **independent of other chemical properties of the solute**.

2. **Colligative properties** include the following:

   a. **Lowering of vapor pressure**. The **partial vapor pressure** of each volatile component in a solution is equal to the product of the mole fraction of the component in the solution and the vapor pressure of the pure component. This is **Raoult's law**:

   $$P_A = P_A^0 \times x_A$$

   where P_A is the partial vapor pressure above a solution in which the mole fraction of the solute A is x_A and P_A^0 is the **vapor pressure** of the pure component A. The vapor pressure is the pressure at which equilibrium is established between the molecules of A in the liquid state and the molecules of A in the gaseous (vapor) state in a closed, evacuated container. The vapor pressure is temperature dependent, but independent of the amount of liquid and vapor. Raoult's law holds for ideal solutions of nonelectrolytes. For a **binary solution** (i.e., a solution of component B in component A)

   $$\frac{P_A^0 - P_A}{P_A^0} = (1 - x_A) = x_B$$

   The lowering of the vapor pressure of the solution relative to the vapor pressure of the pure solvent is proportional to the number of molecules of solute in the solution. The actual lowering of the vapor pressure by the solute, Δp_A, is given by

   $$\Delta p_A = (P_A^0 - p_A) = x_B P_A^0$$

   b. **Elevation of the boiling point**. The **boiling point** is the temperature at which the vapor pressure of a liquid equals an external pressure of 760 mm Hg. A solution of a nonvolatile solute has a higher boiling point than a pure solvent because the solute lowers the vapor pressure of the solvent. The amount of elevation of the boiling point (ΔT_b) depends on the concentration of the solute:

   $$\Delta T_b = \frac{RT_0^2 M_1 m}{1000 \times \Delta H_{vap}} = K_b m$$

   where K_b is the molal boiling point elevation constant, R is the molar gas constant, T is absolute temperature (degrees K), M_1 is the molecular weight of the solute, m is the molality of the solution, and ΔH_{vap} is the molal enthalpy of vaporization of the solvent.

   c. **Depression of the freezing point**. The **freezing point**, or melting point, of a pure compound is the temperature at which the solid and the liquid phases are in equilibrium under a pressure of 1 atmosphere (atm). The freezing point of a solution is the temperature at which the solid

phase of the pure solvent and the liquid phase of the solution are in equilibrium under a pressure of 1 atm. The amount of depression of the freezing point (ΔT_f) depends on the molality of the solution:

$$\Delta T_f = \frac{RT_0^2\, M_1 m}{1000 \times \Delta H_{fusion}} = K_f m$$

where K_f is the molal freezing point constant and ΔH_{fusion} is the molal heat of fusion.

  d. Osmotic pressure. **Osmosis** is the process by which solvent molecules pass through a semipermeable membrane (a barrier through which only solvent molecules may pass) from a region of dilute solution to one of more concentrated solution. Solvent molecules transfer because of the inequality in chemical potential on the two sides of the membrane. Solvent molecules in a concentrated solution have a lower chemical potential than solvent molecules in a more dilute solution.

    (1) Osmotic pressure is the **pressure** that must be applied to the solution to prevent the flow of pure solvent into the concentrated solution.

    (2) Solvent molecules move from a region where their **escaping tendency is high** to one where their **escaping tendency is low**. The presence of dissolved solute lowers the escaping tendency of the solvent in proportion to the solute concentration.

    (3) The **van't Hoff equation** defines the osmotic pressure π as a function of the number of moles of solute n_2 in the solution of volume V:

$$\pi V = n_2 RT$$

3. Electrolyte solutions and ionic equilibria

  a. Acid–base equilibria

    (1) According to the **Arrhenius dissociation theory**, an **acid** is a substance that liberates H^+ in aqueous solution. A **base** is a substance that liberates hydroxyl ions (OH^-) in aqueous solution. This definition applies only under aqueous conditions.

    (2) The **Lowry–Brønsted theory** is a more powerful concept that applies to aqueous and nonaqueous systems. It is most commonly used for pharmaceutical and biologic systems because these systems are primarily aqueous.

      (a) According to this definition, an **acid** is a substance (charged or uncharged) that is capable of donating a proton. A **base** is a substance (charged or uncharged) that is capable of accepting a proton from an acid. The dissociation of an acid (HA) always produces a base (A^-) according to the following formula:

$$HA \leftrightarrow H^+ + A^-$$

      (b) HA and A^- are a **conjugate acid–base pair** (an acid and a base that exist in equilibrium and differ in structure by a proton). The proton of an acid does not exist free in solution, but combines with the solvent. In water, this **hydrated proton** is a **hydronium ion** (H_3O^+).

      (c) The relative **strengths** of acids and bases are determined by their ability to donate or accept protons. For example, in water, HCl donates a proton more readily than does acetic acid. Thus HCl is a stronger acid. Acid strength is also determined by the affinity of the solvent for protons. For example, HCl may dissociate completely in liquid ammonia, but only very slightly in glacial acetic acid. Thus, HCl is a strong acid in liquid ammonia and a weak acid in glacial acetic acid.

    (3) The **Lewis theory** extends the acid–base concept to reactions that do not involve protons. It defines an **acid** as a molecule or ion that accepts an electron pair from another atom and a **base** as a substance that donates an electron pair to be shared with another atom.

  b. H^+ concentration values are very small. Therefore, they are expressed in **exponential notation as pH**. The pH is the logarithm of the reciprocal of the H^+ concentration

$$pH = \log\left(\frac{1}{[H^+]}\right)$$

where $[H^+]$ is the molar concentration of H^+. Because the logarithm of a reciprocal equals the **negative logarithm** of the number, this equation may be rewritten as

$$pH = -\log [H^+]$$

or

$$[H^+] = 10^{-pH}$$

Thus, the pH value may be defined as the negative logarithm of the $[H^+]$ value. For example, if the H^+ concentration of a solution is 5×10^{-6}, the pH value may be calculated as follows:

$$pH = -\log (5 \times 10^{-6})$$
$$\log 5 = 0.699$$
$$\log 10^{-6} = -6.0$$
$$pH = -(-6 + 0.699)$$
$$= -(-5.301)$$
$$= 5.301$$

c. As pH decreases, **H^+ concentration increases exponentially**. When the pH decreases from 6 to 5, the H^+ concentration increases from 10^{-6} to 10^{-5}, or 10 times its original value. When the pH falls from 5 to 4.7, the H^+ concentration increases from 1×10^{-5} to 2×10^{-5}, or double its initial value.

d. **Dissociation constants**. **Ionization** is the complete separation of the ions in a crystal lattice when the salt is dissolved. **Dissociation** is the separation of ions in solution when the ions are associated by interionic attraction.

   (1) For **weak electrolytes**, dissociation is a reversible process. The equilibrium of this process can be expressed by the law of mass action. This law states that the rate of the chemical reaction is proportional to the product of the concentration of the reacting substances, each raised to a power of the number of moles of the substance in solution.

   (2) For **weak acids**, dissociation in water is expressed as

$$HA \leftrightarrow H^+ + A^-$$

   The dynamic equilibrium between the simultaneous forward and reverse reactions is indicated by the arrows. By the law of mass action,

$$\text{rate of forward reaction} = K_1[HA]$$
$$\text{rate of reverse reaction} = K_2[H^+][A^-]$$

   At equilibrium, the forward and reverse rates are equal. Therefore,

$$K_1[HA] = K_2[H^+][A^-]$$
   Thus, **the equilibrium expression for the dissociation of a weak acid** is written as

$$K_a = \frac{K_1}{K_2} = \frac{[H^+][A^-]}{[HA]}$$

   where K_a represents the acid dissociation constant. For a weak acid, the **acid dissociation constant** is conventionally expressed as **pK_a**, which is $-\log K_a$. For example, the K_a of acetic acid at 25°C is 1.75×10^{-5}. The pK_a is calculated as follows:

$$pK_a = -\log (1.75 \times 10^{-5})$$
$$\log 1.75 = 0.243$$
$$\log 10^{-5} = -5$$
$$pH = -(-5 + 0.243)$$
$$= -(-4.757)$$
$$= 4.76$$
(3) For **weak bases**, dissociation may also be expressed with the K_a expression for the **conjugate acid of the base**. This acid is formed when a proton reacts with the base. For a base that does not contain a hydroxyl group,

$$BH^+ \leftrightarrow H^+ + B$$

The **dissociation constant** for this reaction is expressed as

$$K_a = \frac{[H^+][B]}{[BH^+]}$$

However, a **base dissociation constant** is traditionally defined for a weak base with this expression:

$$B + H_2O \leftrightarrow OH^- + BH^+$$

$$K_b = \frac{[OH^-][BH^+]}{[B]}$$

where K_b represents the dissociation constant of a weak base. This **dissociation constant** can be expressed as **pK_b** as follows:

$$pK_b = -\log K_b$$

(4) Certain compounds (acids or bases) can accept or donate more than one proton. Consequently, they have **more than one dissociation constant**.

e. Henderson–Hasselbalch equations describe the relation between the ionized and the un-ionized species of a weak electrolyte.

(1) For **weak acids**, the Henderson–Hasselbalch equation is obtained from the equilibrium relation described in IV.A.3d.(2).

$$pH = pK_a + \log \frac{[salt]}{[acid]}$$

(2) Similarly, the Henderson–Hasselbalch equation for **weak bases** is as follows:

$$pH = pK_a + \log \frac{[B]}{[BH^+]}$$

where B is the un-ionized weak base and BH^+ is the protonated base.

f. The **degree of ionization (α)**, the fraction of a weak electrolyte that is ionized in solution, is calculated from the following equation:

$$\alpha = \frac{[I]}{[I] + [U]}$$

where [I] and [U] represent the concentrations of the ionized and un-ionized species, respectively. The degree of ionization depends solely on the pH of the solution and the pK_a of the weak electrolyte. **When pH = pK_a,** the Henderson–Hasselbalch equations are for a weak acid and a weak base, respectively:

$$pH - pK_a = 0 = \log \frac{[A^-]}{[HA]}$$

thus

$$\frac{[A^-]}{[HA]} = 1$$

$$pH - pK_a = 0 = \log \frac{[B]}{[BH^+]}$$

thus

$$\frac{[B]}{[BH^+]} = 1$$

In effect, when the pH of the solution is numerically equivalent to the pK_a of the weak electrolyte, whether a weak base or a weak acid, $[I] = [U]$ and the degree of ionization $\alpha = 0.5$ (i.e., 50% of the solute is ionized).

g. **Solubility of a weak electrolyte** varies as a function of pH.

(1) For a **weak acid**, the total solubility C_s is given by the expression

$$C_s = [HA] + [A^-]$$

where $[HA]$ is the intrinsic solubility of the un-ionized weak acid and is denoted as C_0, whereas $[A^-]$ is the concentration of its anion. Because $[A^-]$ can be expressed in terms of C_0 and the dissociation constant K_a,

$$C_s = C_0 + \frac{K_a\, C_0}{[H^+]}$$

Thus, the **solubility of a weak acid increases with increasing pH** (i.e., with an increasing degree of ionization, as the anion is more polar and therefore more water soluble than the un-ionized weak acid).

(2) Similarly, for **weak bases**,

$$C_s = C_0 + \frac{C_0[H^+]}{K_a}$$

Thus, the **solubility decreases with increasing pH** because more of the weak base is in the unprotonated form. This form is less polar and therefore less water soluble.

h. **Buffers and buffer capacity**

(1) A **buffer** is a mixture of salt with acid or base that resists changes in pH when small quantities of acid or base are added. A buffer can be a **combination** of a weak acid and its conjugate base (salt) or a combination of a weak base and its conjugate acid (salt). However, buffer solutions are more **commonly prepared** from weak acids and their salts. They are not ordinarily prepared from weak bases and their salts because weak bases are often unstable and volatile.

(a) For a **weak acid and its salt**, the following buffer equation is satisfactory for calculations with a pH of 4 to 10. It is important in the preparation of buffered pharmaceutical solutions:

$$pH = pK_a + \log \frac{[salt]}{[acid]}$$

(b) For a **weak base and its salt**, the buffer equation is similar but also depends on the dissociation constant of water (pK_w). The equation becomes

$$pH = pK_w - pK_b \log \frac{[base]}{[salt]}$$

(2) **Buffer action** is the resistance to a change in pH.

(3) **Buffer capacity** is the ability of a buffer solution to resist changes in pH. The **smaller the pH change** caused by addition of a given amount of acid or base, the **greater the buffer capacity** of the solution.

(a) Buffer capacity is the number of gram equivalents of an acid or base that changes the pH of 1 L of buffer solution by 1 U.

(b) Buffer capacity is affected by the concentration of the buffer constituents. A higher concentration provides a greater acid or base reserve. Buffer capacity (β) is related to total concentration (C) as follows:

$$\beta = \frac{2.3\, CK_a[H^+]}{(K_a + [H^+])^2}$$

where C represents the molar concentrations of the acid and the salt.

(c) Thus, buffer capacity depends on the value of the ratio of the salt to the acid form. It increases as the ratio approaches unity. Maximum buffer capacity occurs when $pH = pK_a$ and is represented by $\beta = 0.576C$.

B. **Heterogeneous (disperse) systems**

1. **Introduction**

   a. A **suspension** is a two-phase system that is composed of a solid material dispersed in an oily or aqueous liquid. The particle size of the dispersed solid is usually > 0.5 μm.

   b. An **emulsion** is a heterogeneous system that consists of at least one immiscible liquid that is intimately dispersed in another in the form of droplets. The droplet diameter usually exceeds 0.1 μm. Emulsions are **inherently unstable** because the droplets of the dispersed liquid tend to coalesce to form large droplets until all of the dispersed droplets have coalesced. The third component of the system is an **emulsifying agent**. This agent prevents coalescence and maintains the integrity of the individual droplets.

2. **Dispersion stability**. In an **ideal dispersion**, the dispersed particles do not interact. The particles are uniform in size and undergo no change in position other than the random movement that results from Brownian motion. In contrast, in a **real dispersion**, the particles are not uniformly sized (i.e., they are not **monodisperse**). The particles are subject to particulate aggregation, or clumping, and the dispersion becomes more heterogeneous with time. The **rate of settling (separating or creaming)** of the dispersed phase in the dispersion medium is a function of the particle size, dispersion phase viscosity, and difference in density between the dispersed phase and the dispersion medium, in accordance with **Stokes's law**:

$$\text{sedimentation rate} = \frac{d^2 g(\rho_1 - \rho_2)}{18\,\eta}$$

where d is the particle diameter, g is the acceleration owing to gravity, η is the viscosity of the dispersion medium, and $(\rho_1 - \rho_2)$ is the difference between the density of the particles (ρ_1) and the density of the dispersion medium (ρ_2). Although Stokes's law was derived to determine the settling, or sedimentation, of noninteracting spherical particles, it also provides guidance for determining the stabilization of dispersion:

   a. **Particle size** should be as **small** as possible. Smaller particles yield slower sedimentation, or flotation, rates.

   b. **High particulate (dispersed phase) concentrations** increase the rate of particle–particle collisions and interaction. As a result, particle aggregation occurs, and instability increases as the aggregates behave as larger particles. In the case of liquid–liquid dispersions, particle–particle collisions can lead to coalescence (i.e., larger particles) and decrease dispersion stability.

   c. **Avoidance of particle–particle interactions**

   (1) Aggregation can be prevented if the particles have a similar electrical charge. Particles in an aqueous system always have some electrical charge because of **ionization** of chemical groups on the particle surface or **adsorption** of charged molecules or ions at the interface. If the adsorbed species is an **ionic surfactant** (e.g., sodium lauryl sulfate), the charge associated with the surfactant ion (e.g., lauryl sulfate anion) will accumulate at the interface. However, if a relatively non–surface-active electrolyte is adsorbed, the sign of the charge of the adsorbed ion is less readily predicted.

   (2) The **magnitude of the charge** is the difference in electrical potential between the charged surface of the particle and the bulk of the dispersion medium. This magnitude is approximated by the **electrokinetic**, or **zeta**, **potential (ζ)**. The zeta potential is measured from the fixed, avidly bound layers of ions and solvent molecules on the particle surface. When ζ is high (e.g., ≥ 25 mV), interparticulate **repulsive forces** exceed the attractive forces. As a result, the dispersion is **deflocculated** and relatively stable to collision and subsequent aggregation (**flocculation**). When ζ is so low that interparticulate **attractive forces** predominate, loose particle aggregates, or **flocs**, form (i.e., **flocculation** occurs).

   d. **Density** can be manipulated to decrease the rate of dispersion instability. The settling rate decreases as $(\rho_1 - \rho_2)$ approaches zero. However, the density of the dispersion medium usually cannot be altered sufficiently to halt the settling (or flotation) process. In the dispersed phase, the density of solid particles is not readily altered; altering the density of liquid particles would require the addition of a miscible liquid of higher (or lower) density. Altering the composition of suspensions is also problematic because most solid particles are denser than the dispersion medium. Additives of higher (or lower) density might alter the biopharmaceutical

characteristics of the formulation (e.g., rate of drug release, residence time at the site of administration, or absorption).

e. The **sedimentation**, or **flotation**, **rate** is inversely proportional to the **viscosity**. An **increase** in the **viscosity of the dispersion medium** decreases the rate of settling, or flotation. However, although the rate of destabilization can be slowed by an increase in viscosity, it cannot be halted.

3. **Emulsion stability**. **Coalescence** occurs in emulsion systems when the liquid particles of the dispersed phase merge to form larger particles. Coalescence is largely prevented by the **interfacial film** of surfactant around the droplets. This film prevents direct contact of the liquid phase of the droplets. Coalescence of droplets in oil in water (o/w) emulsions is also inhibited by the **electrostatic repulsion** of similarly charged particles. **Creaming** is the **reversible** separation of a layer of emulsified particles. Because mixing or shaking may be sufficient to reconstitute the emulsion system, creaming is not necessarily unacceptable. However, **cracking**, or **irreversible phase separation**, is never acceptable. **Phase inversion**, or emulsion-type reversal, involves the reversion of an emulsion from an o/w to water in oil (w/o) form, or vice versa. Phase inversion can change the consistency or texture of the emulsion or cause further deterioration in its stability.

V. CHEMICAL KINETICS AND DRUG STABILITY

A. **Introduction**. The **stability** of the **active component** of a drug is a major criterion in the rational design and evaluation of drug dosage forms. Problems with **stability** can determine whether a given formulation is accepted or rejected.

1. Extensive chemical degradation of the active ingredient can cause **substantial loss** of active ingredient from the dosage form.

2. Chemical degradation can produce a **toxic product** that has undesirable side effects.

3. Instability of the drug product can cause **decreased bioavailability**. As a result, the therapeutic efficacy of the dosage form may be substantially reduced.

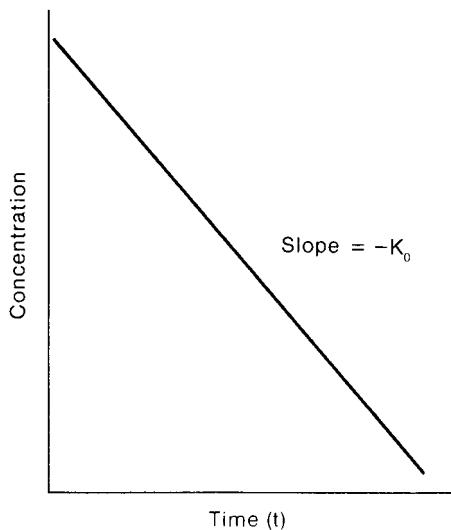
B. **Rates and orders of reactions**

1. The **rate of a reaction**, or degradation rate, is the velocity with which the reaction occurs. This rate is expressed as dC/dt (the change in concentration, or C, within a given time interval, or dt).

a. Reaction rates depend on certain conditions (e.g., **reactant concentration**, **temperature**, **pH**, **presence of solvents or additives**). Radiation and catalytic agents (e.g., polyvalent cations) also have an effect.

b. The effective study of reaction rates in the body requires application of **pharmacokinetic principles** (see Chapter 5).

2. The **order of a reaction** is the way in which the concentration of the drug or reactant in a chemical reaction affects the rate. The rate of a reaction, dC/dt, is proportional to the concentration to the nth power, where n is the order of the reaction—that is,

$$\frac{dC}{dt} \propto C^n$$


The study of reaction orders is a crucial aspect of pharmacokinetics (see Chapter 5). Usually, **pharmaceutical degradation** can be treated as a **zero-order**, **first-order**, or **higher order reaction**. The first two are summarized as follows:

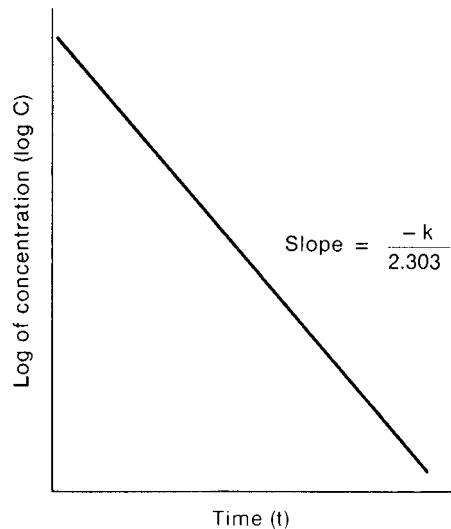
a. In a **zero-order reaction**, the **rate is independent of the concentration of the reactants** (i.e., $dC/dt \propto C^0$) (see Chapter 5). Other factors, such as absorption of light in certain photochemical reactions, determine the rate.

(1) A **zero-order reaction** can be expressed as

$$C = -k_0 t + C_0$$

where C is the drug concentration, k_0 is the zero-order rate constant in units of concentration/time, t is the time, and C_0 is the initial concentration.

(2) When this equation is plotted with C on the vertical axis (ordinate) against t on the horizontal axis (abscissa), the **slope of the line is equal to $-k_0$** (*Figure 2-6*). The negative sign indicates that the slope is decreasing.

Figure 2-6. Concentration *(C)* versus time *(t)* for a zero-order reaction. The slope of the line equals $-k_0$. The slope of the line is not equal to the rate constant because it includes the minus sign.


b. In a **first-order reaction**, the **rate depends on the first power of the concentration of a single reactant** (i.e., $dC/dt \propto C^1$).

    (1) In a first-order reaction, **drug concentration decreases exponentially with time**, in accordance with the equation

$$C = C_0 e^{-k_1 t}$$

    where C is the concentration of the reacting material, C_0 is the initial concentration, k_1 is the first-order rate constant in units of reciprocal time, and t is time. A plot of the logarithm of concentration against time produces a straight line with a slope of $-k/2.303$ (*Figure 2-7*).

    (2) The **half-life** ($t_{\frac{1}{2}}$) of a reaction is the time required for the concentration of a drug to decrease by one-half. For a first-order reaction, half-life is expressed by

$$t_{\frac{1}{2}} = \frac{0.693}{k_1}$$

Figure 2-7. Logarithm of concentration (log *C*) versus time *(t)* for a first-order reaction. The slope of the line equals $-k/2.303$.

(3) The **time required for a drug to degrade** to 90% of its original concentration ($t_{90\%}$) is also important. This time represents a reasonable limit of degradation for the active ingredients. The $t_{90\%}$ can be calculated as

$$t_{90\%} = \frac{2.303}{k_1} \log \frac{100}{90} = \frac{0.105}{k_1}$$

(a) because

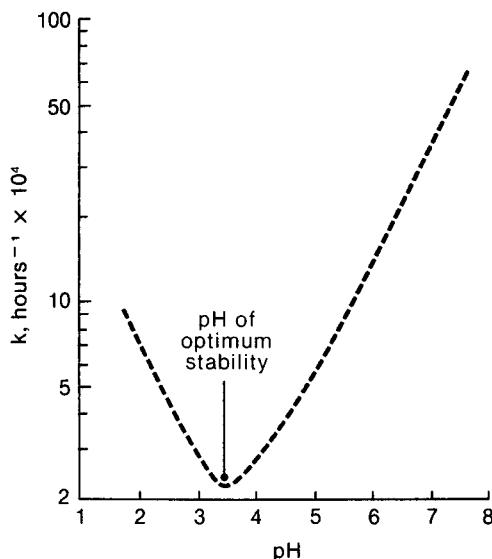
$$k_1 = 0.693 / t_{\frac{1}{2}}$$

(b) then

$$t_{90\%} = \frac{0.105}{0.693 / t_{\frac{1}{2}}} = 0.152 \times t_{\frac{1}{2}}$$

(4) Both $t_{\frac{1}{2}}$ and $t_{90\%}$ are **concentration independent**. Thus, for $t_{\frac{1}{2}}$, it takes the same amount of time to reduce the concentration of the drug from 100 to 50 mM as it does from 50 to 25 mM.

C. **Factors that affect reaction rates**. Factors other than concentration can affect the reaction rate and stability of a drug. These factors include temperature, the presence of a solvent, pH, and the presence of additives.

1. **Temperature**. An **increase in temperature** causes an increase in reaction rate, as expressed in the equation first suggested by Arrhenius:


$$k = A \cdot e^{-Ea/RT}$$

or

$$\log k = \log A - \left(\frac{Ea}{2.303} \times \frac{1}{RT} \right)$$

where k is the specific reaction rate constant, A is a constant known as the frequency factor, Ea is the energy of activation, R is the molar gas constant (1.987 cal/degree $\times$ mole), and T is the absolute temperature.

a. The **constants A and Ea** are obtained by determining k at several temperatures and then plotting $\log k$ against $1/T$. The slope of the resulting line equals $-Ea/(2.303 \times R)$. The intercept on the vertical axis equals $\log A$.

b. The activation energy (Ea) is the amount of energy required to put the molecules in an **activated state**. Molecules must be activated to react. As **temperature increases**, more molecules are activated, and the **reaction rate increases**.

2. **Presence of solvent**. Many dosage forms require the incorporation of a water-miscible solvent—for example, low-molecular-weight alcohols, such as the polyethylene glycols (PEGs)—to stabilize the drug.

a. A change in the solvent system **alters** the transition state and the **activity coefficients** of the reactant molecules. It can also cause simultaneous changes in physicochemical parameters, such as pK_a, surface tension, and viscosity. These changes **indirectly affect the reaction rate**.

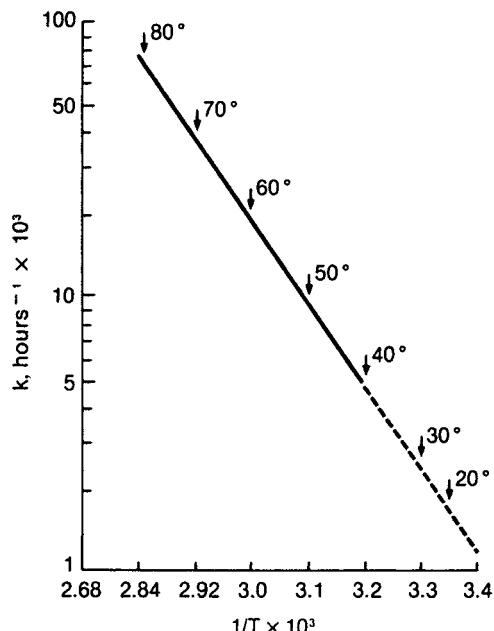
b. In some cases, **additional reaction pathways** are generated. For example, with an increasing concentration of ethanol in an aqueous solution, aspirin degrades by an extra route and forms the ethyl ester of acetylsalicylic acid. However, a **change in solvent can also stabilize the drug**.

3. **Change in pH**. The magnitude of the rate of a hydrolytic reaction catalyzed by H^+ and OH^- can vary considerably with pH.

a. **H^+ catalysis** predominates at **lower pH**, whereas **OH^- catalysis** operates at **higher pH**. At **intermediate pH**, the rate may be **pH independent** or may be catalyzed by **both H^+ and OH^-**. Rate constants in the intermediate pH range are typically less than those at higher or lower pH.

b. To determine the **effect of pH on degradation kinetics**, decomposition is measured at several H^+ concentrations. The **pH of optimum stability** can be determined by plotting the logarithm of the rate constant (k) as a function of pH (*Figure 2-8*). The **point of inflection** of the plot is the pH of optimum stability. This value is useful in the development of a stable drug formulation.

Figure 2-8. Semilogarithmic plot of the rate constant (k) versus pH. This plot is used to determine the pH of optimum stability.

4. **Presence of additives**
    a. **Buffer salts** must be added to many drug solutions to maintain the formulation at optimum pH. These salts **can affect the rate of degradation**, primarily as a result of salt increasing the ionic strength.
        (1) Increasing salt concentrations, particularly from polyelectrolytes (e.g., citrate, phosphate), can **substantially affect the magnitude of pK$_a$**. In this way, they change the rate constant.
        (2) Buffer salts can also **promote drug degradation** through general acid or base catalysis.
    b. The **addition of surfactants** may accelerate or decelerate drug degradation.
        (1) **Acceleration of degradation** is common and is caused by micellar catalysis.
        (2) **Stabilization of a drug** through the addition of a surfactant is less common.
    c. **Complexing agents** can improve drug stability. Aromatic esters (e.g., benzocaine, procaine, tetracaine) **increase in half-life** in the presence of caffeine. This increased stability appears to result from the formation of a less reactive complex between the aromatic ester and the caffeine.
D. **Modes of pharmaceutical degradation**. The decomposition of active ingredients in a dosage form occurs through several pathways (e.g., hydrolysis, oxidation, photolysis; see Chapter 8, II.A).
    1. **Hydrolysis** is the most common type of degradation because many medicinal compounds are esters, amides, or lactams.
        a. **H$^+$ and OH$^-$** are the most common catalysts of hydrolytic degradation in solution.
        b. **Esters** usually undergo hydrolytic reactions that cause drug instability. Because esters are rapidly degraded in aqueous solution, formulators are reluctant to incorporate drugs that have ester functional groups into liquid dosage forms.
    2. **Oxidation** is usually mediated through reaction with atmospheric oxygen under ambient conditions (auto-oxidation).
        a. Medicinal compounds that undergo auto-oxidation at room temperature are affected by **oxygen dissolved in the solvent** and in the head space of their packages. These compounds should be packed in an **inert atmosphere** (e.g., nitrogen) to exclude air from their containers.
        b. Most oxidation reactions involve a **free radical mechanism** and a **chain reaction**. Free radicals tend to take electrons from other compounds.
            (1) **Antioxidants** in the formulation react with the free radicals by providing electrons and easily available hydrogen atoms. In this way, they prevent the propagation of chain reactions.
            (2) **Commonly used antioxidants** include ascorbic acid, butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT), propyl gallate, sodium bisulfite, sodium sulfite, and the tocopherols.
    3. **Photolysis** is the degradation of drug molecules by normal sunlight or room light.
        a. Molecules may absorb the proper wavelength of light and **acquire sufficient energy to undergo reaction**. Usually, photolytic degradation occurs on exposure to light of wavelengths < 400 nm.


b. An **amber glass bottle** or an **opaque container** acts as a barrier to this light, thereby preventing or retarding photolysis. For example, sodium nitroprusside in aqueous solution has a shelf life of only 4 hrs if exposed to normal room light. When protected from light, the solution is stable for at least 1 year.

 E. **Determination of shelf life.** The shelf life of a drug preparation is the amount of time that the product can be stored before it becomes unfit for use, through either chemical decomposition or physical deterioration.

 1. **Storage temperature** affects shelf life. It is generally understood to be ambient temperature unless special storage conditions are specified.

 2. **In general, a preparation is considered fit for use if it varies from the nominal concentration or dose by no more than 10%,** provided that the decomposition products are not more toxic or harmful than the original material.

 3. **Shelf life testing** aids in determining the standard shelf life of a formulation.

 a. Samples are stored at 3° to 5°C and at room temperature (20° to 25°C). The samples are then analyzed at various intervals to determine the **rate of decomposition**. Shelf life is calculated from this rate.

 b. Because storage time at these temperatures can result in an extended testing time, **accelerated testing** is conducted as well, with a range of higher temperatures. The **rate constants** obtained from these samples are used to predict shelf life at ambient or refrigeration temperatures. **Temperature-accelerated stability testing** is not useful if temperature changes are accompanied by changes in the reaction mechanism or by physical changes in the system (e.g., change from the solid to the liquid phase).

 c. **Stability at room temperature** can be predicted from accelerated testing data by the Arrhenius equation:

$$\log\left(\frac{k_{T_2}}{k_{T_1}}\right) = \frac{Ea(T_2 - T_1)}{2.303 \times R \times T_2 \times T_1}$$

 where k_{T_2} and k_{T_1} are the rate constants at the absolute temperatures T_2 and T_1, respectively; R is the molar gas constant; and Ea is the energy of activation.

 d. Alternatively, an expression of concentration can be plotted as a linear function of time. Rate constants (k) for degradation at several temperatures are obtained. The logarithm of the rate constant ($\log k$) is plotted against the reciprocal of absolute temperature ($1/T$) to obtain, by extrapolation, the rate constant for degradation at room temperature (*Figure 2-9*).

Figure 2-9. Semilogarithmic plot of the rate constant (k) versus the reciprocal of absolute temperature ($1/T$), showing the temperature dependency of degradation rates.

    e. The **length of time that the drug will maintain its required potency** can also be predicted by calculation of the $t_{90\%}$ (see V.B.2.b.(3)). This method applies to chemical reactions with activation energies of 10 to 30 kcal/mol—the magnitude of the activation energy for many pharmaceutical degradations that occur in a solution.

VI. DRUG DOSAGE FORMS AND DELIVERY SYSTEMS

A. Oral solutions. The *United States Pharmacopeia* (*USP*) **34**/*National Formulary* (*NF*) **29** categorizes **oral solutions** as "liquid preparations, intended for oral administration, that contain one or more substances with or without flavoring, sweetening, or coloring agents dissolved in water or cosolvent-water mixtures." Oral solutions can contain certain polyols (e.g., sorbitol, glycerin) to inhibit crystallization and to modify solubility, taste, mouth feel, and other vehicle properties. They can be "formulated for direct oral administration to the patient or they may be dispensed in a more concentrated form that must be diluted prior to administration." **Drugs in solution** are more homogeneous and easier to swallow than drugs in solid form. For drugs that have a slow dissolution rate, onset of action and bioavailability are also improved. However, drugs in solution are bulkier dosage forms, degrade more rapidly, and are more likely to interact with constituents than those in solid form.

    1. Water is the **most commonly used vehicle** for drug solutions. The *USP* recognizes seven types of water for the preparation of dosage forms:

        a. Purified water *USP* is water obtained by distillation, ion exchange, reverse osmosis, or other suitable treatment. It cannot contain more than 10 parts per million (ppm) of total solid and should have a pH between 5 and 7. Purified water is used in prescriptions and finished manufactured products except parenteral and ophthalmic products.

        b. Water for injection *USP* is water obtained by distillation or by reverse osmosis. It conforms to the standards of purified water but is also free of pyrogen. Water for injection is used as a solvent for the preparation of parenteral solutions.

        c. Sterile water for injection *USP* is water for injection that is sterilized and packaged in single-dose containers of type I and II glass. These containers do not exceed a capacity of 1 L. The limitations for total solids depend on the size of the container.

        d. Bacteriostatic water for injection *USP* is sterile water for injection that contains one or more suitable antimicrobial agents. It is also packaged in single- or multiple-dose containers of type I or II glass. These containers do not exceed the capacity of 30 mL.

        e. Sterile water for inhalation *USP* is water that is purified by distillation or by reverse osmosis (i.e., water for injection) and rendered sterile. It contains no antimicrobial agents, except when used in humidifiers or similar devices. This type of water should not be used for parenteral administration or for other sterile dosage forms.

        f. Sterile water for irrigation *USP* is water for injection that is sterilized and suitably packaged. It contains no antimicrobial agents or other added substance.

        g. Sterile purified water *USP* is purified water sterilized and suitably packaged. It contains no antimicrobial agent. It is not intended for use in parenterals.

    2. Oral drug solutions include **syrups** and **elixirs** as well as other less widely prescribed classic (**galenical**) formulations, such as **aromatic waters**, **tinctures**, **fluid extracts**, and **spirits**.

        a. Syrups are traditionally per oral solutions that contain high concentrations of sucrose or other sugars. Through common usage, the term *syrup* has also come to include any other liquid dosage form prepared in a sweet, viscous vehicle, including per oral suspensions.

            (1) Syrup *NF* (**simple syrup**) is a concentrated or nearly saturated aqueous solution of sugar (85%; 65% w/w).

            (2) Syrups have a **low solvent capacity for water-soluble drugs** because the hydrogen bonding between sucrose and water is very strong. For this reason, it can be difficult or impossible to dissolve a drug in syrup. Often, the drug is best dissolved in a small quantity of water, and the flavoring syrup is added.

            (3) The **sucrose concentration** of syrup plays a crucial role in the control of microbial growth. Dilute sucrose solutions are excellent media for microorganisms. As the concentration of sucrose approaches saturation, the syrup becomes self-preserving (i.e., requires no additional preservative). However, a saturated solution is undesirable because temperature

fluctuations may cause crystallization. **Syrup *NF*** is a self-preserved solution with a minimal tendency to undergo crystallization.

    b. Elixirs are traditionally per oral solutions that contain alcohol as a cosolvent. Many per oral solutions are not described as elixirs but contain alcohol.

        (1) To be considered an elixir, the solution **must contain alcohol**. Traditionally, the alcohol content of elixirs has varied from 5% to 40%. Most elixirs become turbid when moderately diluted by aqueous liquids. Elixirs are not the preferred vehicle for salts because alcohol accentuates saline taste. Salts also have limited solubility in alcohol. Therefore, the alcoholic content of salt-containing elixirs must be low.

        (2) Aromatic elixir *NF*, prepared in part from syrup, contains approximately 22% alcohol. The limited usefulness of this elixir as a solvent for drugs was offset by the development of **iso-alcoholic elixir**. It is a combination of **low-alcoholic elixir**, an elixir with low alcoholic content (8% to 10% alcohol), and **high-alcoholic elixir**, an elixir with high alcoholic content (73% to 78% alcohol). Mixing appropriate volumes of the two elixirs provides an alcoholic content sufficient to dissolve the drugs.

B. Miscellaneous solutions

    1. Aromatic waters are clear, **saturated aqueous solutions of volatile oils** or other aromatic or volatile substances. Aromatic waters may be used as pleasantly flavored vehicles for a water-soluble drug or as an aqueous phase in an emulsion or suspension. If a large amount of water-soluble drug is added to aromatic water, then an insoluble layer may form at the top. This **"salting out"** is a competitive process. The molecules of water-soluble drugs have more attraction for the solvent molecules of water than the "oil" molecules. The associated water molecules are pulled away from the oil molecules, which are no longer held in solution. Aromatic waters should be stored in tight, light-resistant bottles to reduce volatilization and degradation from sunlight. Aromatic waters are usually prepared by one of the following methods:

        a. Distillation is a universal method but is not practical or economical for most products. It is the only method, however, for preparing strong rose water and orange flower water.

        b. With the **solution method**, the volatile or aromatic substance is admixed with water, with or without the use of a dispersant (e.g., talc).

    2. Spirits, or **essences**, are alcoholic or hydroalcoholic solutions of volatile substances that contain 50% to 90% alcohol. This **high alcoholic content** maintains the water-insoluble volatile oils in solution. If water is added to a spirit, the oils separate. Some spirits are **medicinal** (e.g., aromatic ammonia spirit). Many spirits (e.g., compound orange spirit, compound cardamom spirit) are used as flavoring agents. Spirits should be stored in tight containers to reduce loss by evaporation.

    3. Tinctures are alcoholic or hydroalcoholic solutions of chemicals or soluble constituents of vegetable drugs. Although tinctures vary in drug concentration ($\leq 50\%$), those prepared from potent drugs are usually 10% in strength (i.e., 100 mL of the tincture has the activity of 10 g of the drug). Tinctures are usually considered stable. The alcohol content of the official tinctures varies from 17% to 21% for opium tincture *USP* and from 74% to 80% for compound benzoin tincture *USP*. Most tinctures are prepared by an **extraction process** of maceration or percolation. The selection of a **solvent**, or menstruum, is based on the solubility of the active and inert constituents of the crude drugs. Aging can cause precipitation of the inactive constituents of tinctures. Glycerin may be added to the hydroalcoholic solvent to increase the solubility of the active constituent and reduce precipitation on storage. Tinctures must be tightly stoppered and kept from excessive temperatures. Because many of their constituents undergo a photochemical change when exposed to light, tinctures must be stored in light-resistant containers.

    4. Fluid extracts are liquid extracts of vegetable drugs that contain alcohol as a solvent, preservative, or both. Fluid extracts are prepared by percolation so that each milliliter contains the therapeutic constituents of 1 g of the standard drug. Because of their high drug content, fluid extracts are sometimes referred to as "100% tinctures." Fluid extracts of potent drugs are usually 10 times as concentrated, or potent, as the corresponding tincture. For example, the usual dose of tincture belladonna is 0.6 mL; the equivalent dose of the more potent fluid extract is 0.06 mL. Many fluid extracts are considered too potent for self-administration by patients, so they are almost never prescribed. In addition, many fluid extracts are simply too bitter. Today, most fluid extracts are modified by either flavoring or sweetening agents.

5. **Nasal**, **ophthalmic**, **otic**, and **parenteral solutions** are classified separately because of their specific use and method of preparation.

6. **Mouthwashes** are solutions that are used to cleanse the mouth or treat diseases of the oral mucous membrane. They often contain alcohol or glycerin to aid in dissolving the volatile ingredients. Mouthwashes are more often used cosmetically than therapeutically.

7. **Astringents** are locally applied solutions that precipitate protein. They reduce cell permeability without causing injury. Astringents cause **constriction**, with wrinkling and blanching of the skin. Because astringents **reduce secretions**, they can be used as antiperspirants.
   a. **Aluminum acetate** and **aluminum subacetate solutions** are used as wet dressings in contact dermatitis. The precipitation is minimized by the addition of boric acid.
   b. **Calcium hydroxide solution** is a mild stringent that is used in lotions as a reactant and an alkalizer.

8. **Antibacterial topical solutions** (e.g., benzalkonium chloride, strong iodine, povidone–iodine) kill bacteria when applied to the skin or mucous membrane in the proper strength and under appropriate conditions.

C. **Suspensions**

1. **Lotions**, **magmas** (i.e., suspensions of finely divided material in a small amount of water), and **mixtures** are all suspensions that have had official formulas for some time (e.g., calamine lotion *USP*, kaolin mixture with pectin *NF*). Official formulas are given in the *USP/NF*.
   a. A **complete formula** and a **detailed method of preparation** are available for some official suspensions. For others, only the **concentration** of the active ingredients is given, and the manufacturer has considerable latitude in the formulation.
   b. Some drugs are packaged in a **dry form** to circumvent the instability of aqueous dispersions. Water is added at the time of dispensing to reconstitute the suspension.

2. **Purposes of suspension**
   a. **Sustaining effect**. For a sustained-release preparation, a suspension necessitates drug dissolution before absorption.
   b. **Stability**. Drug degradation in suspension or solid dosage forms occurs much more slowly than degradation in solution form.
   c. **Taste**. A drug with an unpleasant taste can be converted into an insoluble form and then prepared as a suspension.
   d. **Basic solubility**. When suitable solvents are not available, the suspension provides an alternative. For example, only water can be used as a solvent for ophthalmic preparations because of the possibility of corneal damage. Ophthalmic suspensions provide an alternative to ophthalmic solutions.

3. **Suspending agents** include hydrophilic colloids, clays, and a few other agents. Some are also used as **emulsifying agents** (see VI.D.3).
   a. **Hydrophilic colloids** (i.e., **hydrocolloids**) increase the viscosity of water by binding water molecules, thus limiting their mobility, or fluidity. Viscosity is proportional to the concentration of the hydrocolloid. These agents **support the growth of microorganisms** and require a preservative. They are mostly **anionic**, with the exception of methyl cellulose (neutral) and chitosan (cationic). Thus, the anionic hydrocolloids are incompatible with quaternary antibacterial agents and other positively charged drugs. Chitosan is incompatible with negatively charged drugs and excipients. Most hydrocolloids are **insoluble in alcoholic solutions**.
      (1) **Acacia** is usually used as 35% dispersion in water (mucilage). Its viscosity is greatest between pH 5 and pH 9. Acacia is susceptible to microbial decomposition.
      (2) **Tragacanth** is usually used as 6% dispersion in water (mucilage). One advantage of tragacanth over acacia is that less is needed. Also, tragacanth does not contain the oxidase that is present in acacia. This oxidase catalyzes the decomposition of organic chemicals. The viscosity of tragacanth is greatest at pH 5.
      (3) **Methyl cellulose** is a polymer that is nonionic and stable to heat and light. It is available in several viscosity grades. Because it is soluble in cold water, but not in hot water, dispersions are prepared by adding methyl cellulose to boiling water and then cooling the preparation until the material dissolves.
      (4) **Carboxymethylcellulose** is an anionic material that is soluble in water. Prolonged exposure to heat causes loss of viscosity.

    b. Clays (e.g., bentonite, Veegum) are silicates that are anionic in aqueous dispersions. They are strongly hydrated and exhibit **thixotropy** (the property of forming a gel-like structure on standing and becoming fluid on agitation).

      (1) The official form of **bentonite** is the 5% magma.

      (2) Veegum is hydrated to a greater degree than bentonite. Thus, it is more viscous at the same concentration.

    c. Other agents include agar, chondrus (carrageenan), gelatin, pectin, and gelatinized starch. Their use is limited by their susceptibility to bacterial attack, their incompatibilities, and their cost. Xanthan gum is used in many modern suspension formulations because of its cosolvent compatibility, its stability, and its solution's high viscosity relative to concentration.

  4. Preparation

    a. Solids are wetted initially to separate individual particles and coat them with a layer of dispersion medium. Wetting is accomplished by **levigation** (i.e., addition of a suitable nonsolvent, or **levigating agent**, to the solid material, followed by blending to form a paste), using a glass mortar and pestle or an ointment slab. A **surfactant** can also be used.

    b. Suspending agents are then added as dry powder along with the active ingredient. For best results, the suspending agent is added in the form of its **aqueous dispersion**.

      (1) The aqueous dispersion is added to the solid (or the levigated solid) by **geometric dilution**.

      (2) The preparation is brought to the desired volume by stirring in the appropriate vehicle.

D. Emulsions

  1. Purposes of emulsions

    a. Increased drug solubility. Many drugs have limited aqueous solubility but have maximum solubility in the oil phase of an emulsion. Drug partitioning from the oil phase to the water phase can maintain or enhance activity.

    b. Increased drug stability. Many drugs are more stable when incorporated into an emulsion rather than an aqueous solution.

    c. Prolonged drug action. Incorporation of a drug into an emulsion can prolong bioavailability, as with certain intramuscular injection preparations.

    d. Improved taste. Drugs with an unpleasant taste are more palatable and thus more conveniently administered in emulsion form.

    e. Improved appearance. Oily materials intended for topical application are more appealing in an emulsified form.

  2. Phases of emulsions. Most emulsions are considered **two-phase systems**.

    a. The **liquid droplet** is known as the **dispersed**, **internal**, or **discontinuous phase**. The other liquid is known as the **dispersion medium**, **external phase**, or **continuous phase**.

    b. In pharmaceutical applications, one phase is usually an **aqueous solution**. The other phase is usually **lipid** or **oily**. The lipids range from vegetable or hydrocarbon oils to semisolid hydrocarbons and waxes. Emulsions are usually described in terms of water and oil. Oil is the lipid, or nonaqueous, phase regardless of its composition.

      (1) If water is the **internal phase**, the emulsion is classified as **w/o**.

      (2) If water is the **external phase**, the emulsion is classified as **o/w**.

    c. The **type of emulsion** formed is primarily determined by the **relative phase volumes** and the **emulsifying agent** used.

      (1) For an ideal emulsion, the maximum concentration of internal phase is 74% (i.e., theoretically, an o/w emulsion can be prepared containing $\leq$ 74% oil).

      (2) The choice of an emulsifying agent is more important than the relative phase volumes in determining the final emulsion type. Most agents preferentially form one type of emulsion or the other if the phase volume permits.

  3. Emulsifying agents. Any compound that lowers the interfacial tension and forms a film at the interface can potentially function as an emulsifying agent. The effectiveness of the emulsifying agent depends on its chemical structure, concentration, solubility, pH, physical properties, and electrostatic effect. **True emulsifying agents** (primary agents) can form and stabilize emulsions by themselves. **Stabilizers** (auxiliary agents) do not form acceptable emulsions when used alone,

but assist primary agents in stabilizing the product (e.g., increase viscosity). Emulsifying agents are either **natural** or **synthetic**.

a. Natural emulsifying agents

   (1) **Acacia** forms a good, stable emulsion of low viscosity. It tends to cream easily, is acidic, and is stable at a pH range of 2 to 10. Like other gums, it is negatively charged, dehydrates easily, and usually requires a preservative. It is incompatible with Peruvian balsam, bismuth salts, and carbonates.

   (2) **Tragacanth** forms a stable emulsion that is coarser than acacia emulsion. It is anionic, is difficult to hydrate, and is used mainly for its effects on viscosity. Less than 1/10 of the amount used for acacia is needed.

   (3) **Agar** is an anionic gum that is primarily used to increase viscosity. Its stability is affected by heating, dehydration, and destruction of charge. It is also susceptible to microbial degradation.

   (4) **Pectin** is a quasi-emulsifier that is used in the same proportion as tragacanth.

   (5) **Gelatin** provides good emulsion stabilization in a concentration of 0.5% to 1.0%. It may be anionic or cationic, depending on its isoelectric point. Type A gelatin (+), prepared from an acid-treated precursor, is used in acidic media. Type B gelatin (−), prepared from an alkali-treated precursor, is used in basic media.

   (6) **Methyl cellulose** is nonionic and induces viscosity. It is used as a primary emulsifier with mineral oil and cod liver oil, and yields an o/w emulsion. It is usually used in 2% concentration.

   (7) **Carboxymethylcellulose** is anionic and is usually used to increase viscosity. It tolerates alcohol up to 40%, forms a basic solution, and precipitates in the presence of free acids.

b. Synthetic emulsifying agents are anionic, cationic, or nonionic. Although these surfactants are amphiphilic molecules, their lipophilic and hydrophilic regions are seldom inverse equals of each other: Some surfactant molecules tend to be predominantly lipophilic, whereas others are predominantly hydrophilic. This imbalance is reflected in the hydrophilic–lipophilic balance (HLB) scale: The larger the HLB value, the more hydrophilic the molecule. *Table 2-1* lists HLB values for surfactants and their corresponding uses.

   (1) **Anionic** synthetic agents include **sulfuric acid esters** (e.g., sodium lauryl sulfate), **sulfonic acid derivatives** (e.g., dioctyl sodium sulfosuccinate), and **soaps**. Soaps are for external use. They have a high pH and are, therefore, sensitive to the addition of acids and electrolytes.

   (a) **Alkali soaps** are hydrophilic and form an o/w emulsion.

   (b) **Metallic soaps** are water insoluble and form a w/o emulsion.

   (c) **Monovalent soaps** form an o/w emulsion.

   (d) **Polyvalent soaps** form a w/o emulsion.

   (2) **Cationic** synthetic agents (e.g., benzalkonium chloride) are used as surface-active agents in 1% concentration. They are incompatible with soaps.

   (3) **Nonionic** synthetic agents are resistant to the addition of acids and electrolytes.

   (a) The **sorbitan esters** known as **Spans** are hydrophobic in nature and form w/o emulsions. They have low hydrophilic–lipophilic balance values (1–9) (*Table 2-2*).

Table 2-1	HYDROPHILIC–LIPOPHILIC BALANCE (HLB)

HLB Value Range	Surfactant Application
0–3	Antifoaming agents
4–6	Water-in-oil emulsifying agents
7–9	Wetting agents
8–18	Oil-in-water emulsifying agents
13–15	Detergents
10–18	Solubilizing agents

| Table 2-2 | COMMONLY USED SURFACTANTS AND THEIR HYDROPHILIC–LIPOPHILIC BALANCE (HLB) VALUES |

Agent	HLB Value
Sorbitan trioleate (Span 85, Arlacel 85)	1.8
Sorbitan tristearate (Span 65)	2.1
Propylene glycol monostearate (pure)	3.4
Sorbitan sesquioleate (Arlacel C)	3.7
Sorbitan monooleate (Span 80y)	4.3
Sorbitan monostearate (Arlacel 60)	4.7
Sorbitan monopalmitate (Span 40, Arlacel 40)	6.7
Sorbitan monolaurate (Span 20, Arlacel 20)	8.6
Glyceryl monostearate (Aldo 28, Tegin)	5.5
Gelatin	9.8
Triethanolamine oleate (Trolamine)	12.0
Polyoxyethylene alkyl phenol (Igepal CA-630)	12.8
Tragacanth	13.2
Polyoxyethylene sorbitan monolaurate (Tween 21)	13.3
Polyoxyethylene castor oil (Atlas G-1794)	13.3
Polyoxyethylene sorbitan monooleate (Tween 80)	15.0
Polyoxyethylene sorbitan monopalmitate (Tween 40)	15.6
Polyoxyethylene sorbitan monolaurate (Tween 20)	16.7
Polyoxyethylene lauryl ether (Brij 35)	16.9
Sodium oleate	18.0
Sodium lauryl sulfate	40.0

  (b) The **polysorbates** known as **Tweens** are hydrophilic and tend to form o/w emulsions. They may form complexes with phenolic compounds. They have high hydrophilic–lipophilic balance values (11–20).

 4. **Preparation**. Various methods are used to prepare emulsions, depending on the type of emulsifying agent.

  a. Classical, acacia-stabilized emulsions are prepared by one of the following four methods:

   (1) **Wet gum (English) method**. A primary emulsion of fixed oil, water, and acacia (in a 4:2:1 ratio) is prepared as follows:

    (a) Two parts of water are added all at once to one part of acacia. The mixture is triturated until a smooth mucilage is formed.

    (b) Oil is added in small increments (1 to 5 mL), with continuous trituration, until the primary emulsion is formed.

    (c) The mixture (an o/w emulsion) is triturated for another 5 mins.

    (d) The o/w mixture can then be brought to volume with water and mixed to achieve homogeneity.

   (2) **Dry gum (continental) method**. A primary emulsion of the fixed oil, water, and acacia (in a 4:2:1 ratio) is prepared as follows:

    (a) Oil is added to the acacia, and the mixture is triturated until the powder is distributed uniformly throughout the oil. Water is added all at once, followed by rapid trituration to form the primary emulsion.

    (b) Any remaining water and other ingredients are added to finish the product.

     (i) **Electrolytes in high concentration** tend to crack an emulsion. They should be added last and in as dilute a form as possible.

     (ii) **Alcoholic solutions** tend to dehydrate and precipitate hydrocolloids. They should be added in as dilute a concentration as possible.

(3) **Bottle method** (a variation of the dry gum method used for volatile oils). Oil is added to the acacia in a bottle. The ratio of oil, water, and acacia should be 3:2:1 or 2:1:1. The low viscosity of the volatile oil requires a higher proportion of acacia.

(4) **Nascent soap method**. A soap is formed by mixing relatively equal volumes of an oil and an aqueous solution that contains a sufficient amount of alkali. The soap acts as an emulsifying agent.

    (a) This method is used to form an o/w or a w/o emulsion, depending on the soap formed. For example, olive oil, which contains oleic acid, is mixed with lime water during the preparation of calamine lotion to calcium oleate, an emulsifying agent.

    (b) A 50:50 ratio of oil to water ensures sufficient emulsion, provided that the oil contains an adequate amount of free fatty acid. Olive oil usually does. Cottonseed oil, peanut oil, and some other vegetable oils do not.

    (c) The addition of an acid destroys the emulsifying soap and causes the emulsion to separate.

b. Emulsions stabilized by synthetic emulsifying agents are readily prepared by a two-phase procedure.

(1) Oil-miscible ingredients and water-miscible ingredients are separately admixed, using heat if necessary to ensure liquefaction and ease of mixing of each phase.

    (a) High melting point oil-miscible ingredients (e.g., waxes) are melted before lower melting point ingredients (e.g., oils) are added.

(2) The two phases are heated to 70° to 80°C and then combined with stirring until the resultant emulsion has cooled.

    (a) In general, heat-labile or volatile ingredients should not be incorporated in the separate phases but in the resultant emulsion after it has cooled to about 40°C or less.

(3) Further mechanical processing of the emulsion by a hand homogenizer, immersion blender, or other equipment may be warranted to improve the homogeneity and stability of the product.

5. **Incorporation of medicinal agents**. Medicinal agents can be incorporated into an emulsion either during or after its formation.

a. **Addition of a drug during emulsion formation**. It is best to incorporate a drug into a vehicle during emulsion formation, when it can be incorporated in molecular form. Soluble drugs should be dissolved in the appropriate phase (e.g., drugs that are soluble in the external phase of the emulsion should be added as a solution to the primary emulsion).

b. **Addition of a drug to a preformed emulsion** can present some difficulty, depending on the type of emulsion and the nature of the emulsifier (*Table 2-3*).

(1) **Addition of oleaginous materials to a w/o emulsion** presents no problem because of the miscibility of the additive with the external phase. However, **addition of oleaginous materials to an o/w emulsion** can be difficult after emulsion formation.

    (a) Occasionally, a small amount of oily material is added if excess emulsifier was used in the original formation.

    (b) A small amount of an oil-soluble drug can be added if it is dissolved in a very small quantity of oil with geometric dilution techniques.

(2) **Addition of water or an aqueous material to a w/o emulsion** is extremely difficult, unless enough emulsifier has been incorporated into the emulsion. However, **addition of aqueous materials to an o/w emulsion** usually presents no problems if the added material does not interact with the emulsifying agent. Potential interactions should be expected with cationic compounds and salts of weak bases.

(3) **Addition of small quantities of alcoholic solutions to an o/w emulsion** is possible if the solute is compatible or dispersible in the aqueous phase of the emulsion. If acacia or another gum is used as the emulsifying agent, the alcoholic solution should be diluted with water before it is added. *Table 2-3* lists some commercial emulsion bases and their general composition.

(4) **Addition of crystalline drugs to a w/o emulsion** occurs more easily if the drugs are dissolved or dispersed in a small quantity of oil before they are added.

Table 2-3 SELECTED COMMERCIAL EMULSION BASES: EMULSION TYPE
AND EMULSIFIER USED

Commercial Base	Emulsion Type	Emulsifier Type
Allercreme skin lotion	o/w	Triethanolamine stearate
Almay emulsion base	o/w	Fatty acid glycol esters
Cetaphil	o/w	Sodium lauryl sulfate
Dermovan	o/w	Fatty acid amides
Eucerin	w/o	Wool wax alcohol
HEB base	o/w	Sodium lauryl sulfate
Keri lotion	o/w	Nonionic emulsifiers
Lubriderm	o/w	Triethanolamine stearate
Neobase	o/w	Polyhydric alcohol esters
Neutrogena lotion	o/w	Triethanolamine lactate
Nivea cream	w/o	Wool wax alcohols
pHorsix	o/w	Polyoxyethylene emulsifiers
Polysorb hydrate	w/o	Sodium sesquioleate
Velvachol	o/w	Sodium lauryl sulfate

o/w, oil in water; w/o, water in oil.

E. Ointments
1. **Introduction**. **Ointments** are **semisolid preparations intended for external use**. They are easily spread. Modifying the formulation controls their plastic viscosity. Ointments are typically used as
   a. **emollients** to make the skin more pliable,
   b. **protective barriers** to prevent harmful substances from coming in contact with the skin, and
   c. **vehicles** in which to incorporate medication.
2. **Ointment bases**
   a. **Oleaginous bases** are anhydrous and insoluble in water. They cannot absorb or contain water and are not washable in water.
      (1) **Petrolatum** is a good base for oil-insoluble ingredients. It forms an occlusive film on the skin, absorbs < 5% water under normal conditions, and does not become rancid. Wax can be incorporated to stiffen the base.
      (2) **Synthetic esters** are used as constituents of oleaginous bases. These esters include glyceryl monostearate, isopropyl myristate, isopropyl palmitate, butyl stearate, and butyl palmitate. Long-chain alcohols (e.g., cetyl alcohol, stearyl alcohol, PEG) can also be used.
      (3) **Lanolin derivatives** are often used in topical and cosmetic preparations. Examples are lanolin oil and hydrogenated lanolin.
   b. **Absorption bases** are anhydrous and water insoluble. Therefore, they are not washable in water, although they can absorb water. These bases permit water-soluble medicaments to be included through prior solution and uptake as the internal phase.
      (1) **Wool fat** (anhydrous lanolin) contains a high percentage of cholesterol as well as esters and alcohol that contain fatty acids. It absorbs twice its weight in water and melts between 36°C and 42°C.
      (2) **Hydrophilic petrolatum** is a white petrolatum combined with 8% beeswax, 3% stearyl alcohol, and 3% cholesterol. These components are added to a w/o emulsifier. Prepared forms include Aquaphor, which uses wool alcohol to render white petrolatum emulsifiable. Aquaphor is superior in its ability to absorb water.
   c. **Emulsion bases** may be w/o emulsions, which are water insoluble and are not washable in water. These emulsions can absorb water because of their aqueous internal phase. Emulsion bases may also be o/w emulsions, which are water insoluble but washable in water. They can absorb water in their aqueous external phase.
      (1) **Hydrous wool fat** (lanolin) is a w/o emulsion that contains approximately 25% water. It acts as an emollient and occlusive film on the skin, effectively preventing epidermal water loss.

(2) Cold cream is a w/o emulsion that is prepared by melting white wax, spermaceti, and expressed almond oil together; adding a hot aqueous solution of sodium borate; and stirring until the mixture is cool.

  (a) The use of mineral oil rather than almond oil makes a more stable cold cream. However, cold cream prepared with almond oil makes a better emollient base.

  (b) This ointment should be freshly prepared.

(3) Hydrophilic ointment is an o/w emulsion that uses sodium lauryl sulfate as an emulsifying agent. It absorbs 30% to 50% w/w without losing its consistency. It is readily miscible with water and is removed from the skin easily.

(4) Vanishing cream is an o/w emulsion that contains a large percentage of water as well as humectant (e.g., glycerin, propylene glycol) that retards moisture loss. An excess of stearic acid in the formula helps form a thin film when the water evaporates.

(5) Other emulsion bases include Dermovan, a hypoallergenic, greaseless emulsion base, and Unibase, a nongreasy emulsion base that absorbs approximately 30% of its weight in water and has a pH close to that of the skin.

  d. Water-soluble bases may be anhydrous or may contain some water. They are washable in water and absorb water to the point of solubility.

(1) PEG ointment is a blend of water-soluble polyethylene glycols that form a semisolid base. This base can solubilize water-soluble drugs and some water-insoluble drugs. It is compatible with a wide range of drugs.

  (a) This base contains 40% PEG 3350 and 60% PEG 400. It is prepared by the fusion method (see VI.E.3.b).

  (b) Only a small amount of liquid ($<$ 5%) can be incorporated without loss of viscosity. This base can be made stiffer by increasing the amount of PEG 3350 to 60%.

  (c) If 6% to 25% of an aqueous solution is to be incorporated, 5 g of the 40 g of PEG 3350 can be replaced with an equal amount of stearyl alcohol.

(2) Propylene glycol and **propylene glycol–ethanol** form a clear gel when mixed with 2% hydroxypropyl cellulose. This base is a popular dermatologic vehicle.

3. Incorporation of medicinal agents. Medicinal substances may be incorporated into an ointment base by **levigation** or by the **fusion method**. Insoluble substances should be reduced to the finest possible form and levigated before incorporation with a small amount of compatible levigating agent or with the base itself.

  a. Levigation. The substance is incorporated into the ointment by levigation on an ointment slab.

(1) A stainless-steel spatula with a long, broad, flexible blade should be used. If the substance may interact with a metal spatula (e.g., when incorporating iodine and mercuric salts), then a hard rubber spatula can be used.

(2) Insoluble substances should be powdered finely in a mortar and mixed with an equal quantity of base until a smooth, grit-free mixture is obtained. The rest of the base is added in increments.

(3) Levigation of powders into a small portion of base is facilitated by the use of a melted base or a small quantity of compatible levigation aid (e.g., mineral oil, glycerin).

(4) Water-soluble salts are incorporated by dissolving them in the smallest possible amount of water and incorporating the aqueous solution directly into a compatible base.

  (a) Usually, organic solvents (e.g., ether, chloroform, alcohol) are not used to dissolve the drug because the drug may crystallize as the solvent evaporates.

  (b) Solvents are used as levigating aids only if the solid will become a fine powder after the solvent evaporates.

  b. Fusion method. This method is used when the base contains solids that have higher melting points (e.g., waxes, cetyl alcohol, glyceryl monostearate). This method is also useful for solid medicaments, which are readily soluble in the melted base.

(1) The oil phase should be melted separately, starting with materials that have the highest melting point. All other oil-soluble ingredients are added in decreasing order of melting point.

(2) The ingredients in the water phase are combined and heated separately to a temperature that is equal to or several degrees above that of the melted oil phase.

(3) The two phases are combined. If a w/o system is desired, then the hot aqueous phase is incorporated into the hot oil phase with agitation. If an o/w system is preferred, then the hot oil phase is incorporated into the hot aqueous phase.

(4) Volatile materials (e.g., menthol, camphor, iodine, alcohol, perfumes) are added after the melted mixture cools to 40°C or less.

F. Suppositories

1. **Introduction**. A suppository is a **solid or semisolid mass intended to be inserted into a body orifice** (i.e., rectum, vagina, urethra). After it is inserted, a suppository either melts at body temperature or dissolves (or disperses) into the aqueous secretions of the body cavity.

   a. Suppositories are often used for local effects (e.g., relief of hemorrhoids or infection).

   b. When used rectally, suppositories can provide systemic medication. The absorption of a drug from a suppository through the rectal mucosa into the circulation involves two steps:

   (1) The drug is released from a vehicle and partitions/diffuses through the mucosa.

   (2) The drug is transported through the veins or lymph vessels into systemic fluids or tissues. The first-pass effect is avoided because the rectal veins "bypass" the liver.

   c. Rectal suppositories are useful when oral administration is inappropriate, as with infants, debilitated or comatose patients, and patients who have nausea, vomiting, or gastrointestinal disturbances. Some drugs can cause disturbances of the gastrointestinal tract.

2. **Types of suppositories**

   a. Rectal suppositories are usually cylindrical and tapered to a point, forming a bullet-like shape. As the rectum contracts, a suppository of this shape moves inward rather than outward. Suppositories for adults weigh approximately 2 g. Suppositories for infants and children are smaller.

   b. Vaginal suppositories are oval and typically weigh approximately 5 g. Drugs administered by this route are intended to have a local effect, but systemic absorption can occur. Antiseptics, contraceptive agents, and drugs used to treat trichomonal, monilial, or bacterial infections are often formulated as vaginal suppositories.

   c. Urethral suppositories are typically long and tapered. They are approximately 60 mm long and 4 to 5 mm in diameter. They are administered for a local effect and are most often used for anti-infective agents. Alprostadil, or prostaglandin E_1 (PGE_1), when used to treat erectile dysfunction, is available for urethral insertion in the form of a micropellet, or microsuppository, that is only 3 to 6 mm long and 1.4 mm in diameter.

3. **Suppository bases**

   a. Criteria for satisfactory suppository bases. Suppository bases should

   (1) Remain firm at room temperature to allow insertion. The suppository should not soften < 30°C to avoid melting during storage.

   (2) Have a narrow, or sharp, melting range

   (3) Yield a clear melt just below body temperature or dissolve rapidly in the cavity fluid

   (4) Be inert and compatible with a variety of drugs

   (5) Be nonirritating and nonsensitizing

   (6) Have wetting and emulsifying properties

   (7) Have an acid value of < 0.2, a saponification value of 200 to 245, and an iodine value of < 7 if the base is fatty

   b. Selecting a suppository base. Lipid–water solubility must be considered because of its relation to the drug-release rate.

   (1) If an oil-soluble drug is incorporated into an oily base, then the rate of absorption is somewhat less than that achieved with a water-soluble base. The lipid-soluble drug tends to remain dissolved in the oily pool from the suppository. It is less likely to escape into the mucous secretions from which it is ultimately absorbed.

   (2) Conversely, a water-soluble drug tends to pass more rapidly from the oil phase to the aqueous phase. Therefore, if rapid onset of action is desired, the water-soluble drug should be incorporated into the oily base.

   c. Bases that melt include **cocoa butter**, other **combinations of fats and waxes**, **Witepsol bases**, and **Wecobee bases** (*Table 2-4*).

   (1) Cocoa butter (theobroma oil) is the most widely used suppository base. It is firm and solid up to a temperature of 32°C, at which point it begins to soften. At 34° to 35°C, it melts to produce a thin, bland, oily liquid.

   (a) Cocoa butter is a good base for a **rectal suppository**, but it is less than ideal for a vaginal or urethral suppository.

Table 2-4	COMPOSITION, MELTING RANGE, AND CONGEALING RANGE OF SELECTED BASES THAT MELT		
Base	**Composition**	**Melting Range (°C)**	**Congealing Range (°C)**
Cocoa butter	Mixed triglycerides of oleic, palmitic, and stearic acids	34–35	28 or less
Cotmar	Partially hydrogenated cottonseed oil	34–75	—
Dehydag	Hydrogenated fatty alcohols		
Base I	and esters	33–36	32–33
Base II		37–39	36–37
Base III		9 ranges	9 ranges
Wecobee R	Glycerides of saturated fatty acids C_{12}–C_{18}	33–35	31–32
Wecobee SS	Triglycerides derived from coconut oil	40–43	33–35
Witepsol	Triglycerides of saturated fatty		
H12	acids C_{12}–C_{18}, with varied	32–33	29–32
H15	portions of the corresponding	33–35	32–34
H85	partial glycerides	42–44	36–38

       (b) A mixture of triglycerides, cocoa butter exhibits polymorphism. Depending on the fusion temperature, it can crystallize into any one of four crystal forms.

       (c) **Major limitations of cocoa butter**. Because of the following limitations, many combinations of fats and waxes are used as substitutes (*Table 2-4*):

          (i) **An inability to absorb aqueous solutions**. The addition of nonionic surfactants to the base ameliorates this problem to some extent. However, the resultant suppositories have poor stability and may turn rancid rapidly.

          (ii) **The lowering of the melting point produced by certain drugs** (e.g., chloral hydrate).

     (2) **Witepsol** bases contain natural saturated fatty acid chains between C_{12} and C_{18}. Lauric acid is the major component. All 12 bases of this series are colorless and almost odorless. The drug-release characteristics of Witepsol H15 are similar to those of cocoa butter.

       (a) Unlike cocoa butter, Witepsol bases do not exhibit polymorphism when heated and cooled.

       (b) The interval between softening and melting temperatures is very small. Because Witepsol bases solidify rapidly in the mold, lubrication of the mold is not necessary.

     (3) **Wecobee** bases are derived from coconut oil. Their action is similar to that of Witepsol bases. Incorporation of glyceryl monostearate and propylene glycol monostearate makes these bases emulsifiable.

   d. **Bases that dissolve** include **PEG** polymers with a molecular weight of 400 to 6000.

     (1) At room temperature, PEG 400 is a liquid, PEG 1000 is a semisolid, PEG 1500 and 1600 are fairly firm semisolids, and PEG 3350 and 6000 are firm waxlike solids.

     (2) These bases are water soluble, but the dissolution process is very slow. In the rectum and vagina, where the amount of fluid is very small, they dissolve very slowly, but they soften and spread.

     (3) PEGs complex with several drugs and affect drug release and absorption.

     (4) Mixtures of PEG polymers in varying proportions provide a base of different properties (*Table 2-5*).

 4. **Preparation**. Suppositories are prepared by the following three methods:

   a. **Hand-rolling** involves molding the suppository with the fingers after a plastic mass is formed.

     (1) A finely powdered drug is mixed with the grated base in a mortar and pestle, using levigation and geometric dilution techniques. A small quantity of fixed oil may be added to facilitate preparation.

Table 2-5   MIXTURES OF POLYETHYLENE GLYCOL (PEG) BASES PROVIDING
SATISFACTORY ROOM TEMPERATURE STABILITY AND
DISSOLUTION CHARACTERISTICS

Base	Comments	Components	Proportion (%)
1	Provides a good general-purpose, water-soluble suppository	PEG 6000	50
		PEG 1540	30
		PEG 400	20
2	Provides a good general-purpose base that is slightly softer than base 1 and dissolves more rapidly	PEG 4000	60
		PEG 1500	30
		PEG 400	10
3	Has a higher melting point than the other bases, which is usually sufficient to compensate for the melting point lowering effect of such drugs as chloral hydrate and camphor	PEG 6000	30
		PEG 1540	70

      (2) The uniformly mixed semiplastic mass is kneaded further, rolled into a cylinder, and divided into the requisite number of suppositories. Each small cylinder is rolled by hand until a suppository shape is fashioned.

  b. **Compression** is generally used when cocoa butter is used as a base.

      (1) A uniform mixture of drug and base is prepared as for the hand-rolling method.

      (2) The mixture is placed into a suppository compression device. Pressure is applied, and the mixture is forced into lubricated compression mold cavities. The mold is then cooled and the suppositories ejected.

      (3) This procedure generally produces a 2-g suppository. However, a large volume of the active ingredients can affect the amount of cocoa butter required for an individual formula.

         (a) The amount of cocoa butter needed is determined by calculating the total amount of active ingredient to be used, dividing this number by the cocoa butter density factor (*Table 2-6*), and subtracting the resulting number from the total amount of cocoa butter required for the desired number of suppositories.

         (b) For example, suppose 12 suppositories, each containing 300 mg aspirin, are required. Each mold cavity has a 2-g capacity. For 13 suppositories (calculated to provide one

Table 2-6   COCOA BUTTER DENSITY FACTORS OF DRUGS COMMONLY USED
IN SUPPOSITORIES

Drug	Cocoa Butter Density Factor	Drug	Cocoa Butter Density Factor
Aloin	1.3	Dimenhydrinate	1.3
Aminophylline	1.1	Diphenhydramine hydrochloride	1.3
Aminopyrine	1.3	Gallic acid	2.0
Aspirin	1.1	Morphine hydrochloride	1.6
Barbital sodium	1.2	Pentobarbital	1.2
Belladonna extract	1.3	Phenobarbital sodium	1.2
Bismuth subgallate	2.7	Salicylic acid	1.3
Chloral hydrate	1.3	Secobarbital sodium	1.2
Codeine phosphate	1.1	Tannic acid	1.6
Digitalis leaf	1.6		

extra), 3.9 g aspirin (13 $\times$ 0.3 g = 3.9 g) is required. This number is divided by the density factor of aspirin (1.1) (*Table 2-6*). Thus, 3.9 g of aspirin replaces 3.55 g of cocoa butter. The total amount of cocoa butter needed for 13 suppositories of 2 g each equals 26 g. The amount of cocoa butter required is 26 g − 3.55 g, or 22.45 g.

  c. The **fusion method** is the principal way that suppositories are made commercially. This method is used primarily for suppositories that contain cocoa butter, PEG, and glycerin–gelatin bases. Molds made of aluminum, brass, or nickel–copper alloys are used and can make 6 to 50 suppositories at one time.

    (1) The **capacity of the molds** is determined by melting a sufficient quantity of base over a steam bath, pouring it into the molds, and allowing it to congeal. The "blank" suppositories are trimmed, removed, and weighed. Once the weight is known, the drug-containing suppositories are prepared.

      (a) To prepare suppositories, the drug is reduced to a fine powder. A small amount of grated cocoa butter is liquefied in a suitable container placed in a water bath at 33°C or less.

      (b) The finely powdered drug is mixed with melted cocoa butter with continuous stirring.

      (c) The remainder of the grated cocoa butter is added with stirring. The temperature is maintained at or below 33°C. The liquid should appear creamy rather than clear.

      (d) The mold is very lightly lubricated with mineral oil, and the creamy melt is poured into the mold at room temperature. The melt is poured continuously to avoid layering.

      (e) After the suppositories congeal, they are placed in a refrigerator to harden. After 30 mins, they are removed from the refrigerator, trimmed, and unmolded.

    (2) The fusion process should be used carefully with **thermolabile drugs** and **insoluble powders**.

      (a) Insoluble powders in the melt may settle or float during pouring, depending on their density. They may also collect at one end of the suppository before the melt congeals, and cause a nonuniform drug distribution.

      (b) Hard crystalline materials (e.g., iodine, merbromin) can be incorporated by dissolving the crystals in a minimum volume of suitable solvent before they are incorporated into the base.

      (c) Vegetable extracts can be incorporated by moistening with a few drops of alcohol and levigating with a small amount of melted cocoa butter.

G. Powders

  1. Introduction. A pharmaceutical powder is a mixture of finely divided drugs or chemicals in dry form. The powder may be used internally or externally.

    a. Advantages of powders

      (1) Flexibility of compounding

      (2) Good chemical stability

      (3) Rapid dispersion of ingredients because of the small particle size

    b. Disadvantages of powders

      (1) Time-consuming preparation

      (2) Inaccuracy of dose

      (3) Unsuitability for many unpleasant-tasting, hygroscopic, and deliquescent drugs

    c. Milling is the mechanical process of reducing the particle size of solids (**comminution**) before mixing with other components, further processing, or incorporation into a final product (*Tables 2-7 and 2-8*). The particle size of a powder is related to the proportion of the powder that can pass through the opening of standard sieves of various dimensions in a specified amount of time. **Micromeritics** is the study of particles.

      (1) Advantages of milling

        (a) Increases the surface area, which may increase the dissolution rate as well as bioavailability (e.g., griseofulvin)

        (b) Increases extraction, or leaching, from animal glands (e.g., liver, pancreas) and from crude vegetable extracts

        (c) Facilitates drying of wet masses by increasing the surface area and reducing the distance that moisture must travel to reach the outer surface. Micronization and subsequent drying, in turn, increase stability as occluded solvent is removed.

Table 2-7   *UNITED STATES PHARMACOPEIA* STANDARDS FOR POWDERS OF ANIMAL AND VEGETABLE DRUGS

Type of Powder	Sieve Size All Particles Pass Through	Sieve Size Percentage of Particles Pass Through
Very coarse (#8)	#20 sieve	20% through a #60 sieve
Coarse (#20)	#20 sieve	40% through a #60 sieve
Moderately coarse (#40)	#40 sieve	40% through a #80 sieve
Fine (#60)	#60 sieve	40% through a #100 sieve
Very fine (#80)	#80 sieve	No limit

    (d) Improves mixing, or blending, of several solid ingredients if they are reduced to approximately the same size; also minimizes segregation and provides greater dose uniformity

    (e) Permits uniform distribution of coloring agents in artificially colored solid pharmaceuticals

    (f) Improves the function of lubricants used to coat the surface of the granulation or powder in compressed tablets and capsules

    (g) Improves the texture, appearance, and physical stability of ointments, creams, and pastes

  (2) Disadvantages of milling

    (a) Can change the polymorphic form of the active ingredient, rendering it less active

    (b) Can degrade the drug as a result of heat buildup, oxidation, or adsorption of unwanted moisture because of increased surface area

    (c) Decreases the bulk density of the active compound and excipients, causing flow problems and segregation.

    (d) Decreases the particle size of the raw materials and may create problems with static charge, which may cause particle aggregation and decrease the dissolution rate

    (e) Increases surface area, which may promote air adsorption and inhibit wettability

  (3) Comminution techniques. On a large scale, various mills and pulverizers (e.g., rotary cutter, hammer, roller, fluid energy mill) are used during manufacturing. On a small scale, the pharmacist usually uses one of the following comminution techniques:

    (a) Trituration. The substance is reduced to small particles by rubbing it in a mortar with a pestle. Trituration also describes the process by which fine powders are intimately mixed in a mortar.

    (b) Pulverization by intervention. Substances are reduced and subdivided with an additional material (i.e., solvent) that is easily removed after pulverization. This technique is often used with gummy substances that reagglomerate or resist grinding. For example, camphor is readily reduced after a small amount of alcohol or other volatile solvent is added. The solvent is then permitted to evaporate.

Table 2-8   *UNITED STATES PHARMACOPEIA* STANDARDS FOR POWDERS OF CHEMICALS

Type of Powder	Sieve Size All Particles Pass Through	Sieve Size Percentage of Particles Pass Through
Coarse (#20)	#20 sieve	60% through a #40 sieve
Moderately coarse (#40)	#40 sieve	60% through a #60 sieve
Fine (#80)	#80 sieve	No limit
Very fine (#120)	#120 sieve	No limit

        (c) Levigation. The particle size of the substance is reduced by adding a suitable non-solvent (levigating agent) to form a paste. The paste is then rubbed in a mortar and pestle or using an ointment slab and spatula. This method is often used to prevent a gritty feel when solids are incorporated into dermatologic or ophthalmic ointments and suspensions. Mineral oil is a common levigating agent.

  2. Mixing powders. Powders are mixed, or blended, by the following five methods:

    a. Spatulation. A spatula is used to blend small amounts of powders on a sheet of paper or a pill tile.

      (1) This method is not suitable for large quantities of powders or for powders that contain potent substances because homogeneous blending may not occur.

      (2) This method is particularly useful for solid substances that liquefy or form **eutectic mixtures** (i.e., mixtures that melt at a lower temperature than any of their ingredients) when in close, prolonged contact with one another because little compression or compaction results.

        (a) These substances include phenol, camphor, menthol, thymol, aspirin, phenylsalicylate, and phenacetin.

        (b) To diminish contact, powders prepared from these substances are commonly mixed with an inert diluent (e.g., light magnesium oxide or magnesium carbonate, kaolin, starch, bentonite).

        (c) Silicic acid (approximately 20%) prevents eutexia with aspirin, phenylsalicylate, and other troublesome compounds.

    b. Trituration is used both to comminute and to mix powders.

      (1) If comminution is desired, a porcelain or ceramic mortar with a rough inner surface is preferred to a glass mortar with a smooth working surface.

      (2) A glass mortar is preferable for chemicals that stain a porcelain or ceramic surface as well as for simple admixture of substances without special need for comminution. A glass mortar cleans more readily after use.

    c. Geometric dilution is used when potent substances must be mixed with a large amount of diluent.

      (1) The potent drug and an approximately equal volume of diluent are placed in a mortar and thoroughly mixed by trituration.

      (2) A second portion of diluent, equal in volume to the powder mixture in the mortar, is added, and trituration is repeated. The process is continued; equal volumes of diluent are added to the powder mixture in the mortar until all of the diluent is incorporated.

    d. Sifting. Powders are mixed by passing them through sifters similar to those used to sift flour. This process results in a light, fluffy product. Usually, it is not acceptable for incorporating potent drugs into a diluent base.

    e. Tumbling is the process of mixing powders in a large container rotated by a motorized process. These blenders are widely used in industry, as are large-volume powder mixers that use motorized blades to blend the powder in a large mixing vessel.

  3. Use and packaging of powders. Depending on their intended use, powders are packaged and dispensed by pharmacists as bulk powders or divided powders.

    a. Bulk powders are dispensed by the pharmacist in bulk containers. A **perforated**, or **sifter**, **can** is used for external dusting, and an **aerosol container** is used for spraying on skin. A **wide-mouthed glass jar** permits easy removal of a spoonful of powder.

      (1) Powders commonly dispensed in bulk form

        (a) Antacid and laxative powders are used by mixing the directed amount of powder (usually approximately 1 teaspoon) in a portion of liquid, which the patient then drinks.

        (b) Douche powders are dissolved in warm water and applied vaginally.

        (c) Medicated and nonmedicated powders for external use are usually dispensed in a sifter for convenient application to the skin.

        (d) Dentifrices, or **dental cleansing powders**, are used for oral hygiene.

        (e) Powders for the **ear**, **nose**, **throat**, **tooth sockets**, or **vagina** are administered with an insufflator or powder blower.

      (2) Nonpotent substances are usually dispensed in bulk powder form. Those intended for external use should be clearly labeled.

(3) **Hygroscopic**, **deliquescent**, or **volatile** powders should be packed in glass jars rather than pasteboard containers. Amber or green glass should be used if needed to prevent decomposition of light-sensitive components. All powders should be stored in tightly closed containers.

b. **Divided powders** are dispensed in individual doses, usually in folded **papers** (i.e., chartulae). They may also be dispensed in metal foil, small heat-sealed or resealable **plastic bags**, or other containers.

(1) After the ingredients are weighed, comminuted, and mixed, the powders must be accurately **divided** into the prescribed number of doses.

(2) Depending on the potency of the drug substance, the pharmacist decides whether to **weigh** each portion separately before packaging or to approximate portions by the **block-and-divide method**.

(3) **Powder papers** can be of any convenient size that fits the required dose. Four basic types are used:

(a) **Vegetable parchment** is a thin, semiopaque, moisture-resistant paper.

(b) **White bond** is an opaque paper that has no moisture-resistant properties.

(c) **Glassine** is a glazed, transparent, moisture-resistant paper.

(d) **Waxed paper** is a transparent waterproof paper.

(4) Hygroscopic and volatile drugs are best protected with waxed paper that is double wrapped and covered with a bond paper to improve the appearance. Parchment and glassine papers are of limited use for these drugs.

4. **Special problems**. Volatile substances, eutectic mixtures, liquids, and hygroscopic or deliquescent substances present problems when they are mixed into powders that require special treatment.

a. **Volatile substances** (e.g., camphor, menthol, essential oils) can be lost by volatilization after they are incorporated into powders. This process is prevented or retarded by the use of heat-sealed plastic bags or by double wrapping with waxed or glassine paper inside white bond paper.

b. **Liquids** are incorporated into divided powders in small amounts.

(1) Magnesium carbonate, starch, or lactose can be added to increase the absorbability of the powders by increasing the surface area.

(2) When the liquid is a solvent for a nonvolatile heat-stable compound, it is evaporated gently in a water bath. Some fluid extracts and tinctures are treated in this way.

c. **Hygroscopic and deliquescent substances** that become moist because of an affinity for moisture in the air can be prepared as divided powders by adding inert diluents. Double wrapping is desirable for further protection.

d. **Eutectic mixtures**

H. **Capsules**

1. **Introduction**. Capsules are solid dosage forms in which one or more medicinal or inert substances (as powder, compact, beads, or granulation) are enclosed within a small gelatin shell. Gelatin capsules may be hard or soft. Most capsules are intended to be swallowed whole, but occasionally, the contents are removed from the gelatin shell and used as a premeasured dose.

2. **Hard gelatin capsules**

a. **Preparation of filled hard capsules** includes preparing the formulation, selecting the appropriate capsule, filling the capsule shells, and cleaning and polishing the filled capsules.

(1) Empty hard capsule shells are manufactured from a mixture of gelatin, colorants, and sometimes an opacifying agent (e.g., titanium dioxide). The *USP* also permits the addition of 0.15% sulfur dioxide to prevent decomposition of gelatin during manufacture.

(2) Gelatin *USP* is obtained by partial hydrolysis of collagen obtained from the skin, white connective tissue, and bones of animals. Types A and B are obtained by acid and alkali processing, respectively.

(3) Capsule shells are cast by dipping cold metallic molds or pins into gelatin solutions that are maintained at a uniform temperature and an exact degree of fluidity.

(a) Variation in the viscosity of the gelatin solution increases or decreases the thickness of the capsule wall.

(b) After the pins are withdrawn from the gelatin solution, they are rotated while being dried in kilns. A strong blast of filtered air with controlled humidity is forced through the kilns. Each capsule is then mechanically stripped, trimmed, and joined.

   b. Storage. Hard capsules should be stored in tightly closed glass containers and protected from dust and extremes of humidity and temperature.

   (1) These capsules contain 12% to 16% water, varying with storage conditions. When humidity is low, the capsules become brittle. When humidity is high, the capsules become flaccid and shapeless.

   (2) Storage at high temperatures also affects the quality of hard gelatin capsules.

   c. Sizes. Hard capsules are available in various sizes.

   (1) Empty capsules are **numbered** from 000, which is the largest size that can be swallowed, to 5, the smallest size. The approximate capacity of capsules ranges from 600 to 30 mg for capsules from 000 to 5, respectively. The capacity varies because of varying densities of powdered drug materials and the degree of pressure used to fill the capsules.

   (2) Large capsules are available for **veterinary medicine**.

   (3) Selecting capsules. Capsule size should be chosen carefully. A properly filled capsule should have its body filled with the drug mixture and its cap fully extended down the body. The cap is meant to enclose the powder, not to retain additional powder. Typically, hard gelatin capsules are used to encapsulate between 65 mg and 1 g of powdered material, including the drug and any diluents needed.

   (a) If the drug dose is inadequate to fill the capsule, a diluent (e.g., lactose) is added.

   (b) If the amount of drug needed for a usual dose is too large to place in a single capsule, two or more capsules may be required.

   (c) Lubricants such as magnesium stearate (frequently, 1%) are added to facilitate the flow of the powder when an automatic capsule-filling machine is used.

   (d) Wetting agents (e.g., sodium lauryl sulfate) may be added to capsule formulations to enhance drug dissolution.

   d. Filling capsules. Whether on a large- or a small-production scale, the cap is first separated from the body of the capsule before filling the capsule body with the formulation and then reattaching the cap. Automated and semiautomated capsule-filling equipment fill the capsule bodies with the formulation by gravity fill, tamping, or a screw-feed (i.e., auger) mechanism. Extemporaneously compounded capsules are usually filled by the punch method.

   (1) The powder is placed on paper and flattened with a spatula so that the layer of powder is no more than approximately one-third the length of the capsule. The paper is held in the left hand. The body of the capsule is held in the right hand and repeatedly pressed into the powder until the capsule is filled. The cap is replaced and the capsule weighed.

   (2) Granular material that does not lend itself well to the punch method can be poured into each capsule from the powder paper on which it was weighed.

   (3) Crystalline materials, especially those that consist of a mass of filament-like crystals (e.g., quinine salts), will not fit into a capsule easily unless they are powdered.

   (4) After they are filled, capsules must be cleaned and polished.

   (a) On a **small scale**, capsules are cleaned individually or in small numbers by rubbing them on a clean gauze or cloth.

   (b) On a **large scale**, many capsule-filling machines have a cleaning vacuum that removes any extraneous material as the capsules leave the machine.

3. Soft gelatin capsules

   a. Preparation

   (1) Soft gelatin capsules are prepared from gelatin shells. Glycerin or a polyhydric alcohol (e.g., sorbitol) is added to these shells to make them elastic or plastic-like.

   (2) These shells contain preservatives (e.g., methyl and propyl parabens, sorbic acid) to prevent the growth of fungi.

   b. Uses. Soft gelatin shells are oblong, elliptical, or spherical. They are used to contain liquids, suspensions, pastes, dry powders, or pellets.

   (1) Drugs that are commercially prepared in soft capsules include demeclocycline hydrochloride (Declomycin, Lederle), chloral hydrate, digoxin (Lanoxicaps, GlaxoSmithKline), vitamin A, and vitamin E.

   (2) Soft gelatin capsules are usually prepared by the plate process or by the rotary or reciprocating die process.

    4. **Uniformity and disintegration**
      a. The **uniformity** of dosage forms can be demonstrated by either weight variation or content uniformity methods. The official compendia should be consulted for details of these procedures.
      b. **Disintegration** tests are not usually required for capsules unless they have been treated to resist solution in gastric fluid (enteric coated). In this case, they must meet the requirements for disintegration of enteric-coated tablets.

I. Tablets

    1. **Introduction**
      a. The **oral route** is the most important method for administering drugs for systemic effect. Oral drugs can be given as solids or liquids.
        (1) **Advantages of solid dosage forms**
          (a) Accurate dosage
          (b) Easy shipping and handling
          (c) Less shelf space needed per dose than for liquid
          (d) No preservation requirements
          (e) No taste-masking problem
          (f) Generally more stable than liquids, with longer expiration dates
        (2) **Advantages of liquid dosage forms**
          (a) For some drugs (e.g., adsorbents, antacids), greater effectiveness than solid form
          (b) Useful for patients who have trouble swallowing solid dosage forms
      b. **Tablets** are the **most commonly used solid dosage form**.
        (1) **Advantages**
          (a) Precision and low content variability of the unit dose
          (b) Low manufacturing cost
          (c) Easy to package and ship
          (d) Simple to identify
          (e) Easy to swallow
          (f) Appropriate for special-release forms
          (g) Best suited to large-scale production
          (h) Most stable of all oral dosage forms
          (i) Essentially tamperproof
        (2) **Disadvantages**
          (a) Some drugs resist compression into tablets.
          (b) Some drugs (i.e., those with poor wetting, slow dissolution properties, intermediate to large doses, optimum absorption high in the gastrointestinal tract, or any combination of these features) may be difficult to formulate to provide adequate bioavailability.
          (c) Some drugs (e.g., those with an objectionable taste or odor, those sensitive to oxygen or atmospheric moisture) require encapsulation or entrapment before compression. These drugs are more appropriate in capsule form.

    2. **Tablet design and formulation**
      a. **Characteristics of ideal tablets**
        (1) Free of defects (e.g., chips, cracks, discoloration, contamination)
        (2) Strong enough to withstand the mechanical stresses of production
        (3) Chemically and physically stable over time
        (4) Capable of releasing medicinal agents in a predictable and reproducible manner
      b. **Tablet excipients**. Tablets are manufactured by **wet granulation**, **dry granulation**, or **direct compression**. Regardless of the method of manufacture, tablets for oral ingestion usually contain excipients, which are components added to the active ingredients that have special functions (*Table 2-9*).
        (1) **Diluents** are fillers designed to make up the required bulk of the tablet when the drug dosage amount is inadequate. Diluents may also improve cohesion, permit direct compression, or promote flow.
          (a) **Common diluents** include kaolin, lactose, mannitol, starch, microcrystalline cellulose, powdered sugar, and calcium phosphate.
          (b) **Selection of the diluent** is based on the experience of the manufacturer as well as on the cost of the diluent and its compatibility with the other tablet ingredients.

Table 2-9	SOME COMMON TABLET EXCIPIENTS

Diluents
Calcium phosphate dihydrate *NF* (dibasic)
Calcium sulfate dihydrate *NF*
Cellulose *NF* (microcrystalline)
Cellulose derivatives
Dextrose
Lactose *USP*
Lactose *USP* (anhydrous)
Lactose *USP* (spray dried)
Mannitol *USP*
Starches (directly compressible)
Starches (hydrolyzed)
Sorbitol
Sucrose *USP* (powder)
Sucrose-based materials

Binders and adhesives
Acacia
Cellulose derivatives
Gelatin
Glucose
Povidone (PVP)
Sodium alginate and alginate derivatives
Sorbitol
Starch (paste)
Starch (pregelatinized)
Tragacanth

Disintegrants
Alginates
Cellulose
Cellulose derivatives
Clays
Crospovidone (cross-linked PVP)
Starch
Starch derivatives

Lubricants
PEGs
Stearic acid
Stearic acid salts
Stearic acid derivatives
Surfactants
Talc
Waxes

Glidants
Cornstarch
Silica derivatives
Talc

Colors, flavors, and sweeteners
FD&C and D&C dyes and lakes
Flavors available in two forms (spray dried, oil)
Artificial sweeteners
Natural sweetener

D&C, drugs and cosmetics; *FD&C,* food, drugs, and cosmetics; *NF, National Formulary; PEG,* polyethylene glycol; *PVP,* polyvinylpyrrolidone (more commonly, povidone); *USP, United States Pharmacopeia.*

For example, calcium salts cannot be used as fillers for tetracycline products because calcium interferes with the absorption of tetracycline from the gastrointestinal tract.

(2) **Binders and adhesives** are added in either dry or liquid form to promote granulation or to promote cohesive compacts during direct compression.

(a) **Common binding agents** include a 10% to 20% aqueous preparation of cornstarch, a 25% to 50% solution of glucose, molasses, various natural gums (e.g., acacia), cellulose derivatives (e.g., methylcellulose, carboxymethylcellulose, microcrystalline cellulose), gelatins, and povidone. The natural gums are variable in composition and are usually contaminated with bacteria.

(b) If the drug substance is adversely affected by an aqueous binder, a **nonaqueous binder** can be used or the binder can be added dry. The binding action is usually more effective when the binder is mixed in liquid form.

(c) The **amount** of binder or adhesive used depends on the experience of the manufacturer as well as on the other tablet ingredients. Overwetting usually produces granules that are too hard to allow proper tableting. Underwetting usually produces tablets that are too soft and tend to crumble.

(3) **Disintegrants** are added to tablet formulations to facilitate disintegration when the tablet contacts water in the gastrointestinal tract. Disintegrants function by drawing water into the tablet, swelling, and causing the tablet to burst.

(a) Tablet disintegration may be critical to the subsequent dissolution of the drug and to satisfactory drug bioavailability.

    (b) **Common disintegrants** include cornstarch and potato starch, starch derivatives (e.g., sodium starch glycolate), cellulose derivatives (e.g., sodium carboxymethyl-cellulose, croscarmellose sodium), clays (e.g., Veegum, bentonite), and cation exchange resins.

    (c) The total **amount of disintegrant** is not always added to the drug–diluent mixture. A portion can be added, with the lubricant, to the prepared granulation of the drug. This approach causes double disintegration of the tablet. The portion of disintegrant that is added last causes the tablet to break into small pieces or chunks. The portion that is added first breaks the pieces of tablet into fine particles.

(4) **Lubricants**, **antiadherents**, and **glidants** have overlapping function.

    (a) **Lubricants** reduce the friction that occurs between the walls of the tablet and the walls of the die cavity when the tablet is ejected. Talc, magnesium stearate, and calcium stearate are commonly used.

    (b) **Antiadherents** reduce sticking, or adhesion, of the tablet granulation or powder to the faces of the punches or the die walls.

    (c) **Glidants** promote the flow of the tablet granulation or powder by reducing friction among particles.

(5) **Colors and dyes** disguise off-color drugs, provide product identification, and produce a more aesthetically appealing product. **Food**, **drug**, and **cosmetic dyes** are applied as solutions. **Lakes** are dyes that have been absorbed on a hydrous oxide. Lakes are typically used as dry powders.

(6) **Flavoring agents** are usually limited to chewable tablets or tablets that are intended to dissolve in the mouth.

    (a) Water-soluble flavors usually have poor stability. For this reason, flavor oils or dry powders are typically used.

    (b) Flavor oils may be added to tablet granulations in solvents, dispersed on clays and other adsorbents, or emulsified in aqueous granulating agents. Usually, the maximum amount of oil that can be added to a granulation without affecting its tablet characteristics is 0.5% to 0.75%.

(7) **Artificial sweeteners**, like flavors, are typically used only with chewable tablets or tablets that are intended to dissolve in the mouth.

    (a) Some **sweetness** may come from the diluent (e.g., mannitol, lactose). Other agents (e.g., saccharin, aspartame) may also be added.

    (b) **Saccharin** has an unpleasant aftertaste.

    (c) **Aspartame** is not stable in the presence of moisture and heat.

(8) **Adsorbents** (e.g., magnesium oxide, magnesium carbonate, bentonite, silicon dioxide) hold quantities of fluid in an apparently dry state.

3. **Tablet types and classes**. Tablets are classified according to their route of administration, drug delivery system, and form and method of manufacture (*Table 2-10*).

  a. **Tablets for oral ingestion** are designed to be swallowed intact, with the exception of chewable tablets. Tablets may be coated for a number of reasons: to mask the taste, color, or odor of the drug; to control drug release; to protect the drug from the acid environment of the stomach; to incorporate another drug and provide sequential release or avoid incompatibility; or to improve appearance.

    (1) **Compressed tablets** are formed by compression and have no special coating. They are made from powdered, crystalline, or granular materials, alone or in combination with excipients such as binders, disintegrants, diluents, and colorants.

    (2) **Multiple compressed tablets** are layered or compression coated.

      (a) **Layered tablets** are prepared by compressing a tablet granulation around a previously compressed granulation. The operation is repeated to produce multiple layers.

      (b) **Compression-coated**, **or dry-coated**, **tablets** are prepared by feeding previously compressed tablets into a special tableting machine. This machine compresses an outer shell around the tablets. This process applies a thinner, more uniform coating than sugar coating, and it can be used safely with drugs that are sensitive to moisture.

Table 2-10	TABLET TYPES AND CLASSES

Tablets for oral ingestion	**Tablets used in the oral cavity**
Compressed	Buccal
Multiple compressed	Sublingual
Layered	Troches, lozenges, and dental
Compression coated	cones
Repeat-action	
Delayed action and enteric coated	**Tablets used to prove solutions**
Sugar coated and chocolate coated	Effervescent
Film coated	Dispensing
Air suspension coated	Hypodermic
Chewable	Triturates

This process can be used to separate incompatible materials, to produce repeat-action or prolonged-action products, or to produce tablets with a multilayered appearance.

(3) **Repeat-action tablets** are layered or compression-coated tablets in which the outer layer or shell rapidly disintegrates in the stomach (e.g., Repetabs, Schering, Extentabs, Wyeth). The components of the inner layer or inner tablet are insoluble in gastric media but soluble in intestinal media.

(4) **Delayed-action** and **enteric-coated tablets** delay the release of a drug from a dosage form. This delay is intended to prevent destruction of the drug by gastric juices, to prevent irritation of the stomach lining by the drug, or to promote absorption, which is better in the intestine than in the stomach.

  (a) **Enteric-coated** tablets are coated and remain intact in the stomach, but yield their ingredients in the intestines (e.g., Ecotrin, GlaxoSmithKline). Enteric-coated tablets are a form of delayed-action tablet. However, not all delayed-action tablets are enteric or are intended to produce an enteric effect.

  (b) Agents used to coat these tablets include fats, fatty acids, waxes, shellac, and cellulose acetate phthalate.

(5) **Sugar-coated** and **chocolate-coated tablets** are compressed tablets that are coated for various reasons. The coating may be added to protect the drug from air and humidity, to provide a barrier to a drug's objectionable taste or smell, or to improve the appearance of the tablet.

  (a) Tablets may be coated with a colored or an uncolored sugar. The process includes **seal coating** (waterproofing), **subcoating**, **syrup coating** (for smoothing and coloring), and **polishing**. These steps take place in a series of mechanically operated coating pans.

  (b) **Disadvantages** of sugar-coated tablets include the time and expertise required for the process and the increase in tablet size and weight. Sugar-coated tablets may be 50% larger and heavier than the original tablets.

  (c) Chocolate-coated tablets are rare today.

(6) **Film-coated tablets** are compressed tablets that are coated with a thin layer of a water-insoluble or water-soluble polymer (e.g., hydroxypropyl methylcellulose [hypromellose], ethylcellulose, povidone, PEG).

  (a) The film is usually colored. It is more durable, less bulky, and less time consuming to apply than sugar coating. Although the film typically increases tablet weight by only 2% to 3%, it increases formulation efficiency, resistance to chipping, and output.

  (b) Film-coating solutions usually contain a film former, an alloying substance, a plasticizer, a surfactant, opacifiers, sweeteners, flavors, colors, glossants, and a volatile solvent.

  (c) The volatile solvents used in these solutions are expensive and potentially toxic when released into the atmosphere. Specifically formulated **aqueous dispersions** of

polymers (e.g., ethylcellulose) are now available as alternatives to organic solvent-based coating solutions.

(7) **Air suspension–coated tablets** are fed into a vertical cylinder and supported by a column of air that enters from the bottom of the cylinder. As the coating solution enters the system, it is rapidly applied to the suspended, rotating solids (**Wurster process**). Rounding coats can be applied in < 1 hr when blasts of warm air are released in the chamber.

(8) **Chewable tablets** disintegrate smoothly and rapidly when chewed or allowed to dissolve in the mouth. These tablets contain specially colored and flavored mannitol and yield a creamy base.

   (a) Chewable tablets are especially useful in formulations for children.

   (b) They are commonly used for multivitamin tablets and are used for some antacids and antibiotics.

   b. Tablets used in the oral cavity are allowed to dissolve in the mouth.

   (1) **Buccal** and **sublingual** tablets allow absorption through the oral mucosa after they dissolve in the buccal pouch (buccal tablets) or below the tongue (sublingual tablets). These forms are useful for drugs that are destroyed by gastric juice or poorly absorbed from the intestinal tract. Examples include sublingual nitroglycerin tablets, which dissolve promptly to give rapid drug effects, and buccal progesterone tablets, which dissolve slowly.

   (2) **Troches**, **lozenges**, and **dental cones** dissolve slowly in the mouth and provide primarily local effects.

   c. Tablets used to prepare solutions are dissolved in water before administration.

   (1) **Effervescent tablets** are prepared by compressing granular effervescent salts or other materials (e.g., citric acid, tartaric acid, sodium bicarbonate) that release carbon dioxide gas when they come into contact with water. Commercial alkalinizing analgesic tablets are often made to effervesce to encourage rapid dissolution and absorption (e.g., Alka-Seltzer, Bayer).

   (2) Other tablets used to prepare solutions include **dispensing tablets**, **hypodermic tablets**, and **tablet triturates**.

4. Processing problems

   a. **Capping** is the partial or complete separation of the top or bottom crown from the main body of the tablet. **Lamination** is separation of a tablet into two or more distinct layers. These problems are usually caused by entrapment of air during processing.

   b. **Picking** is removal of the surface material of a tablet by a punch. Sticking is adhesion of tablet material to a die wall. These problems are caused by excessive moisture or the inclusion of substances with low melting temperatures in the formulation.

   c. **Mottling** is unequal color distribution, with light or dark areas standing out on an otherwise uniform surface. This problem occurs when a drug has a different color than the tablet excipients or when a drug has colored degradation products. Colorants solve the problem but can create other problems.

5. Tablet evaluation and control

   a. The general appearance of tablets is an important factor in consumer acceptance. It also allows monitoring of lot-to-lot uniformity, tablet-to-tablet uniformity, and elements of the manufacturing process. The appearance of the tablet includes visual identity and overall appearance. The appearance of the tablet is controlled by measurement of attributes such as size, shape, color, odor, taste, surface, texture, physical flaws, consistency, and legibility of markings.

   b. Hardness and resistance to friability are necessary for tablets to withstand the mechanical shocks of manufacture, packaging, and shipping, and to ensure consumer acceptance. Hardness involves both tablet disintegration and drug dissolution. Certain tablets that are intended to dissolve slowly are made hard. Other tablets that are intended to dissolve rapidly are made soft. Friability is the tendency of the tablet to crumble.

   (1) Tablet hardness testers measure the degree of force required to break a tablet.

   (2) **Friabilators** determine **friability** by allowing the tablet to roll and fall within a rotating tumbling apparatus. The tablets are weighed before and after a specified number of rotations, and the weight loss is determined.

      (a) Resistance to weight loss indicates the ability of the tablet to withstand abrasion during handling, packaging, and shipping. Compressed tablets that lose < 0.5% to 1% of their weight are usually considered acceptable.

          (b) Some chewable tablets and most effervescent tablets are highly friable and require special unit packaging.

    c. Tablets are routinely weighed to ensure that they contain the proper amount of drug.

        (1) The *USP* defines a **weight variation standard** to which tablets must conform.

        (2) These standards apply to tablets that contain 50 mg or more of drug substance when the drug substance is 50% or more (by weight) of the dosage form unit.

    d. Content uniformity is evaluated to ensure that each tablet contains the desired amount of drug substance, with little variation among contents within a batch. The *USP* defines content uniformity tests for tablets that contain 50 mg or less of drug substance.

    e. Disintegration is evaluated to ensure that the drug substance is fully available for dissolution and absorption from the gastrointestinal tract.

        (1) All *USP* tablets must pass an official **disintegration test** that is conducted in vitro with special equipment.

            (a) Disintegration times for uncoated *USP* tablets are as low as 2 mins (nitroglycerin) to 5 mins (aspirin). Most have a maximum disintegration time of less than 30 mins.

            (b) Buccal tablets must disintegrate within 4 hrs.

            (c) Enteric-coated tablets must show no evidence of disintegration after 1 hr in simulated gastric fluid. In simulated intestinal fluid, they should disintegrate in 2 hrs plus the time specified.

        (2) Dissolution requirements in the *USP* have replaced earlier disintegration requirements for many drugs.

    f. Dissolution characteristics are tested to determine drug absorption and physiologic availability.

        (1) The *USP* gives standards for tablet dissolution.

        (2) An increased emphasis on testing tablet dissolution and determining drug bioavailability has increased the use of sophisticated testing systems.

J. Aerosol products

  1. Introduction. Aerosol products, or **aerosols**, are **pressurized dosage forms**. They are designed to deliver drug systemically or topically with the aid of a liquefied or propelled gas (propellant). Aerosol products consist of a pressurizable container (tin-plated steel, aluminum, glass, or plastic), a valve that allows the pressurized product to be expelled from the container (either continuously or intermittently) when the actuator is pressed, and a dip tube that conveys the formulation from the bottom of the container to the valve assembly. Aerosols are prepared by special methods (cold filling, pressure filling) because of the gaseous components.

  2. Systemic or pulmonary drug delivery is provided by aerosol drug delivery systems, or **metered dose inhalers (MDIs)**. These devices allow a drug to be inhaled as a fine mist of drug or drug-containing particles. MDIs use special metering valves to regulate the amount of formulation and drug that is dispensed with each dose (i.e., each actuation of the container). Aerosol products are used for topical drug delivery. The formulations range from solutions to dispersions. Metering valves may also be used with topical aerosol products to regulate the amount of drug applied per application.

  3. Propellants used in aerosol products

    a. Compressed gases include carbon dioxide, nitrogen, and nitrous oxide. Aerosol products that contain compressed gas tend to lose pressure over time as the product is dispensed. The drop in pressure reflects the expansion of the head space in the container (i.e., increase in the volume that the gas can occupy) as formulation is withdrawn for use. For this reason, higher initial pressures are typically used with compressed gas-based systems than with liquefiable gas-based formulations.

    b. Liquefiable gases include saturated hydrocarbons (n-butane, isobutane, propane); chlorofluorocarbons (CFCs), including tetrafluorodichloroethane (propellant 114), dichlorodifluoromethane (propellant 12), and trichlorofluoromethane (propellant 11); dimethyl ether; and hydrofluorocarbons, such as 1,1,1,2-fluoroethane (propellant 134a) and 1,1-difluoroethane (propellant 152a). The negative effect of older CFCs on atmospheric ozone and the potential for global warming led to the worldwide reduction in CFC production under the Montreal Protocol. This plan called for a general ban on CFC production in industrialized countries by January 1996. As a result, the use of CFCs in pharmaceutical products is being phased out. Temporary exemptions for CFCs in MDIs will eventually lapse (in 2008) as stable, safe,

and effective alternative formulations are developed with more acceptable propellants (e.g., hydrofluorocarbons).

4. Advantages of aerosol products include the convenience of push-button dispensing of medication and the stability afforded by a closed, pressurized container that minimizes the likelihood of tampering and protects the contents from light, moisture, air (oxygen), and microbial contamination. Aerosol formulations and packaging components (valves, actuators) permit a wide range of products to be dispensed as sprays, foams, or semisolids.

5. The principal disadvantage of aerosol products is environmental (e.g., disposal of pressurized packages, venting of propellants to the atmosphere).

K. Controlled-release dosage forms

1. **Introduction.** Controlled-release dosage forms are also known as delayed-release, sustained-action, prolonged-action, sustained-release, prolonged-release, timed-release, slow-release, extended-action, and extended-release forms. They are designed to release drug substance slowly to provide prolonged action in the body.

2. Advantages of controlled-release forms:
   a. Fewer problems with patient compliance
   b. Use of less total drug
   c. Fewer local or systemic side effects
   d. Minimal drug accumulation with long-term dosage
   e. Fewer problems with potentiation or loss of drug activity with long-term use
   f. Improved treatment efficiency
   g. More rapid control of the patient's condition
   h. Less fluctuation in drug level
   i. Improved bioavailability for some drugs
   j. Improved ability to provide special effects (e.g., morning relief of arthritis by bedtime dose)
   k. Reduced cost

3. **Sustained-release forms** can be grouped according to their pharmaceutical mechanism.
   a. **Coated beads** or **granules** (e.g., Spansules, GlaxoSmithKline, Sequels, Wyeth) produce a blood level profile similar to that obtained with multiple dosing.
      (1) A solution of the drug substance in a nonaqueous solvent (e.g., alcohol) is coated on small, inert beads, or granules, made of a combination of sugar and starch. When the drug dose is large, the starting granules may be composed of the drug itself.
      (2) Some of the granules are left uncoated to provide immediate release of the drug.
      (3) Coats of a lipid material (e.g., beeswax) or a cellulosic material (e.g., ethylcellulose) are applied to the remaining granules. Some granules receive few coats, and some receive many. The various coating thicknesses produce a sustained-release effect.
   b. **Microencapsulation** is a process by which solids, liquids, or gases are encased in microscopic capsules. Thin coatings of a "wall" material are formed around the substance to be encapsulated.
      (1) **Coacervation** is the most common method of microencapsulation. It occurs when a hydrophilic substance is added to colloidal drug dispersion and causes layering and the formation of microcapsules.
      (2) Film-forming substances that are used as the coating material include a variety of natural and synthetic polymers. These materials include shellacs, waxes, gelatin, starches, cellulose acetate phthalate, and ethylcellulose. After the coating material dissolves, all of the drug inside the microcapsule is immediately available for dissolution and absorption. The thickness of the wall can vary from 1 to 200 mm, depending on the amount of coating material used (3% to 30% of total weight).
   c. **Matrix tablets** use insoluble plastics (e.g., polyethylene, polyvinyl acetate, polymethacrylate), hydrophilic polymers (e.g., methylcellulose, hydroxypropyl methylcellulose), or fatty compounds (e.g., various waxes, glyceryl tristearate). Examples include Gradumet (Abbott) and Dospan (Aventis).
      (1) The most common method of preparation is mixing of the drug with the matrix material followed by compression of the material into tablets.
      (2) The primary dose, or the portion of the drug to be released immediately, is placed on the tablet as a layer, or coat. The rest of the dose is released slowly from the matrix.

    d. **Osmotic systems** include the Oros system (Alza), which is an oral osmotic pump composed of a core tablet and a semipermeable coating that has a small hole (0.4 mm in diameter) for drug exit. The hole is produced by a laser beam. Examples include Glucotrol XL (glipizide extended-release tablets, Pfizer) and Procardia XL (nifedipine extended-release tablets, Pfizer).

        (1) This system requires only osmotic pressure to be effective. It is essentially independent of pH changes in the environment.

        (2) The drug-release rate can be changed by changing the tablet surface area, the nature of the membrane, or the diameter of the drug-release aperture.

    e. **Ion-exchange resins** can be complexed with drugs by passage of a cationic drug solution through a column that contains the resin. The drug is complexed to the resin by replacement of hydrogen atoms. Examples include Ionamin capsules (Celltech; resin complexes of phentermine) and the Pennkinetic system (Celltech), which incorporates a polymer barrier coating and bead technology in addition to the ion-exchange mechanism.

        (1) After the components are complexed, the resin–drug complex is washed and tableted, encapsulated, or suspended in an aqueous vehicle.

        (2) Release of drug from the complex depends on the ionic environment within the gastrointestinal tract and on the properties of the resin. Usually, release is greater in the highly acidic stomach than in the less acidic small intestine.

    f. **Complex formation** is used for certain drug substances that combine chemically with other agents. For example, hydroxypropyl-β-cyclodextrin forms a chemical complex that can be only slowly soluble from body fluids, depending on the pH of the environment. Tannic acid (i.e., tannates) complexes with the amino groups of weak bases dissolve at a slow rate in the gastrointestinal tract, thereby providing for a prolonged release of drug. Examples of the latter include brompheniramine tannate (Brovex, Athlon) and chlorpheniramine/phenylephrine tannates (Rynatan, Wallace).

Study Questions

Directions for questions 1–28: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by one of the suggested answers or phrases. Choose the best answer.

1. Which substance is classified as a weak electrolyte?

    (A) glucose
    (B) urea
    (C) ephedrine
    (D) sodium chloride
    (E) sucrose

2. The pH value is calculated mathematically as the

    (A) log of the hydroxyl ion (OH^-) concentration.
    (B) negative log of the OH^- concentration.
    (C) log of the hydrogen ion (H^+) concentration.
    (D) negative log of the H^+ concentration.
    (E) ratio of H^+/OH^- concentration.

3. Which property is classified as colligative?

    (A) solubility of a solute
    (B) osmotic pressure
    (C) hydrogen ion (H^+) concentration
    (D) dissociation of a solute
    (E) miscibility of the liquids

4. The colligative properties of a solution are related to the

    (A) pH of the solution.
    (B) number of ions in the solution.
    (C) total number of solute particles in the solution.
    (D) number of un-ionized molecules in the solution.
    (E) pK_a of the solution.

5. The pH of a buffer system can be calculated with the

    (A) Noyes–Whitney equation.
    (B) Henderson–Hasselbalch equation.
    (C) Michaelis–Menten equation.
    (D) Young equation.
    (E) Stokes equation.

6. Which mechanism is most often responsible for chemical degradation?

   (A) racemization
   (B) photolysis
   (C) hydrolysis
   (D) decarboxylation
   (E) oxidation

7. Which equation is used to predict the stability of a drug product at room temperature from experiments at accelerated temperatures?

   (A) Stokes equation
   (B) Young equation
   (C) Arrhenius equation
   (D) Michaelis–Menten equation
   (E) Hixson–Crowell equation

8. Based on the relation between the degree of ionization and the solubility of a weak acid, the drug aspirin ($pK_a = 3.49$) will be most soluble at

   (A) pH 1.0.
   (B) pH 2.0.
   (C) pH 3.0.
   (D) pH 4.0.
   (E) pH 6.0.

9. Which solution is used as an astringent?

   (A) strong iodine solution *USP*
   (B) aluminum acetate topical solution *USP*
   (C) acetic acid *NF*
   (D) aromatic ammonia spirit *USP*
   (E) benzalkonium chloride solution *NF*

10. The particle size of the dispersed solid in a suspension is usually greater than

    (A) 0.5 μm.
    (B) 0.4 μm.
    (C) 0.3 μm.
    (D) 0.2 μm.
    (E) 0.1 μm.

11. In the extemporaneous preparation of a suspension, levigation is used to

    (A) reduce the zeta potential.
    (B) avoid bacterial growth.
    (C) reduce particle size.
    (D) enhance viscosity.
    (E) reduce viscosity.

12. Which compound is a natural emulsifying agent?

    (A) acacia
    (B) lactose
    (C) polysorbate 20
    (D) polysorbate 80
    (E) sorbitan monopalmitate

13. Vanishing cream is an ointment that may be classified as

    (A) a water-soluble base.
    (B) an oleaginous base.
    (C) an absorption base.
    (D) an emulsion base.
    (E) an oleic base.

14. Rectal suppositories intended for adult use usually weigh approximately

    (A) 1 g.
    (B) 2 g.
    (C) 3 g.
    (D) 4 g.
    (E) 5 g.

15. In the fusion method of making cocoa butter suppositories, which substance is most likely to be used to lubricate the mold?

    (A) mineral oil
    (B) propylene glycol
    (C) cetyl alcohol
    (D) stearic acid
    (E) magnesium silicate

16. A very fine powdered chemical is defined as one that

    (A) completely passes through a #80 sieve.
    (B) completely passes through a #120 sieve.
    (C) completely passes through a #20 sieve.
    (D) passes through a #60 sieve and not more than 40% through a #100 sieve.
    (E) passes through a #40 sieve and not more than 60% through a #60 sieve.

17. Which technique is typically used to mill camphor?

    (A) trituration
    (B) levigation
    (C) pulverization by intervention
    (D) geometric dilution
    (E) attrition

18. The dispensing pharmacist usually blends potent powders with a large amount of diluent by

    (A) spatulation.
    (B) sifting.
    (C) trituration.
    (D) geometric dilution.
    (E) levigation.

19. Which type of paper best protects a divided hygroscopic powder?

    (A) waxed paper
    (B) glassine
    (C) white bond
    (D) blue bond
    (E) vegetable parchment

20. Which capsule size has the smallest capacity?

(A) 5
(B) 4
(C) 1
(D) 0
(E) 000

21. The shells of soft gelatin capsules may be made elastic or plastic-like by the addition of

(A) sorbitol.
(B) povidone.
(C) polyethylene glycol (PEG).
(D) lactose.
(E) hydroxypropyl methylcellulose.

22. The *United States Pharmacopeia* (*USP*) content uniformity test for tablets is used to ensure which quality?

(A) bioequivalency
(B) dissolution
(C) potency
(D) purity
(E) toxicity

23. All of the following statements about chemical degradation are true *except*

(A) as temperature increases, degradation decreases.
(B) most drugs degrade by a first-order process.
(C) chemical degradation may produce a toxic product.
(D) chemical degradation may result in a loss of active ingredients.
(E) chemical degradation may affect the therapeutic activity of a drug.

24. All of the following statements concerning zero-order degradation are true *except*

(A) its rate is independent of the concentration.
(B) a plot of concentration versus time yields a straight line on rectilinear paper.
(C) its half-life is a changing parameter.
(D) its concentration remains unchanged with respect to time.
(E) the slope of a plot of concentration versus time yields a rate constant.

25. All of the following statements about first-order degradation are true *except*

(A) its rate is dependent on the concentration.
(B) its half-life is a changing parameter.
(C) a plot of the logarithm of concentration versus time yields a straight line.
(D) its $t_{90\%}$ is independent of the concentration.
(E) a plot of the logarithm of concentration versus time allows the rate constant to be determined.

26. A satisfactory suppository base must meet all of the following criteria *except*

(A) it should have a narrow melting range.
(B) it should be nonirritating and nonsensitizing.
(C) it should dissolve or disintegrate rapidly in the body cavity.
(D) it should melt $< 30°C$.
(E) it should be inert.

27. Cocoa butter (theobroma oil) exhibits all of the following properties *except*

(A) it melts at temperatures between 33°C and 35°C.
(B) it is a mixture of glycerides.
(C) it is a polymorph.
(D) it is useful in formulating rectal suppositories.
(E) it is soluble in water.

28. *United States Pharmacopeia* (*USP*) tests to ensure the quality of drug products in tablet form include all of the following *except*

(A) disintegration.
(B) dissolution.
(C) hardness and friability.
(D) content uniformity.
(E) weight variation.

Directions for questions 29–42: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E.**

    A   if **I only** is correct
    B   if **III only** is correct
    C   if **I and II** are correct
    D   if **II and III** are correct
    E   if **I, II**, and **III** are correct

29. Forms of water that are suitable for use in parenteral preparations include

    I. purified water *USP*.
    II. water for injection *USP*.
    III. sterile water for injection *USP*.

30. The particles in an ideal suspension should satisfy which of the following criteria?

    I. Their size should be uniform.
    II. They should be stationary or move randomly.
    III. They should remain discrete.

31. The sedimentation of particles in a suspension can be minimized by

    I. adding sodium benzoate.
    II. increasing the viscosity of the suspension.
    III. reducing the particle size of the active ingredient.

32. Ingredients that may be used as suspending agents include

    I. methylcellulose.
    II. acacia.
    III. talc.

33. Mechanisms that are thought to provide stable emulsifications include the

    I. formation of interfacial film.
    II. lowering of interfacial tension.
    III. presence of charge on the ions.

34. Nonionic surface-active agents used as synthetic emulsifiers include

    I. tragacanth.
    II. sodium lauryl sulfate.
    III. sorbitan esters (Spans).

35. Advantages of systemic drug administration by rectal suppositories include

    I. avoidance of first-pass effects.
    II. suitability when the oral route is not feasible.
    III. predictable drug release and absorption.

36. True statements about the milling of powders include

    I. a fine particle size is essential if the lubricant is to function properly.
    II. an increased surface area may enhance the dissolution rate.
    III. milling may cause degradation of thermolabile drugs.

37. Substances used to insulate powder components that liquefy when mixed include

    I. talc.
    II. kaolin.
    III. light magnesium oxide.

38. A ceramic mortar may be preferable to a glass mortar when

    I. a volatile oil is added to a powder mixture.
    II. colored substances (dyes) are mixed into a powder.
    III. comminution is desired in addition to mixing.

39. Divided powders may be dispensed in

    I. individual-dose packets.
    II. a bulk container.
    III. a perforated, sifter-type container.

40. True statements about the function of excipients used in tablet formulations include

    I. binders promote granulation during the wet granulation process.
    II. glidants help promote the flow of the tablet granulation during manufacture.
    III. lubricants help the patient swallow the tablets.

41. Which manufacturing variables would be likely to affect the dissolution of a prednisone tablet in the body?

    I. the amount and type of binder added
    II. the amount and type of disintegrant added
    III. the force of compression used during tableting

42. Agents that may be used to coat enteric-coated tablets include

    I. hydroxypropyl methylcellulose.
    II. carboxymethylcellulose.
    III. cellulose acetate phthalate.

Directions for questions 43–46: Each of the following tablet-processing problems can be the result of one of the following reasons. The processing problems may be used more than once or not at all. Choose the **best** answer, **A–E**.

    A excessive moisture in the granulation
    B entrapment of air
    C tablet friability
    D degraded drug
    E tablet hardness

43. Picking

44. Mottling

45. Capping

46. Sticking

Directions for questions 47–49: Each of the following processes can be described by one of the following comminution procedures. The processes may be used more than once or not at all. Choose the **best** answer, **A–E**.

    A trituration
    B spatulation
    C levigation
    D pulverization by intervention
    E tumbling

47. Rubbing or grinding a substance in a mortar that has a rough inner surface

48. Reducing and subdividing a substance by adding an easily removed solvent

49. Adding a suitable agent to form a paste and then rubbing or grinding the paste in a mortar

Directions for questions 50–53: Each of the following controlled-release dosage forms is represented by one of the following drug products. The dosage forms may be used more than once or not at all. Choose the **best** answer, **A–E**.

   A   matrix formulations
   B   ion-exchange resin complex
   C   drug complexes
   D   osmotic system
   E   coated beads or granules

50. Ionamin capsules

51. Thorazine Spansule capsules

52. Rynatan pediatric suspension

53. Procardia XL

Answers and Explanations

1. The answer is C *[see IV.A.1.a; IV.A.3.d].*
Glucose, urea, and sucrose are nonelectrolytes. Sodium chloride is a strong electrolyte. Electrolytes are substances that form ions when dissolved in water. Thus, they can conduct an electric current through the solution. Ions are particles that bear electrical charges: Cations are positively charged, and anions are negatively charged. Strong electrolytes are completely ionized in water at all concentrations. Weak electrolytes (e.g., ephedrine) are only partially ionized at most concentrations. Because nonelectrolytes do not form ions when in solution, they are nonconductors.

2. The answer is D *[see IV.A.3.b].*
The pH is a measure of the acidity, or hydrogen ion concentration, of an aqueous solution. The pH is the logarithm of the reciprocal of the hydrogen ion (H^+) concentration expressed in moles per liter. Because the logarithm of a reciprocal equals the negative logarithm of the number, the pH is the negative logarithm of the H^+ concentration. A pH of 7.0 indicates neutrality. As the pH decreases, the acidity increases. The pH of arterial blood is 7.35 to 7.45; of urine, 4.8 to 7.5; of gastric juice, approximately 1.4; and of cerebrospinal fluid, 7.35 to 7.40. The concept of pH was introduced by Sörensen in the early 1900s. Alkalinity is the negative logarithm of $[OH^-]$ and is inversely related to acidity.

3. The answer is B *[see IV.A.2.d].*
Osmotic pressure is an example of a colligative property. The osmotic pressure is the magnitude of pressure needed to stop osmosis across a semipermeable membrane between a solution and a pure solvent. The colligative properties of a solution depend on the total number of dissociated and undissociated solute particles. These properties are independent of the size of the solute. Other colligative properties of solutes are reduction in the vapor pressure of the solution, elevation of its boiling point, and depression of its freezing point.

4. The answer is C *[see IV.A.1.b].*
The colligative properties of a solution are related to the total number of solute particles that it contains. Examples of colligative properties are the osmotic pressure, lowering of the vapor pressure, elevation of the boiling point, and depression of the freezing or melting point.

5. The answer is B *[see IV.A.3.e].*
The Henderson–Hasselbalch equation for a weak acid and its salt is as follows:

$$pH = pK_a + \log \frac{[\text{salt}]}{[\text{acid}]}$$

where pK_a is the negative log of the dissociation constant of a weak acid and [salt]/[acid] is the ratio of the molar concentration of salt and acid used to prepare a buffer.

6. The answer is C *[see V.D.1].*
Although all of the mechanisms listed can be responsible, the chemical degradation of medicinal compounds, particularly esters in liquid formulations, is usually caused by hydrolysis. For this reason, drugs that have ester functional groups are formulated in dry form whenever possible. Oxidation is another common mode of degradation and is minimized by including antioxidants (e.g., ascorbic acid) in drug formulations. Photolysis is reduced by packaging susceptible products in amber or opaque containers. Decarboxylation, which is the removal of COOH groups, affects compounds that include carboxylic acid. Racemization neutralizes the effects of an optically active compound by converting half of its molecules into their mirror-image configuration. As a result, the dextrorotatory and levorotatory forms cancel each other out. This type of degradation affects only drugs that are characterized by optical isomerism.

7. The answer is C *[see V.E.3.d].*
Testing of a drug formulation to determine its shelf life can be accelerated by applying the Arrhenius equation to data obtained at higher temperatures. The method involves determining the rate constant (k) values for the degradation of a drug at various elevated temperatures. The log of k is plotted against the reciprocal of the absolute temperature, and the k value for degradation at room temperature is obtained by extrapolation.

8. The answer is E *[see IV.A.3.g].*
The solubility of a weak acid varies as a function of pH. Because pH and pK_a (the dissociation constant) are related, solubility is also related to the degree of ionization. Aspirin is a weak acid that is completely ionized at a pH that is two units greater than its pK_a. Therefore, it is most soluble at pH 6.0.

9. The answer is B *[see VI.B.7].*
Aluminum acetate and aluminum subacetate solutions are astringents that are used as antiperspirants and as wet dressings for contact dermatitis. Strong iodine solution and benzalkonium chloride are topical antibacterial solutions. Acetic acid is added to products as an acidifier. Aromatic ammonia spirit is a respiratory stimulant.

10. The answer is A *[see IV.B.1.a].*
A suspension is a two-phase system that consists of a finely powdered solid dispersed in a liquid vehicle. The particle size of the suspended solid should be as small as possible to minimize sedimentation, but it is usually $> 0.5 \mu m$.

11. The answer is C *[see VI.E.3.a].*
Levigation is the process of blending and grinding a substance to separate the particles, reduce their size, and form a paste. Levigation is performed by adding a small amount of suitable levigating agent (e.g., glycerin) to the solid and blending the mixture with a mortar and pestle.

12. The answer is A *[see VI.D.3].*
Acacia, or gum arabic, is the exudate obtained from the stems and branches of various species of *Acacia*, a woody plant native to Africa. Acacia is a natural emulsifying agent that provides a stable emulsion of low viscosity. Emulsions are droplets of one or more immiscible liquids dispersed in another liquid. Emulsions are inherently unstable: The droplets tend to coalesce into larger and larger drops. The purpose of an emulsifying agent is to keep the droplets dispersed and prevent them from coalescing. Polysorbate 20, polysorbate 80, and sorbitan monopalmitate are also emulsifiers, but are synthetic, not natural, substances.

13. The answer is D *[see VI.E.2].*
Ointments are typically used as emollients to soften the skin, as protective barriers, or as vehicles for medication. A variety of ointment bases are available. Vanishing cream, an emulsion type of ointment base, is an oil-in-water emulsion that contains a high percentage of water. Stearic acid is used to create a thin film on the skin when the water evaporates.

14. The answer is B *[see VI.F.2.a].*
By convention, a rectal suppository for an adult weighs approximately 2 g. Suppositories for infants and children are smaller. Vaginal suppositories typically weigh approximately 5 g. Rectal suppositories are usually shaped like an elongated bullet (cylindrical and tapered at one end). Vaginal suppositories are usually ovoid.

15. The answer is A *[see VI.F.4.c].*
In the fusion method of making suppositories, molds made of aluminum, brass, or nickel–copper alloys are used. Finely powdered drug mixed with melted cocoa butter is poured into a mold that is lubricated very lightly with mineral oil.

16. The answer is B *[see VI.G; Table 2-8].*
The *USP* defines a very fine chemical powder as one that completely passes through a standard #120 sieve, which has 125-μm openings. The *USP* classification for powdered vegetable and animal drugs differs from that for powdered chemicals. To be classified as very fine, powdered vegetable and animal drugs must pass completely through a #80 sieve, which has 180-μm openings.

17. The answer is C *[see VI.G.1.c.(3.(b)].*
Pulverization by intervention is the milling technique that is used for drug substances that are gummy and tend to reagglomerate or resist grinding (e.g., camphor, iodine). In this sense, intervention is the addition of a small amount of material that aids milling and can be removed easily after pulverization is complete. For example, camphor can be reduced readily if a small amount of volatile solvent (e.g., alcohol) is added. The solvent is then allowed to evaporate.

18. The answer is D *[see VI.G.2.c].*
The pharmacist uses geometric dilution to mix potent substances with a large amount of diluent. The potent drug and an equal amount of diluent are first mixed in a mortar by trituration. A volume of diluent equal to the mixture in the mortar is added, and the mix is again triturated. The procedure is repeated, and each time, diluent equal in volume to the mixture then in the mortar is added, until all of the diluent is incorporated.

19. The answer is A *[see VI.G.3.b.(4)].*

Hygroscopic and volatile drugs are best protected by waxed paper, which is waterproof. The packet may be double-wrapped with a bond paper to improve the appearance of the completed powder.

20. The answer is A *[see VI.H.2.c.(1)].*

Hard capsules are numbered from 000 (largest) to 5 (smallest). Their approximate capacity ranges from 600 to 30 mg; however, the capacity of the capsule depends on the density of the contents.

21. The answer is A *[see VI.H.3.a–b].*

The shells of soft gelatin capsules are plasticized by the addition of a polyhydric alcohol (polyol), such as glycerin or sorbitol. An antifungal preservative can also be added. Both hard and soft gelatin capsules can be filled with a powder or another dry substance. Soft gelatin capsules are also useful dosage forms for fluids or semisolids.

22. The answer is C *[see VI.H.4.a].*

A content uniformity test is a test of potency. To ensure that each tablet or capsule contains the intended amount of drug substance, the *USP* provides two tests: weight variation and content uniformity. The content uniformity test can be used for any dosage unit but is required for coated tablets, for tablets in which the active ingredient makes up $< 50\%$ of the tablet, for suspensions in single-unit containers or in soft capsules, and for many solids that contain added substances. The weight variation test can be used for liquid-filled soft capsules, for any dosage form unit that contains at least 50 mg of a single drug if the drug makes up at least 50% of the bulk, for solids that do not contain added substances, and for freeze-dried solutions.

23. The answer is A *[see V.A and V.B].*

The reaction velocity, or degradation rate, of a pharmaceutical product is affected by several factors, including temperature, solvents, and light. The degradation rate increases two to three times with each 10°C increase in temperature. The effect of temperature on reaction rate is given by the Arrhenius equation:

$$k = Ae^{-Ea/RT}$$

where k is the reaction rate constant, A is the frequency factor, Ea is the energy of activation, R is the gas constant, and T is the absolute temperature.

24. The answer is D *[see V.B.2.a].*

In zero-order degradation, the concentration of a drug decreases over time. However, the change of concentration with respect to time is unchanged. In the equation

$$-\frac{dC}{dt} = k$$

the fact that dC/dt is negative signifies that the concentration is decreasing. However, the velocity of the concentration change is constant.

25. The answer is B *[see V.B.2.b.(2)].*

The half-life ($t_{\frac{1}{2}}$) is the time required for the concentration of a drug to decrease by one-half. For a first-order degradation:

$$t_{\frac{1}{2}} = \frac{0.693}{k}$$

Because both k and 0.693 are constants, $t_{\frac{1}{2}}$ is a constant.

26. The answer is D *[see VI.F.3].*

A satisfactory suppository base should remain firm at room temperature. Preferably, it should not melt $< 30°C$ to avoid premature softening during storage and insertion. It should also be inert, nonsensitizing, nonirritating, and compatible with a variety of drugs. Moreover, it should melt just below body temperature and should dissolve or disintegrate rapidly in the fluid of the body cavity into which it is inserted.

27. The answer is E *[see VI.F.3.c.(1)].*

Cocoa butter is a fat that is obtained from the seed of *Theobroma cacao*. Chemically, it is a mixture of stearin, palmitin, and other glycerides that are insoluble in water and freely soluble in ether and chloroform. Depending on the fusion temperature, cocoa butter can crystallize into any one of four crystal forms. Cocoa butter is a good base for rectal suppositories, although it is less than ideal for vaginal or urethral suppositories.

28. The answer is C *[see VI.I.5].*

To satisfy the *USP* standards, tablets are required to pass one of two tests. A weight variation test is used if the active ingredient makes up the bulk of the tablet. A content uniformity test is used if the tablet is coated or if the active ingredient makes up $< 50\%$ of the bulk of the tablet. Many tablets for oral administration are required to meet a disintegration test. Disintegration times are specified in the individual monographs. A dissolution test may be required instead if the active component of the tablet has limited water solubility. Hardness and friability would affect the disintegration and dissolution rates, but hardness and friability tests are in-house quality control tests, not official *USP* tests.

29. The answer is D (II, III) *[see VI.A.1].*
Water for injection *USP* is water that has been purified by distillation or by reverse osmosis. This water is used to prepare parenteral solutions that are subject to final sterilization. For parenteral solutions that are prepared aseptically and not subsequently sterilized, sterile water for injection *USP* is used. Sterile water for injection *USP* is water for injection *USP* that has been sterilized and suitably packaged. This water meets the *USP* requirements for sterility. Bacteriostatic water for injection *USP* is sterile water for injection *USP* that contains one or more antimicrobial agents. It can be used in parenteral solutions if the antimicrobial additives are compatible with the other ingredients in the solution, but it cannot be used in newborns. Purified water *USP* is not used in parenteral preparations.

30. The answer is E (I, II, III) *[see IV.B.2].*
An ideal suspension would have particles of uniform size, minimal sedimentation, and no interaction between particles. Although these ideal criteria are rarely met, they can be approximated by keeping the particle size as small as possible, the densities of the solid and the dispersion medium as similar as possible, and the dispersion medium as viscous as possible.

31. The answer is D (II, III) *[see IV.B.2].*
As Stokes's law indicates, the sedimentation rate of a suspension is slowed by reducing its density, reducing the size of the suspended particles, or increasing its viscosity by incorporating a thickening agent. Sodium benzoate is an antifungal agent and would not reduce the sedimentation rate of a suspension.

32. The answer is C (I, II) *[see VI.C.3].*
Acacia and methylcellulose are common suspending agents. Acacia is a natural product, and methylcellulose is a synthetic polymer. By increasing the viscosity of the liquid, these agents enable particles to remain suspended for a longer period.

33. The answer is E (I, II, III) *[see VI.D.3].*
Emulsifying agents provide a mechanical barrier to coalescence. They also reduce the natural tendency of the droplets in the internal phase (oil or water) of the emulsion to coalesce. Three mechanisms appear to be involved. Some emulsifiers promote stability by forming strong, pliable interfacial films around the droplets. Emulsifying agents also reduce interfacial tension. Finally, ions (from the emulsifier) in the interfacial film can lead to charge repulsion that causes droplets to repel one another, thereby preventing coalescence.

34. The answer is B (III) *[see VI.D.3].*
All of the substances listed are emulsifying agents, but only sorbitan esters are nonionic synthetic agents. Tragacanth, like acacia, is a natural emulsifying agent. Sodium lauryl sulfate is an anionic surfactant. Sorbitan esters (known colloquially as Spans because of their trade names) are hydrophobic and form water-in-oil emulsions. The polysorbates (known colloquially as Tweens) are also nonionic, synthetic sorbitan derivatives. However, they are hydrophilic and therefore form oil-in-water emulsions. Sodium lauryl sulfate, as alkali soap, is also hydrophilic and thus forms oil-in-water emulsions.

35. The answer is C (I, II) *[see VI.F.1–2].*
Rectal suppositories are useful for delivering systemic medication under certain circumstances. Absorption of a drug from a rectal suppository involves release of the drug from the suppository vehicle, diffusion through the rectal mucosa, and transport to the circulation through the rectal veins. The rectal veins bypass the liver, so this route avoids rapid hepatic degradation of certain drugs (first-pass effect). The rectal route is also useful when a drug cannot be given orally (e.g., because of vomiting). However, the extent of drug release and absorption is variable. It depends on the properties of the drug, the suppository base, and the environment in the rectum.

36. The answer is E (I, II, III) *[see VI.G.1.c].*
Milling is the process of mechanically reducing the particle size of solids before they are formulated into a final product. To work effectively, a lubricant must coat the surface of the granulation or powder. Hence, fine particle size is essential. Decreasing the particle size increases the surface area and can enhance the dissolution rate. Thermolabile drugs may undergo degradation because of the buildup of heat during milling.

37. The answer is D (II, III) *[see VI.G.2.a.(2)].*
Some solid substances (e.g., aspirin, phenylsalicylate, phenacetin, thymol, camphor) liquefy or form eutectic mixtures when in close, prolonged contact with one another. These substances are best insulated by the addition of light magnesium oxide or magnesium carbonate. Other inert diluents that can be used are kaolin, starch, and bentonite.

38. The answer is B (III) *[see VI.G.2.b].*
When powders are mixed, if comminution is especially important, a porcelain or ceramic mortar that has a rough inner surface is preferred over the smooth working surface of a glass mortar. Because a glass mortar cleans more easily after use, it is preferred for chemicals that may stain a porcelain or ceramic mortar as well as for simple mixing of substances that do not require comminution.

39. The answer is A (I) *[see VI.G.3.a–b].*

Powders for oral use can be dispensed by the pharmacist in bulk form or divided into premeasured doses (divided powders). Divided powders are traditionally dispensed in folded paper packets (chartulae) made of parchment, bond paper, glassine, or waxed paper. However, individual doses can be packaged in metal foil or small plastic bags if the powder needs greater protection from humidity or evaporation.

40. The answer is C (I, II) *[see VI.I.2.b].*

Tablets for oral ingestion usually contain excipients that are added to the formulation for their special functions. Binders and adhesives are added to promote granulation or compaction. Diluents are fillers that are added to make up the required tablet bulk. They can also aid in the manufacturing process. Disintegrants aid in tablet disintegration in gastrointestinal fluids. Lubricants, antiadherents, and glidants aid in reducing friction or adhesion between particles or between tablet and die. For example, lubricants are used in the manufacture of tablets to reduce friction when the tablet is ejected from the die cavity. Lubricants are usually hydrophobic substances that can affect the dissolution rate of the active ingredient.

41. The answer is E (I, II, III) *[see VI.2.b.(3)].*

Disintegrants are added to tablet formulations to facilitate disintegration in gastrointestinal fluids. Disintegration of the tablet in the body is critical to its dissolution and subsequent absorption and bioavailability. The binder and the compression force used during tablet manufacturing affect the hardness of the tablet as well as tablet disintegration and drug dissolution.

42. The answer is B (III) *[see VI.I.3.a.(4)].*

An enteric-coated tablet has a coating that remains intact in the stomach, but dissolves in the intestines to yield the tablet ingredients there. Enteric coatings include various fats, fatty acids, waxes, and shellacs. Cellulose acetate phthalate remains intact in the stomach because it dissolves only when the pH > 6. Other enteric-coating materials include povidone (polyvinylpyrrolidone), polyvinyl acetate phthalate, and hydroxypropyl methylcellulose phthalate.

43. The answer is A *[see VI.I.4].*

44. The answer is D *[see VI.I.4].*

45. The answer is B *[see VI.I.4].*

46. The answer is A *[see VI.I.4].*

Sticking is adhesion of tablet material to a die wall. It may be caused by excessive moisture or by the use of ingredients that have low melting temperatures. Mottling is uneven color distribution. It is most often caused by poor mixing of the tablet granulation but may also occur when a degraded drug produces a colored metabolite. Capping is separation of the top or bottom crown of a tablet from the main body. Capping implies that compressed powder is not cohesive. Reasons for capping include excessive force of compression, use of insufficient binder, worn tablet tooling equipment, and entrapment of air during processing. Picking is adherence of tablet surface material to a punch. It can be caused by a granulation that is too damp, by a scratched punch, by static charges on the powder, and particularly by the use of a punch tip that is engraved or embossed.

47. The answer is A *[see VI.G.1.c; VI.G.2].*

48. The answer is D *[see VI.G.1.c; VI.G.2].*

49. The answer is C *[see VI.G.1.c; VI.G.2].*

Comminution is the process of reducing the particle size of a powder to increase its fineness. Several comminution techniques are suitable for small-scale use in a pharmacy. Trituration is used both to comminute and to mix dry powders. If comminution is desired, the substance is rubbed in a mortar that has a rough inner surface. Pulverization by intervention is often used for substances that tend to agglomerate or resist grinding. A small amount of easily removed (e.g., volatile) solvent is added. After the substance is pulverized, the solvent is allowed to evaporate or is otherwise removed. Levigation is often used to prepare pastes or ointments. The powder is reduced by adding a suitable nonsolvent (levigating agent) to form a paste and then either rubbing the paste in a mortar with a pestle or rubbing it on an ointment slab with a spatula. Spatulation and tumbling are techniques that are used to mix or blend powders, not to reduce them. Spatulation is blending small amounts of powders by stirring them with a spatula on a sheet of paper or a pill tile. Tumbling is blending large amounts of powder in a large rotating container.

50. The answer is B *[see VI.K.3.e].*

51. The answer is E *[see VI.K.3.a].*

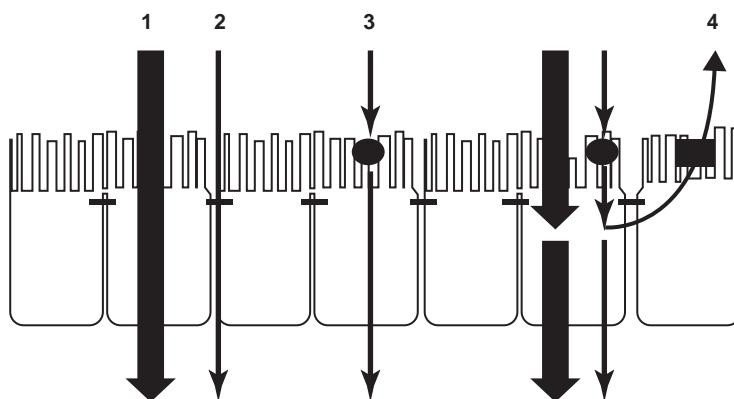
52. The answer is C *[see VI.K.3.f].*

53. The answer is D *[see VI.K.3.d].*

Controlled-release dosage forms are designed to release a drug slowly for prolonged action in the body. A variety of pharmaceutical mechanisms are used to provide the controlled release. Ion-exchange resins may be complexed to drugs by passing a cationic drug solution through a column that contains the resin. The drug is complexed to the resin by replacement of hydrogen atoms. Release of drug from the complex depends on the ionic environment within the gastrointestinal tract and on the properties of the resin. Coated beads (e.g., Thorazine Spansule capsules) or granules produce blood levels similar to those obtained with multiple dosing. The various coating thicknesses produce a sustained-release effect.

Matrix devices may use insoluble plastics, hydrophilic polymers, or fatty compounds. These components are mixed with the drug and compressed into a tablet. The primary dose, or the portion of the drug to be released immediately, is placed on the tablet as a layer or coat. The remainder of the dose is released slowly from the matrix. Relatively insoluble tannate–amine complexes provide for a prolonged gastrointestinal absorption phase and sustained systemic concentrations of the weak bases. Osmotic systems employ osmotic pressure to control the release of the active ingredient from the formulation. Osmotic tablet formulations provide a semipermeable membrane as a coating that surrounds the osmotically active core. The coating allows water to diffuse into the core but does not allow drug to diffuse out. As water flows into the tablet, the drug dissolves. The laser-drilled hole in the coating allows the drug solution within the tablet to flow to the outside at a rate that is equivalent to the rate of water flow into the tablet. The osmotic pressure gradient and a zero-order drug-release rate will be maintained as long as excess osmotically active solute (e.g., electrolyte) remains in the tablet core.

Biopharmaceutics and Drug Delivery Systems

3


LAWRENCE H. BLOCK

I. INTRODUCTION

- **A.** **Biopharmaceutics** is the study of the relation of the physical and chemical properties of a drug to its bioavailability, pharmacokinetics, and pharmacodynamic and toxicologic effects.
  - **1.** A **drug product** is the finished dosage form (e.g., tablet, capsule, solution) that contains the active drug ingredient in association with nondrug (usually inactive) ingredients (**excipients**) that make up the **vehicle** or **formulation matrix**.
  - **2.** The phrase *drug delivery system* is often used interchangeably with the terms *drug product* or *dosage form*. However, a **drug delivery system** is a more comprehensive concept, which includes the drug formulation and the dynamic interactions among the drug, its formulation matrix, its container, and the patient.
  - **3.** **Bioavailability** is a measurement of the rate and extent (amount) of systemic absorption of the therapeutically active drug.
- **B.** **Pharmacokinetics** is the study of the time course of drug movement in the body during absorption, distribution, and elimination (excretion and biotransformation).
- **C.** **Pharmacodynamics** is the study of the relation of the drug concentration or amount at the site of action (receptor) and its pharmacologic response as a function of time.

II. DRUG TRANSPORT AND ABSORPTION

- **A.** **Transport of drug molecules *across* cell membranes.** Drug absorption requires the drug to be transported across various cell membranes. Drug molecules may enter the bloodstream and be transported to the tissues and organs of the body. Drug molecules may cross additional membranes to enter cells. Drug molecules may also cross an intracellular membrane, such as the nuclear membrane or endoplasmic reticulum, to reach the site of action. *Figure 3-1* demonstrates some of the key transport processes involved in drug absorption.

Figure 3-1. The key drug transport processes in intestinal epithelial cells. *1*, Transcellular passive (diffusion and partitioning); *2*, paracellular transport (diffusion and convection); *3*, carrier-mediated transport; *4*, P-glycoprotein–mediated efflux. Modified from Brayden DJ. Human intestinal epithelial cell monolayers as prescreens for oral drug delivery. *Pharm News*. 1997;4(1):11–15.

1. **General principles**
   a. A **cell membrane** is a semipermeable structure composed primarily of lipids and proteins.
   b. Drugs may be transported by **passive diffusion**, **partitioning**, **carrier-mediated transport**, **paracellular transport**, or **vesicular transport**.
   c. Usually, **proteins**, **drugs bound to proteins**, and **macromolecules** do not easily cross cell membranes.
   d. **Nonpolar lipid-soluble drugs** traverse cell membranes more easily than do **ionic** or **polar water-soluble drugs**.
   e. **Low-molecular-weight drugs** diffuse across a cell membrane more easily than do **high-molecular-weight drugs**.
2. **Passive diffusion and partitioning**
   a. *Within* the cytoplasm or in **interstitial fluid**, most drugs undergo transport by simple diffusion.
   b. **Fick's law of diffusion. Simple passive diffusion** involves the transfer of drugs from an area of high concentration (C_1) to an area of lower concentration (C_2) according to Fick's law of diffusion:

   $$\frac{dQ}{dt} = \frac{DA}{h}(C_1 - C_2)$$

   where dQ/dt is the rate of drug diffusion, D is the diffusion coefficient for the drug, A is the surface area of the plane across which transfer occurs, h is the thickness of the region through which diffusion occurs, and $(C_1 - C_2)$ is the difference between the drug concentration in area 1 and area 2, respectively.
   c. Passive drug transport *across* cell membranes involves the successive **partitioning** of a solute between aqueous and lipid phases as well as **diffusion** within the respective phases. Modifying Fick's law of diffusion to accommodate the partitioning of drug gives the following:

   $$\frac{dQ}{dt} = \frac{DAK}{h}(C_1 - C_2)$$

   The rate of drug diffusion, dQ/dt, now reflects its direct dependence on K, the oil to water partition coefficient of the drug, as well as on A and $(C_1 - C_2)$.
   d. **Ionization of a weak electrolyte** is affected by the pH of the medium in which the drug is dissolved as well as by the pK_a of the drug. The nonionized species is more lipid soluble than the ionized species, and it partitions more readily across cell membranes.
3. **Carrier-mediated transport**
   a. **Active transport** of the drug across a membrane is a carrier-mediated process that has the following characteristics:
      (1) The drug moves against a concentration gradient.
      (2) The process requires energy.
      (3) The carrier may be selective for certain types of drugs that resemble natural substrates or metabolites that are normally actively transported.
      (4) The carrier system may be saturated at a high drug concentration.
      (5) The process may be competitive (i.e., drugs with similar structures may compete for the same carrier).
   b. **Facilitated diffusion** is also a carrier-mediated transport system. However, facilitated diffusion occurs with (i.e., in the direction of) a concentration gradient and does not require energy.
4. **Paracellular transport.** Drug transport across tight (narrow) junctions between cells or trans-endothelial channels of cells is known as **paracellular transport**. It involves both diffusion and the **convective** (bulk) flow of water and accompanying water-soluble drug molecules through the paracellular channels.
5. **Vesicular transport** is the process of engulfing particles or dissolved materials by a cell. Vesicular transport is the only transport mechanism that does not require a drug to be in an aqueous solution to be absorbed. **Pinocytosis** and **phagocytosis** are forms of vesicular transport.
   a. **Pinocytosis** is the engulfment of small solute or fluid volumes.
   b. **Phagocytosis** is the engulfment of larger particles, or macromolecules, generally by macrophages.
   c. **Endocytosis** and **exocytosis** are the movement of macromolecules into and out of the cell, respectively.

6. **Other transport mechanisms: transporter proteins.** Various **transporter proteins** (e.g., **P-glycoprotein**) are embedded in the lipid bilayer of cell membranes in tandem in α-helical transmembrane regions or domains. These proteins are adenosine triphosphate (ATP; energy) dependent "pumps," which can facilitate the efflux of drug molecules from the cell. Because these transmembrane efflux pumps are often found in conjunction with metabolizing enzymes such as **cytochrome P450 3A4**, their net effect is to substantially reduce intracellular drug concentrations. Thus they determine, to a large extent, the pharmacokinetic disposition and circulating plasma concentrations of drugs (e.g., cyclosporine, nifedipine, digoxin) that are substrates for these proteins.

B. **Routes of drug administration**
1. **Parenteral administration**
   a. **Intravenous bolus injection.** The drug is injected directly into the bloodstream, distributes throughout the body, and acts rapidly. Any side effects, including an intense pharmacologic response, anaphylaxis, or overt toxicity, also occur rapidly.
   b. **Intra-arterial injection.** The drug is injected into a specific artery to achieve a high drug concentration in a specific tissue before drug distribution occurs throughout the body. Intra-arterial injection is used for diagnostic agents and occasionally for chemotherapy.
   c. **Intravenous infusion.** The drug is given intravenously at a constant input rate. Constant-rate intravenous infusion maintains a relatively constant plasma drug concentration once the infusion rate is approximately equal to the drug's elimination rate from the body (i.e., once steady state is reached).
   d. **Intramuscular injection.** The drug is injected deep into a skeletal muscle. The rate of absorption depends on the vascularity of the muscle site, the lipid solubility of the drug, and the formulation matrix.
   e. **Subcutaneous injection.** The drug is injected beneath the skin. Because the subcutaneous region is less vascular than muscle tissues, drug absorption is less rapid. The factors that affect absorption from intramuscular depots also affect subcutaneous absorption.
   f. **Miscellaneous parenteral routes**
      (1) **Intra-articular injection.** The drug is injected into a joint.
      (2) **Intradermal (intracutaneous) injection.** The drug is injected into the dermis (i.e., the vascular region of the skin below the epidermis).
      (3) **Intrathecal injection.** The drug is injected into the spinal fluid.
2. **Enteral administration**
   a. **Buccal and sublingual administration.** A tablet or lozenge is placed under the tongue (**sublingual**) or in contact with the mucosal (**buccal**) surface of the cheek. This type of administration allows a nonpolar, lipid-soluble drug to be absorbed across the epithelial lining of the mouth. After buccal or sublingual administration, the drug is absorbed directly into the systemic circulation, bypassing the liver and any first-pass effects.
   b. **Peroral (oral) drug administration.** The drug is administered orally, is swallowed, and undergoes absorption from the gastrointestinal tract through the mesenteric circulation to the hepatic portal vein into the liver and then to the systemic circulation. The peroral route is the most common route of administration.
      (1) The peroral route is the most convenient and the safest route.
      (2) Disadvantages of this route include the following:
         (a) The drug may not be absorbed from the gastrointestinal tract consistently or completely.
         (b) The drug may be digested by gastrointestinal enzymes or decomposed by the acid pH of the stomach.
         (c) The drug may irritate mucosal epithelial cells or complex with the contents of the gastrointestinal tract.
         (d) Some drugs may be incompletely absorbed because of first-pass effects or presystemic elimination (e.g., the drug is metabolized by the liver before systemic absorption occurs).
         (e) The absorption rate may be erratic because of delayed gastric emptying or changes in intestinal motility.
      (3) Most drugs are **xenobiotics** or **exogenous** molecules and, consequently, are absorbed from the gastrointestinal tract by **passive diffusion** and **partitioning**. **Carrier-mediated transport**, **paracellular transport**, and **vesicular transport** play smaller—but critical—roles, particularly for endogenous molecules.

(4) Drug molecules are absorbed throughout the gastrointestinal tract; but the **duodenal region**, which has a large surface area because of the villi and microvilli, is the primary absorption site. The large blood supply provided by the mesenteric vessels allows the drug to be absorbed more efficiently (see II.A.2).

(5) **Altered gastric emptying** affects arrival of the drug in the duodenum for systemic absorption. **Gastric emptying time** is affected by food content, food composition (fats, acids delay gastric emptying), emotional state, circadian effects (gastric emptying tends to be more rapid in the morning than in the evening), and drugs that alter gastrointestinal tract motility (e.g., anticholinergics, narcotic analgesics, prokinetic agents). In general, the T_{max} (**time** of peak systemic drug concentration) occurs earlier, when gastric emptying is faster than normal, and later, when gastric emptying is slower than normal. The effect of gastric emptying on C_{max} (**peak** systemic drug concentration) varies, depending on the absorption mechanism, pH dependence of dissolution, extent of presystemic elimination, etc.

(6) Normal intestinal motility from **peristalsis** brings the drug in contact with the intestinal epithelial cells. A sufficient period of contact (residence time) is needed to permit drug absorption across the cell membranes from the mucosal to the serosal surface.

(7) Some drugs, such as **cimetidine** and **acetaminophen**, when given in an immediate-release peroral dosage form to fasted subjects produce a systemic drug concentration time with two peaks. This **double-peak phenomenon** is attributed to variability in stomach emptying, variable intestinal motility, and enterohepatic cycling.

c. **Rectal administration.** The drug in solution (enema) or suppository form is placed in the rectum. Drug diffusion from the solution or release from the suppository leads to absorption across the mucosal surface of the rectum. Drug absorbed in the lower two-thirds of the rectum enters the systemic circulation directly, bypassing the liver and any first-pass effects.

3. **Respiratory tract administration**

a. **Intranasal administration.** The drug contained in a solution or suspension is administered to the nasal mucosa, either as a spray or as drops. The medication may be used for local (e.g., nasal decongestants, intranasal steroids) or systemic effects.

b. **Pulmonary inhalation.** The drug, as liquid or solid particles, is inhaled perorally (with a nebulizer or a metered-dose aerosol) into the pulmonary tree. In general, **particles > 60 μm** are primarily deposited in the **trachea**. **Particles > 20 μm** do not reach the bronchioles, and **particles < 0.6 μm** are not deposited and are **exhaled**. Particles between **2 and 6 μm** can reach the **alveolar ducts**, although only particles of **1 to 2 μm are retained in the alveoli**.

4. **Transdermal and topical administration**

a. **Transdermal** (**percutaneous**) drug absorption is the placement of the drug (in a lotion, ointment, cream, paste, or patch) on the skin surface for systemic absorption. An occlusive dressing or film improves systemic drug absorption from the skin. Small lipid-soluble molecules, such as nitroglycerin, nicotine, scopolamine, clonidine, fentanyl, and steroids (e.g., 17-β-estradiol, testosterone), are readily absorbed from the skin.

b. Drugs (e.g., antibacterials, local anesthetic agents) are applied **topically** to the skin for a local effect.

5. Miscellaneous routes of drug administration include **ophthalmic**, **otic**, **urethral**, and **vaginal** administration. These routes of administration are generally used for local therapeutic activity. However, some systemic drug absorption may occur.

C. **Local drug activity** versus **systemic drug absorption.** The route of administration, absorption site, and bioavailability of the drug from the dosage form are major factors in the design of a drug product.

1. Drugs intended for **local activity** such as topical antibiotics, anti-infectives, antifungal agents, and local anesthetics are formulated in dosage forms that minimize systemic absorption. The concentration of these drugs at the application site affects their activity.

2. When **systemic absorption** is desired, the bioavailability of the drug from the dosage form at the absorption site must be considered (e.g., a drug given intravenously is 100% bioavailable because all of the drug is placed directly into the systemic circulation). The amount, or dose, of drug in the dosage form is based on the extent of drug absorption and the desired systemic drug concentration. The type of dosage form (e.g., immediate release, controlled release) affects the rate of drug absorption.

III. BIOPHARMACEUTIC PRINCIPLES

A. Physicochemical properties

1. **Drug dissolution.** For most drugs with limited water solubility, the rate at which the solid drug enters into solution (i.e., the rate of dissolution) is often the rate-limiting step in bioavailability. The **Noyes–Whitney** equation describes the diffusion-controlled rate of drug dissolution (dm/dt; i.e., the change in the amount of drug in solution with respect to time):

$$\frac{dm}{dt} = \frac{DA}{\delta}(C_s - C_b)$$

where D is the diffusion coefficient of the solute, A is the surface area of the solid undergoing dissolution, δ is the thickness of the diffusion layer, C_s is the concentration of the solvate at saturation, and C_b is the concentration of the drug in the bulk solution phase at time t.

2. **Drug solubility** in a saturated solution (see Chapter 2, IV) is a static (equilibrium) property. The dissolution rate of a drug is a dynamic property related to the rate of absorption.

3. **Particle size** and **surface area** are inversely related. As solid drug particle size decreases, particle surface area increases.

   a. As described by the Noyes–Whitney equation, the dissolution rate is directly proportional to the surface area. An increase in surface area allows for more contact between the solid drug particles and the solvent, resulting in a faster dissolution rate (see III.A.1).

   b. With certain **hydrophobic drugs**, excessive particle size reduction does not always increase the dissolution rate. Small particles tend to reaggregate into larger particles to reduce the high surface free energy produced by particle size reduction.

   c. To prevent the formation of aggregates, small drug particles are molecularly dispersed in polyethylene glycol (PEG), polyvinylpyrrolidone (PVP; povidone), dextrose, or other agents. For example, a molecular dispersion of griseofulvin in a water-soluble carrier such as PEG 4000 (e.g., Gris–PEG) enhances its dissolution and bioavailability.

4. **Partition coefficient and extent of ionization**

   a. The **partition coefficient** of a drug is the ratio of the solubility of the drug, at equilibrium, in a nonaqueous solvent (e.g., n-octanol) to that in an aqueous solvent (e.g., water; pH 7.4 buffer solution). Hydrophilic drugs with higher water solubility have a faster dissolution rate than do hydrophobic or lipophilic drugs, which have poor water solubility.

   b. **Extent of ionization.** Drugs that are weak electrolytes (acids or bases) exist in both an ionized form and a nonionized form in solution. The extent of ionization depends on the pK_a of the weak electrolyte and the pH of the solution. The ionized form is more polar, and therefore more water soluble, than the nonionized form. The **Henderson–Hasselbalch equation** describes the relation between the ionized and the nonionized forms of a drug as a function of pH and pK_a. When the pH of the medium equals the pK_a of the drug, 50% of the drug in solution is nonionized and 50% is ionized, as can be shown from the following equations:

   (1) For weak acids:

   $$pH = pK_a + \log\left(\frac{salt}{nonionized\ acid}\right)$$

   (2) For weak bases:

   $$pH = pK_a + \log\left(\frac{nonionized\ base}{salt}\right)$$

5. **Salt formation**

   a. The choice of salt form for a drug depends on the desired physical, chemical, or pharmacologic properties. Certain salts are designed to provide slower dissolution, slower bioavailability, and longer duration of action. Other salts are selected for greater stability, less local irritation at the absorption site, or less systemic toxicity.

   (1) Some soluble salt forms are less stable than the nonionized form. For example, sodium aspirin is less stable than aspirin in the acid form.

   (2) A solid dosage form containing buffering agents may be formulated with the free acid form of the drug (e.g., buffered aspirin).

      (a) The buffering agent forms an alkaline medium in the gastrointestinal tract, and the drug dissolves in situ.

      (b) The dissolved salt form of the drug diffuses into the bulk fluid of the gastrointestinal tract, forms a fine precipitate that redissolves rapidly, and becomes available for absorption.

    b. Effervescent granules or **tablets** containing the acid drug in addition to sodium bicarbonate, tartaric acid, citric acid, or other ingredients are added to water just before oral administration. The excess sodium bicarbonate forms an alkaline solution in which the drug dissolves. Carbon dioxide is also formed by the decomposition of carbonic acid.

    c. For weakly acidic drugs, potassium and sodium salts are more soluble than divalent cation salts (e.g., calcium, magnesium) or trivalent cation salts (e.g., aluminum).

    d. For weak bases, common water-soluble salts include the hydrochloride, sulfate, citrate, and gluconate salts. The estolate, napsylate, and stearate salts are less water soluble.

6. Polymorphism is the ability of a drug to exist in more than one crystalline form.

    a. Different polymorphs have different physical properties, including melting point and dissolution rate.

    b. Amorphous, or **noncrystalline**, **forms** of a drug have faster dissolution rates than do crystalline forms.

7. Chirality is the ability of a drug to exist as **optically active stereoisomers** or **enantiomers**. Individual enantiomers may not have the same pharmacokinetic and pharmacodynamic activity. Because most chiral drugs are used as racemic mixtures, the results of studies with such mixtures may be misleading because the drug is assumed to behave as a single entity. For example, ibuprofen exists as the *R*- and *S*-enantiomers; only the *S*-enantiomer is pharmacologically active. When the racemic mixture of ibuprofen is taken orally, the *R*-enantiomer undergoes presystemic inversion in the gut to the *S*-enantiomer. Because the rate and extent of inversion are site specific and formulation dependent, ibuprofen activity may vary considerably.

8. Hydrates. Drugs may exist in a **hydrated**, or **solvated**, **form** or as an **anhydrous molecule**. Dissolution rates differ for hydrated and anhydrous forms. For example, the anhydrous form of ampicillin dissolves faster and is more rapidly absorbed than the hydrated form.

9. Complex formation. A **complex** is a species formed by the reversible or irreversible association of two or more interacting molecules or ions. **Chelates** are complexes that typically involve a ringlike structure formed by the interaction between a partial ring of atoms and a metal. Many biologically important molecules (e.g., hemoglobin, insulin, cyanocobalamin) are chelates. Drugs such as tetracycline form chelates with divalent (e.g., Ca^{++}, Mg^{++}) and trivalent (e.g., Al^{+++}, Bi^{+++}) metal ions. Many drugs adsorb strongly on charcoal or clay (e.g., kaolin, bentonite) particles by forming complexes. Drug complexes with proteins, such as albumin or α_1-acid glycoprotein, often occur.

    a. Complex formation usually alters the physical and chemical characteristics of the drug. For example:

      (1) The chelate of tetracycline with calcium is less water soluble and is poorly absorbed.

      (2) Theophylline complexed with ethylenediamine to form aminophylline is more water soluble and is used for parenteral and rectal administration.

      (3) Cyclodextrins are used to form complexes with many drugs to increase their water solubility.

    b. Large drug complexes, such as drug–protein complexes, do not cross cell membranes easily. These complexes must dissociate to free the drug for absorption at the absorption site or to permit transport across cell membranes or glomerular filtration before the drug is excreted into the urine.

B. Drug product and delivery system formulation

    1. General considerations

      a. Design of the appropriate dosage form or **delivery system** depends on the

        (1) physical and chemical properties of the drug,

        (2) dose of the drug,

        (3) route of administration,

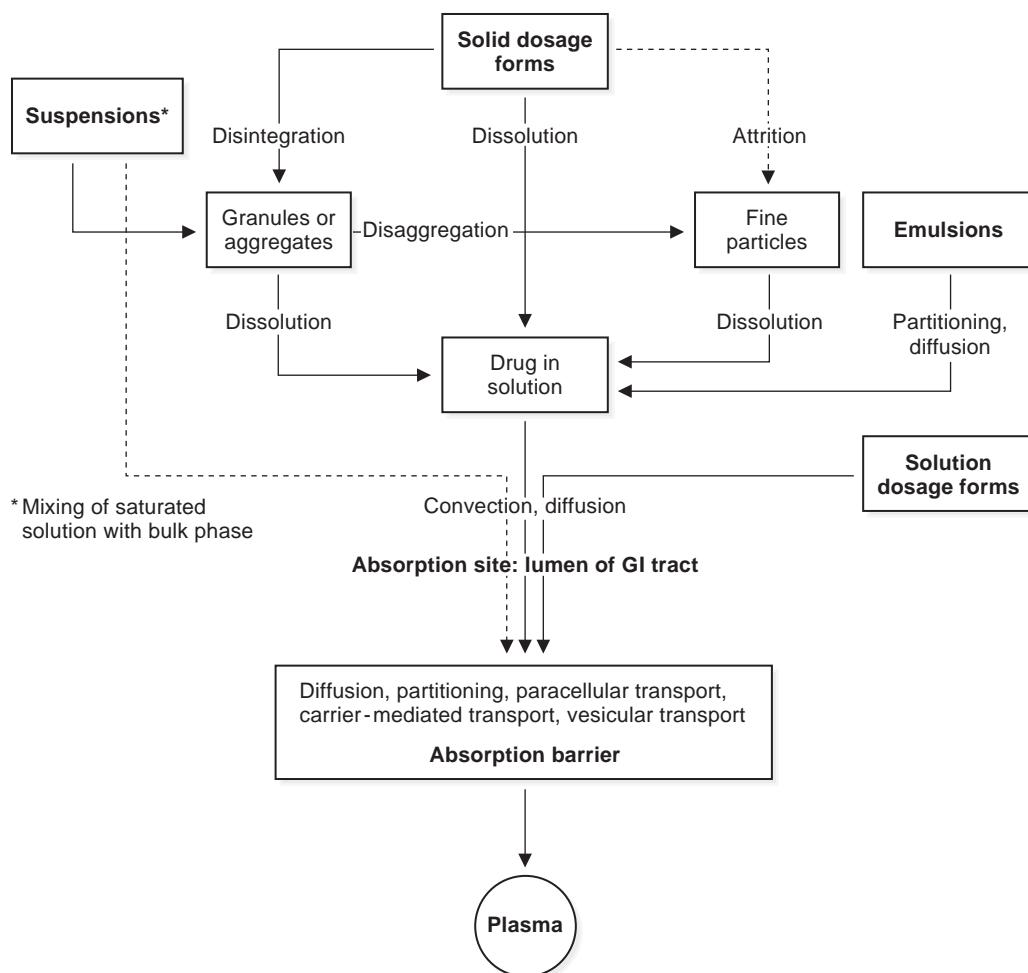
        (4) type of drug delivery system desired,

        (5) desired therapeutic effect,

        (6) physiologic release of the drug from the delivery system,

(7) bioavailability of the drug at the absorption site, and

(8) pharmacokinetics and pharmacodynamics of the drug.

b. Bioavailability. The more complicated the formulation of the finished drug product (e.g., controlled-release tablet, enteric-coated tablet, transdermal patch), the greater the potential for a bioavailability problem. For example, the **release** of a drug from a peroral dosage form and its subsequent bioavailability depend on a succession of rate processes (*Figure 3-2*). These processes may include the following:


(1) Attrition, **disintegration**, or **disaggregation** of the drug product

(2) Dissolution of the drug in an aqueous environment

(3) Convection and **diffusion** of the drug molecules to the absorbing surface

(4) Absorption of the drug across cell membranes into the systemic circulation

c. The **rate-limiting step** in the bioavailability of a drug from a drug product is the slowest step in a series of kinetic processes.

(1) For most conventional solid drug products (e.g., capsules, tablets), the dissolution rate is the slowest, or rate-limiting, step for bioavailability.

(2) For a controlled- or sustained-release drug product, the release of the drug from the delivery system is the rate-limiting step.

2. Solutions are homogeneous mixtures of one or more solutes dispersed molecularly in a dissolving medium (solvent).

a. Compared with other oral and peroral drug formulations, a drug dissolved in an aqueous solution is in the most bioavailable and consistent form. Because the drug is already in solution,

Figure 3-2. The processes involved in drug release from peroral dosage forms. *GI*, gastrointestinal.

no dissolution step is necessary before systemic absorption occurs. Peroral drug solutions are often used as the reference preparation for solid peroral formulations.

   b. A drug dissolved in a hydroalcoholic solution (e.g., elixir) also has good bioavailability. Alcohol aids drug solubility. However, when the drug is diluted by gastrointestinal tract fluid and other gut contents (e.g., food), it may form a finely divided precipitate in the lumen of the gastrointestinal tract. Because of the extensive dispersion and large surface area of such finely divided precipitates, redissolution and subsequent absorption occur rapidly.

   c. A viscous drug solution (e.g., syrup) may interfere with dilution and mixing with gastrointestinal tract contents. The solution decreases the gastric emptying rate and the rate of transfer of drug solution to the duodenal region, where absorption is most efficient.

3. Suspensions are dispersions of finely divided solid particles of a drug in a liquid medium in which the drug is not readily soluble. The liquid medium of a suspension comprises a saturated solution of the drug in equilibrium with the solid drug.

   a. The bioavailability of the drug from suspensions may be similar to that of a solution because the finely divided particles are dispersed and provide a large surface area for rapid dissolution. On the other hand, a slow dissolution rate decreases the absorption rate.

   b. Suspending agents are often hydrophilic colloids (e.g., cellulose derivatives, acacia, xanthan gum) added to suspensions to increase viscosity, inhibit agglomeration, and decrease the rate at which particles settle. Highly viscous suspensions may prolong gastric emptying time, slow drug dissolution, and decrease the absorption rate.

4. Capsules are solid dosage forms with hard or soft gelatin shells that contain drugs, usually admixed with excipients. **Coating** the capsule shell or the drug particles within the capsule can affect bioavailability.

   a. Hard gelatin capsules are usually filled with a powder blend that contains the drug. Typically, the powder blend is simpler and less compacted than the blend in a compressed tablet. After ingestion, the gelatin softens, swells, and begins to dissolve in the gastrointestinal tract. Encapsulated drugs are released rapidly and dispersed easily, and bioavailability is good. Hard gelatin capsules are the preferred dosage form for early clinical trials of new drugs.

   b. Soft gelatin capsules may contain a nonaqueous solution, a powder, or a drug suspension. The vehicle may be water miscible (e.g., PEG). The cardiac glycoside digoxin, dispersed in a water-miscible vehicle (Lanoxicaps), has better bioavailability than a compressed tablet formulation (Lanoxin). However, a soft gelatin capsule that contains the drug dissolved in a **hydrophobic** vehicle (e.g., vegetable oil) may have poorer bioavailability than a compressed tablet formulation of the drug.

   c. Aging and **storage conditions** can affect the moisture content of the gelatin component of the capsule shell and the bioavailability of the drug.

   (1) At low moisture levels, the capsule shell becomes brittle and is easily ruptured.

   (2) At high moisture levels, the capsule shell becomes moist, soft, and distorted. Moisture may be transferred to the capsule contents, particularly if the contents are hygroscopic.

5. Compressed tablets are solid dosage forms in which high pressure is used to compress a powder blend or granulation that contains the drug and other ingredients, or excipients, into a solid mass.

   a. Excipients, including diluents (fillers), binders, disintegrants, lubricants, glidants, surfactants, dye, and flavoring agents, have the following properties:

   (1) They permit the efficient manufacture of compressed tablets.

   (2) They affect the physical and chemical characteristics of the drug.

   (3) They affect bioavailability. The higher the ratio of excipient to active drug, the greater the likelihood that the excipients affect bioavailability.

   b. Examples

   (1) Disintegrants (e.g., starch, croscarmellose, sodium starch glycolate) vary in action, depending on their concentration; the method by which they are mixed with the powder formulation or granulation; and the degree of tablet compaction. Although tablet disintegration is usually not a problem because it often occurs more rapidly than drug dissolution, it is necessary for dissolution in immediate-release formulations. Inability to disintegrate may interfere with bioavailability.

      (2) Lubricants are usually hydrophobic, water-insoluble substances such as stearic acid, magnesium stearate, hydrogenated vegetable oil, and talc. They may reduce wetting of the surface of the solid drug particles, slowing the dissolution and bioavailability rates of the drug. Water-soluble lubricants, such as L-leucine, do not interfere with dissolution or bioavailability.

      (3) Glidants (e.g., colloidal silicon dioxide) improve the flow properties of a dry powder blend before it is compressed. Rather than posing a potential problem with bioavailability, glidants may reduce tablet-to-tablet variability and improve product efficacy.

      (4) Surfactants enhance drug dissolution rates and bioavailability by reducing interfacial tension at the boundary between solid drug and liquid and by improving the wettability (contact) of solid drug particles by the solvent.

  c. Coated compressed tablets have a sugar coat, a film coat, or an enteric coat with the following properties:

      (1) It protects the drug from moisture, light, and air.

      (2) It masks the taste or odor of the drug.

      (3) It improves the appearance of the tablet.

      (4) It may affect the release rate of the drug.

  d. In addition, **enteric coatings** minimize contact between the drug and the gastric region by resisting dissolution or attrition and preventing contact between the underlying drug and the gastric contents or gastric mucosa. Some enteric coatings minimize gastric contact because they are insoluble at acidic pHs. Other coatings resist attrition and remain whole long enough for the tablet to leave the gastric area. By resisting dissolution or attrition, enteric coatings may decrease bioavailability. Enteric coatings are used to

      (1) minimize irritation of the gastric mucosa by the drug;

      (2) prevent inactivation or degradation of the drug in the stomach; and

      (3) delay the release of drug until the tablet reaches the small intestine, where conditions for absorption may be optimal.

6. Modified-release dosage forms are drug products that alter the rate or timing of drug release. Because modified-release dosage forms are more complex than conventional immediate-release dosage forms, more stringent quality control and bioavailability tests are required. **Dose dumping** or the abrupt, uncontrolled release of a large amount of drug is a problem.

  a. Extended-release dosage forms include **controlled-release**, **sustained-action**, and **long-acting drug delivery systems.** These delivery systems allow at least a twofold reduction in dosing frequency compared with conventional immediate-release formulations.

      (1) The extended, slow release of controlled-release drug products produces a relatively flat, sustained plasma drug concentration that avoids toxicity (from high drug concentrations) or lack of efficacy (from low drug concentrations).

      (2) Extended-release dosage forms provide an immediate (initial) release of the drug, followed by a slower sustained release.

  b. Delayed-release dosage forms release active drug at a time other than immediately after administration at a desired site in the gastrointestinal tract. For example, an enteric-coated drug product does not allow for dissolution in the acid environment of the stomach but, rather, in the less acidic environment of the small intestine.

7. Transdermal drug delivery systems, or **patches**, are controlled-release devices that contain the drug for systemic absorption after topical application to the skin surface. Transdermal drug delivery systems are available for a number of drugs (nitroglycerin, nicotine, scopolamine, clonidine, fentanyl, 17-β-estradiol, and testosterone). Although the formulation matrices of these delivery systems differ somewhat, they all differ from conventional topical formulations in the following ways:

  a. They have an impermeable **occlusive backing film** that prevents insensible water loss from the skin beneath the patch. This film causes increased hydration and skin temperature under the patch and enhanced permeation of the skin by the drug.

  b. The formulation matrix of the patch maintains the drug concentration gradient within the device after application so that drug delivery to the interface between the patch and the skin is sustained. As a result, drug partitioning and diffusion into the skin persist, and systemic absorption is maintained throughout the dosing interval.

  c. Transdermal drug delivery systems are kept in place on the skin surface by an **adhesive layer**, ensuring drug contact with the skin and continued drug delivery.

8. **Targeted (site-specific) drug delivery systems** are drug carrier systems that place the drug at or near the receptor site. Examples include macromolecular drug carriers (protein drug carriers), particulate drug delivery systems (e.g., liposomes, nanoparticles), and monoclonal antibodies. With targeted drug delivery, the drug may be delivered to
   a. the capillary bed of the active site,
   b. a special type of cell (e.g., tumor cells) but not to normal cells, and
   c. a specific organ or tissue by complexing with a carrier that recognizes the target.
9. **Inserts**, **implants**, and **devices** are used to control drug delivery for localized or systemic drug effects. The drug is impregnated into a biodegradable or nonbiodegradable material and is released slowly. The inserts, implants, and devices are inserted into a variety of cavities (e.g., vagina, buccal cavity) or tissues (e.g., skin). For example, the leuprolide acetate implant, Viadur, is inserted beneath the skin of the upper arm. It provides palliative treatment of advanced prostate cancer for 1 year.

Study Questions

Directions: Each question, statement, or incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which statement best describes bioavailability?
   (A) relation between the physical and the chemical properties of a drug and its systemic absorption
   (B) measurement of the rate and amount of therapeutically active drug that reaches the systemic circulation
   (C) movement of the drug into body tissues over time
   (D) dissolution of the drug in the gastrointestinal tract
   (E) amount of drug destroyed by the liver before systemic absorption from the gastrointestinal tract occurs

2. The route of drug administration that gives the most rapid onset of the pharmacologic effect is
   (A) intramuscular injection.
   (B) intravenous injection.
   (C) intradermal injection.
   (D) peroral administration.
   (E) subcutaneous injection.

3. The route of drug administration that provides complete (100%) bioavailability is
   (A) intramuscular injection.
   (B) intravenous injection.
   (C) intradermal injection.
   (D) peroral administration.
   (E) subcutaneous injection.

4. After peroral administration, drugs generally are absorbed best from the
   (A) buccal cavity.
   (B) stomach.
   (C) duodenum.
   (D) ileum.
   (E) rectum.

5. The characteristics of an active transport process include all of the following *except* for which one?
   (A) Active transport moves drug molecules against a concentration gradient.
   (B) Active transport follows Fick's law of diffusion.
   (C) Active transport is a carrier-mediated transport system.
   (D) Active transport requires energy.
   (E) Active transport of drug molecules may be saturated at high drug concentrations.

6. The passage of drug molecules from a region of high drug concentration to a region of low drug concentration is known as
   (A) active transport.
   (B) bioavailability.
   (C) biopharmaceutics.
   (D) simple diffusion.
   (E) pinocytosis.

7. Which equation describes the rate of drug dissolution from a tablet?
   (A) Fick's law
   (B) Henderson–Hasselbalch equation
   (C) Law of mass action
   (D) Michaelis–Menten equation
   (E) Noyes–Whitney equation

8. Which condition usually increases the rate of drug dissolution from a tablet?

   (A) increase in the particle size of the drug
   (B) decrease in the surface area of the drug
   (C) use of the free acid or free base form of the drug
   (D) use of the ionized, or salt, form of the drug
   (E) use of sugar coating around the tablet

9. Dose dumping is a problem in the formulation of

   (A) compressed tablets.
   (B) modified-release drug products.
   (C) hard gelatin capsules.
   (D) soft gelatin capsules.
   (E) suppositories.

10. The rate-limiting step in the bioavailability of a lipid-soluble drug formulated as an immediate-release compressed tablet is the rate of

    (A) disintegration of the tablet and release of the drug.
    (B) dissolution of the drug.
    (C) transport of the drug molecules across the intestinal mucosal cells.
    (D) blood flow to the gastrointestinal tract.
    (E) biotransformation, or metabolism, of the drug by the liver before systemic absorption occurs.

11. The extent of ionization of a weak electrolyte drug depends on the

    (A) pH of the media and pK_a of the drug.
    (B) oil to water partition coefficient of the drug.
    (C) particle size and surface area of the drug.
    (D) Noyes–Whitney equation for the drug.
    (E) polymorphic form of the drug.

12. The rate of drug bioavailability is most rapid when the drug is formulated as a

    (A) controlled-release product.
    (B) hard gelatin capsule.
    (C) compressed tablet.
    (D) solution.
    (E) suspension.

13. The amount of drug that a transdermal patch (i.e., transdermal drug delivery system) delivers within a 24-hrs period depends on the

    (A) patch composition, which includes an occlusive backing and an adhesive film in contact with the skin.
    (B) affinity of the drug for the formulation matrix relative to its affinity for the stratum corneum.
    (C) rate of drug partitioning and/or diffusion through the patch to the skin surface.
    (D) surface area of the patch.
    (E) All of the above

Answers and Explanations

1. **The answer is B** *[see I.A.3]*.
   Bioavailability is the measurement of the rate and extent (amount) of therapeutically active drug that reaches the systemic circulation. The relation of the physical and the chemical properties of a drug to its systemic absorption (i.e., bioavailability) is known as its biopharmaceutics. The movement of a drug into body tissues is an aspect of pharmacokinetics, which is the study of drug movement in the body over time. The dissolution of a drug in the gastrointestinal tract is a physicochemical process that affects bioavailability. Significant destruction of a drug by the liver before it is systemically absorbed (known as the first-pass effect because it occurs during the first passage of the drug through the liver) decreases bioavailability.

2. **The answer is B** *[see II.B.1.a]*.
   When the active form of the drug is given intravenously, it enters the systemic circulation directly. The drug is delivered rapidly to all tissues, including the drug receptor sites. For all other routes of drug administration, except intra-arterial injection, the drug must be systemically absorbed before it is distributed to the drug receptor sites. For this reason, the onset of pharmacologic effects is slower. If the drug is a prodrug that must be converted to an active drug, oral administration, not intravenous injection, may not provide the most rapid onset of activity if conversion to the active form takes place in the gastrointestinal tract or liver.

3. **The answer is B** *[see II.C.2]*.
   When a drug is given by intravenous injection, the entire dose enters the systemic circulation. With other routes of administration, the drug may be lost before it reaches the systemic circulation. For example, with first-pass effects, a portion of an orally administered drug is eliminated, usually through degradation by liver enzymes, before the drug reaches its receptor sites.

4. **The answer is C** *[see II.B.2.b.(4)]*.
   Drugs given orally are well absorbed from the duodenum. The duodenum has a large surface area because of the presence of villi and microvilli. In addition, because the duodenum is well perfused by the mesenteric blood vessels, a concentration gradient is maintained between the lumen of the duodenum and the blood.

5. The answer is B *[see II.A.2–3]*.
Fick's law of diffusion describes passive diffusion of drug molecules moving from a high concentration to a low concentration. This process is not saturable and does not require energy.

6. The answer is D *[see II.A.2]*.
The transport of a drug across a cell membrane by passive diffusion follows Fick's law of diffusion: The drug moves with a concentration gradient (i.e., from an area of high concentration to an area of low concentration). In contrast, drugs that are actively transported move against a concentration gradient.

7. The answer is E *[see III.A.1]*.
The Noyes–Whitney equation describes the rate at which a solid drug dissolves. Fick's law is similar to the Noyes–Whitney equation in that both equations describe drug movement caused by a concentration gradient. Fick's law generally refers to passive diffusion, or passive transport, of drugs. The law of mass action describes the rate of a chemical reaction, the Michaelis–Menten equation involves enzyme kinetics, and the Henderson–Hasselbalch equation gives the pH of a buffer solution.

8. The answer is D *[see III.A.1–3]*.
The ionized, or salt, form of a drug has a charge and is generally more water soluble and therefore dissolves more rapidly than the nonionized (free acid or free base) form of the drug. The dissolution rate is directly proportional to the surface area and inversely proportional to the particle size. An increase in the particle size or a decrease in the surface area slows the dissolution rate.

9. The answer is B *[see III.B.6]*.
A modified-release, or controlled-release, drug product contains two or more conventional doses of the drug. An abrupt release of the drug, known as dose dumping, may cause intoxication.

10. The answer is B *[see III.B.1.c]*.
For lipid-soluble drugs, the rate of dissolution is the slowest (i.e., rate-limiting) step in drug absorption and thus in bioavailability. The disintegration rate of an immediate-release or conventional compressed tablet is usually more rapid than the rate of drug dissolution. Because the cell membrane is a lipoprotein structure, transport of a lipid-soluble drug across the cell membrane is usually rapid.

11. The answer is A *[see III.A.4.b]*.
The extent of ionization of a weak electrolyte is described by the Henderson–Hasselbalch equation, which relates the pH of the solution to the pK_a of the drug.

12. The answer is D *[see III.B.2.a]*.
Because a drug in solution is already dissolved, no dissolution is needed before absorption. Consequently, compared with other drug formulations, a drug in solution has a high rate of bioavailability. A drug in aqueous solution has the highest bioavailability rate and is often used as the reference preparation for other formulations. Drugs in hydroalcoholic solution (e.g., elixirs) also have good bioavailability. The rate of drug bioavailability from a hard gelatin capsule, compressed tablet, or suspension may be equal to that of a solution if an optimal formulation is manufactured and the drug is inherently rapidly absorbed.

13. The answer is E *[see III.B.7]*.
Drug delivery from a transdermal drug delivery system depends on all of the factors cited—that is, on the presence of an occlusive backing (to maintain skin hydration and elevate skin temperature slightly) and an adhesive film to maintain contact of the formulation matrix with the skin to enable drug transfer from the patch into the skin. If the drug's affinity for the formulation matrix is greater than its affinity for the stratum corneum, the drug's escaping tendency from the patch will be reduced, minimizing the gradient for drug transfer into the skin. The microviscosity of the formulation matrix, the presence of a membrane between the drug reservoir in the patch and the skin surface, and the interaction of the drug with the formulation matrix affect the rate and extent of diffusion and/or partitioning of the drug through the patch to the skin surface. Finally, the extent of drug delivery from the patch is directly proportional to the surface area of the patch in contact with the skin surface.

Extemporaneous Prescription Compounding

LOYD V. ALLEN JR.

I. INTRODUCTION

A. **Definitions**

1. **Compounding versus manufacturing**
2. It is important, but oftentimes difficult, to distinguish between compounding and manufacturing.
3. **Compounding** is defined by the *United States Pharmacopeia* (*USP*) as the preparation, mixing, assembling, altering, packaging, and labeling of a drug, drug delivery device, or device in accordance with a licensed practitioner's prescription, medication order, or initiative based on the practitioner/patient/pharmacist/compounder relationship in the course of professional practice. Compounding includes the following:
   - Preparation of drug dosage forms for both human and animal patients
   - Preparation of drugs or devices in anticipation of prescription drug orders based on routine, regularly observed prescribing patterns
   - Reconstitution or manipulation of commercial products that may require the addition of one or more ingredients
   - Preparation of drugs or devices for the purposes of, or as an incident to, research (clinical or academic), teaching, or chemical analysis
   - Preparation of drugs and devices for prescriber's office use where permitted by federal and state law
4. **Manufacturing** has been defined as the production, preparation, propagation, conversion, or processing of a drug or device, either directly or indirectly, by extraction of the drug from substances of natural origin or by means of chemical or biological synthesis. Manufacturing may also include any packaging or repackaging of the substance(s) or labeling or relabeling of container for resale by pharmacies, practitioners, or other persons.
5. The purpose of pharmaceutical compounding is to prepare an individualized drug treatment for a patient based on an order from a duly licensed prescriber. The fundamental difference between compounding and manufacturing is the existence of a pharmacist/prescriber/patient relationship that controls the compounding of the drug preparation. Compounded drugs are not for resale but rather are personal and responsive to the patient's immediate needs. They are prepared and administered by the patient, caregiver, or patient's health care professionals, which allows for the monitoring of patient outcomes. On the other hand, drug manufacturers produce batches consisting of tens or hundreds of thousands of dosage units, such as tablets or capsules, for resale, using many personnel and large-scale manufacturing equipment. These products are distributed through the normal channels of interstate commerce to individuals unknown to the company. Manufacturers are not required to, and do not, provide oversight of individual patients. It is also acceptable and routine practice for pharmacists to compound for "office use" those preparations that are not commercially available. These preparations are "for office use only" and are not for resale or to be given to the patients to take home; they are to be administered at the office.

6. The *USP* uses the term *preparation* to refer to compounded prescriptions and the term *products* to refer to manufactured pharmaceuticals. Also, for stability purposes, compounded preparations are assigned a "beyond-use" date, and manufactured products are assigned an "expiration date."

B. Regulation

1. **Current good manufacturing practices (cGMPs)** are the standards of practice used in the pharmaceutical industry and are regulated by the U.S. Food and Drug Administration (FDA).

2. **Good compounding practices (GCPs)** are the standards of practice detailed in the *USP*, Chapter [795]. Community pharmacists must comply with state board of pharmacy laws, regulations, and guidelines to ensure a quality preparation, which includes using proper materials, weighing equipment, documented techniques, and dispensing and storage instructions.

3. **Legal considerations**
   a. Extemporaneous compounding by the pharmacist or a prescription order from a licensed practitioner, as with the dispensing of any other prescription, is controlled by the state boards of pharmacy.
   b. The legal risk (liability) of compounding is no greater than the risk of filling a prescription for a manufactured product because the pharmacist must ensure that the correct drug, dose, and directions are provided. The pharmacist is also responsible for preparing a quality pharmaceutical preparation, providing proper instructions regarding its storage, and advising the patient of any adverse effects.

4. **U.S. Food and Drug Administration.** The FDA has developed a list of preparations that should not be extemporaneously compounded. This list was developed primarily from commercial products that have been removed from the market owing to safety and/or efficacy concerns. This is a lengthy list and must be read carefully because, in some cases, only certain dosage forms of a specific drug are included on the list and others are not. The list is too extensive to include here but can be accessed at http://www.gpo.gov/fdsys/pkg/FR-1999-03-08/html/99-5517.htm.

C. Stability and quality control of compounded preparations

1. **Beyond-use dates.** The assignment of a beyond-use date is one of the most difficult tasks required of a compounding pharmacist. Chapters [795] and [797] of the *USP* provide guidelines for this task. Chapter [795] involves nonsterile preparations, and Chapter [797] involves sterile preparations. For nonsterile preparations, the current *USP* criteria are applicable in the absence of stability information to a specific drug and preparation. For nonaqueous liquids and solid formulations (for which a manufactured drug product is the source of active ingredients), include a beyond-use date not later than 25% of the time remaining until the product's expiration date or 6 months, whichever is earlier. When a *USP* or *National Formulary* (*NF*) substance is the source of active ingredient, the beyond-use date is not later than 6 months. For water-containing oral formulations, the beyond-use date is not later than 14 days when stored at cold temperatures; for water-containing topical/dermal and mucosal liquid and semisolid formulations, the beyond-use date is not later than the intended duration of therapy or 30 days. These beyond-use dates may be exceeded when there is supporting valid scientific stability information that is directly applicable to the specific preparation.

For sterile preparations and if not sterility tested, the following can be used provided that the preparation is properly packaged and stored. If the preparation is sterility tested, the beyond-use dates for nonsterile preparations apply.

Low-risk level compounded sterile preparations: Not more than 48 hrs at controlled room temperature, not more than 14 days at a cold temperature (refrigerator), and for 45 days frozen at −20°C or colder.

Medium-risk level compounded sterile preparations: Not more than 30 hrs at controlled room temperature, not more than 9 days at cold temperature (refrigerator), and for 45 days frozen at −20°C or colder.

High-risk level compounded sterile preparations: Not more than 24 hrs at controlled room temperature, not more than 3 days at cold temperature (refrigerator), and for 45 days frozen at −20°C or colder.

As in nonsterile compounding, these beyond-use dates for sterile compounding may be exceeded when there is supporting valid scientific stability information that is directly applicable to the specific preparation.

2. **Quality control.** Quality control is becoming one of the fastest growing aspects of pharmacy compounding. Guidelines for establishing a quality control program are detailed in *USP* [1163] Quality Assurance in Pharmaceutical Compounding. Pharmacists are becoming more involved in the final testing of compounded preparations or are sending them to contract laboratories for testing. For example, the following quality control tests can be considered for the respective compounded dosage forms:

   a. **Ointments, creams, and gels.** Theoretical weight compared to actual weight, pH, specific gravity, active drug assay, physical observations (color, clarity, texture–surface, texture–spatula spread, appearance, feel), and rheological properties

   b. **Hard gelatin capsules.** Weight overall, average weight, individual weight variation, dissolution of capsule shell, disintegration of capsule contents, active drug assay, physical appearance (color, uniformity, extent of fill, locked), and physical stability (discoloration, changes in appearance)

   c. **Special hard gelatin capsules.** Weight overall, average weight, individual weight variation, dissolution of capsule shell, disintegration of capsule contents, active drug assay, physical appearance (color, uniformity of appearance, uniformity of extent of fill, closures), and physical stability (discoloration or other changes)

   d. **Suppositories, troches, lollipops, and sticks.** Weight, specific gravity, active drug assay, physical observations (color, clarity, texture of surface, appearance, feel), melting test, dissolution test, and physical stability

   e. **Oral and topical liquids.** Weight to volume, pH, specific gravity, active drug assay, globule size range, rheological properties/pourability, physical observations (color, clarity), and physical stability (discoloration, foreign materials, gas formation, mold growth)

   f. **Parenteral preparations.** Weight or volume, pH, specific gravity, osmolality, assay, physical observations (color, clarity), particulate matter, sterility, and pyrogenicity

3. **Quality control testing.** Pharmacists have the option of doing testing in-house or outsourcing it to laboratories.

   a. **In-house testing** can include measurements such as weight, volume, pH, specific gravity, osmolality, physical observations, sterility, and endotoxins.

   b. **Out-sourced testing** can include sterility, endotoxins, potency, and dissolution.

   c. **Test results** should be kept on file with the compounding records for the individual compounded preparations.

II. REQUIREMENTS FOR COMPOUNDING

A. **Sources for chemicals and drugs.** Pharmacists can obtain small quantities of the appropriate chemicals or drugs from wholesalers or chemical supply houses. These suppliers then may also serve as compounding consultants to the pharmacists to aid in ensuring their product's purity and quality.

B. **Equipment.** The correct equipment is important in a compounding pharmacy. Many state boards of pharmacy have a required minimum list of equipment for compounding prescriptions. Equipment appropriate for the type and extent of compounding being conducted is vital. Appropriate standard operating procedures must be in place and followed for the maintenance, operation, and calibration of the equipment.

C. **Location of compounding area.** Many pharmacies actively involved in compounding have dedicated a separate area in the pharmacy to this process. The ideal location is away from heavy foot traffic and is near a sink where there is sufficient space to work and store all chemicals and equipment. For compounding of sterile preparations, a laminar airflow hood and a clean room are current practice, or isolation barrier technology equipment appropriately positioned.

III. COMPOUNDING OF SOLUTIONS

A. Definition. *USP* 34 defines **solutions** as liquid preparations that contain one or more chemical substances dissolved (i.e., molecularly dispersed) in a suitable solvent or mixture of mutually miscible solvents. Although the uniformity of the dosage in a solution can be assumed, the stability, pH, solubility of the drug or chemicals, taste (for oral solutions), and packaging need to be considered.

B. Types of solutions

  1. Sterile parenteral and ophthalmic solutions require special consideration for their preparation (see XI).

  2. Nonsterile solutions include oral, topical, and otic solutions.

C. Preparation of solutions. Solutions are the easiest of the dosage forms to compound extemporaneously, as long as a few general rules are followed.

  1. Each drug or chemical is dissolved in the solvent in which it is most soluble. Thus, the solubility characteristics of each drug or chemical must be known.

  2. If an alcoholic solution of a poorly water-soluble drug is used, the aqueous solution is added to the alcoholic solution to maintain as high an alcohol concentration as possible.

  3. The salt form of the drug—not the free acid or base form, which both have poor solubility—is used.

  4. Flavoring or sweetening agents are prepared ahead of time.

  5. When adding a salt to a syrup, dissolve the salt in a few milliliters of water first; then add the syrup to volume.

  6. The proper vehicle (e.g., syrup, elixir, aromatic water, purified water) must be selected.

D. Examples

  1. Example 1

      a. Medication order

Triamcinolone acetonide	100 mg
Menthol	50 mg
Ethanol	10 mL
Propylene glycol	30 mL
Glycerin	20 mL
Sorbitol 70% solution, q.s.	100 mL
Sodium saccharin	100 mg
Sodium metabisulfite	20 mg
Disodium EDTA	100 mg
Purified water	5 mL

      b. Compounding procedure. Triamcinolone acetonide 0.1% mouthwash solution is prepared by dissolving the triamcinolone acetonide and menthol in the ethanol. Add the propylene glycol, glycerin, and about 10 mL of the 70% sorbitol and mix well. Dissolve the sodium saccharin, sodium metabisulfite, and disodium EDTA in the purified water. Add the aqueous

solution to the drug mixture and mix well. Add sufficient 70% sorbitol solution to volume and mix well.

How much of the triamcinolone base is present in this prescription? The molecular weight of triamcinolone is 394.4 and that of triamcinolone acetonide is 434.5.

$$\frac{394.4}{434.5} \times 100 \text{ mg} = 91 \text{ mg of triamcinolone base}$$

2. **Example 2**
   a. **Medication order**
Potassium chloride	1 mEq/mL
Preserved flavored, oral vehicle, q.s.	100 mL

   b. **Calculations.** The molecular weight of potassium chloride is 74.5 (K = 39; Cl = 35.5). One milliequivalent (mEq) weighs 74.5 mg.

   $$100 \text{ mL} \times 74.5 \text{ mg/mL} = 7450 \text{ mg or } 7.45 \text{ g of KCl required}$$

   What is the molar concentration of this prescription?
   7.45 g per 100 mL or 74.5 g per 1000 mL
   1 mole of KCl weighs 74.5 g
   It is a 1 molar solution.

   c. **Compounding procedure.** The solubility of potassium chloride is 1 g in 2.8 mL water. Therefore, dissolve the 7.45 g KCl in 21 mL of purified water. Add sufficient preserved flavored oral vehicle to volume and mix well.

3. **Example 3**
   a. **Medication order**
Salicylic acid	2%
Lactic acid	6 mL
Flexible collodion, a.d.	30 mL

   b. **Compounding procedure.** Pharmacists must use caution when preparing this prescription because flexible collodion is extremely flammable. A 1-oz applicator-tip bottle is calibrated, using ethanol, which is poured out and any remaining alcohol is allowed to evaporate, resulting in a dry bottle. Salicylic acid (0.6 g) is added directly into the bottle, to which is added the 6 mL of lactic acid. The bottle is agitated or a glass stirring rod is used to dissolve the salicylic acid. Flexible collodion is added up to the calibrated 30-mL mark on the applicator-tip bottle.

4. **Example 4**
   a. **Medication order**
Iodine	2%
Sodium iodide	2.4%
Alcohol, q.s.	30 mL

   b. **Compounding procedure.** Iodine (0.6 g) and sodium iodide (0.72 g) are dissolved in the alcohol, and the final solution is placed in an amber bottle. A rubber or plastic spatula is used because iodine is corrosive.

IV. COMPOUNDING OF SUSPENSIONS

A. **Definition.** **Suspensions** are defined by *USP* 34 as liquid preparations that consist of solid particles dispersed throughout a liquid phase in which the particles are not soluble.

B. **General characteristics**
   1. Some suspensions should contain an antimicrobial agent as a preservative.
   2. Particles settle in suspensions even when a suspending agent is added; thus, suspensions must be well shaken before use to ensure the distribution of particles for a uniform dose.
   3. Tight containers are necessary to ensure the stability of the final preparation.
   4. Principles to keep in mind when compounding include the following:
      a. Insoluble powders should be small and uniform in size to decrease settling.
      b. The suspension should be viscous.
      c. Topical suspensions should have a smooth, impalpable texture.
      d. Oral suspensions should have a pleasant odor and taste.

C. Formation of suspensions. Suspensions are easy to compound; however, physical stability after compounding the final preparation is problematic. The following steps may minimize stability problems.

1. The particle size of all powders used in the formulation should be reduced.
2. A thickening (suspending) agent may be used to increase viscosity. Common thickening agents include alginic acid, bentonite, VEEGUM, methylcellulose, and tragacanth.
3. A levigating agent may aid in the initial dispersion of insoluble particles. Common levigating agents include glycerin, propylene glycol, alcohol, syrups, and water.
4. Flavoring agents and preservatives should be selected and added if the preparation is intended for oral use. Common preservatives include methylparaben, propylparaben, benzoic acid, and sodium benzoate. Flavoring agents may be any flavored syrup or flavored concentrate (*Table 4-1*).
5. The source of the active ingredients (e.g., bulk powders vs. tablets or capsules) must be considered; if commercial dosage forms are used, the inactive ingredients must be considered and only immediate-release tablets or capsules should be used and not modified release, unless necessary and they can be used appropriately.

D. Preparation of suspensions

1. The insoluble powders are triturated to a fine powder.
2. A small portion of liquid is used as a levigating agent, and the powders are triturated until a smooth paste is formed.
3. The vehicle containing the suspending agent is added in divided portions. A high-speed mixer greatly increases the dispersion.
4. The preparation is brought to the required volume using the vehicle.
5. The final mixture is transferred to a "tight" bottle for dispensing to the patient.
6. All suspensions are dispensed with a "shake well" label.
7. Suspensions are not filtered.
8. The water-soluble ingredients, including flavoring agents, are mixed in the vehicle before mixing with the insoluble ingredients.

E. Examples

1. **Example 1**
   a. **Medication order**
      Propranolol HCl   4 mg/mL
      Disp   30 mL
      Sig: 1 mL p.o. t.i.d.
   b. **Calculations.** Propranolol HCl: 4 mg/mL × 30 mL = 120 mg. Propranolol HCl is available as a powder or in immediate-release and extended-release (long-acting) dosage forms. Only the powder or the immediate-release tablets are used for compounding prescriptions; therefore, some combination of propranolol HCl tablets that yields 120-mg active drug (e.g., 3 × 40-mg tablets) may be used.
   c. **Compounding procedure.** The propranolol tablets are reduced to a fine powder in a mortar. The powder or the comminuted tablets are levigated to a smooth paste, using a 2% methylcellulose

| Table 4-1 | SELECTED FLAVOR APPLICATIONS |

Drug Category	Preferred Flavors
Antibiotics	Cherry, maple, pineapple, orange, raspberry, banana-pineapple, banana-vanilla, butterscotch-maple, coconut custard, strawberry, vanilla, lemon custard, cherry custard, fruit-cinnamon
Antihistamines	Apricot, black currant, cherry, cinnamon, custard, grape, honey, lime, loganberry, peach-orange, peach-rum, raspberry, root beer, wild cherry
Barbiturates	Banana-pineapple, banana-vanilla, black currant, cinnamon-peppermint, grenadine-strawberry, lime, orange, peach-orange, root beer
Decongestants and expectorants	Anise, apricot, black currant, butterscotch, cherry, coconut custard, custard mint-strawberry, grenadine-peach, strawberry, lemon, coriander, orange-peach, pineapple, raspberry, strawberry, tangerine
Electrolyte solutions	Cherry, grape, lemon-lime, raspberry, wild cherry, black currant, grenadine-strawberry, lime, Port wine, Sherry wine, root beer, wild strawberry

solution. To this mixture, about 10 mL of a suitable flavoring agent is added. The mixture is transferred to a calibrated container and brought to the final volume with purified water or suitable suspending vehicle. A "shake well" label is attached to the prescription container.

2. **Example 2**
   a. Medication order

Zinc oxide	10 g
Ppt sulfur	10 g
Bentonite	3.6 g
Purified water, a.d.	90 mL
Sig:	Apply t.i.d.

   b. **Compounding procedure.** The powders are reduced to a fine uniform mixture in a mortar. The powders are mixed to form a smooth paste using water and transferred to a calibrated bottle. The final volume is attained with purified water. A "shake well" label is attached to the prescription container.

3. **Example 3**
   a. **Medication order**

Rifampin suspension	20 mg/mL
Disp	120 mL
Sig:	u.d.

   b. **Calculations.** Rifampin: 20 mg/mL $\times$ 120 mL = 2400 mg. Rifampin is available in 150-mg and 300-mg capsules. Hence, 8 capsules containing 300 mg of rifampin in each capsule or 16 capsules containing 150 mg of rifampin per capsule are needed.

   c. **Compounding procedure.** The contents of the appropriate number of rifampin capsules are emptied into a mortar and comminuted with a pestle. This powder is levigated with a small amount of 1% methylcellulose solution. Then 20 mL of simple syrup are added and mixed. The mixture is brought to the final volume with simple syrup. "Shake well" and "refrigerate" labels are attached to the prescription container.

V. EMULSIONS

A. **Definition.** Emulsions are **two-phase systems** in which one liquid is dispersed throughout another liquid in the form of small droplets.

B. **General characteristics.** Emulsions can be used externally as lotions and creams or internally to mask the taste of medications.
   1. The two liquids in an emulsion are immiscible and require the use of an emulsifying agent.
   2. Emulsions are classified as either **oil-in-water (o/w)** or **water-in-oil (w/o)**; there can also be multiple emulsions, such as **oil-in-water-in-oil (o/w/o)** and **water-in-oil-in-water (w/o/w)**, as well as emulsion gels, in which the external phase of an oil in water emulsion is thickened with a gelling agent.
   3. Emulsions are **unstable** by nature, and the following steps should be taken to prevent the two phases of an emulsion from separating into two layers after preparation.
      a. The correct **proportions** of oil and water should be used during preparation. The internal phase should represent 40% to 60% of the total volume.
      b. An emulsifying **agent** is needed for emulsion formation.
      c. A **hand homogenizer**, which reduces the size of globules of the internal phase, may be used; if small quantities are compounded, two 60-mL syringes attached with a Luer-Lock adapter can be used and the materials pushed back and forth between the two syringes.
      d. **Preservatives** should be added if the preparation is intended to last longer than a few days. Generally, a combination of methylparaben (0.2%) and propylparaben (0.02%) may be used.
      e. A **"shake well"** label should be placed on the final preparation.
      f. The preparation should be **protected** from light and extreme temperature. Both freezing and heat may have an effect on stability.

C. **Emulsifying agents**
   1. **Gums**, such as acacia or tragacanth, are used to form o/w emulsions. These emulsifying agents are for general use, especially for emulsions intended for internal administration (*Table 4-2*).
      a. Use 1 g of acacia powder for every 4 mL of fixed oil or 1 g to 2 mL for a volatile oil.
      b. If using tragacanth in place of acacia, 0.1 g of tragacanth is used for every 1 g of acacia.

Table 4-2 AGENTS USED IN PRESCRIPTION COMPOUNDING

Ointments

Oleaginous or hydrocarbon bases
  Anhydrous
  Nonhydrophilic
  Insoluble in water
  Not water removable (occlusive)
  Good vehicles for antibiotics
Example
  Petrolatum
Absorption bases
  Anhydrous
  Will absorb water
  Insoluble in water
  Not water removable (occlusive)
Examples
  Hydrophilic petrolatum
  Lanolin *USP* (anhydrous)

Hydrous emulsion bases (w/o)
  Hydrous
  Will absorb water
  Insoluble in water
  Not water removable (occlusive)
Examples
  Cold cream
  Hydrous lanolin
Emulsion bases (o/w)
  Hydrous
  Hydrophilic
  Insoluble in water
  Water removable
  Can absorb 30%–50% of weight
Examples
  Hydrophilic ointment *USP*
  Acid mantle cream
Water soluble
  Anhydrous or hydrous
  Soluble in water
  Water removable
  Hydrophilic
Example
  Polyethylene glycol ointment

Suspending Agents

Acacia 10%
Alginic acid 1%–2%
Bentonite 6%
Carboxymethylcellulose 1%–5%

Methylcellulose 1%–7%
Sodium alginate 1%–2%
Tragacanth 1%–3%
VEEGUM 6%

Preservatives

Methylparaben 0.02%–0.2%

Propylparaben 0.01%–0.04%

Emulsifying Agents

Hydrophilic colloids
  Acacia
  Tragacanth
  Pectin; favor o/w
  Carboxymethylcellulose
  Methylcellulose
Proteins
  Gelatin
  Egg whites; favor o/w
Inorganic gels and magmas
  Milk of magnesia
  Bentonite; favor o/w

Surfactants, nonionic
Concentrations used (1%–30%)
Tweens (e.g., polysorbate 80)
Spans

Soaps
  Triethanolamine
  Stearic acid
Others
  Sodium lauryl sulfate
  Dioctyl sodium sulfosuccinate
  Cetylpyridinium chloride

o/w, oil-in-water; *w/o*, water-in-oil.

2. **Methylcellulose and carboxymethylcellulose** are used for o/w emulsions. The concentrations of these agents vary, depending on the grade that is used. Methylcellulose is available in several viscosity grades, ranging from 15 to 4000 and designated by a centipoise number, which is a unit of viscosity.

3. **Soaps** can be used to prepare o/w or w/o emulsions for external preparations.

4. **Nonionic emulsifying agents** can be used for o/w and w/o emulsions.

D. **Formation and preparation of emulsions.** The procedure for preparing an emulsion depends on the desired emulsifying agent in the formulation.

1. A **mortar** and **pestle** are frequently all the equipment that is needed.
   a. A mortar with a **rough surface** (e.g., Wedgwood) should be used. This rough surface allows maximal dispersion of globules to produce a fine particle size.
   b. A **rapid motion** is essential when triturating an emulsion using a mortar and pestle.
   c. The mortar should be able to hold at least three times the **quantity** being made. Trituration seldom requires more than 5 mins to create the emulsion.

2. **Electric mixers** and hand homogenizers are useful for producing emulsions after the coarse emulsion is formed in the mortar.

3. The **order** of mixing of ingredients in an emulsion depends on the type of emulsion being prepared (i.e., o/w or w/o) as well as the emulsifying agent chosen. Methods used for compounding include the following:
   a. **Dry gum** (continental) method is used for forming emulsions using natural emulsifying agents and requires a specific order of mixing.
   b. **Wet gum** (English) method is used for forming emulsions using natural emulsifying agents and requires a specific order of mixing.
   c. **Bottle method** is used for forming emulsions using natural emulsifying agents and requires a specific order of mixing.
   d. **Beaker method** is used to prepare emulsions using synthetic emulsifying agents and produces a satisfactory preparation regardless of the order of mixing.

4. **Preservatives.** If the emulsion is kept for an extended period, refrigeration is usually sufficient. The preparation should not be frozen. If a preservative is used, it must be soluble in the water phase to be effective.

5. **Flavoring agents.** If the addition of a flavor is needed to mask the taste of the oil phase, the flavor should be added to the external phase before emulsification (*Table 4-3*).

E. **Examples**

1. **Example 1**
   a. **Medication order**

Mineral oil	18 mL
Acacia	q.s.
Distilled water, q.s. a.d.	90 mL
Sig:	1 tablespoon q.d.

   b. **Compounding procedure.** With the dry gum method, an initial emulsion (primary emulsion) is formed, using four parts (18 mL) of oil, two parts (9 mL) of water, and one part (4.5 g) of powdered acacia. The mineral oil is triturated with the acacia in a Wedgwood mortar. The 9 mL of water is added all at once and, with rapid trituration, form the primary emulsion, which is triturated for about 5 mins. The remaining water is incorporated in small amounts

Table 4-3	FLAVOR SELECTION GUIDE

Taste	Masking Flavor
Salt	Butterscotch, maple
Bitter	Wild cherry, walnut, chocolate mint, licorice
Sweet	Fruit, berry, vanilla
Acid	Citrus

with trituration. The emulsion is transferred to a 90-mL prescription bottle, and a "shake well" label is attached to the container.

2. **Example 2**
   a. **Medication order**

Olive oil	30 mL
Zinc oxide	8 g
Calamine	8 g
Limewater	30 mL

   b. **Compounding procedure.** The olive oil is placed in a suitably sized beaker. Using an electric mixer, the zinc oxide, the calamine, and the limewater are added in that order. This yields a w/o emulsion. This procedure is known as the *nascent soap method*. The olive oil reacts with the calcium hydroxide solution (limewater) and forms a soap. For this reaction to occur, fresh limewater (calcium hydroxide solution) is required. A small quantity of oleic acid can also be added to further stabilize the emulsion.

3. **Example 3**
   a. **Medication order**

Mineral oil	50 mL
Water, q.s.	100 mL
Sig:	2.5 mL p.o. h.s.

   b. **Compounding procedure.** Using a combination of nonionic emulsifying agents, such as Span 40 and Tween 40, the correct hydrophilic–lipophilic balance (HLB) is obtained. Next, the mineral oil is warmed in a water bath to about 60°C, and the Span 40 is dissolved in the heated mineral oil. The water is warmed to about 65°C, and the Tween 40 is dissolved in the heated water. This mixture is added to the mineral oil and dissolved Span 40 and stirred until cooled. An "external use only" label is added to the container.

VI. POWDERED DOSAGE FORMS

A. **Definition.** **Powders** are intimate mixtures of dry, finely divided drugs and/or chemicals that may be intended for internal (oral powders) or external (topical powders) use. The major types are powder papers, bulk powders, and insufflations.

B. **General characteristics**
   1. Powder dosage forms are used when **drug stability** or **solubility** is a concern. These dosage forms may also be used when the powders are too bulky to make into capsules and when the patient has difficulty swallowing a capsule.
   2. Some **disadvantages** to powders include unpleasant-tasting medications and, occasionally, the rapid deterioration of powders.
   3. **Blending** of powders may be accomplished by using trituration in a mortar, stirring with a spatula, and sifting. Geometric dilution should be used if needed. When heavy powders are mixed with lighter ones, the heavier powder should be placed on top of the lighter one and then blended. When mixing two or more powders, each powder should be pulverized separately to about the same particle size before blending together.
      a. The mortar and pestle method is preferred when **pulverization** and a thorough mixing of ingredients are desired (geometric dilution). A Wedgwood mortar is preferable, but glass or porcelain may also be used.
      b. Light powders are mixed best by using the **sifting method**. The sifting is repeated three to four times to ensure thorough mixing of the powders.

C. **Preparation of powder dosage forms**
   1. **Bulk powders**, which may be used internally or topically, include dusting powders, douche powders, laxatives, antacids, and insufflation powders.
   2. After a bulk powder has been pulverized and blended, it should be dispensed in an appropriate container.
      a. **Hygroscopic** or **effervescent** salts should always be placed in a tight, wide-mouth jar.
      b. **Dusting** powders should be placed in a container with a sifter top.
   3. **Eutectic mixtures** of powders can cause problems because they may liquefy. One remedy is to add an inert powder, such as magnesium oxide, to separate the eutectic materials.

4. **Powder papers** are also called *divided powders*.
   a. The entire powder is initially blended. Each dose is then individually weighed.
   b. The dosage should be weighed, then transferred onto a powder paper and folded. This technique requires practice. Hygroscopic, deliquescent, and effervescent powders require the use of glassine paper as an inside lining. Plastic bags or envelopes with snap-and-seal closures offer a convenient alternative to powder papers.
   c. The folded papers are dispensed in a powder box or other suitable container; however, these containers are not child resistant.

D. **Examples**
   1. **Example 1**
      a. **Medication order**

Camphor	100 mg
Menthol	200 mg
Zinc oxide	800 mg
Talc	1.9 g
M foot powder	
Sig:	Apply to feet b.i.d.

      b. **Compounding procedure.** The camphor and menthol are triturated together in a glass mortar, where a liquid eutectic is formed. The zinc oxide and talc are blended and mixed with the eutectic, using geometric dilution. This mixing results in a dry powder, which is passed through a wire mesh sieve. The final preparation is dispensed in a container with a sifter top.

   2. **Example 2**
      a. **Medication order**

Citric acid	0.3 g
Sodium bicarbonate	0.25 g
Psyllium mucilloid	2 g
Powdered flavor, q.s.	

      M. Ft d.t.d. charts v
      Sig: Empty the contents of one chart into a glass of water and take h.s.

      b. **Calculations.** Calculate for one extra powder paper:
      Citric acid 0.3 g $\times$ 6 doses = 1.8 g
      Sodium bicarbonate 0.25 g $\times$ 6 doses = 1.5 g
      Psyllium mucilloid 2 g $\times$ 6 doses = 12 g
      Total weight = 15.3 g
      15.3 g/6 doses = 2.55 g/dose
      Note: Also consider the weight of the powdered flavor.

      c. **Compounding procedure.** The ingredients are first pulverized and weighed. The citric acid and sodium bicarbonate are mixed together first; the psyllium mucilloid is then added along with the powdered flavor, using geometric dilution. Each dose (2.55 g) of the resultant mixture is weighed and placed into a powder paper. This preparation is an effervescent powder. When dissolved in water, the citric acid and sodium bicarbonate react to form carbonic acid, which yields carbon dioxide, making the solution more palatable.

VII. CAPSULES

A. **Definition. Capsules** are solid dosage forms in which the drug is enclosed within either a hard or soft soluble container or shell. The shells are usually made from a suitable gelatin. Hard gelatin capsules may be manually filled for extemporaneous compounding.

B. **Capsule sizes**
   1. A list of capsule sizes and the approximate amount of powder that may be contained in the capsule appear on the side of the capsule box (*Table 4-4*).
   2. Capsule sizes for oral administration in humans range from no. 5, the smallest, to no. 000, the largest.
   3. No. 0 is usually the largest oral size suitable for human patients, although larger sizes are occasionally used.

Table 4-4	APPROXIMATE AMOUNT OF POWDER CONTAINED IN CAPSULES

Capsule Size	Range of Powder Capacity (mg)
No. 5	60–130
No. 4	95–260
No. 3	130–390
No. 2	195–520
No. 1	225–650
No. 0	325–910
No. 00	390–1300
No. 000	650–2000

4. Capsules for veterinarians are available in no. 10, no. 11, and no. 12, containing approximately 30, 15, and 7.5 g, respectively.

C. Preparation of hard and soft capsules

1. As with the bulk powders, all ingredients are triturated and blended, using geometric dilution.
2. The correct size capsule must be determined by trying different capsule sizes, weighing them, and then choosing the appropriate size.
3. Before filling capsules with the medication, the body and cap of the capsule are separated. Filling is accomplished by using the "punch" method (Alternatively, small capsule machines are commonly used to prepare up to 300 capsules at a time, extemporaneously).
   a. The powder formulation is compressed with a spatula on a pill tile or paper sheet with a uniform depth of approximately half the length of the capsule body.
   b. The empty capsule body is repeatedly pressed into the powder until full.
   c. The capsule is then weighed to ensure an accurate dose. An empty tare capsule of the same size is placed on the pan containing the weights.
4. For a large number of capsules, capsule-filling machines can be used for small-scale use to save time. Most commonly, capsule machines used are capable of preparing 100 to 300 capsules at a time.
5. The capsule is wiped clean of any powder or oil and dispensed in a suitable prescription vial.

D. Examples

1. **Example 1**
   a. **Medication order**
      Rifampin   100 mg
      dtd #50
      Sig: 1 cap p.o. q.d.
   b. **Calculations.** Compound this prescription using the commercially available 300-mg capsules as the drug source. Calculate for at least one extra capsule.

$$51 \text{ caps} \times 100 \text{ mg/cap} = 5100 \text{ mg rifampin}$$

$$5100 \text{ mg rifampin} \div 300 \text{ mg/cap} = 17 \text{ caps}$$

   c. **Compounding procedure.** Use 17 rifampin capsules, each containing 300 mg rifampin. The content of each capsule is emptied, and the powder is weighed. The powder equivalent to 100 mg rifampin is placed in a capsule (e.g., if the total contents of one capsule weigh 360 mg; then $100/300 = x/360$; $x = 120$ mg of active drug powder required from the capsule contents to provide 100 mg active drug) and sufficient lactose added to fill the capsule. The total filled capsule contents weigh 200 mg. The weight of the active drug powder is subtracted from 200 mg to obtain the amount of lactose required per capsule, which is 200 mg − 120 mg = 80 mg. This is multiplied by 51 capsules. Enough lactose (51 capsules × 80 mg/

cap = 4.08 g) is added to make a total of 10.2 g of powder. The powders are combined, using geometric dilution, and 50 capsules can be punched out. Each capsule should weigh 200 mg (10.2 g/51 caps).

2. Example 2

    a. Medication order. This order is for veterinary use only.

Castor oil	8 mL
Disp	12 caps
Sig:	2 caps p.o. h.s.

    b. Calculations. No calculations are necessary.

    c. Compounding procedure. A no. 11 veterinary capsule is used. Using a calibrated dropper or a pipette, 8 mL of the oil is carefully added to the inside of each capsule body. Next, the lower inside portion of the cap is moistened, using a glass rod or brush. The cap and body are joined together, using a twisting motion, to form a tight seal. The capsules are placed on a piece of filter paper and checked for signs of leakage. The capsules are dispensed in the appropriate size and type of prescription vial. They can be stored in a refrigerator if desired.

VIII. MOLDED TABLETS (TABLET TRITURATES)

A. Definition. Tablet triturates are small, usually cylindrical molded or compressed tablets. They are made of powders created by moistening the powder mixture with alcohol and water or by the process of sintering. They can be used for compounding potent drugs in small doses and for preparation of a rapidly disintegrating/dissolving dosage form.

B. Formulation and preparation of tablet triturates using moistened powders

    1. Tablet triturates are made in special molds consisting of a pegboard and a corresponding perforated plate.

    2. In addition to the mold, a diluent, usually a mixture of lactose and sucrose (80:20), and a moistening agent, usually a mixture of ethyl alcohol and water (60:40), are required.

    3. The diluent is triturated with the active ingredients.

    4. A paste is then made, using the alcohol and water mixture.

    5. This paste is spread into the mold; the tablets are punched out and remain on the pegs until dry.

C. Example

    1. Medication order

Atropine sulfate	0.4 mg
Disp	#500 TT
Sig:	u.d.

    2. Calculations. For 500 TT: 500 × 0.4 mg = 200 mg atropine sulfate

    3. Compounding procedure. The mold prepares 70-mg tablets. The 200 mg of atropine sulfate, 6.8 g of sucrose, and 28 g of lactose are weighed and mixed by geometric dilution. The powder is wet with a mixture of 40% purified water and 60% ethyl alcohol (95%). The paste that is formed is spread onto the tablet triturate mold; the tablets are then punched out of the mold and allowed to dry on the pegs. This procedure is repeated until the required number of tablet triturates has been prepared.

D. Formulation and preparation of tablet triturates using sintering

    1. These tablet triturates are made in special molds consisting of materials that can tolerate heat to about 100°C.

    2. In addition to the mold, a diluent, usually a mixture of active drug and diluent, which make up approximately 65% of the tablet weight, are blended together. Mannitol is good to use in combination with lactose for particle sizes of 60 to 80 mesh fraction.

    3. The mixture is triturated with polyethylene glycol 3350 with a particle size of 80 to 100 mesh fraction.

    4. The powder mixture is placed into appropriate molds and lightly tamped.

    5. The molds containing the powder are placed in an oven at about 90°C for 10 to 20 mins, removed, and allowed to cool. Depending on the molds used, the tablets can be dispensed in the molds or removed from the molds and packaged and labeled.

E. **Example**
   1. **Medication order**

Homatropine hydrobromide	300 mg
Mannitol	3.5 g
Lactose	3.47 g
Flavor (dry powder type)	q.s.
Polyethylene glycol 3350	3.5 g

   2. **Calculations.** As presented, this formula is for 100 rapid-dissolving tablet triturates.
   3. **Compounding procedure.** Blend the homatropine hydrobromide, mannitol, lactose, and dry flavor together until fine and uniformly mixed. Separately, reduce the particle size of the polyethylene glycol 3350 to 100 to 200 mesh fraction. Lightly blend in the polyethylene glycol 3350 into the previously blended powders. Place 100 mg of the powder into the cavities of a mold (some blister packs work well; otherwise, obtain a tablet triturate mold or a special mold for preparing these tablets). Place the mold containing the powder in an oven at 80° to 90°C for 15 to 20 mins. The time depends on the mold, formulation, oven, etc. Remove from the oven and place in a refrigerator for approximately 5 mins. Remove from the refrigerator and let set at room temperature. Package and label.

IX. OINTMENTS, CREAMS, PASTES, AND GELS

A. **Definitions**
   1. **Ointments**, **creams**, and **pastes** are semisolid dosage forms intended for topical application to the skin or mucous membranes. **Ointments** are characterized as being oleaginous in nature; **creams** are generally o/w or w/o emulsions, and **pastes** are characterized by their high content of solids (about 25%).
   2. Gels (sometimes called jellies) are semisolid systems consisting of suspensions made up of either small inorganic particles or large organic molecules interpenetrated by a liquid.
B. **General characteristics.** These dosage forms are semisolid preparations generally applied externally. Semisolid dosage forms may contain active drugs intended to
   1. act solely on the surface of the skin to produce a local effect (e.g., antifungal agent, topicals);
   2. release the medication, which, in turn, penetrates into the skin (e.g., hydrocortisone cream); and
   3. release medication for systemic absorption through the skin (e.g., nitroglycerin, transdermals).
C. **Types of ointment bases**
   1. Hydrophobic bases feel greasy and contain mixtures of fats, oils, and waxes. Hydrophobic bases cannot be washed off using water.
   2. Hydrophilic bases are usually emulsion bases. The o/w-type emulsion bases can be easily washed off with water, but the w/o type is slightly more difficult to remove.
D. **Preparation of ointments, creams, pastes, and gels**
   1. Mixing can be done in a mortar or on an ointment slab or tile or using an ointment mill.
   2. Liquids are incorporated by gradually adding them to an absorption-type base and mixing.
   3. Insoluble powders are reduced to a fine powder and then added to the base, using geometric dilution.
   4. Water-soluble substances are dissolved with water and then incorporated into the base.
   5. The final preparation should be smooth (impalpable) and free of any abrasive particles.
E. **Examples**
   1. **Example 1**
      a. **Medication order**

Sulfur	
Salicylic acid, a.a.	600 mg
White petrolatum, a.d.	30 g
Sig:	Apply t.i.d.

      b. **Compounding procedure.** The particle sizes of the sulfur and salicylic acid are reduced separately in a Wedgwood mortar and then blended together. Using a pill tile, the powder mixture is levigated with the base. Using geometric dilution, the base and powders are blended to the final weight. An ointment jar or plastic tube is used for dispensing, and an "external use only" label is placed on the container.

c. **Alternate method.** Suppose you have sulfur 5% in white petrolatum ointment and a salicylic acid 5% ointment. **How can you prepare the prescription using these and diluting with white petrolatum?**

However, since we are using two different 5% ointments, two parts of each, this leaves one part for the white petrolatum. A total of five parts is to be used to make 30 g (6 g per part): two parts (12 g) of the sulfur 5%, two parts (12 g) of the salicylic acid 5%, and one part (6 g) of the white petrolatum could be used. To check:

$$12 \text{ g} \times 0.05 = 600 \text{ mg of sulfur}$$

$$12 \text{ g} \times 0.05 = 600 \text{ mg of salicylic acid}$$

$$12 \text{ g} + 12 \text{ g} + 6 \text{ g} = 30 \text{ g}$$

2. **Example 2**
   a. **Medication order**

Methylparaben	0.25 g
Propylparaben	0.15 g
Sodium lauryl sulfate	10 g
Propylene glycol	120 g
Stearyl alcohol	250 g
White petrolatum	250 g
Purified water	370 g
Disp	60 g
Sig:	Apply u.d.

   b. **Calculations.** The quantity of each ingredient required to prepare 60 g is obtained as follows. The medication order is for 1000 g; therefore, the multiplication factor is 60/1000 = 0.06.

   $$0.25 \text{ g} \times 0.06 = 0.15 \text{ g methylparaben}$$
   $$0.15 \text{ g} \times 0.06 = 0.009 \text{ g propylparaben}$$
   $$10 \text{ g} \times 0.06 = 0.6 \text{ g sodium lauryl sulfate}$$
   $$120 \text{ g} \times 0.06 = 7.2 \text{ g propylene glycol}$$
   $$250 \text{ g} \times 0.06 = 15 \text{ g stearyl alcohol}$$
   $$250 \text{ g} \times 0.06 = 15 \text{ g white petrolatum}$$
   $$370 \text{ g} \times 0.06 = 22.2 \text{ g purified water}$$

   Since the 0.009 g of propylparaben is too small to accurately weigh, a dilution can be prepared as follows, assuming a minimum weighable quantity of 120 mg. Weigh 120 mg of propylparaben and add to 40 mL of propylene glycol, resulting in a propylparaben concentration of 3 mg/mL. Take 3 mL of this solution to obtain the propylparaben and subtract the 3 mL from the quantity of propylene glycol required in the formula.

   c. **Compounding procedure.** The stearyl alcohol and the white petrolatum are melted on a steam bath and heated to about 75°C. The other ingredients, previously dissolved in purified water at about 78°C, are added. The mixture is stirred until it congeals. An ointment jar is used for dispensing, and an "external use only" label is placed on the jar.

3. **Example 3**
   a. **Medication order**

Scopolamine hydrobromide	0.25%
Soy lecithin	12 g
Isopropyl palmitate	12 g
Pluronic F-127 20% gel, q.s.	100 mL
Sig:	Apply 0.1 mL t.i.d.

   b. **Calculations.** The quantity of scopolamine hydrobromide required for the prescription will be

   $$0.0025 \times 100 \text{ mL} = 0.25 \text{ g or 250 mg}$$

   c. **Compounding procedure.** Mix the soy lecithin with the isopropyl palmitate. Dissolve the scopolamine hydrobromide in about 3 mL of purified water and add to about 70 mL of the Pluronic F-127 gel. Add the soy lecithin–isopropyl palmitate mixture, and mix well. Add sufficient Pluronic F-127 gel to volume and mix well using a shearing technique. Package and label.

X. SUPPOSITORIES

A. **General characteristics**
1. Suppositories are **solid bodies** of various weights and shapes, adapted for introduction into the rectal, vaginal, or urethral orifices of the human body. They are used to deliver drugs for their local or systemic effects.
2. Suppositories differ in **size** and **shape** and include
   a. rectal,
   b. vaginal, and
   c. urethral.
B. **Common suppository bases**
1. **Cocoa butter** (theobroma oil), which melts at body temperature, is a fat-soluble mixture of triglycerides that is most often used for rectal suppositories. Witepsol is a synthetic triglyceride. Fatty acid bases include Fattibase.
2. **Polyethylene glycol** (PEG, carbowax) derivatives are water-soluble bases suitable for vaginal and rectal suppositories. Polybase is an example.
3. **Glycerinated gelatin** is a water-miscible base often used in vaginal and rectal suppositories.
C. **Suppository molds**
1. Suppository molds can be made of rubber, plastic, brass, stainless steel, or other suitable material.
2. The formulation and volume of the base depend on the size of the mold used, less the displacement caused by the active ingredient.
D. **Methods of preparing and dispensing suppositories**
1. **Molded suppositories** are prepared by first melting the base and then incorporating the medications uniformly into the base. This mixture is then poured into the suppository mold (fusion method).
2. **Hand-rolled suppositories** require a special technique. With proper technique, it is possible to make a preparation equal in quality to the molded suppositories.
3. **Containers for the suppositories** are determined by the method and base used in preparation. Hand-rolled and molded suppositories should be dispensed in special boxes that prevent the suppositories from coming in contact with each other. Suppositories made using plastic strip molds are easily dispensed in various types of packages.
4. **Storage conditions.** If appropriate, a "refrigerate" label should appear on the container. Regardless of the base or medication used in the formulation, the patient should be instructed to store the suppositories in a cool, dry place.
E. **Examples**
1. **Example 1**
   a. **Medication order**

Naproxen suppository	500 mg
Disp	#12
Sig:	Insert u.d. into rectum

   b. **Calculations.** Each standard adult suppository should weigh 2 g, but it depends on the mold used and should be calibrated before compounding. Also, the displacement must be determined for the added powder.

   2 g (total weight) − 0.540 g (weight of base displaced by the 500-mg tablet) per suppository

   $$= 1.46 \text{ g cocoa butter per suppository} \times 13 \text{ suppositories}$$
   $$= 18.98 \text{ g cocoa butter}$$

   c. **Compounding procedure.** The 13 naproxen 500-mg tablets are triturated to a fine powder, using a Wedgwood or porcelain mortar. The 18.98 g cocoa butter base is melted in a beaker, using a water bath. The temperature of the water bath should not exceed 36°C. The powder is then added and stirred until mixed. The mixture is poured into an appropriate rectal suppository mold (about 2 g per suppository) and placed into a refrigerator until the suppositories congeal. Any excess is scraped from the top of the mold, and a suppository box is used for dispensing. A "refrigerate" label is placed on the box.

2. **Example 2**
   a. **Medication order**
      Progesterone   50 mg
      Disp   #14
      Sig: 1 per vagina once daily on days 14 to 28 of cycle
   b. **Calculations.** Total weight of each vaginal suppository is 1.9 g. Assuming 50 mg progesterone displaces 50 mg PEG base:

      50 mg progesterone/suppository $\times$ 15 = 750 mg progesterone

      1.9 g (total weight) $-$ 0.050 g progesterone

      = 1.85 g PEG $\times$ 15 suppositories

      = 27.75 g PEG total
   c. **Compounding procedure.** The PEG is melted to 55° to 57°C, and 750 mg progesterone is added. This mixture is poured into a vaginal suppository mold, allowed to cool, cleaned, and dispensed.

XI. STERILE PREPARATIONS

A. **General requirements.** The extemporaneous compounding of sterile preparations occurs in many pharmacy environments, including community, home health care, hospital, and nuclear. Minimum requirements include
   1. proper equipment and supplies;
   2. proper facilities, including a laminar-flow clean bench and a clean room or isolation barrier technology equipment;
   3. proper documentation of all preparations made;
   4. quality control, including batch sterility testing;
   5. proper storage both at the facility and in transport to the patient's home;
   6. proper labeling of the prescription preparation;
   7. knowledge of product's/preparation's stability and incompatibilities; and
   8. knowledge of all ancillary equipment involved in compounding or delivery of the medications.
B. **Compounding of parenteral preparations**
   1. Compounding of sterile preparations, including intravenous admixtures, requires special skills and training. Compounding parenteral preparations or providing this service without proper training should not be attempted.
   2. These preparations must be compounded in a clean environment, using aseptic technique (i.e., working under controlled conditions to minimize contamination).
   3. Dry powders of parenteral drugs for reconstitution are used for drug products or preparations that are unstable as solutions. It is important to know the correct diluents that can be used to yield a solution.
   4. Solutions of drugs for parenteral administration may also be further diluted before administration. If further dilution is required, then the pharmacist must know the stability and compatibility of the drug in the diluent.
C. **Reconstitution of a dry powder from a vial**
   1. Work takes place in a clean-air environment, observing aseptic technique.
   2. The manufacturer's instructions should be checked to determine the required volume of diluent.
   3. The appropriate needle size and syringe are chosen, keeping in mind that the capacity of the syringe should be slightly larger than the volume required for reconstitution.
   4. Using the correct diluent, the surface of the container is cleaned, using an alcohol prep pad, after which the alcohol is permitted to evaporate.
   5. The syringe is filled with the diluent to the proper volume.
   6. The surface of the vial containing the sterile powder is cleaned, using an alcohol prep pad, after which it is permitted to dry. The diluent is injected into the vial containing the dry powder.
   7. The vial is gently shaken or rolled, and the powder is allowed to dissolve.
   8. After the powder has dissolved, the vial is inverted, and the desired volume is withdrawn.

9. The vehicle is prepared by swabbing the medication port of the bag or bottle with an alcohol prep pad.
10. The solution in the syringe is injected into the vehicle. If a plastic container is used, care must be taken not to puncture the sidewalls of the container with the tip of the needle.
11. The container should be shaken or kneaded or rotated to ensure thorough mixing of the contents.
12. The contents of the container should be checked for particulate matter.
13. A sterile seal or cap is applied over the port of the container.
14. All needles and syringes should be properly discarded.
15. The bag is labeled.

D. **Removing the fluid contents from an ampule**
1. The ampule is held upright to open it, and the top is tapped to remove any solution trapped in this area.
2. The neck of the ampule is swabbed with an alcohol swab.
3. The ampule is grasped on each side of the neck with the thumb and index finger of each hand and quickly snapped open.
4. A 5-μm filter needle is attached to a syringe of the appropriate size.
5. The ampule is tilted, and the needle is inserted.
6. The needle is positioned near the neck of the ampule, and the solution is withdrawn from the ampule.
7. If the solution is for an intravenous push (bolus injection), the filter needle is removed from the syringe and replaced with a cap.
8. If the solution is for an intravenous infusion, then the filter needle is removed and replaced with a new needle of the appropriate size. The drug is injected into the appropriate vehicle.
9. All materials should be discarded properly, and the final product or preparation should be labeled.

E. **Removing drug solution from a vial**
1. The tab around the rubber closure on the vial is removed, and this surface is swabbed with an alcohol prep pad.
2. An equivalent amount of sterile air is injected into the vial to prevent a negative vacuum from being created and to allow the drug to be removed.
3. Using the appropriate needle size and syringe, the needle is inserted into the rubber closure.
4. The plunger is pushed down, and air is released into the vial; when the plunger is pulled back, the solution is withdrawn.
5. The solution is then injected into the appropriate vehicle.

F. **Examples**
1. **Example 1**
    a. **Medication order**

Progesterone	5 g
Benzyl alcohol	10 mL
Sesame oil, q.s.	100 mL

    b. **Compounding procedure.** Dissolve the progesterone in the benzyl alcohol. Add sufficient sesame oil to make 100 mL. Sterilize by filtration through a sterile 0.2-μm filter or by dry heat (170°C for 1.5 hrs). Package in sterile vials and label.

2. **Example 2**
    a. **Medication order**

Fentanyl (as the citrate)	2 mg
Bupivacaine hydrochloride	125 mg
0.9% sodium chloride injection, q.s.	100 mL

    b. **Calculations.** Since 157 μg fentanyl citrate is equivalent to 100 μg fentanyl, the quantity of fentanyl citrate required is (157/100) $\times$ 2 mg = 3.14 mg fentanyl citrate. This is the quantity of fentanyl citrate that would be required if compounding as a high-risk preparation from bulk powders. It would also require 125 mg bupivacaine, and the remainder is the 0.9% sodium chloride injection. However, commercial products are available so we can calculate how much of each might be required using fentanyl 50 μg/mL injection and bupivacaine hydrochloride 0.5% injection.

$$2 \text{ mg fentanyl} = 2000 \text{ } \mu g$$

$$\frac{2000 \ \mu g}{50 \ \mu g/mL} = 40 \text{ mL of fentanyl injection}$$

Bupivacaine hydrochloride 0.5% injection contains 500 mg/100 mL; therefore,

$$\frac{500}{100} = 125/x \qquad x = 25 \text{ mL}$$

If 40 mL of fentanyl injection is used, and 25 mL of bupivacaine hydrochloride injection is used, then $40 + 25 = 65$ mL; the quantity of 0.9% sodium chloride injection required is 100 mL $-$ 65 mL $= 35$ mL. Note: **If the order is to be filled in a 20-mL pump with delivery for 30 days, what is the delivery rate in microliter per hour?**

$$\frac{20 \text{ mL}}{30 \text{ d}} = 0.667 \text{ mL/d}$$

$$\frac{0.667 \text{ mL}}{\text{day/24 hrs}} = 0.0277 \text{ mL/hr}$$

$$0.0277 \text{ mL} \times 1000 \ \mu L/mL = 27.7 \ \mu L/hr$$

   c. **Compounding procedure.** Using commercially available injections, accurately measure the volume of each and fill into a sterile ambulatory pump reservoir. An air bubble can be injected and used to thoroughly mix the solution. Remove the air from the reservoir, and tightly seal/close the outlet. Label.

3. **Example 3**
   a. **Medication order**

Morphine sulfate	5 g
Citric acid	100 mg
Sodium chloride, q.s. to isotonic	
Methylparaben	150 mg
Sterile water for injection, q.s.	100 mL

   b. **Calculations.** Using a sodium chloride equivalent of 0.09 for a 5% morphine sulfate solution, 0.18 for citric acid, 1 for sodium chloride, and ignoring the methylparaben, the calculations can be made as follows:
5 g morphine sulfate is equivalent to 450 mg sodium chloride (5 g $\times$ 0.09 $=$ 450 mg).
100 mg citric acid is equivalent to 18 mg sodium chloride (100 mg $\times$ 0.18 $=$ 18 mg)

$$450 \text{ mg} + 18 \text{ mg} = 468 \text{ mg}$$

To be isotonic, the solution needs the equivalent of 900 mg of sodium chloride in the 100 mL: 900 mg $-$ 468 mg $=$ 432 mg sodium chloride needs to be added.

   c. **Compounding procedure.** Dissolve the methylparaben in about 90 mL of sterile water for injection. A small amount of heat may be required. Cool the solution to room temperature, then add the morphine sulfate, citric acid, and sodium chloride. Add sufficient sterile water for injection to volume and mix well. Sterilize by filtration through a sterile 0.2-μm filter into a sterile vial or reservoir. Package and label.

4. **Example 4**
   a. **Medication order**
Mefoxitin   1 g
Diluent to final concentration of 125 mg/mL

   b. **Calculations.** A 1-g vial of Mefoxin (cefoxitin for injection) is reconstituted with 10 mL of diluent to provide for approximate withdrawal of 10.5 mL and an approximate average concentration of 95 mg/mL. **What quantity of diluent should be added to provide an approximate average concentration of 125 mg/mL?**

$$10.5 \text{ mL} - 10 \text{ mL} = 0.5 \text{ mL occupied by the powder}$$

$$\frac{1000 \text{ mg}}{125 \text{ mg/mL}} = 8 \text{ mL total volume}$$

$$8 \text{ mL} - 0.5 \text{ mL} = 7.5 \text{ mL diluent to be added}$$

   c. **Compounding procedure.** Aseptically, withdraw 7.5 mL of diluent and inject into the vial to be reconstituted, using an appropriate vented needle. Gently swirl until dissolved.

Study Questions

Directions for questions 1–3: Each question or incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

The following medication order is given to the pharmacist by the physician.

Olive oil	60 mL
Vitamin A	60,000 U
Water	120 mL
Sig:	15 mL t.i.d.

1. The final dosage form of this prescription will be
   - (A) a solution.
   - (B) an elixir.
   - (C) an emulsion.
   - (D) a suspension.
   - (E) a lotion.

2. When preparing this prescription, the pharmacist needs to add
   - (A) Tween 80.
   - (B) acacia.
   - (C) glycerin.
   - (D) alcohol.
   - (E) propylene glycol.

3. Which of the following caution labels should the pharmacist affix to the container when dispensing this preparation?
   - (A) Do not refrigerate.
   - (B) Shake well.
   - (C) For external use only.
   - (D) No preservatives added.

Directions for questions 4–9: Each question or statement in this section can be correctly answered or completed by one or more of the suggested answers or phrases. Choose the correct answer, A–E:

- **A** if **I** only is correct
- **B** if **III** only is correct
- **C** if **I** and **II** are correct
- **D** if **II** and **III** are correct
- **E** if **I**, **II**, and **III** are correct

4. Which statements about the following prescription are correct?

Morphine	1 mg/mL
Flavored vehicle, q.s. a.d.	120 mL
Sig:	5 to 20 mg p.o. q
	3 to 4 hrs p.r.n. pain

   I. The amount of morphine needed is 240 mg.
   II. Powdered morphine alkaloid should be used when compounding this prescription.
   III. The final dosage form of this prescription is a solution.

5. When preparing the following prescription, the pharmacist should

Podophyllum	5%
Salicylic acid	10%
Acetone	20%
Flexible collodion, a.d.	30 mL
Sig:	Apply q h.s.

   I. triturate 1.5 g of podophyllum with the 8 mL of acetone.
   II. add 3 g of salicylic acid to the collodion with trituration.
   III. affix an "external use only" label to the container.

6. Which statements about the following prescription are correct?

Sulfur	6 g
Purified water	
Camphor water, a.a. q.s. a.d.	60

   I. Precipitated sulfur can be used to prepare this prescription.
   II. The sulfur can be triturated with glycerin before mixing with other ingredients.
   III. A "shake well" label should be affixed to the bottle.

7. Which statements about the following prescription are correct?

Starch	10%
Menthol	1%
Camphor	2%
Calamine, q.s. a.d.	120

   I. The powders should be blended together in a mortar, using geometric dilution.
   II. The prescription should be prepared by dissolving the camphor in a sufficient amount of 90% alcohol.
   III. A eutectic mixture should be avoided.

8. When preparing the following prescription, the pharmacist should

Salicylic acid	3 g
Sulfur ppt	7 g
Lanolin	10 g
White petrolatum	10 g

 I. reduce the particle size of the powders, using a mortar and pestle or using the pill tile with a spatula.

 II. place on an ointment tile and levigate the ingredients, using geometric dilution.

 III. package the ointment in an ointment jar or tube.

9. An equal volume of air is injected when removing drug solutions from

 I. vials.
 II. ampules.
 III. syringes.

Answers and Explanations

1. The answer is C *[see V.B.1.]*.

2. The answer is B *[see V.B.2; V.C.1]*.

3. The answer is B *[see V.B.3]*.
For 1–3: Because olive oil and water are two immiscible liquids, their incorporation requires a two-phase system in which one liquid is dispersed throughout another liquid in the form of small droplets. To accomplish this, an emulsifying agent is necessary. Acacia is the most suitable emulsifying agent when forming an oil-in-water emulsion that is intended for internal use. Emulsions are physically unstable, and they must be protected against the effects of microbial contamination and physical separation. Shaking before use redistributes the two layers of emulsion. Because light, air, and microorganisms also affect the stability of an emulsion, preservatives can be added.

4. The answer is B (III) *[see III.C.3]*.
The concentration of morphine needed for the prescription described in the question is 1 mg/mL, and because 120 mL is the final volume, 120 mg of morphine is needed to compound this prescription. Morphine alkaloid has poor solubility; therefore, one of the salt forms should be used. Because morphine is dissolved in the vehicle, resulting in a liquid preparation, the final dosage form is a solution.

5. The answer is B (III) *[see III.C.1; III.C.5; III.D.3]*.
Calculating for the amount of each ingredient of the prescription in the question requires 1.5 g of podophyllum, 3 g of salicylic acid, and 6 mL of acetone. The correct procedure would be to triturate the podophyllum with the acetone, then add the triturated salicylic acid to a calibrated bottle containing the podophyllum and acetone. Flexible collodion is then added up to the 30-mL calibration. An "external use only" label should be affixed to the container.

6. The answer is E (I, II, and III) *[see IV.B.2; IV.C.5; IV.D.1–2]*.
Although precipitated sulfur can be used to prepare the prescription described in the question, it is difficult to triturate; therefore, it must first be levigated with a suitable levigating agent (e.g., glycerin). All suspensions, owing to their instability, require shaking before use to redistribute the insoluble ingredients.

7. The answer is A (I) *[see VI.C.3; VI.D.1]*.
The proper procedure for compounding the prescription described in the question is to first form a liquid eutectic. This is done by triturating the menthol and camphor together in a mortar. This eutectic is then blended with the powdered starch and calamine, using geometric dilution.

8. The answer is E (I, II, and III) *[see IX.D.1–3; IX.E.1]*.
The proper procedure for preparing the prescription given in the question is to reduce the particle size of each powder and mix them together, using geometric dilution. This ensures the proper blending of the powders. Next, this powdered mixture is incorporated, geometrically, with the petrolatum. Then, the lanolin is added geometrically.

9. The answer is A (I) *[see XI.E.2]*.
An equal volume of air must be injected when removing a drug solution from a vial. This is done to prevent the formation of a vacuum within the vial. This problem does not occur with ampules and syringes containing drug solutions; therefore, it is unnecessary to inject any air when removing them.

Basic Pharmacokinetics

ELISE DUNZO, LEON SHARGEL

I. PHARMACOKINETICS

- A. **Introduction**
    1. **Pharmacokinetics** is the quantitative measurement of drug absorption, distribution, and elimination (i.e., excretion and metabolism) and includes the rate processes for drug movement into the body, within the body, and out of the body.
    2. Commonly used units in pharmacokinetics are tabulated in *Table 5-1*.
    3. **Rates and orders of reactions.** The **rate** of a chemical reaction or pharmacokinetic process is the velocity with which it occurs. **The order** of a reaction is the way in which the concentration of a drug or reactant in a chemical reaction affects the rate.
        - a. **Zero-order reaction.** The drug concentration changes with respect to time at a constant rate, according to the following equation:

$$\frac{\mathrm{d}C}{\mathrm{d}t} = -k_0$$

Table 5-1   COMMON UNITS IN PHARMACOKINETICS

Pharmacokinetic Parameter	Abbreviation	Fundamental Units	Units Example
Area under the curve	AUC	Concentration $\times$ time	μg $\times$ hr/mL
Total body clearance	Cl_T	Volume/time	L/hr
Renal clearance	Cl_R	Volume/time	L/hr
Hepatic clearance	Cl_H	Volume/time	L/hr
Apparent volume of distribution	V_D	Volume	L
Volume of distribution at steady state	V_{ss}	Volume	L
Peak plasma drug concentration	C_{max}	Concentration	mg/L
Plasma drug concentration	C_p	Concentration	mg/L
Steady-state drug concentration	C_{ss} or C_{av}	Concentration	mg/L
Time for peak drug concentration	T_{max}	Time	hr
Dose	D_0	Mass	mg
Loading dose	D_L	Mass	mg
Maintenance dose	D_M	Mass	mg
Amount of drug in the body	D_B	Mass	mg
Rate of drug infusion	R	Mass/time	mg/hr
First-order rate constant for drug absorption	k_A	1/time	1/hr or hr^{-1}
Zero-order rate constant for drug absorption	k_0	Mass/time	mg/hr
First-order rate constant for drug elimination	k (sometimes referred to as kel)	1/time	1/hr or hr^{-1}
Elimination half-life	$t_{1/2}$	Time	hr
Fraction of drug absorbed	F	(no units)	Ranges from 0 to 1 (0%–100%)

where C is the drug concentration and k_0 is the **zero-order rate constant** expressed in units of concentration per time (e.g., milligrams per milliliter per hour). Integration of this equation yields the linear (straight-line) equation:

$$C = -k_0 t + C_0$$

where k_0 is the slope of the line (see *Figure 2-6*) and C_0 is the y intercept, or drug concentration, when time (t) equals zero. The negative sign indicates that the slope is decreasing.

  b. **First-order reaction.** The change in drug concentration with respect to time equals the product of the rate constant and the concentration of drug remaining, according to the following equation:

$$\frac{dC}{dt} = -kC$$

where k is the first-order rate constant, expressed in units of reciprocal time, or time^{-1} (e.g., 1/hr or hr^{-1}).

  (1) Integration and subsequent transformation of this equation yields the following mathematically equivalent equations:

$$C = C_0 e^{-kt}$$
$$\ln C = -kt + \ln C_0$$
$$\log C = \frac{-kt}{2.3} + \log C_0$$

  (2) A graph of the equation in *Figure 5-1* shows the linear relation of the log of the concentration versus time. In *Figure 5-1*, the slope of the line is equal to $-k/2.3$, and the y intercept is C_0. The values for C are plotted on logarithmic coordinates, and the values for t are shown on linear coordinates.

  (3) The **half-life** ($t_{1/2}$) of a reaction or process is the time required for the concentration of a drug to decrease by one-half. For a first-order reaction or process, the half-life is a constant and is related to the first-order rate constant, according to the following equation:

$$t_{1/2} = \frac{0.693}{k}$$

4. **Models and compartments**
  a. A **model** is a mathematic description of a biologic system and is used to express quantitative relationships.
  b. A **compartment** is a group of tissues with similar blood flow and drug affinity. A compartment is not a real physiologic or anatomic region.
5. **Drug distribution**
  a. Drugs distribute rapidly to tissues with high blood flow (e.g., liver) and more slowly to tissues with low blood flow (e.g., adipose).
  b. Drugs rapidly cross capillary membranes into tissues because of **passive diffusion** and **hydrostatic pressure. Drug permeability** across capillary membranes varies.
    (1) Drugs easily cross the capillaries of the glomerulus of the kidney and the sinusoids of the liver.
    (2) The capillaries of the brain are surrounded by glial cells that create a **blood–brain barrier**, which acts as a thick lipid membrane. Polar and ionic hydrophilic drugs cross this barrier slowly.
    (3) In disease states, membranes may become more permeable to drugs. For example, in meningitis, the blood–brain barrier becomes more permeable to the penetration of drugs into the brain.
  c. **Drugs may accumulate in tissues** as a result of their physicochemical characteristics or special affinity of the tissue for the drug.
    (1) Lipid-soluble drugs may accumulate in adipose (fat) tissue because of partitioning of the drug.
    (2) Tetracycline may accumulate in bone because complexes are formed with calcium.

d. Plasma protein binding of drugs affects drug distribution.

   (1) A drug bound to a protein forms a complex that is too large to cross cell membranes.

   (2) Albumin is the major plasma protein involved in drug protein binding. α_1-**Glycoprotein**, also found in plasma, is important for the binding of such basic drugs as propranolol.

   (3) Potent drugs, such as phenytoin, that are highly bound ($> 95\%$) to plasma proteins may be displaced by other highly bound drugs. The displacement of the bound drug results in more free (nonbound) drug, which rapidly reaches the drug receptors and may cause a more intense pharmacologic response.

   (4) A few hormonal drugs bind to specific plasma proteins. For example, prednisone binding to transcortin (and albumin) results in dose-dependent pharmacokinetics of prednisone. This nonlinear pharmacokinetics is due to saturable protein binding. Transcortin has high affinity and low capacity, whereas albumin has low affinity and high capacity.

B. One-compartment model
   1. Intravenous bolus injection. The entire drug dose enters the body instantaneously, and the rate of absorption is therefore assumed to be negligible in calculations (*Figure 5-1*). The entire body acts as a single compartment, and the drug rapidly equilibrates with all of the tissues in the body.

   a. Drug elimination is generally a first-order kinetic process according to the equations in I.A.3.b.

   (1) The first-order elimination rate constant (k or k_{el}) is the sum of the rate constants for removal of drug from the body, including the rate constants for renal excretion and metabolism (**biotransformation**) as described by the following equation:

$$k = k_e + k_m$$

   where k_e is the rate constant for renal excretion and k_m is the rate constant for metabolism. This equation assumes that all rates are first-order processes.

   (2) The **elimination half-life ($t_{1/2}$)** is given by the following equation:

$$t_{1/2} = \frac{0.693}{k}$$

Figure 5-1. Generalized pharmacokinetic model for a drug administered by rapid intravenous bolus injection. C_P^0, extrapolated drug concentration; V_D, apparent volume of distribution; D_B, amount of drug in the body; k, elimination rate constant; $t_{1/2}$, elimination half-life. Adapted with permission from Gibaldi M, Perrier D. *Pharmacokinetics*. 2nd ed. New York, NY: Marcel Dekker, Inc.; 1982. Copyright © 1982 Routledge/Taylor & Francis Group, LLC.

    b. Apparent volume of distribution (V_D) is the hypothetical volume of body fluid in which the drug is dissolved. This value is not a true anatomic or physical volume.

      (1) V_D is needed to estimate the amount of drug in the body relative to the concentration of drug in the plasma, as shown in the following:

$$V_D \times C_p = D_B$$

      where V_D (liters) is the apparent volume of distribution, C_p (milligrams per liter) is the plasma drug concentration, and D_B (milligram) is the amount of drug in the body.

      (2) To calculate the V_D after an intravenous bolus injection, the equation is rearranged to give:

$$V_D = \frac{D_B^0}{C_P^0}$$

      where D_B^0 is the dose (D_B) of drug given by intravenous bolus and C_P^0 is the extrapolated drug concentration at zero time on the *y* axis, after the drug equilibrates (*Figure 5-1*).

      (3) According to the equation, V_D is increased and C_P^0 is decreased when the drug is distributed more extravascularly into the tissues. When more drug is contained in the vascular space or plasma, C_P^0 is increased and V_D is decreased.

  2. Single oral dose. If the drug is given in an oral dosage form (e.g., tablet, capsule), the drug is generally absorbed by first-order kinetics. Elimination of the drug also follows the principles of first-order kinetics (*Figure 5-2*).

    a. The following equation describes the pharmacokinetics of **first-order absorption and elimination**:

$$C_P = \frac{FD_0 k_A}{V_D(k_A - k)}(e^{-kt} - e^{-K_A t})$$

    where k_A is the first-order absorption rate constant and F is the fraction of drug bioavailable. Changes in F, D_0, V_D, k_A, and k affect the plasma drug concentration.

    b. The time for maximum, or **peak**, **drug absorption** is given by the following equations:

$$t_{max} = \frac{2.3 \log (k_A/k)}{k_A - k}$$
    where t_{max} depends only on the rate constants k_A and k, not on F, D_0, or V_D.

    c. After t_{max} is obtained, the peak drug concentration (C_{max}) is calculated, using the equation in I.B.2.a and substituting t_{max} for t.

    d. The area under the curve (AUC) may be determined by integration of $\int_0^t C_P \, dt$ using the trapezoidal rule or by the following equation:

$$[AUC]_0^\infty = \int_0^\infty C_P \, dt = \frac{FD_0}{V_D k}$$

    changes in F, D_0, k, and V_D affect the AUC. Minor changes in k_A do not affect the AUC.

Figure 5-2. Generalized plot for a one-compartment model showing first-order drug absorption and first-order drug elimination. Adapted with permission from Shargel L, Wu-Pong S, Yu ABC. *Applied Biopharmaceutics and Pharmacokinetics.* 5th ed. New York, NY: McGraw-Hill; 2005.

e. To obtain $[\text{AUC}]_0^\infty$, obtain the [AUC] from 0 to t by the trapezoidal rule and add on the extrapolated section of AUC, which is the last measurable drug concentration at time, t, divided by the slope of the terminal elimination curve, as shown in the following equation:

$$[\text{AUC}]_0^\infty = [\text{AUC}]_0^t + \frac{C_{P,t}}{k}$$

f. **Lag time** occurs at the beginning of systemic drug absorption. For some individuals, systemic drug absorption is delayed after oral drug administration because of delayed stomach emptying or other factors.

3. **Intravenous infusion**

a. Intravenous infusion is an example of zero-order absorption and first-order elimination (*Figure 5-3*).

b. A few oral controlled-release drug products release the drug by zero-order kinetics and have **zero-order systemic absorption.**

c. The plasma drug concentration at any time after the start of an intravenous infusion is given by the following equation:

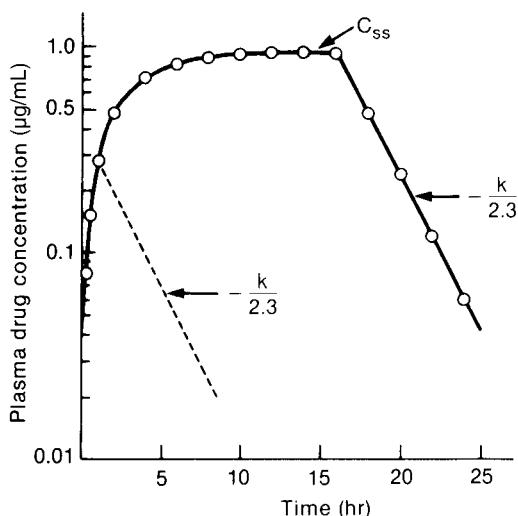
$$C_p = \frac{R}{V_D k}\left(1 - e^{-kt}\right)$$

where R is the zero-order rate of infusion given in units as milligrams per hour or milligrams per minute.

d. If the intravenous infusion is discontinued, the plasma drug concentration declines by a first-order process. The elimination half-life or elimination rate constant, k, may be obtained from the declining plasma drug concentration versus time curve.

e. As the drug is infused, the plasma drug concentration increases to a plateau, or **steady-state concentration (C_{SS})**.

(1) Under steady-state conditions, the fraction of drug absorbed equals the fraction of drug eliminated from the body.

(2) The plasma concentration at steady state (C_{ss}) is given by the following equation:


$$C_{ss} = \frac{R}{V_D k} = \frac{R}{Cl_T}$$

where Cl_T is total body clearance (see section I.E.).

(3) The rate of drug infusion (R) may be calculated from a rearrangement of the equation if the desired C_{ss}, the V_D, and the k are known. These values can often be obtained from the drug literature. To calculate the rate of infusion, the following equation is used:

$$R = C_{ss} V_D k = C_{ss} Cl_T$$

where C_{ss} is the desired (target) plasma drug concentration and Cl_T is total body clearance.

Figure 5-3. Generalized semilogarithmic plot for a drug showing zero-order absorption and first-order elimination. C_{ss}, steady-state concentration; k, elimination rate constant. Adapted with permission from Gibaldi M, Perrier D. *Pharmacokinetics.* 2nd ed. New York, NY: Marcel Dekker, Inc.; 1982. Copyright © 1982 Routledge/Taylor & Francis Group, LLC.

f. A **loading dose** (D_L) is given as an initial intravenous bolus dose to produce the C_{ss} as rapidly as possible. The intravenous infusion is started at the same time as the D_L.

    (1) The time to reach C_{ss} depends on the elimination half-life of the drug. Reaching 90%, 95%, or 99% of the C_{ss} without a D_L takes 3.32, 4.32, or 6.65 half-lives, respectively. Thus, for a drug with an elimination $t_{1/2}$ of 8 hrs, it will take 3.32×8 hrs, or 26.56 hrs, to reach 90% of C_{ss} if no loading dose is given.

    (2) The D_L is the amount of drug that, when dissolved in the apparent V_D, produces the desired C_{ss}. Thus, D_L is calculated by the following equation:

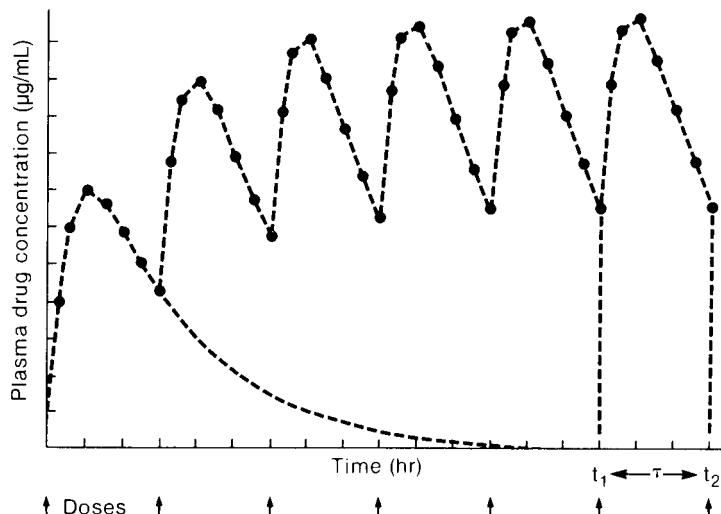
$$D_L = C_{ss}V_D \text{ and } D_L = \frac{R}{k}$$

g. An intravenous infusion provides a relatively constant plasma drug concentration and is particularly useful for drugs that have a narrow therapeutic range. The IV infusion keeps the plasma drug concentration between the *minimum toxic concentration* (MTC) and the *minimum effective concentration* (MEC).

4. Intermittent intravenous infusions

    a. Intermittent intravenous infusions are infusions in which the drug is infused for short periods to prevent accumulation and toxicity.

    b. Intermittent intravenous infusions are used for a few drugs, such as the aminoglycosides. For example, gentamicin may be given as a 1-hr infusion every 12 hrs. In this case, steady-state drug concentrations are not achieved.

    c. The peak drug concentration in the plasma for a drug given by intermittent intravenous infusion may be calculated by the following equation:


$$C_{p,\,n} = \frac{R(1 - e^{-kt})(1 - e^{-nk\tau})}{Cl(1 - e^{-k\tau})}$$

where $C_{p,n}$ is the peak drug concentration, R is the rate of drug infusion, Cl is total body clearance, k is the dosage interval, n is the number of infusions, t is the time for the infusion, and τ is the dosage interval.

5. Multiple doses. Many drugs are given intermittently in a multiple-dose regimen for continuous or prolonged therapeutic activity. This regimen is often used to treat chronic disease.

    a. If drug doses are given frequently before the previous dose is completely eliminated, then plasma drug concentrations accumulate and increase to a steady-state level.

    b. At **steady state**, plasma drug concentration fluctuates between a maximum $\left(C_{min}^{\infty}\right)$ and a minimum $\left(C_{min}^{\infty}\right)$ value (*Figure 5-4*).

    c. When a multiple-dose regimen is calculated, the **superposition principle** assumes that previous drug doses have no effect on subsequent doses. Thus, the predicted plasma drug

Figure 5-4. Generalized plot showing plasma drug concentration levels after administration of multiple doses and levels of accumulation when equal doses are given at equal time intervals. τ, time interval between doses (*t*), or the frequency of dosing. Adapted with permission from Shargel L, Wu-Pong S, Yu ABC. *Applied Biopharmaceutics and Pharmacokinetics.* 5th ed. New York, NY: McGraw-Hill; 2005.

concentration is the total plasma drug concentration obtained by adding the residual drug concentrations found after each previous dose.

d. When a multiple-dose regimen is designed, only the **dosing rate** (D_0/τ) can be adjusted easily.

   (1) The dosing rate is based on the **size of the dose** (D_0) and the **interval** (τ) **between doses**, or the **frequency of dosing**.

   (2) The dosing rate is given by the following equation:

   $$\text{Dosing rate} = \frac{D_0}{\tau}$$

   (3) As long as the dosing rate is the same, the expected **average drug concentration at steady state** $\left(C_{\min}^{\infty}\right)$ is the same (*Figure 5-4*).

   (a) For example, if a 600-mg dose is given every 12 hrs, the dosing rate is 600 mg/12 hrs, or 50 mg/hr.

   (b) A dose of 300 mg every 6 hrs or 200 mg every 4 hrs also gives the same dosing rate (50 mg/hr), with the same expected C_{Av}^{∞}. However, the $C_{\max}^{\infty}$ and $C_{\min}^{\infty}$ values will be different.

   (c) For a larger dose given over a longer interval (e.g., 600 mg every 12 hrs), the $C_{\max}^{\infty}$ is higher and the $C_{\min}^{\infty}$ is lower compared with a smaller dose given more frequently (e.g., 200 mg every 4 hrs).

e. Certain antibiotics are given by **multiple rapid intravenous bolus injections.**

   (1) The peak, or **maximum**, **serum drug concentration** at steady state may be estimated by the following equation:

   $$C_{\max}^{\infty} = \frac{\dfrac{D_0}{V_D}}{1 - e^{-k\tau}}$$

   (2) The **minimum serum drug concentration** $\left(C_{\min}^{\infty}\right)$ at steady state is the drug concentration after the drug declines one dosage interval. Thus, $C_{\min}^{\infty}$ is determined by the following equation:

   $$C_{\min}^{\infty} = C_{\min}^{\infty} e^{-k\tau}$$

   (3) The **average drug concentration** $\left(C_{\text{Av}}^{\infty}\right)$ at steady state is estimated with the equation used for multiple oral doses:

   $$C_{\text{Av}}^{\infty} = \frac{FD_0}{kV_D\tau}$$

   For intravenous bolus injections, $F = 1$.

f. Orally administered drugs given in **immediate-release dosage forms** (e.g., solutions, conventional tablets, capsules) by multiple oral doses are usually rapidly absorbed ($k_A \geq k$) and slowly eliminated. $C_{\max}^{\infty}$ and $C_{\min}^{\infty}$ for these drugs are approximated by the equations shown in I.B.5.e.(1)–(2).

   (1) For more exact calculations of $C_{\min}^{\infty}$ and $C_{\max}^{\infty}$ after multiple oral doses, the following equations are used:

   $$C_{\max}^{\infty} = \frac{FD_0 k_A}{V_D(k_A - k)} \left(\frac{1}{1 - e^{-k\tau}}\right) \text{ and}$$

   $$C_{\min}^{\infty} = \frac{FD_0 k_A}{V_D(k_A - k)} \left(\frac{1}{1 - e^{-k\tau}}\right) e^{-k\tau}$$

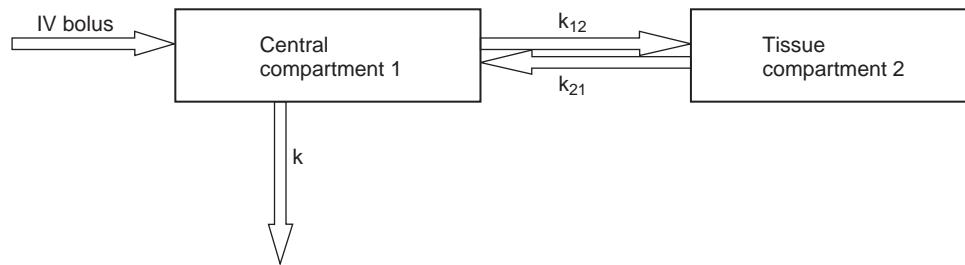
   (2) The calculation of C_{Av}^{∞} is the same as for multiple intravenous bolus injections, using the equation shown in I.B.5.e.(3).

   (3) The term $1/(1 - e^{-k\tau})$ is known as the **accumulation rate.**

   (4) The fraction of drug remaining in the body (f) after a dosage interval is given by the following equation:

   $$f = e^{-k\tau}$$

g. Loading dose. An initial loading dose (D_L) is given to obtain a therapeutic steady-state drug level quickly.

    (1) For multiple oral doses, D_L is calculated by:


$$D_L = D_M \frac{1}{1 - e^{-k\tau}}$$

    where D_M is the maintenance dose.

    (2) If D_M is given at a dosage interval equal to the elimination half-life of the drug, then D_L equals twice the maintenance dose.

C. Multicompartment models

  1. Drugs that exhibit multicompartment pharmacokinetics distribute into different tissue groups at different rates. Tissues with high blood flow equilibrate with a drug more rapidly than tissues with low blood flow. Drug concentration in various tissues depends on the physical and chemical characteristics of the drug and the nature of the tissue. For example, highly lipid-soluble drugs accumulate slowly in fat (lipid) tissue.

  2. Two-compartment model (intravenous bolus injection)

    a. After an intravenous bolus injection, the drug distributes and equilibrates rapidly into highly perfused tissues (**central compartment**) and more slowly into peripheral tissues (**tissue compartment**).
    b. The initial rapid decline in plasma drug concentration is known as the **distribution phase**. The slower rate of decline in drug concentration after complete equilibration is achieved is known as the **elimination phase** (*Figure 5-5*).

    c. The **plasma drug concentration** at any time is the sum of two first-order processes, as given in the following equation:

$$C_p = Ae^{-at} + Be^{-bt}$$

    where a and b are hybrid first-order rate constants and A and B are y intercepts.

    (1) The **hybrid first-order rate constant b** is obtained from the slope of the elimination phase of the curve (*Figure 5-5*) and represents the first-order elimination of drug from the body after the drug equilibrates with all tissues.

    (2) The **hybrid first-order rate constant a** is obtained from the slope of the residual line of the distribution phase after the elimination phase is subtracted.

    d. The **apparent volume of distribution** depends on the type of pharmacokinetic calculation. Volumes of distribution include the volume of the central compartment (V_p), the volume of distribution at steady state (V_{ss}), and the volume of the tissue compartment (V_t).

  3. Two-compartment model (oral drug administration)

    a. A drug with a rapid distribution phase may not show two-compartment characteristics after oral administration. As the drug is absorbed, it equilibrates with the tissues so that the elimination half-life of the elimination portion of the curve equals $0.693/b$.

    b. Two-compartment characteristics are seen if the drug is absorbed rapidly and the distribution phase is slower.

Figure 5-5. Generalized plot showing drug distribution and equilibration for a two-compartment model (intravenous bolus injection). The distribution phase is the initial rapid decline in plasma drug concentration. The elimination phase is the slower rate of decline after complete equilibration of the drug is achieved. Adapted with permission from Shargel L, Wu-Pong S, Yu ABC. *Applied Biopharmaceutics and Pharmacokinetics.* 5th ed. New York, NY: McGraw-Hill; 2005.

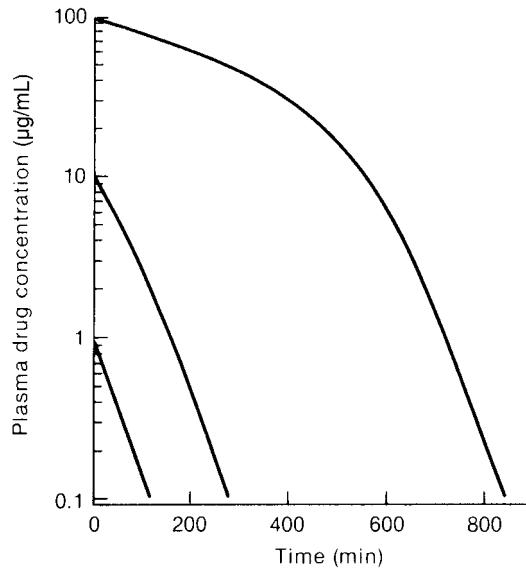
4. **Models with additional compartments**
   a. The addition of each new compartment to the model requires an additional first-order plot.
   b. The addition of a third compartment suggests that the drug slowly equilibrates into a deep tissue space. If the drug is given at frequent intervals, the drug begins to accumulate into the third compartment.
   c. The terminal linear phase generally represents the elimination of the drug from the body after equilibration occurs. The rate constant from the elimination phase is used to calculate dosage regimens.
   d. Adequate pharmacokinetic description of multicompartment models is often difficult and depends on proper plasma sampling and determination of drug concentrations.
5. **Elimination rate constants**
   a. The elimination rate constant, k, represents drug elimination from the central compartment.
   b. The terminal elimination rate constant (λ or b in the two-compartment model) represents drug elimination after drug distribution is mostly completed.
D. **Nonlinear pharmacokinetics** is also known as capacity-limited, dose-dependent, or saturation pharmacokinetics. Nonlinear pharmacokinetics do not follow first-order kinetics as the dose increases (*Figure 5-6*). Nonlinear pharmacokinetics may result from the saturation of an enzyme- or carrier-mediated system.
   1. **Characteristics of nonlinear pharmacokinetics** include the following:
      a. The AUC is not proportional to the dose.
      b. The amount of drug excreted in the urine is not proportional to the dose.
      c. The elimination half-life may increase at high doses.
      d. The ratio of metabolites formed changes with increased dose.


Figure 5-6. Generalized plot showing plasma drug concentration versus time for a drug with Michaelis–Menten (nonlinear) elimination kinetics. For this one-compartment model (intravenous injection), the doses are 1 mg, 10 mg, and 100 mg, and the apparent in vivo rate constant (k_M) is 10 mg. The maximum velocity of the reaction (V_{max}) is 0.2 mg/min. Adapted with permission from Gibaldi M, Perrier D. *Pharmacokinetics.* 2nd ed. New York, NY: Marcel Dekker, Inc.; 1982. Copyright © 1982 Routledge/Taylor & Francis Group, LLC.

2. **Michaelis–Menten kinetics** describes the velocity of enzyme reactions. Michaelis–Menten kinetics is used to describe nonlinear pharmacokinetics.
   a. The **Michaelis–Menten equation** describes the rate of change (velocity) of plasma drug concentration after an intravenous bolus injection as follows:

   $$\frac{dC_p}{dt} = \frac{-V_{max}C_p}{k_M + Cp}$$

   where V_{max} is the maximum velocity of the reaction, C_p is the substrate or plasma drug concentration, and k_M is the Michaelis constant equal to the C_p at 0.5 V_{max}.
   b. At low C_p values, where $C_p \ll k_M$, this equation reduces to a first-order rate equation because both k_M and V_{max} are constants.

   $$\frac{dC_p}{dt} = \frac{-V_{max}C_p}{k_M} = -k'C_p$$

   c. At high C_p values, where $C_p \gg k_M$, the Michaelis–Menten equation is a zero-order rate equation as follows:

   $$\frac{dC_p}{dt} = -V_{max}$$

3. Drugs that follow nonlinear pharmacokinetics may show zero-order elimination rates at high drug concentrations, fractional-order elimination rates at intermediate drug concentrations, and first-order elimination rates at low drug concentrations (*Figure 5-6*).
E. **Clearance** is a measurement of drug elimination from the body. Units for clearance are volume per time (e.g., liters per hour).
   1. **Total body clearance (Cl_T)** is the drug elimination rate divided by the plasma drug concentration. According to the concept of clearance, the body contains an apparent volume of distribution in which the drug is dissolved. A constant portion of this volume is cleared, or removed, from the body per unit time.
      a. The following equations express the measurement of total body clearance:

      $$Cl_T = \frac{\text{drug elimination}}{\text{plasma drug concentration}} = \frac{(dDe/dt)}{Cp}$$

      $$Cl_T = V_D k$$

      $$Cl_T = \frac{FD_0}{\text{AUC}}$$

b. For drugs that follow first-order (linear) pharmacokinetics, total body clearance is the sum of all the clearances in the body, as shown in the following equation:

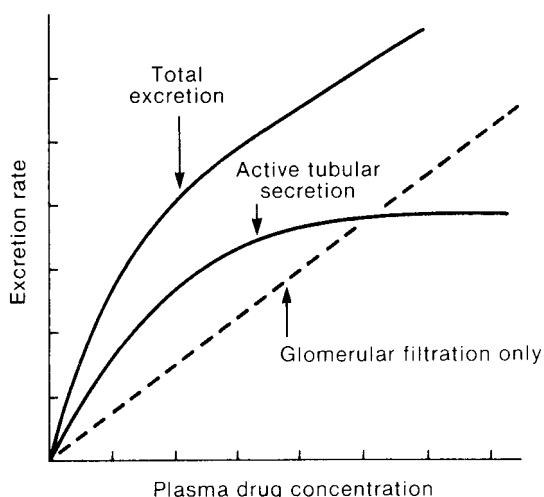
$$Cl_T = Cl_R + Cl_{NR}$$

where Cl_R is renal clearance and Cl_{NR} is nonrenal clearance. Nonrenal clearance, Cl_{NR}, is often equated with hepatic clearance, Cl_H.

c. The relation between Cl_T and $t_{1/2}$ is obtained by substituting $0.693/t_{1/2}$ for k in the equation in I.E.1 a to obtain the following expression:

$$t_{1/2} = \frac{0.693V_D}{Cl_T}$$

where V_D and Cl_T are considered independent variables, and $t_{1/2}$ is considered a dependent variable.

d. As clearance decreases (e.g., in renal disease), $t_{1/2}$ increases. Changes in V_D also cause proportional changes in $t_{1/2}$.


2. Renal drug excretion is the major route of drug elimination for polar drugs, water-soluble drugs, drugs with low molecular weight (< 500 g/mol), and drugs that are biotransformed slowly. The relation between the drug excretion rate and the plasma drug concentration is shown in *Figure 5-7*. Drugs are excreted through the kidney into the urine by glomerular filtration, tubular reabsorption, and active tubular secretion.

  a. Glomerular filtration is a passive process by which small molecules and drugs are filtered through the glomerulus of the nephron.

    (1) Drugs bound to plasma proteins are too large to be filtered at the glomerulus.

    (2) Drugs such as **creatinine and inulin** are not actively secreted or reabsorbed. They are used to measure the **glomerular filtration rate (GFR)**.

  b. Tubular reabsorption is a passive process that follows Fick's law of diffusion.

    (1) Lipid-soluble drugs are reabsorbed from the lumen of the nephron back into the systemic circulation.

    (2) For weak electrolyte drugs, urine pH affects the ratio of nonionized and ionized drug.

      (a) If the drug exists primarily in the nonionized or lipid-soluble form, then it is reabsorbed more easily from the lumen of the nephron.

      (b) If the drug exists primarily in the ionized or water-soluble form, then it is excreted more easily in the urine.

      (c) Depending on the pK_a of the drug, alteration of urine pH alters the ratio of ionized to nonionized drug and affects the rate of drug excretion. For example, alkalinization of the urine by the administration of sodium bicarbonate increases the excretion of salicylates (weak acids) into the urine.

Figure 5-7. Generalized plot showing the excretion rate versus plasma drug concentration for a drug with active tubular secretion and for a drug secreted by glomerular filtration only. Adapted with permission from Shargel L, Wu-Pong S, Yu ABC. *Applied Biopharmaceutics and Pharmacokinetics.* 5th ed. New York, NY: McGraw-Hill; 2005.

(3) An increase in urine flow caused by simultaneous administration of a diuretic decreases the time for drug reabsorption. Consequently, more drug is excreted if given with a diuretic.

c. **Active tubular secretion** is a carrier-mediated active transport system that requires energy.

  (1) Two active tubular secretion pathways exist in the kidney: one system for weak acids and one system for weak bases.

  (2) The active tubular secretion system shows competition effects. For example, **probenecid** (a weak acid) competes for the same system as penicillin, decreasing the rate of penicillin excretion, resulting in a longer penicillin $t_{\frac{1}{2}}$.

  (3) The renal clearance of drugs that are actively secreted, such as **p-aminohippurate (PAH)**, is used to measure **effective renal blood flow (ERBF).**

3. **Renal clearance** is the volume of drug contained in the plasma that is removed by the kidney per unit time. **Units for renal clearance** are expressed in volume per time (e.g., milliliters per minute or liters per hour).

  a. Renal clearance may be measured by dividing the rate of drug excretion by the plasma drug concentration, as shown in the following equation:

$$Cl_R = \frac{\text{rate of drug excretion}}{C_p} = \frac{\frac{dD_u}{dt}}{C_p}$$

  b. Measurement of renal clearance may also be expressed by the following equation:

$$Cl_R = k_e V_D$$

  where k_e is the first-order renal excretion rate constant, and

$$Cl_R = \frac{D_u^\infty}{\text{AUC}}$$

  where D_u^∞ is the total amount of parent (unchanged) drug excreted in the urine.

  c. Renal clearance is measured without regard to the physiologic mechanism of renal drug excretion. The probable mechanism for renal clearance is obtained with a **clearance ratio**, which relates drug clearance to inulin clearance (a measure of GFR).

  (1) If the clearance ratio is < 1.0, the mechanism for drug clearance may result from filtration plus reabsorption.

  (2) If the ratio is 1.0, the mechanism may be filtration only.

  (3) If the ratio is > 1.0, the mechanism may be filtration plus active tubular secretion.

4. **Hepatic clearance** is the volume of plasma-containing drug that is cleared by the liver per unit time.

  a. **Measurement of hepatic clearance**. Hepatic clearance is usually measured indirectly, as the difference between total body clearance and renal clearance, as shown in the following equation:

$$Cl_H = Cl_T - Cl_R$$

  where Cl_H is the hepatic clearance. Hepatic clearance is generally considered to be equivalent to Cl_{NR}, or nonrenal drug clearance. Hepatic clearance can also be calculated as the **product of the liver blood flow (Q)** and the **extraction ratio (ER)**, as shown in the following equation:

$$Cl_H = Q(\text{ER})$$

  (1) The **extraction ratio** is the fraction of drug that is irreversibly removed by an organ or tissue as the plasma-containing drug perfuses that tissue.

  (2) The extraction ratio is obtained by measuring the plasma drug concentration entering the liver and the plasma drug concentration exiting the liver:

$$\text{ER} = \frac{C_a - C_v}{C_a}$$

  where C_a is the arterial plasma drug concentration entering the liver and C_v is the venous plasma drug concentration exiting the liver.

  (3) Values for the ER range from 0 to 1. For example, if the ER is 0.9, then 90% of the incoming drug is removed as the plasma perfuses the liver. If the ER is 0, then no drug is removed by the liver.

b. **Blood flow**, **intrinsic clearance**, and **protein binding** affect hepatic clearance.
   (1) **Blood flow** to the liver is approximately 1.5 L/min and may be altered by exercise, food, disease, or drugs.
      (a) Blood enters the liver through the hepatic portal vein and hepatic artery and leaves through the hepatic vein.
      (b) After oral drug administration, the drug is absorbed from the gastrointestinal tract into the mesenteric vessels and proceeds to the hepatic portal vein, liver, and systemic circulation.
   (2) **Intrinsic clearance**, Cl_{int}, describes the ability of the liver to remove the drug independently of blood flow.
      (a) Intrinsic drug clearance primarily occurs because of the inherent ability of the **biotransformation enzymes** (mixed-function oxidases) to metabolize the drug as it enters the liver.
      (b) Normally, basal level mixed-function oxidase enzymes biotransform drugs. Levels of these enzymes may be increased by various drugs (e.g., phenobarbital) and environmental agents (e.g., tobacco smoke). These enzymes may be inhibited by other drugs and environmental agents (e.g., cimetidine, acute lead poisoning).
   (3) **Protein binding**. Drugs that are bound to protein are not easily cleared by the liver or kidney because only the free, or nonplasma protein-bound, drug crosses the cell membrane into the tissue.
      (a) **The free drug** is available to drug-metabolizing enzymes for biotransformation.
      (b) A sudden increase in free-drug plasma concentration results in more available drug at pharmacologic receptors, producing a more intense effect in the organs (e.g., kidney, liver) involved in drug removal.
      (c) **Blood flow (Q), intrinsic clearance (Cl_{int})**, and fraction of free drug in plasma (f) are related to hepatic clearance as shown in the following equation:

$$Cl_H = Q\left(\frac{fCl_{int}}{Q + fCl_{int}}\right)$$

   (4) The hepatic clearance of drugs that have high extraction ratios and high Cl_{int} values (e.g., propranolol) is most affected by changes in blood flow and inhibitors of the drug metabolism enzymes.
   (5) The hepatic clearance of drugs that have low extraction ratios and low Cl_{int} values (e.g., theophylline) is most affected by changes in Cl_{int} and is affected only slightly by changes in hepatic blood flow.
   (6) Only drugs that are highly plasma protein bound (i.e., > 95%) and have a low intrinsic clearance (e.g., phenytoin) are affected by a sudden shift in protein binding. This shift causes an increase in free drug plasma concentration.
c. **Biliary drug excretion**, an active transport process, is also included in hepatic clearance. Separate active secretion systems exist for weak acids and weak bases.
   (1) Drugs that are excreted in bile are usually high-molecular-weight compounds (i.e., > 500 g/mol) or polar drugs, such as reserpine, digoxin, and various glucuronide conjugates.
   (2) Drugs may be recycled by the **enterohepatic circulation**.
      (a) Some drugs are absorbed from the gastrointestinal tract through the mesenteric and hepatic portal veins, proceeding to the liver. The liver may secrete some of the drug (unchanged or as a glucuronide metabolite) into the bile.
      (b) The bile and drug are stored in the gallbladder and will empty into the gastrointestinal tract through the bile duct and then may be reabsorbed.
      (c) If the drug is a **glucuronide metabolite**, bacteria in the gastrointestinal tract may hydrolyze the glucuronide moiety, allowing the released drug to be reabsorbed.
d. **First-pass effects (presystemic elimination)** occur with drugs given orally. A portion of the drug is eliminated before systemic absorption occurs.
   (1) First-pass effects generally result from rapid drug biotransformation by liver enzymes. Other mechanisms include metabolism of the drug by gastrointestinal mucosal cells, intestinal flora, and biliary secretion.

- **(2)** First-pass effects are usually observed by measuring the **absolute bioavailability** (*F*) of the drug (see Chapter 6). If $F < 1$, then some of the drug was eliminated before systemic drug absorption occurred.
- **(3)** Drugs that have a **high hepatic extraction ratio**, such as propranolol and morphine, show first-pass effects.
- **(4)** To obtain better systemic absorption of a drug that demonstrates high first-pass effects, then either
  - **(a)** the drug dose could be increased (e.g., propranolol, penicillin);
  - **(b)** the drug could be given by an alternate route of administration (e.g., nitroglycerin sublingual, insulin subcutaneous, estradiol transdermal); or
  - **(c)** the dosage form could be modified as a delayed-release drug product (e.g., enteric-coated aspirin, mesalamine), so that the drug may be absorbed more distally in the gastrointestinal (GI) tract.

F. Noncompartment methods. Some pharmacokinetic parameters for absorption, distribution, and elimination may be estimated with noncompartment methods. These methods usually require comparison of the areas under the curve.

  1. **Mean residence time**
     - **a.** **Mean residence time** (**MRT**) is the average time for the drug molecules to reside in the body. MRT is also known as the *mean transit time* and *mean sojourn time*.
     - **b.** The MRT depends on the route of administration and assumes that the drug is eliminated from the central compartment.
     - **c.** The MRT is the total residence time for all molecules in the body divided by the total number of molecules in the body, as shown in the following equation:

$$MRT = \frac{\text{total residence time for all drug molecules in the body}}{\text{total number of drug molecules}}$$

     - **d.** **MRT after IV bolus injection**
       - **(1)** The MRT after a bolus intravenous injection is calculated by the following equation:

$$MRT_{IV} = \frac{AUMC}{AUC_{0-\infty}}$$

         where AUMC is the area under the first moment versus time curve from $t = 0$ to $t = $ infinity and $AUC_{0-\infty}$ is the area under the plasma drug concentration versus time curve from $t = 0$ to $t = $ infinity. $AUC_{0-\infty}$ is also known as the *zero-moment curve*.
       - **(2)** The MRT_{IV} is related to the elimination rate constant by the following expression:

$$MRT_{IV} = 1/k$$

       - **(3)** During MRT_{IV}, 62.3% of the intravenous bolus dose is eliminated.
       - **(4)** The MRT for a drug given by a noninstantaneous input is longer than the MRT_{IV}.

  2. **Mean absorption time** (**MAT**) is the difference between MRT and MRT_{IV} after an extravascular route is used.

$$MAT = MRT_{ev} - MRT_{IV}$$

When first-order absorption occurs, $MAT = 1/ka$.

  3. **Clearance** is the volume of plasma cleared of drug per unit time and may be calculated without consideration of the compartment model.

$$Cl = \frac{FD_0}{AUC_{0-\infty}}$$

After an IV dose, $F = 1$.

  4. **Steady-state volume of distribution** (V_{ss})
     - **a.** The steady-state volume of distribution is the ratio of the amount of drug in the body at steady state and the average steady-state drug concentration.
     - **b.** After an intravenous bolus injection, V_{ss} is calculated by the following equation:

$$V_{ss} = \frac{dose_{IV}\,(AUMC)}{AUC^2}$$

II. CLINICAL PHARMACOKINETICS

A. **Definition**
1. Clinical pharmacokinetics is the application of pharmacokinetic principles for the rational design of an individualized dosage regimen. The two main objectives are **maintenance of an optimum drug concentration at the receptor site** to produce the desired therapeutic response for a specific period and **minimization of any adverse or toxic effects** of the drug.

III. TOXICOKINETICS

A. **Definitions**
1. Toxicokinetics is the application of pharmacokinetic principles to the design, conduct, and interpretation of drug safety evaluation studies.
2. **Toxicokinetics** is also used to validate dose-related exposure in animals. Toxicokinetic studies are performed in animals during preclinical drug development to aid in prediction of human drug toxicity. Toxicokinetic (nonclinical) studies may continue after the drug has been tested in humans.
3. **Clinical toxicology** is the study of adverse effects of drugs and toxic substances (poisons) in the human body. The pharmacokinetics of a drug in an overmedicated (intoxicated) patient may be very different from the pharmacokinetics of the same drug given in therapeutic doses. For example, a very high toxic dose may show nonlinear pharmacokinetics due to saturation kinetics compared to the drug given at lower therapeutic doses in which the drug levels follow linear pharmacokinetics.

IV. POPULATION PHARMACOKINETICS

A. **Definition**
1. Population pharmacokinetics is the study of sources and correlates of variability in drug concentrations among individuals who are the target patient population. Population pharmacokinetics is most often applied to the clinical patient who is receiving relevant doses of a drug of interest. Both pharmacokinetic and nonpharmacokinetic data may be considered, including gender, age, weight, creatinine clearance, and concomitant disease. Population pharmacokinetics can be used to assist with therapeutic drug monitoring and the principles of dosage adjustments (see Chapter 26).

Study Questions

Directions: Each question, statement, or incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Creatinine clearance is used as a measurement of
   - (A) renal excretion rate.
   - (B) glomerular filtration rate (GFR).
   - (C) active renal secretion.
   - (D) passive renal absorption.
   - (E) drug metabolism rate.

For questions 2–5: A new cephalosporin antibiotic was given at a dose of 5 mg/kg by a single intravenous bolus injection to a 58-year-old man who weighed 75 kg. The antibiotic follows the pharmacokinetics of a one-compartment model and has an elimination half-life of 2 hrs. The apparent volume of distribution is 0.28 L/kg, and the drug is 35% bound to plasma proteins.

2. What is the initial plasma drug concentration (C_P^0) in this patient?
   - (A) 0.24 mg/L
   - (B) 1.80 mg/L
   - (C) 17.9 mg/L
   - (D) 56.0 mg/L
   - (E) 1339 mg/L

3. What is the predicted plasma drug concentration (C_p) at 8 hr after the dose?

- **(A)** 0.73 mg/L
- **(B)** 1.11 mg/L
- **(C)** 2.64 mg/L
- **(D)** 4.02 mg/L
- **(E)** 15.10 mg/L

4. How much drug remains in the patient's body (D_B) 8 hrs after the dose?

- **(A)** 15.3 mg
- **(B)** 23.3 mg
- **(C)** 84.4 mg
- **(D)** 100.0 mg
- **(E)** 112.0 mg

5. How long after the dose is exactly 75% of the drug eliminated from the patient's body?

- **(A)** 2 hrs
- **(B)** 4 hrs
- **(C)** 6 hrs
- **(D)** 8 hrs
- **(E)** 10 hrs

For questions 6–11: A 35-year-old man who weighs 70 kg and has normal renal function needs an intravenous infusion of the antibiotic carbenicillin. The desired steady-state plasma drug concentration is 15 mg/dL. The physician wants the antibiotic to be infused into the patient for 10 hrs. Carbenicillin has an elimination half-life ($t_{1/2}$) of 1 hr and an apparent volume distribution (V_D) of 9 L in this patient.

6. Assuming that no loading dose was given, what rate of intravenous infusion is recommended for this patient?

- **(A)** 93.6 mg/hr
- **(B)** 135.0 mg/hr
- **(C)** 468.0 mg/hr
- **(D)** 936.0 mg/hr
- **(E)** 1350.0 mg/hr

7. Assuming that no loading intravenous dose was given, how long after the initiation of the intravenous infusion would the plasma drug concentration reach 95% of the theoretic steady-state drug concentration?

- **(A)** 1.0 hrs
- **(B)** 3.3 hrs
- **(C)** 4.3 hrs
- **(D)** 6.6 hrs
- **(E)** 10.0 hrs

8. What is the recommended loading dose?

- **(A)** 93.6 mg
- **(B)** 135.0 mg
- **(C)** 468.0 mg
- **(D)** 936.0 mg
- **(E)** 1350.0 mg

9. To infuse the antibiotic as a solution containing 10-g drug in 500 mL 5% dextrose, how many milliliters per hour of the solution would be infused into the patient?

- **(A)** 10.0 mL/hr
- **(B)** 46.8 mL/hr
- **(C)** 100.0 mL/hr
- **(D)** 936.0 mL/hr
- **(E)** 1141.0 mL/hr

10. What is the total body clearance rate for carbenicillin in this patient?

- **(A)** 100 mL/hr
- **(B)** 936 mL/hr
- **(C)** 4862 mL/hr
- **(D)** 6237 mL/hr
- **(E)** 9000 mL/hr

11. If the patient's renal clearance for carbenicillin is 86 mL/min, what is the hepatic clearance for carbenicillin?

- **(A)** 108 mL/hr
- **(B)** 1077 mL/hr
- **(C)** 3840 mL/hr
- **(D)** 5160 mL/hr
- **(E)** 6844 mL/hr

12. The earliest evidence that a drug is stored in tissue is

- **(A)** an increase in plasma protein binding.
- **(B)** a large apparent volume of distribution (V_D).
- **(C)** a decrease in the rate of formation of metabolites by the liver.
- **(D)** an increase in the number of side effects produced by the drug.
- **(E)** a decrease in the amount of free drug excreted in the urine.

13. The intensity of the pharmacologic action of a drug is most dependent on the

- **(A)** concentration of the drug at the receptor site.
- **(B)** elimination half-life ($t_{1/2}$) of the drug.
- **(C)** onset time of the drug after oral administration.
- **(D)** minimum toxic concentration (MTC) of the drug in plasma.
- **(E)** minimum effective concentration (MEC) of the drug in the body.

14. Drugs that show nonlinear pharmacokinetics have which property?

- **(A)** A constant ratio of drug metabolites is formed as the administered dose increases.
- **(B)** The elimination half-life ($t_{1/2}$) increases as the administered dose increases.
- **(C)** The area under the plasma drug concentration versus time curve (AUC) increases in direct proportion to an increase in the administered dose.
- **(D)** Both low and high doses follow first-order elimination kinetics.
- **(E)** The steady-state drug concentration increases in direct proportion to the dosing rate.

15. The loading dose (D_L) of a drug is usually based on the

   (A) total body clearance (Cl_T) of the drug.
   (B) percentage of drug bound to plasma proteins.
   (C) fraction of drug excreted unchanged in the urine.
   (D) apparent volume of distribution (V_D) and desired drug concentration in plasma.
   (E) area under the plasma drug concentration versus time curve (AUC).

16. The renal clearance of inulin is used as a measurement of

   (A) effective renal blood flow.
   (B) rate of renal drug excretion.
   (C) intrinsic enzyme activity.
   (D) active renal secretion.
   (E) GFR.

17. All of the following statements about plasma protein binding of a drug are true *except* which one?

   (A) Displacement of a drug from plasma protein binding sites results in a transient increased volume of distribution (V_D).
   (B) Displacement of a drug from plasma protein binding sites makes more free drug available for glomerular filtration.
   (C) Displacement of a potent drug that is normally > 95% bound may cause toxicity.
   (D) Albumin is the major protein involved in protein binding of drugs.
   (E) Drugs that are highly bound to plasma proteins generally have a greater V_D compared with drugs that are highly bound to tissue proteins.

18. The onset time for a drug given orally is the time for the drug to

   (A) reach the peak plasma drug concentration.
   (B) reach the MEC.
   (C) reach the MTC.
   (D) begin to be eliminated from the body.
   (E) begin to be absorbed from the small intestine.

19. The initial distribution of a drug into tissue is determined chiefly by the

   (A) rate of blood flow to tissue.
   (B) GFR.
   (C) stomach emptying time.
   (D) affinity of the drug for tissue.
   (E) plasma protein binding of the drug.

20. Which tissue has the greatest capacity to biotransform drugs?

   (A) brain
   (B) kidney
   (C) liver
   (D) lung
   (E) skin

21. The principle of superposition in designing multiple-dose regimens assumes that

   (A) each dose affects the next subsequent dose, causing nonlinear elimination.
   (B) each dose of drug is eliminated by zero-order elimination.
   (C) steady-state plasma drug concentrations are reached at approximately 10 half-lives.
   (D) early doses of drug do not affect subsequent doses.
   (E) the fraction of drug absorbed is equal to the fraction of drug eliminated.

For questions 22–24: A new cardiac glycoside is developed for oral and intravenous administration. The drug has an elimination half-life ($t_{\frac{1}{2}}$) of 24 hrs and an apparent volume of distribution (V_D) of 3 L/kg. The effective drug concentration is 1.5 ng/mL. Toxic effects of the drug are observed at drug concentrations > 4 ng/mL. The drug is bound to plasma proteins at approximately 25%. The drug is 75% bioavailable after an oral dose.

22. What is the oral maintenance dose, if given once a day, for a 68-year-old man who weighs 65 kg and has congestive heart failure (CHF) and normal renal function?

   (A) 0.125 mg
   (B) 0.180 mg
   (C) 0.203 mg
   (D) 0.270 mg
   (E) 0.333 mg

23. What is the loading dose (D_L) for this patient?

   (A) 0.270 mg
   (B) 0.293 mg
   (C) 0.450 mg
   (D) 0.498 mg
   (E) 0.540 mg

24. If the drug is available in tablets of 0.125 mg and 0.250 mg, what is the patient's plasma drug concentration if he has a dosage regimen of 0.125 mg every 12 hrs?

   (A) 1.39 ng/mL
   (B) 1.85 ng/mL
   (C) 2.78 ng/mL
   (D) 3.18 ng/mL
   (E) 6.94 ng/mL

25. If digoxin has a half-life of 35 hrs how long will it take for a toxic plasma concentration of 8 ng/mL to decline to a therapeutic plasma concentration of 2 ng/mL?

   (A) 17.5 hrs
   (B) 35 hrs
   (C) 70 hrs
   (D) 105 hrs
   (E) 140 hrs

Directions for question 26: The question in this section can be correctly answered by **one or more** of the suggested answers. Choose the correct answer, **A–E**.

    A   if **I only** is correct
    B   if **III only** is correct
    C   if **I and II** are correct
    D   if **II and III** are correct
    E   if **I, II, and III** are correct

26. Which equation is true for a zero-order reaction rate of a drug?

    I. $\dfrac{dA}{dt} = -k$

    II. $t_{\frac{1}{2}} = \dfrac{0.693}{k}$

    III. $A = A_0 e^{-kt}$

Answers and Explanations

1. The answer is B *[see I.E.2.a].*
A substance that is used to measure the GFR must be filtered but not reabsorbed or actively secreted. Although inulin clearance gives an accurate measurement of GFR, creatinine clearance is generally used because no exogenous drug must be given. However, creatinine formation depends on muscle mass and muscle metabolism, which may change with age and various disease conditions.

2. The answer is C *[see I.B.1.b.(2)].*

3. The answer is B *[see I.A.3.b.(1); I.B.1].*

4. The answer is B *[see I.B.1.a.(2)].*

5. The answer is B *[see I.B.1.a.(2)].*
Substituting the data for this patient in the equation for the initial plasma drug concentration (C_P^0) gives

$$C_P^0 = \frac{D_0}{V_D} = \frac{5 \text{ mg}}{0.28 \text{ L/kg}} = 17.9 \text{ mg/L}$$

To obtain the patient's plasma drug concentration (C_p) 8 hrs after the dose, the following calculation is performed:

$$C_p = C_P^0 \, e^{-kt}$$

$$k = \frac{0.693}{t_{\frac{1}{2}}} = \frac{0.963}{2} = 0.347 \text{ hr}^{-1}$$

$$C_p = 17.9 e^{-(0.347)(8)}$$

$$C_p = (17.9)(0.0623) = 1.11 \text{ mg/L}$$

The amount of drug in the patient's body at 8 hrs is calculated as follows:

$$D_B = C_p V_D = (1.11)(0.28)(75) = 23.3 \text{ mg}$$

For any first-order elimination process, 50% of the initial amount of drug is eliminated at the end of the first half-life, and 50% of the remaining drug (i.e., 75% of the original amount) is eliminated at the end of the second half-life. Because the drug in the current case has an elimination half-life $(t_{\frac{1}{2}})$ of 2 hrs, 75% of the dose is eliminated in two half-lives or 4 hrs.

6. The answer is D *[see I.B.3.e.(3)].*

7. The answer is C *[see I.B.3.c].*

8. The answer is E *[see I.B.3.f.(2)].*

9. The answer is B *[see I.B.3.e.(3)].*

10. The answer is D *[see I.B.3.e.(3); I.E.1.a].*

11. The answer is B *[see I.E.4.a].*
The equation for the plasma concentration at steady state (C_{ss}) provides the formula for calculating the rate of an intravenous infusion (R). The equation is

$$C_{ss} = \frac{R}{kV_D}$$

where k is the first-order elimination rate constant and V_D is the apparent volume of distribution. Rearranging the equation and substituting the data for this patient give the following calculations:

$$R = C_{ss} k V_D = \frac{15 \text{ mg}}{100 \text{ mL}} \times \frac{0.693}{1 \text{ hr}} \times 9000 \text{ mL}$$

$$R = 936 \text{ mg/hr}$$

The time it takes for an infused drug to reach the C_{ss} depends on the elimination half-life of the drug. The time required to reach 95% of the C_{ss} is equal to 4.3 times the half-life, whereas the time required to reach 99% of the C_{ss} is equal to 6.6 times the half-life. Because the half-life in the current case is 1 hr, the time to reach 95% of the C_{ss} is 4.3 × 1 hr or 4.3 hrs. The loading dose (D_L) is calculated as follows:

$$D_L = C_{ss} V_D = \frac{15 \text{ mg}}{100 \text{ mL}} \times 9000 \text{ mL} = 1350 \text{ mg}$$

The answer to question 6 shows that the infusion rate should be 936 mg/hr. Therefore, if a drug solution containing 10 g in 500 mL is used, the required infusion rate is

$$\frac{936 \text{ mg}}{1 \text{ hr}} \times \frac{500 \text{ mL}}{10000 \text{ mg}} = 46.8 \text{ mL/hrs}$$

The patient's total body clearance (Cl_T) is calculated as follows:

$$Cl_T = kV_D$$
$$Cl_T = \frac{0.693}{1} \times 9000 \text{ mL} = 6237 \text{ mL/hr}$$

The hepatic clearance (Cl_H) is the difference between total clearance (Cl_T) and renal clearance (Cl_R):

$$Cl_H = Cl_T - Cl_R$$
$$Cl_H = 6237 - (86 \text{ mL/min} \times 60 \text{ min/hr})$$
$$= 1077 \text{ mL/hr}$$

12. The answer is B *[see I.B.1.b.(1)]*.
A large apparent volume of distribution (V_D) is an early sign that a drug is not concentrated in the plasma but is distributed widely in tissue. An increase in plasma protein binding suggests that the drug is located in the plasma rather than in tissue. A decrease in hepatic metabolism, an increase in side effects, or a decrease in urinary excretion of free drug is caused by a decrease in drug elimination.

13. The answer is A *[see I.A.5.d.(3)]*.
As more drug is concentrated at the receptor site, more receptors interact with the drug to produce a pharmacologic effect. The intensity of the response increases until it reaches a maximum. When all of the available receptors are occupied by drug molecules, additional drug does not produce a more intense response.

14. The answer is B *[see I.D]*.
Nonlinear pharmacokinetics is a term used to indicate that first-order elimination of a drug does not occur at all drug concentrations. With some drugs, such as phenytoin, as the plasma drug concentration increases, the elimination pathway for metabolism of the drug becomes saturated and the half-life increases. The area under the plasma drug concentration versus time curve (AUC) of the drug is not proportional to the dose, neither is the rate of metabolite formation. The metabolic rate is related to the effects of the drug.

15. The answer is D *[see I.B.1.b.(2); I.B.5.g.(1)]*.
A loading dose (D_L) of a drug is given to obtain a therapeutic plasma drug level as rapidly as possible. The D_L is calculated based on the apparent volume of distribution (V_D) and the desired plasma level of the drug.

16. The answer is E *[see I.E.3.c]*.
Inulin is neither reabsorbed nor actively secreted. Therefore, it is excreted by glomerular filtration only. The inulin clearance rate is used as a standard measure of the GFR, a test that is useful both in a clinical situation and in the development of new drugs.

17. The answer is E *[see I.A.5.d]*.
Drugs that are highly bound to plasma proteins diffuse poorly into tissue and have a low apparent volume of distribution (V_D).

18. The answer is B *[see I.B.3.g]*.
The onset time is the time from the administration of the drug to the time when absorbed drug reaches the MEC. The MEC is the drug concentration in the plasma that is proportional, but not necessarily equal, to the minimum drug concentration at the receptor site that elicits a pharmacologic response.

19. The answer is A *[see I.A.5.a]*.
The initial distribution of a drug is chiefly determined by blood flow, whereas the affinity of the drug for tissue determines whether the drug concentrates at that site. The GFR affects the renal clearance of a drug, not its initial distribution. The gastric emptying time and degree of plasma protein binding affect drug distribution but are less important than the rate of blood flow to tissue.

20. The answer is C *[see I.E.4.b.(2)]*.
The kidney, lung, skin, and intestine all have some capacity to biotransform, or metabolize, drugs; but the brain has little capacity for drug metabolism. The liver has the highest capacity for drug metabolism.

21. The answer is D *[see I.B.5.c]*.
The superposition principle, which underlies the design of multiple-dose regimens, assumes that earlier drug doses do not affect subsequent doses. If the elimination rate constant or total body clearance of the drug changes during multiple dosing, then the superposition principle is no longer valid. Changes in the total body clearance (Cl_T) may be caused by enzyme induction, enzyme inhibition, or saturation of an elimination pathway. Any of these changes would cause nonlinear pharmacokinetics.

22. The answer is D *[see I.B.5.e.(3)]*.

23. The answer is E *[see I.B.5.g.(1)]*.

24. The answer is A *[see I.B.5.d.(2); I.B.5.e.(3)]*.
The oral maintenance dose (D_0) should maintain the patient's average drug concentration at the effective drug concentration. The bioavailability of the drug (F), the apparent volume of distribution (V_D), the dosage interval (τ), and the excretion rate constant (k) must be considered in calculating the dose. The equation used is

$$C_{Av}^{\infty} = FD_0 / kV_D\tau$$

For this drug, $F = 0.75$, $k = 0.693/24$ hrs, $V_D = 3$ L/kg $\times 65$ kg, $\tau = 24$ hrs, and $C_{Av}^{\infty} = 1.5$ ng/mL, or 1.5 μg/L. Therefore, by substitution, $D_0 = 270$ μg, or 0.270 mg. When the maintenance dose is given at a dosage frequency equal to the half-life, then the loading dose is equal to twice the maintenance dose, in this case 540 μg, or 0.540 mg. To determine the plasma drug concentration for a dosage regimen of 0.125 mg every 12 hrs, the C_{Av}^{∞} formula is used. This time, $F = 0.75$, $D_0 = 0.125$ mg, $k = 0.693/24$ hrs, $V_D = 3$ L/kg $\times 65$ kg, and $\tau = 12$ hrs. Therefore, $C_{Av}^{\infty} = 1.39$ ng/mL. For cardiac glycosides, the peak (C_{max}) and trough (C_{min}) concentrations are calculated, and plasma drug concentrations are monitored after dosing. The loading dose (D_L) may be given in small increments over a specified period, according to the dosage regimen suggested by the manufacturer.

25. **The answer is C** *[see I.A.3.b]*.
    For first-order elimination, it takes two half-lives for plasma drug concentration of 8 ng/mL to decline to 2 ng/mL. The first half-life, the plasma drug concentration declines to 4 ng/mL, and the next half-life, the plasma drug concentration declines to 2 ng/mL.

26. **The answer is A (I)** *[see I.A.3.a]*.
    The first equation in the question describes a zero-order reaction (dA/dt) in which the reaction rate increases or decreases at a constant rate (k). A zero-order reaction produces a graph of a straight line with the equation of $A = -kt + A_o$ when A is plotted against time (t). The other equations in the question represent first-order reactions.

6 Bioavailability and Bioequivalence

MANISH ISSAR, LEON SHARGEL

I. DEFINITIONS[1]

A. **Bioavailability** is a measurement of the rate and extent (amount) to which the active ingredient or active moiety becomes available at the site of action. Bioavailability is also considered a measure of the rate and extent of therapeutically active drug that is systemically absorbed. For drug products that are not intended to be absorbed into the bloodstream, bioavailability may be assessed by measurements intended to reflect the rate and extent to which the active ingredient or active moiety becomes available at the site of action.

B. **Bioequivalent drug products.** A generic drug product is considered bioequivalent to the **reference listed drug (RLD) product** if both products are pharmaceutical equivalents and the generic drug product's rate and extent of systemic drug absorption (bioavailability) do not show a statistically significant difference when administered in the same molar dose of the active ingredient, in the same chemical form, in a similar dosage form, by the same route of administration, and under the same experimental conditions. The RLD is generally the brand product.

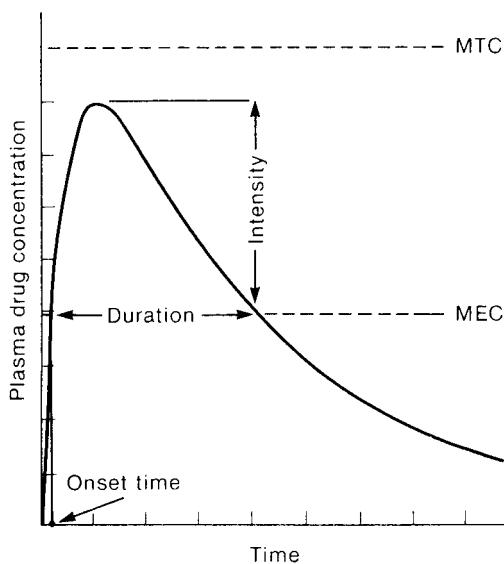
C. **Generic drug product**
   1. The generic drug product requires an **abbreviated new drug application** (ANDA) for approval by the U.S. Food and Drug Administration (FDA) and may be marketed after patent expiration of the reference drug product.
   2. The generic drug product must be a **therapeutic equivalent** to the reference drug product but may differ in certain characteristics, including shape, scoring configuration, packaging, and excipients (such as colors, flavors, preservatives, expiration date, and minor aspects of labeling).
   3. FDA believes that products classified as therapeutically equivalent can be substituted with the full expectation that the substituted product will produce the same clinical effect and safety profile as the prescribed product.

D. **Pharmaceutical equivalents** are drug products that contain the same therapeutically active drug ingredient(s); contain the same salt, ester, or chemical form; are of the same dosage form; and are identical in strength, concentration, and route of administration. Pharmaceutical equivalents may differ in characteristics such as shape, scoring configuration, release mechanisms, packaging, and excipients (including colors, flavoring, and preservatives).

E. **The reference listed drug product** is usually the currently marketed, brand-name product with a full **new drug application** (NDA) approved by the FDA. The RLD is the reference drug product identified by FDA (see *Electronic Orange Book* at http://www.accessdata.fda.gov/scripts/cder/ob/default.cfm).

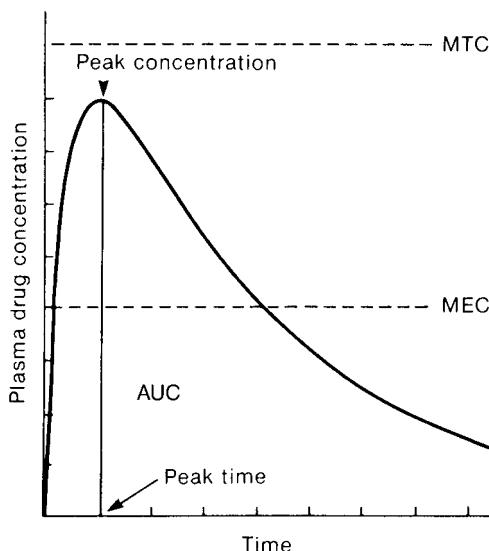
---

[1]The U.S. Food and Drug Administration (FDA) annually publishes the book *Approved Drug Products with Therapeutic Equivalence Evaluation* also known as the *Electronic Orange Book* (available online at http://www.accessdata.fda.gov/scripts/cder/ob/default.cfm). This source should be consulted for the latest definitions of therapeutic equivalence–related terms.

F. **Therapeutic equivalent drug products** are pharmaceutical equivalents that can be expected to have the same clinical effect and safety profile when administered to patients under the same conditions specified in the labeling. Therapeutic equivalent drug products have the following criteria:
   1. The products are safe and effective.
   2. The products are pharmaceutical equivalents that contain the same active drug ingredient in the same dosage form, given by the same route of administration; meet compendial or other applicable standards of strength, quality, purity, and identity; and meet an acceptable in vitro standard.
   3. The drug products are bioequivalent in that they do not present a known potential problem and are shown to meet an appropriate bioequivalence standard.
   4. The drug products are adequately labeled.
   5. The drug products are manufactured in compliance with current good manufacturing practice regulations.
G. **Pharmaceutical alternatives** are drug products that contain the same therapeutic moiety but are different salts, esters, or complexes of that moiety (e.g., tetracycline hydrochloride vs. tetracycline phosphate) or are different dosage forms (e.g., tablet versus capsule; immediate-release dosage form versus controlled-release dosage form) or strengths.


II. DRUG PRODUCT PERFORMANCE

A. **Drug product performance**, in vivo, may be defined as the release of the drug substance from the drug product leading to bioavailability of the drug substance. Performance tests relate the quality of the drug product to its clinical safety and efficacy.
B. **Bioavailability studies** are used for establishing dosage regimens of new drug products. Bioavailability is one attribute to product quality that links in vivo performance of the drug product used to original formulation that was used in the clinical safety and efficacy studies.
C. **Bioequivalence studies** can be useful during the investigational new drug (IND) development or NDA development period to establish links between
   1. early and late clinical trial formulations;
   2. formulations used in clinical trial and stability studies, if different; and
   3. clinical trial formulations and to-be-marketed drug product.
D. **Bioequivalence studies** are a critical component of ANDA submissions.
   1. The purpose of these studies is to demonstrate bioequivalence between a pharmaceutically equivalent generic drug product and the corresponding reference listed drug (usually the brand drug product).
   2. Together with the determination of pharmaceutical equivalence, establishing bioequivalence allows a regulatory conclusion of therapeutic equivalence.
E. **Scale-up and post-approval changes (SUPACs).** After market approval, a drug product may undergo a manufacturing change. A bioequivalence study may be needed to show that the new formulation or the new method of manufacture (test product) and the prior formulation or method of manufacture (reference product) are equivalent.

III. BIOAVAILABILITY AND BIOEQUIVALENCE. These may be determined directly
using pharmacokinetic studies (e.g., plasma drug concentration versus time profiles, urinary drug excretion studies), measurements of an acute pharmacodynamic effect, comparative clinical studies, or in vitro studies. The choice of study used is based on the site of action of the drug and the ability of the study design to compare drug delivered to that site by the two products.


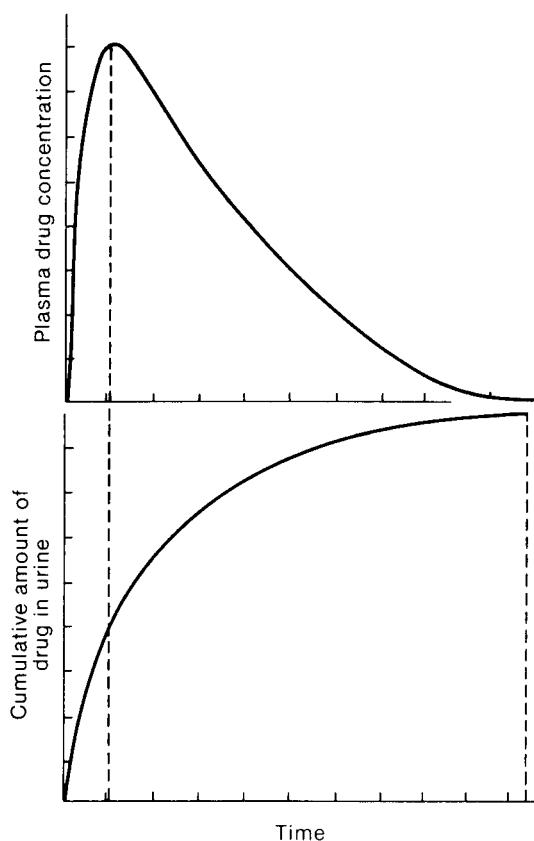
A. **Acute pharmacodynamic effects**, such as changes in heart rate, blood pressure, electrocardiogram (ECG), clotting time, or forced expiratory volume in 1 sec (FEV_1) can be used to measure bioavailability when no assay for plasma drug concentration is available or when the plasma drug concentration does not relate to the pharmacological response (e.g., a bronchodilator such as albuterol given by inhalation). Quantitation of the pharmacological effect versus time profile can be used as a measure of bioavailability and/or bioequivalence (*Figure 6-1*).
   1. **Onset time**. As the drug is systemically absorbed, the drug concentration at the receptor rises to a **minimum effective concentration** (MEC), and a pharmacological response is initiated. The time from drug administration to the MEC is known as the onset time.


Figure 6-1. Generalized plasma drug concentration versus time curve after oral drug administration. *MEC*, minimum effective concentration; *MTC*, minimum toxic concentration. Adapted with permission from Shargel L, Wu-Pong S, Yu ABC. *Applied Biopharmaceutics and Pharmacokinetics.* 5th ed. New York, NY: McGraw-Hill; 2005:6.

2. **Intensity**. The intensity of the pharmacological effect is proportional to the number of receptors occupied by the drug up to a *maximum* pharmacological effect. The maximum pharmacological effect may occur before, after, or at peak drug absorption.

3. **Duration of action**. As long as the drug concentration remains above the MEC, pharmacological activity is observed. The duration of action is the time for which the drug concentration remains above the MEC.

4. **Therapeutic window**. As the drug concentration increases, other receptors may combine with the drug to exert a toxic or adverse response. This drug concentration is the **minimum toxic concentration** (MTC). The drug concentration range between the MEC and the MTC is known as the *therapeutic window.*

B. **Plasma drug concentration**. The plasma drug concentration versus time curve is most often used to measure the systemic bioavailability of a drug from a drug product (*Figure 6-2*).

1. **Time for peak plasma drug concentration** (T_{max}) relates to the rate constants for systemic drug absorption and elimination. If two oral drug products contain the same amount of active drug but different excipients, the dosage form that yields the faster rate of drug absorption has the shorter T_{max}.

Figure 6-2. Generalized plasma drug concentration versus time curve, showing peak time and peak concentration. *AUC*, area under the curve; *MEC*, minimum effective concentration; *MTC*, minimum toxic concentration. Adapted with permission from Shargel L, Wu-Pong S, Yu ABC. *Applied Biopharmaceutics and Pharmacokinetics.* 5th ed. New York, NY: McGraw-Hill; 2005:7.

2. **Peak plasma drug concentration** (C_{max}). The plasma drug concentration at T_{max} relates to the intensity of the pharmacological response. Ideally, C_{max} should be within the therapeutic window.

3. **Area under the plasma drug concentration versus time curve** (AUC) relates to the amount or extent of drug absorption. The amount of systemic drug absorption is directly related to the AUC. The AUC is usually calculated by the **trapezoidal rule** and is expressed in units of concentration multiplied by time (e.g., μg/mL × hr).

C. **Urinary drug excretion.** Measurement of urinary drug excretion can determine bioavailability from a drug product. This method is most accurate if the active therapeutic moiety is excreted unchanged in significant quantity in the urine (*Figure 6-3*).

1. **The cumulative amount of active drug excreted in the urine** $\left(D_U^\infty\right)$ is directly related to the extent of systemic drug absorption.

2. **The rate of drug excretion in the urine** (dD_U/dt) is directly related to the rate of systemic drug absorption.

3. **The time for the drug to be completely excreted** (t^∞) corresponds to the total time for the drug to be systemically absorbed and completely excreted after administration.

D. **Comparative clinical trials** to a drug can be used to measure bioavailability quantitatively. Clinical studies are highly variable and less precise than other methods because of individual differences in drug pharmacodynamics and subjective measurements.

E. **In vitro measurements of bioequivalence.** Bioequivalence may sometimes be demonstrated using an in vitro bioequivalence standard, especially when such an in vitro test has been correlated with human in vivo bioavailability data. For example, the rate of drug dissolution in vitro for certain drug products correlates with drug bioavailability in vivo. If the dissolution test in vitro is considered statistically adequate to predict drug bioavailability, then, in some cases, dissolution may be used in place of an in vivo bioavailability study. This relationship between in vitro dissolution and in vivo bioavailability is also known as in vitro–in vivo correlation (IVIVC).

Figure 6-3. These corresponding plots show the relationship of the plasma drug concentration versus time curve to the cumulative amount of drug in the urine versus time curve. Adapted with permission from Shargel L, Wu-Pong S, Yu ABC. *Applied Biopharmaceutics and Pharmacokinetics.* 5th ed. New York, NY: McGraw-Hill; 2005:463.

IV. RELATIVE AND ABSOLUTE BIOAVAILABILITY

A. **Relative bioavailability** (RBA) is the systemic availability of the drug from a dosage form as compared to a reference standard given by the same route of administration. Relative bioavailability is calculated as the ratio of the AUC for the dosage form to the AUC for the reference dosage form given in the same dose. A relative bioavailability of 1 (or 100%) implies that drug bioavailability from both dosage forms is the same but does not indicate the completeness of systemic drug absorption. The determination of relative bioavailability is important in generic drug studies (e.g., bioequivalence studies). Bioequivalence is a relative bioavailability study.

$$RBA = \frac{[AUC]_{0\,oralTEST}^{\infty}/Dose_{oralTEST}}{[AUC]_{0\,REF.}^{\infty}/Dose_{REF.}}$$

B. **Absolute bioavailability** (F) is the fraction of drug systemically absorbed from the dosage form. F is calculated as the ratio of the AUC for the dosage form given orally to the AUC obtained after intravenous (IV) drug administration (adjusted for dose). A parenteral drug solution given by IV administration is considered to have 100% systemic absorption (i.e., $F = 1$). An F value of 0.80 (or 80%) indicates that only 80% of the drug was systemically available from the oral dosage form.

$$F = \frac{[AUC]_{0\,oral}^{\infty}/Dose_{oral}}{[AUC]_{0\,i.v.}^{\infty}/Dose_{i.v.}}$$

V. BIOEQUIVALENCE STUDIES FOR SOLID ORAL DRUG PRODUCTS

A. **Objective of bioequivalence studies**. The objective of a bioequivalence study is to measure and compare formulation performance between two or more pharmaceutically equivalent drug products.

B. **Design of bioequivalence studies**

1. The FDA's Division of Bioequivalence, Office of Generic Drugs provides guidance for the performance of in vitro dissolution and in vivo bioequivalence studies. These guidances are available at http://www.fda.gov/Drugs/GuidanceComplianceRegulatoryInformation/Guidances/default.htm.

2. **Fasting study**. Bioequivalence studies are usually evaluated by a single-dose, two-period, two-treatment, two-sequence, open-label, randomized crossover design, comparing equal doses of the test (generic) and reference (brand) products in fasted, adult, healthy subjects.
   a. Both men and women may be used in the study.
   b. Blood sampling is performed just before the dose (zero time) and at appropriate intervals after the dose to obtain an adequate description of the plasma drug concentration versus time profile.

3. **Food intervention study**. If the bioavailability of the active drug ingredient is known to be affected by food, the generic drug manufacturer must include a single-dose, randomized, crossover, food effects study comparing equal doses of the test product and reference products given immediately after a standard high-fat–content breakfast.

4. **Other study designs**. Crossover studies may not be practical in drugs with a long half-life in the body, and a parallel study design may be used instead. Alternate study methods, such as in vitro studies or equivalence studies with clinical or pharmacodynamic end points, are used for drug products where plasma concentrations are not useful to determine delivery of the drug substance to the site of activity (such as inhalers, nasal sprays, and topical products applied to the skin).

5. **Waiver of an in vivo bioequivalence study (biowaiver)**
   a. A comparative in vitro dissolution (drug-release) study between the test and the reference products may be used in lieu of an in vivo bioequivalence study for some immediate-release (conventional) oral drug products.
   b. No bioequivalence study is required for certain drug products given as a solution such as oral, parenteral, ophthalmic, or other solutions because bioequivalence is self-evident. In this case, the drug is in a pure aqueous solution, and there is no drug dissolution rate consideration.
   c. Immediate-release (IR) solid oral drug products that meet biopharmaceutics classification system (BCS) class 1 drugs—that is, highly water soluble, rapidly dissolving, and rapid permeation of cellular membranes—may obtain a biowaiver.

     d. Drug products containing a lower dose strength (e.g., 200 mg, 100 mg, and 50 mg IR tablets). The drug product must be in the same dosage form, lower strength, and is proportionately similar in its active and inactive ingredients.

C. Pharmacokinetic evaluation of the data. Pharmacokinetic analysis includes calculation for each subject of the AUC to the last quantifiable concentration (AUC_{0-t}) and to infinity ($AUC_{0-\infty}$), T_{max}, and C_{max}. In addition, the elimination rate constant (k), the elimination half-life ($t_{1/2}$), and other parameters may be estimated.

D. Statistical evaluation of the data

    1. The statistical methodology for analyzing bioequivalence studies is called the *two one-sided test procedures*. Two situations are tested with this statistical methodology.

        a. The first of the two one-sided tests determines whether a generic product (test), when substituted for a brand-name product (reference), is significantly less bioavailable.

        b. The second of the two one-sided tests determines whether a brand-name product (reference), when substituted for a generic product (test), is significantly less bioavailable.

        c. Based on the opinions of FDA medical experts, a difference of $> 20\%$ for each of the aforementioned tests was determined to be significant and, therefore, undesirable for all drug products.

    2. An analysis of variance (ANOVA) should be performed on the log transformed AUC and C_{max} values obtained from each subject. The 90% confidence intervals for both pharmacokinetic parameters, AUC and C_{max}, must be entirely within the 80% to 125% boundaries based on log transformation of the data. The ratio of the means of the study data (test to reference) should lie in the center of the 90% confidence interval, or close to 100% (equivalent to a test to reference ratio of 1) (*Table 6-1*).

    3. Different statistical criteria are sometimes used when bioequivalence is demonstrated through comparative clinical trials, pharmacodynamic studies, or comparative in vitro methodology.

    4. The bioequivalence methodology and criteria described earlier simultaneously control for both differences in the average response between test and reference products as well as the precision with which the average response in the population is estimated. This precision depends on the within-subject (normal volunteer or patient) variability in the pharmacokinetic parameters (AUC and C_{max}) of the two products and on the number of subjects in the study. The width of the 90% confidence interval is a reflection in part of the within-subject variability of the test and reference products in the bioequivalence study.

VI. BIOEQUIVALENCE ISSUES

A. Problems in determining bioequivalence include lack of an adequate study design; inability to accurately measure the drug analytes, including metabolites and enantiomers (chiral drugs); and lack of systemic drug absorption (*Table 6-2*).

B. Bioequivalence studies for which objective blood drug concentrations cannot be obtained require either a pharmacodynamic study, a clinical trial, or an in vitro study that has been correlated with human in vivo bioavailability data.

    1. Pharmacodynamic measurements are more difficult to obtain, and the data tend to be variable, requiring a larger number of subjects compared to the bioequivalence studies for systemically absorbed drugs.

        a. A bioequivalence study using pharmacodynamic measurements tries to obtain a pharmacodynamic effect versus time profile for the drug in each subject.

        b. The area under the effect versus time profile, peak effect, and time for peak effect are obtained for the test and reference products and are then statistically analyzed.

    2. Comparative clinical trials are more difficult to run, do not have easily quantifiable observations, and are quite costly.

    3. In vitro studies may require the development of a reliable surrogate marker that may be correlated with human in vivo bioavailability data. Examples include the following:

        a. Comparative in vitro drug release/dissolution studies in which the dissolution profile of the test and reference drug products under different conditions of pH and media are performed.

        b. Comparison of binding of bile acids to cholestyramine (Questran®) and the test product.

Table 6-1   BIOAVAILABILITY COMPARISON OF A GENERIC (TEST) AND BRAND (REFERENCE) DRUG PRODUCT

PK Variable	Units	Geometric Mean		% Ratio T/R	LN-Transformed Data 90% Confidence Interval (Lower Limit, Upper Limit)	P Values for Product Effects	Power of ANOVA	ANOVA % CV
		Test	Reference					
C_{max}	ng/mL	344.79	356.81	96.6	(89.5, 112)	.3586	0.8791	17.90%
AUC_{0-t}	ng hr/mL	2659.12	2674.92	99.4	(95.1, 104)	.8172	1.0000	12.60%
AUC_{inf}	ng hr/mL	2708.63	2718.52	99.6	(95.4, 103)	.8865	1.0000	12.20%
T_{max}	hr	4.29	4.24	101				
k_{elim}	1/hr	0.0961	0.0980	98.1				
$t_{1/2}$	hr	8.47	8.33	101.7				

AUC, area under the curve; C_{max}, peak plasma drug concentration; T_{max}, time for peak plasma drug concentration.
The results were obtained from a two-way crossover, single-dose, fasting study in 36 healthy adult volunteers. Mean values are reported. No statistical differences were observed between AUC and C_{max} values for the test and reference products.

Table 6-2	PROBLEM ISSUES IN THE DETERMINATION OF BIOEQUIVALENCE

Problem Issues	Example
Drugs with highly variable bioavailability[a]	Propranolol, verapamil
Drugs with active metabolites	Selegiline
Chiral drugs	Ibuprofen, albuterol
Drugs with nonlinear pharmacokinetics	Phenytoin
Orally administered drugs that are not systemically absorbed	Cholestyramine resin, sucralfate
Drugs with long elimination half-lives	Probucol
Variable-dosage forms	Dyazide, conjugated estrogens
Nonoral drug delivery	
Topical drugs	Steroids, antifungals
Transdermal delivery systems	Estrogen patch
Drugs given by inhalation aerosols	Bronchodilators, steroids
Intranasal drugs	Intranasal steroids
Biotechnology-derived drugs	Erythropoietin, interferon
Bioavailable drugs that should not reach peak drug levels	Potassium supplements, hormone replacement therapy
Target population used in the bioequivalence studies	Pediatric patients; renal disease

[a]These drugs have high intrasubject variability.

VII. DRUG PRODUCTION SELECTION

A. Generic drug substitution

1. **Generic drug substitution** is the process of dispensing a generic drug product in place of the prescribed drug product (e.g., generic product for brand-name product, generic product for another generic product, brand-name product for generic product). The substituted product must be a therapeutic equivalent to the prescribed product.

2. Generic drug products that are classified as therapeutic equivalents by the FDA are expected to produce the same clinical effect and safety profile as the prescribed drug.

B. Therapeutic substitution

1. Therapeutic substitution is the process of dispensing a therapeutic alternative in place of the prescribed drug product. For example, amoxicillin is dispensed for ampicillin.

2. The substituted drug product is usually in the same therapeutic class (e.g., calcium channel blocker) and is expected to have a similar clinical profile.

C. Formulary issues

1. A **formulary** is a list of drugs. A **positive** formulary lists all the drugs that may be substituted, whereas a **negative** formulary lists drugs for which the pharmacist may not substitute. A **restrictive** formulary lists only those drugs that may be reimbursed without justification by the prescriber; for drugs not listed in the restrictive formulary, the prescriber must justify the need for the nonlisted drug.

2. Many states have legal requirements that address the issue of drug product selection. States may provide information and guidance in drug product selection through positive, negative, or restrictive formularies.

3. The FDA annually publishes *Approved Drug Products with Therapeutic Equivalence Evaluations* (the *Orange Book*). This publication is also reproduced in the *United States Pharmacopeia* (*USP*), DI Vol. III, *Approved Drug Products and Legal Requirements*, published annually by the *USP* Convention. The *Electronic Orange Book* may be found at http://www.accessdata.fda.gov/scripts/cder/ob/default.cfm.

   a. The *Orange Book* provides therapeutic evaluation codes for drug products (*Table 6-3*).

      (1) "A-rated" drug products are drug products that contain active ingredients and dosage forms that are not regarded as presenting either actual or potential bioequivalence problems or drug quality standards issues. However, all oral dosage forms must meet an appropriate in vitro bioequivalence standard that is acceptable to the FDA to be approved as therapeutically equivalent and may be interchanged.

Table 6-3	THERAPEUTIC EQUIVALENCE EVALUATION CODES

A Codes	Drug products that are considered to be therapeutically equivalent to other pharmaceutically equivalent products
AA	Products in conventional dosage forms not presenting bioequivalence problems
AB	Products meeting bioequivalence requirements
AN	Solutions and powders for aerosolization
AO	Injectable oil solutions
AP	Injectable aqueous solutions
AT	Topical products

B Codes	Drug products that the FDA does not at this time consider to be therapeutically equivalent to other pharmaceutically equivalent products
BC	Extended-release tablets, extended-release capsules, and extended-release injectables
BD	Active ingredients and dosage forms with documented bioequivalence problems
BE	Delayed-release oral dosage forms
BN	Products in aerosol-nebulizer drug delivery systems
BP	Active ingredients and dosage forms with potential bioequivalence problems
BR	Suppositories or enemas for systemic use
BS	Products with drug standard deficiencies
BT	Topical products with bioequivalence issues
BX	Insufficient data

FDA, U.S. Food and Drug Administration.

(2) "B-rated" drug products are drug products for which actual or potential bioequivalence problems have not been resolved by adequate evidence of bioequivalence. These products often have specific dosage form problems rather than a problem with the active ingredients (e.g., two different nicotine patches). "B-rated" drug products are not considered therapeutically equivalent to other pharmaceutically equivalent products and are not interchangeable.

(3) Certain products present special situations that deserve a more complete explanation than can be provided by the two codes used in the *Orange Book*. These drugs have particular problems with standards of identity, analytical methodology, or bioequivalence that are considered individually. For these drugs, consult the *Orange Book*.

(4) FDA may approve drug products containing the same active drug from different pharmaceutical manufacturers under a separate NDA for their own product. The two branded drug products such as Adalat® and Procardia® brands of nifedipine are not bioequivalent to each other. In this case, the practitioner/user must decide which products are bioequivalent and therapeutic equivalent (*Table 6-4*).

   b. For some drug products, bioequivalence has not been established or no generic product is currently available.

4. Various hospitals, institutions, insurance plans, health maintenance organizations (HMOs), and other third-party plans may have a formulary that provides guidance for drug product substitution.

D. **Generic biologics (biosimilar drug products)**

1. *Biologics*, or biotechnology-derived drugs, in contrast to drugs that are chemically synthesized, are derived from living sources such as human, animal, or microorganisms.

2. Many biologics are complex mixtures that are not easily identified or characterized and are manufactured using biotechnology or are purified from natural sources.

3. Other biological drugs, such as insulin and growth hormone, are proteins derived by biotechnology and have been well characterized.

4. Due to the Affordable Care Act (2010), FDA has issued guidances on drug product development regarding biotechnology-derived drug products, sometimes referred to as *generic biologics*, *biosimilar* drug products, or "follow-on" proteins.

Table 6-4		THERAPEUTIC EVALUATION CODES FOR NIFEDIPINE EXTENDED RELEASE TABLETS				
TE Code	RLD	Active Ingredient	Dosage Form; Route	Strength	Propietary Name	Applicant
AB1	Yes	Nifedipine tablet	Extended release; oral	90 mg	Adalat CC	Bayer HealthCare Pharmaceuticals
AB1	No	Nifedipine tablet	Extended release; oral	90 mg	Nifedipine	Biovail
BX	No	Nifedipine tablet	Extended release; oral	90 mg	Nifedipine	Martec USA LLC
AB2	Yes	Nifedipine tablet	Extended release; oral	90 mg	Procardia XL	Pfizer
AB2	No	Nifedipine tablet	Extended release; oral	90 mg	Nifedipine	Osmotica Pharmaceutical

In Table 6-4, AB1 products are bioequivalent to each other and can be substituted. AB2 products are bioequivalent to each other and can be substituted. However, an AB1 product cannot be substituted for an AB2 product. The BX product should not be used.

Study Questions

Directions for questions 1–3: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by one of the suggested answers or phrases. Choose the best answer.

1. The parameters used to describe bioavailability are

   (A) C_{max}, AUC_{0-t}, and $AUC_{0-\infty}$.
   (B) C_{max}, AUC_{0-t}, $AUC_{0-\infty}$, and T_{max}.
   (C) C_{max}, AUC_{0-t}, $AUC_{0-\infty}$, and $t_{\frac{1}{2}}$.
   (D) C_{max} and AUC_{0-t}.
   (E) C_{max}, AUC_{0-t}, $AUC_{0-\infty}$, T_{max}, and $t_{\frac{1}{2}}$.

2. To determine the absolute bioavailability of a drug given as an oral extended-release tablet, the bioavailability of the drug must be compared to the bioavailability of the drug from

   (A) an immediate-release oral tablet containing the same amount of active ingredient.
   (B) an oral solution of the drug in the same dose.
   (C) a parenteral solution of the drug given by intravenous (IV) bolus or IV infusion.
   (D) a reference (brand) extended-release tablet that is a pharmaceutical equivalent.
   (E) an immediate-release hard gelatin capsule containing the same amount of active drug and lactose.

3. A single-dose, two-way crossover, fasting, comparative bioavailability study was performed in 24 healthy, adult male subjects. Plasma drug concentrations were obtained for each subject, and the results shown in *Table 6-Q3* were obtained. The relative bioavailability of the drug from the generic tablet compared to the reference tablet is

   (A) 82.3%.
   (B) 69.8%.
   (C) 91.7%.
   (D) 96.2%.
   (E) 103.9%.

Table 6-Q3				
Drug Product	Dose (mg)	C_{max} (µg/mL)	T_{max} (hr)	$AUC_{0-\infty}$ (µghr/mL)
IV bolus injection	100			1714
Oral solution	200	21.3	1.2	3143
Generic tablet	200	17.0	2.1	2822
Reference tablet	200	16.5	1.9	2715

IV, intravenous.

Directions for questions 4–6: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, A–E.

A   if **I only** is correct
B   if **III only** is correct
C   if **I and II** are correct
D   if **II and III** are correct
E   if **I, II**, **and III** are correct

4. For two drug products, generic (test) and brand (reference), to be considered bioequivalent,

   I. there should be no statistical difference between the extent of bioavailability of the drug from the test product compared to the reference product.
   II. the 90% confidence interval about the ratio of the means of the C_{max} and AUC values for the test product to reference product must be within 80% to 125% of the reference product.
   III. there should be no statistical differences between the mean C_{max} and AUC values for the test product compared to the reference product.

5. For which of the following products is measuring plasma drug concentrations not appropriate for estimating bioequivalence?

   I. metered-dose inhaler containing a bronchodilator
   II. antifungal agent for the treatment of a vaginal infection
   III. enteric-coated tablet containing a nonsteroidal anti-inflammatory agent

6. Bioequivalence studies compare the bioavailability

   I. of the generic drug product to the brand drug product.
   II. of a reformulated brand drug product to the original formulation of the brand product.
   III. of a to-be-marketed brand product to the drug product used in the clinical trials.

Answers and Explanations

1. **The answer is B** *[see III.B]*.
   AUC relates to the extent of drug absorption. C_{max} and T_{max} relate to the rate of drug absorption. The elimination $t_{1/2}$ of the drug is usually independent of the route of drug administration and is not used as a measure of bioavailability. For the FDA, only the C_{max} and AUC parameters must meet 90% confidence intervals of 80% to 125% of the reference (brand) product (*Table 6-1*).

2. **The answer is C** *[see IV.B]*.
   After an IV bolus injection or IV infusion, the entire dose is absorbed into the body. The ratio of the AUC of the drug given orally to the AUC of the drug given by IV injection is used to obtain the absolute bioavailability (*F*) of the drug.

3. **The answer is E** *[see IV.A]*.
   The relative bioavailability is determined from the ratio of the AUC of the generic (test) product to the AUC of the reference standard. Thus, the relative bioavailability can exceed 100%, whereas the absolute bioavailability cannot exceed 100%. $AUC_{generic}/AUC_{reference} = 2822/2715 = 1.039$ or 103.9%.

4. **The answer is E (I, II, III)** *[see V.C]*.
   Although T_{max} is an indication of rate of drug absorption, it is a discrete measurement and usually too variable to use for statistical comparisons in bioequivalence studies. Statistical comparisons use AUC and C_{max} values from test and reference drug products as the basis of bioequivalence.

5. **The answer is C (I, II)** *[see V.A]*.
   Although some systemic absorption may be demonstrated after administering a metered dose inhaler containing a bronchodilator or a vaginal antifungal agent, bioequivalence can be determined only by using a clinical response measurement.

6. **The answer is E (I, II, III)** *[see I.A–E]*.
   Bioequivalence studies compare the bioavailability of a drug from one drug product to another drug product containing the same active ingredient. Drug products such as capsules that are used in clinical trials should be bioequivalent to the marketed drug product, which may be a tablet. Generic drug products and the corresponding brand drug product must be bioequivalent. For any change in a formulation, the manufacturer (brand or generic) must demonstrate that the formulation change does not affect the bioavailability compared to the original product.

7

Biotechnology Drug Products

SUSANNA WU-PONG

I. INTRODUCTION. Pharmaceutical biotechnology has enabled the creation, modification, and manufacture of recombinant biological products for therapeutic use. Cell lines, recombinant DNA, and highly sensitive and specific analytical methods are now routinely used to design, discover, and evaluate highly specific new drugs, imaging agents, and diagnostics.

- **A.** Currently available biological drugs primarily fall into two categories: nucleic acid or protein/peptide drugs.
  - **1. Nucleic acid drugs.** Macromolecular nucleic acid drugs include oligonucleotides and other compounds still in clinical trials, such as gene therapy or microRNAs.
  - **2. Protein drugs.** Protein and peptide drugs include **monoclonal antibodies** (mAbs) and recombinant proteins. mAbs are also used as imaging and targeting agents.
- **B.** Biological drugs are manufactured usually using engineered cells or recombinant methods in vitro, although smaller molecules may be chemically synthesized. Such cell- and gene-based methods are distinctly different from chemical synthetic techniques used to manufacture most small-molecule drugs; the manufacturing process and materials used for biologic products are intricately linked to the quality and properties of the product, even when identical gene sequences are being expressed. Several examples of differences in adverse reactions have been reported for the same recombinant proteins (erythropoietin, interferon-β1a, and botulism A toxin) made by different manufacturers or using slightly different processes or materials.
- **C.** Recombinant DNA techniques are used to design and produce protein drugs and many of the emerging nucleic acid drugs. Therefore, these biologic products can be engineered to a specific sequence and/or structure.
- **D.** Biologic drugs are biological products, so they have unique challenges in the areas of stability, delivery, formulation, and analysis. Protein drugs and products are dependent on having correct protein structure for activity and are often active in very low concentrations. Thus, formulation, storage, and analysis must be able to differentiate, preserve, and measure the active protein in low concentrations.
- **E.** Most biologic products should be refrigerated at 2° to 8°C and should not be frozen, shaken, or exposed to light. Products must be used within a specified time after dilution. Specific product information should always be consulted before storage or use.

II. BASIC TERMINOLOGY

- **A.** An **antigen** is a substance or molecule that stimulates the production of antibodies by the immune system.
- **B.** An **antibody** is an immunoglobulin molecule that is produced by the immune system after stimulation from an antigen. The plasma contains a mixture of antibodies synthesized to bind many different antigens (**polyclonal** antibodies). **Monoclonal antibodies** are produced in vitro and consist of copies of a single antibody that binds a single epitope. Antibodies are part of the body's immune system, which identifies and neutralizes foreign molecules.

C. **Antisense** refers to synthetic and chemically modified DNA or RNA molecules designed to bind and inhibit complementary, or sense, RNA molecules.

D. **Colony-stimulating factors** (**CSFs**) are glycoproteins that regulate the differentiation and proliferation of hematopoietic stem cells into white cells.

E. **Cytokines** are a group of secreted proteins that cause a signaling response to influence cell function in other cells (also see **hormones** in later discussions).

F. **DNA** (deoxyribonucleic acid) is a double-helix, nucleic acid polymer coding genetic information of a cell. DNA consists of four deoxynucleotide subunits: adenosine, guanosine, cytidine, and thymidine.

G. An **enzyme** is a molecule, usually a protein, that catalyzes the conversion of a substrate to a product.

H. An **epitope** is the portion of an antigen that is recognized by an antibody in immune system.

I. A **gene** is a unit of heredity composed of a segment of DNA that is transcribed into RNA.

J. A **genome** is all of the genetic information in a cell or organism.

K. A **glycoprotein** is a protein molecule conjugated to a carbohydrate group.

L. Similar to cytokines, a **hormone** is an endogenous substance that is secreted by one type of cell and causes a response in another type of cell. The current distinction between a hormone and a cytokine may only be their active concentration ranges (10^{-9} M for hormones, 10^{-12} M for cytokines).

M. To **humanize** refers to genetically engineering a protein to modify the sequences that express nonhuman epitopes to be more similar to human variants.

N. A **hybridoma** is a hybrid cell designed to secrete a single antibody (Ab) that binds only one epitope (i.e., an mAb) and produced by fusing a myeloma cell and an antibody-producing B lymphocyte.

O. **Interferons** (**IFNs**) are glycoproteins produced by animal cells used to stimulate the immune response to viral or bacterial infection.

P. **Interleukins** (**ILs**) are cytokines released by white cells and other cell types in response to antigen and other stimulation whose function is primarily to regulate the immune system.

Q. A **lymphokine** is a cytokine produced by a lymphocyte. ILs 2-6 and TNF-γ are examples of lymphokines.

R. An **oligonucleotide** is a short, usually single-stranded DNA or RNA molecule used to identify or inhibit a protein or mRNA molecule.

S. **Pegylated** refers to containing a conjugate of **polyethylene glycol** (PEG). PEG conjugation reduces glomerular filtration so it is often used to extend the half-life of drugs cleared by renal excretion.

T. **Polymorphism** refers to natural sequence variants of a gene.

U. A **plasmid** is a circular piece of nonchromosomal DNA that can replicate independently. Plasmids are used as vectors for the transfer and expression of rDNA.

V. **RNA** (ribonucleic acid) is a polymeric macromolecule made of ribonucleotide subunits that is used for gene regulation. RNA exists in cells as ribosomal (rRNA), transfer (tRNA), microRNA (miRNA), and messenger (mRNA). RNA also comprises the genetic material of some viruses (known as **retroviruses**).

W. **Recombinant DNA** (**rDNA**) are hybrid DNA molecules formed when DNA fragments from different sequences are joined using restriction endonucleases.

X. A **restriction endonuclease** is an enzyme that cleaves DNA in a sequence-specific manner. Restriction enzymes are used in rDNA technology.

Y. **Reverse transcriptase** is an enzyme used by RNA viruses to transcribe viral RNA into DNA.

Z. **Tumor necrosis factor** (**TNF**) is a lymphokine produced by macrophages to induce cell death.

III. PROTEINS AND PEPTIDES

A. **Native proteins.** Proteins and peptides are essential for cell structure and function. These amino acid polymers generally require maintenance of their primary structure as well as secondary, tertiary, and quarternary structures to retain their function and activity. In addition, posttranslational modifications such as glycosylation may be necessary for activity or in vivo properties.

B. **Protein drugs.** Recombinant proteins have become the fastest growing class of pharmaceuticals and have quickly replaced many animal sources for therapeutic agents, such as bovine insulin. Recombinant proteins such as **recombinant human insulin** are used to supplement or replace proteins that are inactive or expressed in insufficient quantity in the body. Some proteins may be naturally expressed in the body, but also given pharmacologically in therapeutic doses to elicit a desired

therapeutic effect, such as **thrombolysis**. Clinicians should understand recombinant proteins' unique properties and requirements for storage, use, and administration because—as biological molecules—they are large, complex, and unstable compared to traditional small-molecule drugs.

IV. IMMUNOGLOBULIN (Ig) AND mAbs

A. Overview

1. Immunoglobulins are glycoprotein antibodies, an important component of the immune system. Polyclonal serum IgGs have been used for many years to provide passive immunity to patients. In contrast, mAbs have more recently been developed to provide purified antibodies that bind a single epitope on an antigen. These mAbs are usually derived from mouse hybridoma cells and, therefore, are proteins of mouse origin, although human mAbs are now made from hybridomas from transgenic mice.

2. mAbs have primarily been developed to **target** cancer cells and for autoimmune diseases such as **rheumatoid arthritis**. mAbs act as antagonists (such as TNF-α blockers) by binding to antigen and/or by binding to cell surface markers on target cells and inducing cell death by **antibody-dependent**, **cell-mediated cytotoxicity** and **complement-dependent cytotoxicity**. Most of the mAb products may have severe side effects. See *Table 7-1* for a list of black box warnings.

3. Because the original mAbs were of mouse origin and therefore immunogenic, newer generation mAbs are genetically engineered to modify the mouse regions to appear more "**humanized**." mAb nomenclature indicates "-umab" as human (produced using transgenic technology), "-ximab" as chimeric, and "-zumab" as humanized (*Table 7-1*).

B. Examples

1. **Abciximab** (ReoPro®) is a chimeric human-murine monoclonal antibody Fab fragment that inhibits platelet aggregation by binding platelet glycoprotein IIb–IIIa receptors. Abciximab is used for **myocardial infarction**, **ischemia**, and **angina**. The recommended dosage for myocardial infarction is a 0.25 mg/kg IV bolus over 5 mins, then 0.125 mcg/kg/min (maximum of 10 mcg/min) for 12 hrs with fibrinolytic treatment. Platelet aggregation is almost completely inhibited 2 hrs after the initiation of abciximab therapy. The major complication of abciximab infusion is dose-related bleeding.

2. **Adalimumab** (Humira®) is a human mAb that binds TNF-α and in the presence of complement lyses cells that express surface TNF-α. Adalimumab is used to treat **autoimmune disorders**, such as **Crohn's disease**, **psoriatic arthritis**, and moderate-to-severe **rheumatoid arthritis**. The maintenance dose is 40 mg SQ every other week but begins with a 160-mg taper in Crohn's disease. Humira® has a black box warning for increased infections and possibly cancer in children, adolescent, and young adult male patients. Patients should report signs of infection, persistent fevers, night sweats, or weight loss.

3. **Alemtuzumab** (Campath-1®) is used for **immunosuppression** in organ transplant by targeting CD52 on T cells and monocytes. Campath-1® is also used to treat chronic **lymphocytic leukemia** and **T-cell prolymphocytic leukemia** where it is dosed 3 g daily as 2-hrs IV infusions, then increased to 30 mg three times per week when tolerated. Serious, even fatal, cytopenias and infections can result from using this drug.

4. **Muromonab-CD3** (Orthoclone-OKT3®) is an immunosuppressive mAb targeted to the CD3 glycoprotein on human T cells. Lymphocytes containing CD3, CD4, CD8, and CD11 levels fall quickly after administration, and after 2 to 7 days, lymphocytes containing CD4, CD8, and CD11 return to circulation. Muromonab-CD3 is used to reverse **acute renal allograft rejection**. Severe side effects have been reported including anaphylaxis, pulmonary edema, shock, cardiac arrest, seizures, and coma. Patients should be premedicated with methylprednisolone to minimize symptoms of cytokine release syndrome. CD3 positive cells and muromonab-CD3 levels (≤ 800 ng/mL) should be monitored during therapy.

5. **Bevacizumab** (Avastin®) is a humanized mAb that binds **VEGF** (vascular endothelial growth factor), thus inhibiting **angiogenesis** in metastatic tissue. Bevacizumab is used to treat **metastatic colorectal cancer** and **nonsquamous**, **non-small cell lung cancer**; **HER-2 negative breast cancer**; **progressive glioblastoma**; and **metastatic renal cell cancer**. Unlabeled uses include **age-related macular degeneration**, **recurrent ovarian and cervical cancer**, and **soft tissue sarcomas**. Doses range from 5 to 15 mg/kg IV every 2 to 3 weeks.

Table 7-1 THERAPEUTIC mAbs

Antibody	Brand Name	Type	Target	Warnings	Indication
Abciximab	ReoPro®	Chimeric	Glycoprotein IIb/IIIa	—	Cardiovascular disease
Adalimumab	Humira®	Human	TNF-α	Risk for fatal infections, malignancies especially in children, adolescents, and young adult males	Autoimmune disorders
Alefacept	Amevive®		CD2	—	Psoriasis
Alemtuzumab	Campath®	Humanized	CD52	Risk for hematologic toxicity, infection, infusion reactions	Chronic lymphocytic leukemia
Basiliximab	Simulect®	Chimeric	IL-2Rα receptor (CD25)	Should be administered by transplant physician	Transplant rejection
Bevacizumab	Avastin®	Humanized	VEGF	Risk for GI perforation, hemorrhage, wound-healing complications	Colorectal cancer
Cetuximab	Erbitux®	Chimeric	EGF receptor	Risk for cardiopulmonary arrest in patients also receiving radiation therapy, infusion reactions	Colorectal cancer, head and neck cancer
Certolizumab pegol	Cimzia®	Pegylated humanized	TNF-α	Risk for T-cell lymphoma, infection risk, evaluate for tuberculosis	Crohn's disease
Daclizumab	Zenapax®	Chimeric humanized	IL-2Rα receptor (CD25)	Should be administered by transplant physician	Transplant rejection
Eculizumab	Soliris®	Humanized	Complement system protein C5	Risk for meningococcal infection	Paroxysmal nocturnal hemoglobinuria
Gemtuzumab ozogamicin	Mylotarg®	Humanized	CD33	—	Acute myeloid and promyelocytic leukemia
Ibritumomab tiuxetan	Zevalin®	Murine (with ^{90}Y or ^{111}In)	CD20	Risk for cutaneous and mucocutaneous reactions, cytopenia, infusion reaction	Non-Hodgkin lymphoma
Infliximab	Remicade®	Chimeric	TNF-α	Risk for fatal infections, malignancies especially in children, adolescents, and young adult males	Autoimmune disorders
Muromonab-CD3	Orthoclone OKT3®	Murine	T-cell CD3 receptor	Risk for anaphylaxis, should be administered by transplant physician	Transplant rejection
Natalizumab	Tysabri®	Humanized	α4-Integrin	Risk for progressive multifocal leukoencephalopathy (PML)	Multiple sclerosis and Crohn's disease
Omalizumab	Xolair®	Humanized	IgE on mast cells and basophils	Risk for anaphylaxis	Allergic asthma
Palivizumab	Synagis®	Humanized	RSV	—	Respiratory syncytial virus
Panitumumab	Vectibix®	Human	EGF receptor	Risk for dermatologic toxicity (90% of patients), infusion reaction	Refractory metastatic colorectal cancer
Ranibizumab	Lucentis®	Humanized	VEGF-A	—	Macular degeneration
Rituximab	Rituxan® MabThera®	Chimeric	CD20	Risk for infusion reactions, mucocutaneous reactions, PML	Chronic lymphocytic leukemia
Tositumomab and ^{131}I tositumomab	Bexxar®	Murine	CD20	Radioisotope; risk for anaphylaxis, bone marrow suppression, and fetal toxicity	Non-Hodgkin lymphoma
Trastuzumab	Herceptin®	Humanized	Human EGFR	Risk for cardiotoxicity, pulmonary toxicity, infusion reactions, and fetal toxicity	HER-2 positive breast cancer and gastric adenocarcinoma

TNF, tumor necrosis factor; IL, interleukin; GI, gastrointestinal; Ig, immunoglobulin; VEGF, vascular endothelial growth factor; EGF, epidermal growth factor; EGFR, epidermal growth factor receptor; RSV, respiratory syncytial virus.

6. **Infliximab** (Remicade®) is a chimeric mAb that binds and inhibits TNF-α. Infliximab is used to treat Crohn's disease and has an onset of action of about 2 weeks and elimination half-life of 7 to 12 days. The drug is infused over 2 or more hrs at 3 to 5 mg/kg starting at 0, 2, and 6 weeks, then every 8 weeks thereafter. The drug is also used to treat other autoimmune diseases such as rheumatoid arthritis.

7. **Rituximab** (Rituxan®) is an mAb targeted to the CD20 major histocompatibility protein on B lymphocytes. It is used to treat cancers such as **CD20-positive non-Hodgkin lymphoma** and also **rheumatoid arthritis**. The elimination half-life is 18 to 78 days depending on the disease and the patient.

V. CYTOKINE IMMUNOMODULATORS

A. **Overview**

1. Cytokine immunomodulators include **colony-stimulating factors**, **interleukins**, **interferons**, **chemokines**, and **thymic hormones**.

2. CSFs are **glycoprotein** cytokines that regulate the production, differentiation, and activation of hematopoietic cells in the body. These include **macrophages**, **megakaryocytes**, **eosinophils**, **neutrophils**, **basophils**, and **platelets**. **Erythropoietin** stimulates red cell production and is in the CSF class. Natural and modified CSFs are used to treat several **congenital disorders** and several forms of cancer.

3. **Interleukins** are proteins secreted by leukocytes that mediate communication between leukocytes. IL actions are similar to TNF but without the ability to produce septic shock symptoms.

4. **Interferons** are secreted in response to infection. In combination with other cytokines, IFNs participate in the immune response to infection. IFN-α and IFN-β are produced by leukocytes and fibroblasts and act in the antiviral immune response, whereas IFN-γ is secreted by T lymphocytes to stimulate macrophages and innate immunity.

5. **Tumor necrosis factor** is secreted in response to bacterial lipopolysaccharide and then recruits neutrophils and monocytes to the site of infection. TNF also mediates the symptoms of **septic shock**, characterized by intravascular collapse and disseminated intravascular coagulation.

B. **Examples**

1. **Darbepoetin alfa** (Aranesp®) and **epoetin alfa** (Epogen® and Procrit®) are recombinant human erythropoietin used for the treatment of **anemia** associated with **chronic renal failure** (darbepoetin or epoetin) or HIV (epoetin). Erythropoiesis-stimulating agents should be used as hemoglobin falls below 10 g/dL. Some recombinant human erythropoietin's in vivo properties are product dependent. Darbepoetin's half-life (21 hrs) is approximately three times longer than epoetin (4 to 13 hrs) when administered IV.

2. **Filgrastim** (Neupogen®) is recombinant hG-CSF (human granulocyte colony-stimulating factor) used for severe, chronic **neutropenia,** neutropenia associated with chemotherapy and for **bone marrow transplant**. hG-CSF and filgrastim both promote the proliferation, differentiation, maturation, and activation of neutrophils. Onset of action is within 24 hrs, levels return to baseline within 4 days. **Pegfilgrastim** (Neulasta®) is **pegylated** filgrastim with a half-life of 15 to 80 hrs compared to 3.5 hrs for the unpegylated filgrastim.

3. **Aldesleukin** (Proleukin®), a lymphokine, is a human recombinant IL-2 product that is used to treat **metastatic renal cell carcinoma** and **metastatic melanoma**. The starting dose is 600,000 IU/kg every 8 hrs by a 15-mins intravenous infusion for no more than 14 doses, then repeated after 9 days. Aldesleukin follows two-compartment pharmacokinetics, with an α-half-life of 6 to 13 mins and a β-half-life of 80 to 120 mins, and is excreted renally. The drug has several black box warnings including risk for capillary leak syndrome, severe central nervous system (CNS) effects, and infection, and should not be used in patients with cardiopulmonary disease.

4. **Etanercept** (Enbrel®) is a dimeric soluble form of the TNF receptor that binds both TNF-α and TNF-β. Like Humira®, Enbrel® is used for autoimmune disorders such as Crohn's disease and rheumatoid arthritis, given as 50-mg weekly injections, either as a single or divided dose. Patients taking Enbrel® are at increased risk for infection.

5. **Interferon-β** (Betaseron®, Extavia®) differs from naturally occurring IFN-β in its lack of carbohydrate side chains and a single amino acid substitution. Many of its effects are similar to those of IFN-α. Betaseron® is used to treat **multiple sclerosis** (**MS**), dosed at 0.0625 mg SQ every other day for relapsing MS (0.125 mg for secondary progressive MS), slowly increasing to a target dose of 0.25 mg every other day. Common side effects include lymphopenia (88%), injection site reaction (85%), headache (5%), muscle weakness (61%), and flulike syndrome (60%).

6. **Interferon β-1a** (Avonex®, Rebif®) is human recombinant IFN β-1a and used for relapsing multiple sclerosis. Avonex is dosed 30 mcg IM once weekly; Rebif® is dosed SQ three times weekly titrating up to 44 or 22 mcg/week.

7. **Interferon-γ** (Actimmune®) is human recombinant IFN-γ and plays a role in macrophage-induced killing. Recombinant IFN-γ is used to treat **chronic granulomatous disease**. Actimmune® has a half-life of 38 mins when given IV, 4 hrs when given IM, and 7 hrs when given SQ.

8. **Sargramostim** (Leukine®) is a GM-CSF used for myeloid reconstitution after **bone marrow transplant or chemotherapy**. Nausea (58% to 70%), diarrhea (< 89%), vomiting (46% to 70%), and fever (81%) are the most common side effects. The onset of action is 7 to 14 days before changes in white blood cell (WBC) levels are measurable.

VI. PLASMA PROTEINS, COAGULATION, FIBRINOLYSIS

A. **Overview**. The human plasma is rich in proteins such as **albumin** that are designed to maintain osmotic balance, acid–base balance, viscosity of the plasma, act as a protein reserve for the body, and transport insoluble molecules such as vitamins and hormones via plasma protein binding. In addition, immune globulins are present in high concentration in the plasma as part of immune surveillance (see antibodies, discussed earlier). Also, **fibrinogen** is an important plasma protein involved in blood clotting. Several key proteins have been made available by recombinant methods for either replacement therapy or given in therapeutic doses for their pharmacologic activity.

B. **Proteins providing pharmacologic activity**
1. **Alteplase** (Activase®, Cathflo®) is a **thrombolytic** agent also known as **tissue plasminogen activator**. Intravenous alteplase lyses thrombi in coronary arteries after ST-elevation **myocardial infarction**, **acute ischemic stroke** (within 3 hrs of onset of symptoms), or **pulmonary embolism**. An unlabeled use is for **acute ischemic stroke** presenting 3 to 4.5 hrs after onset of symptoms. The drug is given as a bolus dose over 1 to 2 mins or over 2 hrs for pulmonary embolism. Practitioners should avoid agitation during dilution. **Bleeding complications** and **reperfusion arrhythmias** are the primary adverse events associated with this therapy. Other examples of thrombolytics include **reteplase** (Retavase®) and **tenecteplase** (TNKase®).

2. **Desirudin** (Iprivask®) inhibits thrombin and is used as an **anticoagulant**. Specifically, it is used for **DVT** prophylaxis and is dosed 15 mg SQ every 12 hrs. Bleeding is the most common adverse reaction with anticoagulants. Other thrombin inhibitors include **lepirudin** (Refludan®) and **bivalirudin** (Angiomax®).

C. **Proteins for replacement therapy**. **Protein C** is available in recombinant form as an anticoagulant for congenital protein C deficiency. **Antihemophilic factors VIIA, VIII, and IX** are also available in recombinant forms in the treatment of patients with hemophilia.

VII. MISCELLANEOUS OTHER PROTEIN DRUGS

A. **Enzymes**. Many congenital disorders result in insufficient or inactive enzyme expression. As a result, recombinant technology is perfectly suited to design drugs for replacement therapy. Examples of these types of drugs include **alglucosidase** for **Pompe disease**, **Pulmozyme** for **cystic fibrosis**, **galsulfase** for **Maroteaux–Lamy syndrome**, **imiglucerase** for **Gaucher disease**, **laronidase** for **Hurler syndrome**, PEG-ADA (pegylated adenosine deaminase) for **ADA deficiency**, and **idursulfase** for **Hunter syndrome**. Some enzyme drugs are used for their pharmacologic properties, such as **glucarpidase** for **methotrexate overdose**, **pegloticase** (pegylated uricase; half-life: 10 to 12 days) for **gout**, and **rasburicase** (uricase; half-life: 8 hrs) to manage uric acid levels in some malignancies.

B. **Hormones**. Congenital defects also can result in insufficient or inactive hormone synthesis or be administered in therapeutic doses to elicit a pharmacologic effect. **Parathyroid hormone (teriparatide)**, **insulin-like growth factor (mecasermin)**, and **platelet-derived growth factor (becaplermin)** are available in recombinant forms for hormone supplement. **Gonadotropin (follitropin-α, follitropin-β, leutropin, urofollitropin)** is also used to stimulate ovulation.

1. **Somatropin** (Genotropin®, Humatrope®, Norditropin®, Nutropin®, Omnitrope®, Saizen®, Serostim®, Tev-Tropin®, Zorbtive®) is recombinant human growth hormone. The most common side effect of somatropin is edema, arthralgias, and myalgias. Many manufacturers produce this protein, and each is dosed differently because of their different SQ bioavailabilities (product dependent, ranging from 70% to 90%) and formulations (*Table 7-2*). A now-discontinued growth hormone

Table 7-2 SOMATROPIN COMPARISONS

Trade (Manufacturer) Cell Line	Adult GH Deficiency	Pediatric GH Deficiency	Other Indications	Formulation
Genotropin® (Pfizer) *Escherichia coli*	0.15–0.3 mg/d SQ; increase by 0.1–0.2 mg/d every 1–2 mo	*GH deficiency:* 0.16–0.24 mg/kg/wk SQ × 6–7 doses/wk	*Turner syndrome:* 0.33 mg/kg divided into equal doses 6–7 d/wk; *Decreased body growth:* 0.24 mg/kg/wk SQ × 6–7 d/wk	*Miniquick (disposable premeasured syringe):* no refrigeration; *Pen (reusable pen):* refrigerate; *Mixer (reusable, automatic mixer):* refrigerate
Humatrope® (Lilly) *E. coli*	0.15–0.3 mg/d SQ; increase by 0.1–0.2 mg/d every 1–2 mo	0.18–0.3 mg/kg/wk SQ	*Turner syndrome:* 0.375 mg/kg divided into equal doses 6–7 d/wk; *SHOX deficiency:* 0.35 mg/kg divided into equal doses 6–7 d/wk	Injection powder for solution; SQ powder for solution
Norditropin® (Novo Nordisk) *E. coli*	0.15–0.3 mg/d SQ; increase by 0.1–0.2 mg/d every 1–2 mo	0.024–0.34 mg/kg/d SQ × 6–7 d/wk	*Turner syndrome:* up to 0.067 mg/kg/d	*FlexPro:* SQ solution; *Nordiflex (prefilled):* no refrigeration after initial use; *PenMate (needle-free):* SQ solution
Nutropin®, Nutropin AQ® (Genentech) *E. coli*	0.15–0.3 mg/d SQ; increase by 0.1–0.2 mg/d every 1–2 mo	0.3 mg/kg/wk SQ × 6–7 d/wk up to 0.7 mg/kg/wk for pubertal patients	*Turner syndrome:* ≤ 0.375 mg/kg divided into equal doses 3–7 d/wk	*AQ NuSpin 5 (prefilled automatic):* SQ solution; *AQ Pen cartridge:* SQ solution *Nutropin:* powder; *Nutropin AQ:* SQ solution
Omnitrope® (Sandoz) *E. coli*	< 0.04 mg/kg/wk SQ in divided dose; may increase to < 0.08 mg/kg/wk	0.16–0.24 mg/kg/wk SQ × 6–7 d	*Decreased body growth:* 0.24 mg/kg/wk SQ × 6–7 d/wk	SQ powder; SQ solution
Serostim® (EMD Serono) mammalian cell			*AIDS-associated cachexia:* body weight < 35 kg, 0.1 mg/kg SQ; otherwise 4–6 mg SQ	SQ powder store at room temperature prior to reconstitution; discard after reconstitution
Saizen® (EMD Serono) mammalian cell	0.005 mg/kg/d SQ or IM; after 4 wks, may adjust to ≤ 0.01 mg/kg/d	0.6 mg/kg SQ or IM 3 × per wk		*Cool Click (needle-free); Easypod (automated device)* Store powder at room temperature; refrigerate after reconstitution
Tev-Tropin®		0.1 mg/kg SQ, 3 × per wk		Store powder at room temperature; refrigerate after reconstitution
Zorbtive® (EMD Serono) *E. coli*			*Short bowel syndrome:* 0.1 mg/kg SQ daily for 4 wks; increase to ≤ 8 mg/d	SQ powder

From Page AV, Caplan ES. Immunomodulators. In: Mandell GL, Bennett JE, Dolin R, eds. *Mandell, Douglas, and Bennett's Principles and Practice of Infectious Diseases.* 7th ed. Philadelphia, PA: Churchill Livingstone; 2010:611–624.

product contained an extra methionine amino acid at the N-terminus (Protropin®). **Growth hormone** antagonist (**pegvisomant**) is a pegylated growth hormone analog used in the treatment of **acromegaly** where growth hormone is overproduced.

2. **Insulin** (Humulin® R, Humulin® R U-500, Novolin®) is regular, short-acting human recombinant insulin used to treat diabetes mellitus. Insulin is either given as regular insulin SQ boluses (baseline plus bolus dosing) or via dosing two to three times per day using a mixture of regular and intermediate-acting isophane insulin, also known as NPH insulin (Humulin® N, Iletin® I NPH, Iletin® II NPH, Novolin®, Novolin® N Innolet®, ReliOn N, ReliOn N Innolet®). **NPH insulin** is insulin modified with zinc and protamine to promote dimer and hexamer formation, resulting in prolonged absorption and action. The disadvantage of NPH insulin is variable absorption but it does have a long clinical history compared to other types of insulin. Lente insulin is another type of intermediate-acting insulin product. Other insulin forms, such as rapid acting (semilente insulin, insulin aspart, insulin glulisine, and insulin lispro) or long acting (ultralente insulin insulin detemir, insulin glargine, protamine-zinc insulin), are also used in various combinations to individualize glucose control. **Insulin pumps** are also used for continuous infusion of basal insulin and also boluses at meals but must be changed every 3 days. **Inhaled insulin** (Exubera®) is no longer on the market.

VIII. MACROMOLECULAR NUCLEIC ACID DRUGS

A. **Background**
1. **DNA** (deoxyribonucleic acid) is a polymeric, double-stranded helix that comprises the genetic material of all organisms. DNA is transcribed into **RNA** (ribonucleic acid), which is translated into protein. DNA sequences can be modified with high accuracy using recombinant DNA technology. **Restriction endonucleases** are key tools for sequence-specific modification and recombination of DNA.
2. **Viruses**' genetic material may consist of either RNA or double-stranded or single-stranded DNA. RNA viruses, or retroviruses, use reverse transcriptase to transcribe their genome into DNA.
3. The **Human Genome Project** was designed to sequence the human genome. Other technologies using high-throughput sequencing have also been useful to sequence individual genes and their variants. Knowledge of the role of these genetic variants, or **polymorphisms**, are useful for better understanding disease etiology and for the development of new, more specific drugs.

B. **Oligonucleotide drugs**
1. **Background**. Oligonucleotide drugs are single-stranded DNA or RNA molecules that are usually chemically modified to improve in vivo stability and cellular uptake. They are used to block gene expression or act as substrate inhibitors. **Antisense** drugs bind to or "hybridize to" mRNA complementary sequences to inhibit translation. The primary applications for antisense therapy are cancer or antiviral therapies, but any disease or disorder where inhibition of a specific gene is desired has a potential application. An **aptamer** is an oligonucleotide with secondary structure that binds with high affinity to a substrate in the same manner that a DNA-binding protein binds DNA.
2. **Examples**. **Pegaptanib** (Macugen®) is a $2'$-fluoro, PEG-conjugated, oligoribonucleotide aptamer, which binds to and inhibits VEGF. It is used in the treatment of **age-related macular degeneration**. The drug is administered 0.3 mg intravitreally every 6 weeks and has a plasma half-life of 6 to 14 days. Pegaptanib may cause hypertension or ocular side effects such as conjunctivitis. **Fomivirsen** (Vitravene®) is an antisense phosphorothioate oligonucleotide used to treat HIV patients with **cytomegaloviral** infections in the eye. It is dosed 330 mcg intravitreally every 2 weeks for two doses, then every 4 weeks thereafter. Onset and duration of action is 8 and 10 days, respectively.

C. **Gene therapy**. Despite decades of research and development, and currently more than 1500 clinical trials worldwide, gene therapy therapeutics have not yet been approved by the U.S. Food and Drug Administration (FDA). Scores of gene therapy formulations are in advanced clinical trials, but the technology continues to be plagued by insufficient expression of the therapeutic gene and safety questions. Should this technology finally resolve its development hurdles, the ability to provide therapeutic genes to somatic cells has incredible potential, especially in the areas of cancer, cardiovascular disease, and genetic disorders.

Study Questions

Directions: Choose the **best** answer to each of the following questions.

1. Most biologic drugs are sensitive to all of the following **except**

   (A) heat.
   (B) shaking.
   (C) stainless steel.
   (D) light.

2. Recombinant protein drugs are designed to replicate which of the following types of molecules?

   (A) Antibodies
   (B) Enzymes
   (C) Proteins in the plasma
   (D) All of the above
   (E) None of the above

3. Nucleic acid drugs or drug candidates include which of the following?

   (A) Gene therapy
   (B) Oligonucleotides
   (C) A and B
   (D) None of the above

4. Glycoprotein is a protein linked to _____.

   (A) a carbohydrate
   (B) a nucleotide
   (C) an amino acid
   (D) a lipid molecule
   (E) None of the above

5. Examples of monoclonal antibody drugs include all of the following **except**

   (A) infliximab.
   (B) Herceptin.
   (C) trypsin.
   (D) rituximab.

6. An example of a recombinant cytokine is _____.

   (A) muromonab
   (B) albumin
   (C) oligonucleotide
   (D) interferon
   (E) growth hormone

7. A recombinant protein will have the same in vivo properties if the genetic sequence is the same. This statement is _____.

   (A) always true
   (B) not necessarily true
   (C) always false

8. Monoclonal antibodies are most often used for what type of clinical indications?

   (A) Cancer
   (B) Correcting congenital deficiencies
   (C) Replacement therapy
   (D) Psychiatric disorders
   (E) None of the above

9. Gene therapy _____.

   (A) is a technology that is widely used in patient care
   (B) involves short nucleic acid sequences to inhibit gene expression
   (C) has not been tested in clinical trials
   (D) All of the above
   (E) None of the above

10. Which of the following statements is true for polyethylene glycol (PEG)?

    (A) It is a carbohydrate used to increase clearance of drugs.
    (B) It is conjugated only to recombinant hormones.
    (C) It blocks the renal filtration of drugs.
    (D) It is naturally occurring on many biologic molecules.

Answers and Explanations

1. **The answer is C** *[see I.E.]*.
   Biologic drugs are sensitive to high (and very low) temperatures, agitation, and light.

2. **The answer is D** *[see IV; VI; VII.A.]*.
   Protein drugs are used for protein replacement or for providing pharmacologic activity when used in therapeutic doses. Besides enzymes, plasma proteins, mAbs,

and cytokines, hormones are also classes of proteins that have been made into recombinant drugs.

3. **The answer is C** *[see VIII]*.
   Many macromolecular nucleic acid drugs are in clinical trials and preclinical development, such as miRNA, ribozymes, siRNA, and gene therapy, but only oligonucleotides have become approved drugs at this time. Nucleoside

drugs are small nucleic acid drug molecules and many are in use, especially for antiviral therapy.

4. **The answer is A** *[see II.K]*.
Glycoproteins are made of a carbohydrate linked to a protein.

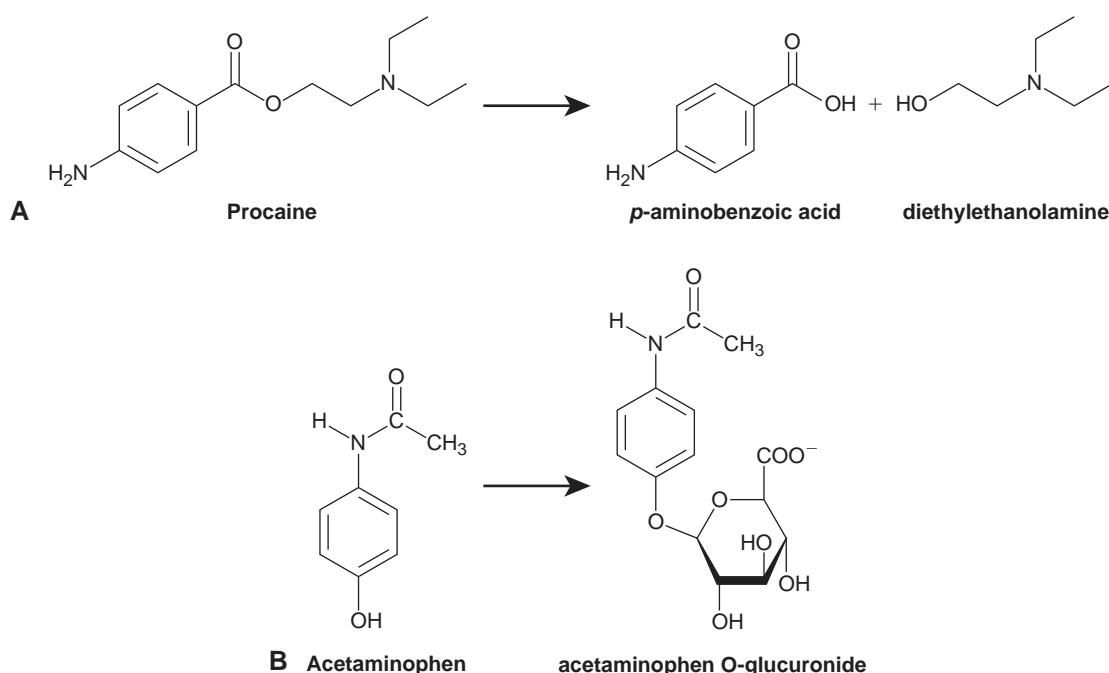
5. **The answer is C** *[see IV.B; Table 7-1]*.
Trypsin is an enzyme that digests proteins. The other drugs listed are examples of mAbs.

6. **The answer is D** *[see V]*.
Muromonab is an mAb, albumin is a plasma protein, oligonucleotides are nucleic acid drugs, and growth hormone is a hormone. Only interferon is considered a cytokine of this list.

7. **The answer is B** *[see I.B; VII.B.1; Table 7-2]*.
Because product quality and even structure are dependent on the manufacturing process (including cell line, equipment, chemicals and their impurities, material handling, etc.), each biologic product is unique even if the original gene sequence used is identical. Therefore, generic versions of biologics are not available; rather, similar products that follow the innovator are called **biosimilars**.

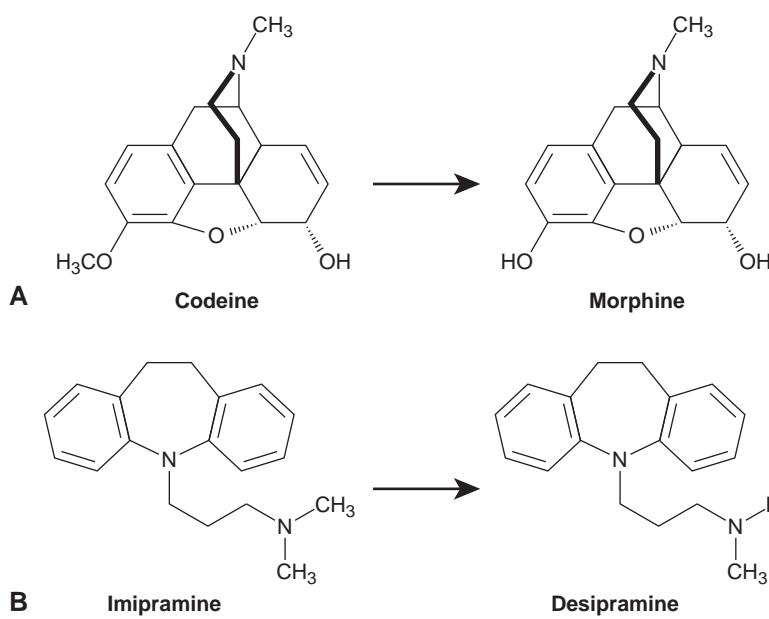
8. **The answer is A** *[see IV.B; Table 7-1]*.
mAbs bind to unique epitopes on specific antigens, which either act as an antagonist to the antigen or employ the immune system to elicit an immune response against the target. Congenital defects in the immune system would result in an overall lack of antibody defense instead of lacking a single antibody type.

9. **The answer is E** *[see VIII.C]*.
Gene therapies are in clinical trials but have not yet been FDA approved. Gene therapy involves delivery of a gene (usually thousands of double-stranded nucleotides in size) compared to an oligonucleotide (15–30 single-stranded nucleotides).

10. **The answer is C** *[see Table 7-1; II.S; V.B.2; VII.A; VII.B.2; VIII.B.2]*.
Polyethylene glycol (PEG) is a synthetic polymer that is conjugated to protein and nucleic acid drugs to increase the half-life and decrease the renal clearance of a drug by glomerular filtration. Many different protein drugs have employed this method to improve the pharmacokinetic properties of the compound, including filgrastim, adenosine deamidase, and anti-TNF antibody.


Drug Metabolism, Prodrugs, and Pharmacogenetics

MICHAEL L. ADAMS, S. THOMAS ABRAHAM

I. INTRODUCTION TO DRUG METABOLISM. *Xenobiotic metabolism* is a general term used to describe the protective biochemical process by which a living organism either enzymatically or nonenzymatically alters a xenobiotic (foreign substance) to a metabolite that is inactive or quickly eliminated from the organism. *Drug metabolism* is a more specific term that applies the concept of xenobiotic metabolism to pharmaceutical agents. In general, drug metabolism begins with a lipophilic drug or substrate and converts it to a more hydrophilic metabolite to facilitate its elimination. There are multiple enzymes and paths that are possible for a single xenobiotic, so it is common for multiple metabolites with varying properties to be observed. An understanding of the drug metabolism process and the potential outcomes is critical for developing safe and useful pharmaceuticals.


II. CONSEQUENCES OF DRUG METABOLISM. In the process of converting a drug to a metabolite, the pharmacological activity of the drug may be changed. Metabolites can be broadly classified as either inactive or active metabolites.

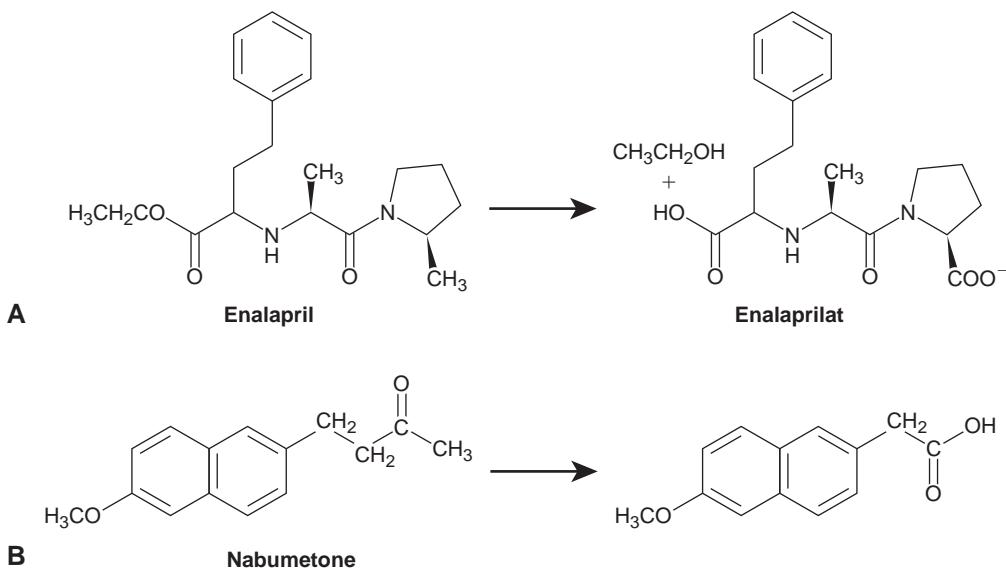
  A. **Inactive metabolites** of drugs are devoid of pharmacological activity that was characteristic of the drug or toxicant. This metabolic change may be considered an **inactivation** or **detoxification**. There may be a disruption in the pharmacophore, the chemical functional groups, and their orientation relative to each other that is required for proper receptor binding or activity, or a change in the distribution of the drug because of the change in the physicochemical properties of the drug that facilitates elimination.
    1. The hydrolysis of procaine (Novocain) to *p*-aminobenzoic acid and diethylethanolamine results in a loss of anesthetic activity (*Figure 8-1A*).
    2. Acetaminophen is glucuronidated on its phenolic hydroxyl group to an inactive metabolite that is rapidly eliminated (*Figure 8-1B*).
  B. **Active metabolites** of drugs have pharmacological activity, which can either be similar to the desired pharmacological activity or a new activity that is absent from the parent drug.
    1. Metabolites with similar pharmacological activity retain the desired biological activity that is inherent in the parent compound.
      a. Codeine is demethylated to the more active analgesic, morphine (*Figure 8-2A*).
      b. Imipramine (Tofranil) is demethylated to the essentially equiactive antidepressant, desipramine (Norpramin) (*Figure 8-2B*).
    2. In the case that the metabolite has the **desired pharmacological activity** although the parent is inactive, the metabolism is called **bioactivation**. The parent compound devoid of pharmacological activity before metabolism is called a prodrug.
      a. The prodrug enalapril (Vasotec) is hydrolyzed to enalaprilat, a potent antihypertensive (*Figure 8-3A*).


Figure 8-1. Examples of metabolism to inactive metabolites. **A.** Ester hydrolysis of the local anesthetic procaine to produce two inactive metabolites. **B.** Glucuronidation of acetaminophen to an inactive metabolite.

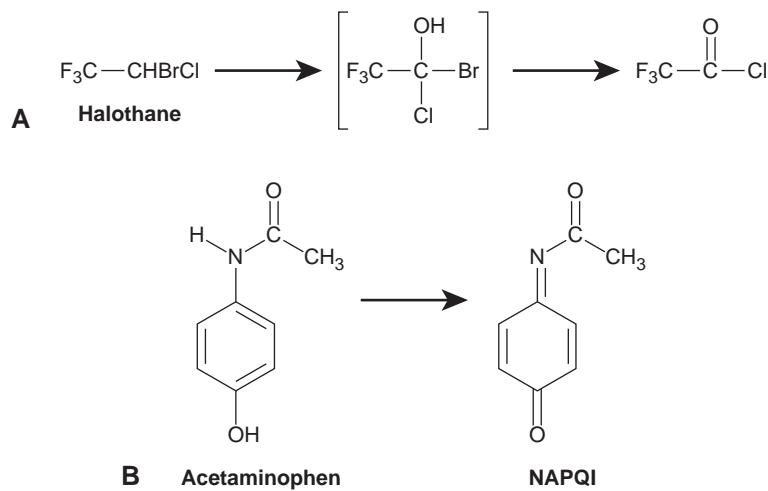
    b. Nabumetone (Relafen) is a prodrug that is oxidized in the body to an active nonsteroidal anti-inflammatory drug (NSAID) (*Figure 8-3B*).
  3. Bioactivation of a drug can also result in a **toxic metabolite**. The parent activated is called a pro-toxicant.
    a. Halothane (Fluothane) is a general anesthetic that is oxidized to a reactive metabolite that is associated with hepatotoxicity (*Figure 8-4A*).
    b. Acetaminophen (Tylenol) can be oxidized into a reactive metabolite, *N*-acetyl-*p*-benzoquinone imine (NAPQI), that can lead to hepatotoxicity (*Figure 8-4B*; Chapter 11, section IV.D.4).


Figure 8-2. Examples of metabolism to metabolites with similar pharmacological activity. **A.** Codeine, a mild analgesic, is metabolized to morphine, a potent analgesic. **B.** Imipramine, a tricyclic antidepressant, is metabolized to the active antidepressant, desipramine.

Figure 8-3. Examples of metabolism of an inactive prodrug to the desired pharmacological activity. **A.** Ester hydrolysis of the prodrug enalapril to the active enalaprilat. **B.** Oxidation of the ketone on the prodrug nabumetone to the active nonsteroidal anti-inflammatory carboxylic acid.

III. METABOLIC PATHWAYS.
Drug metabolism is performed by a large number of different enzymes and even by some nonenzymatic processes. The liver is the organ with the highest concentration of drug-metabolizing enzymes because of its localization between the gastrointestinal (GI) tract, where the body has the highest exposure to foreign substances, and the systemic circulation. The enzymes involved in drug metabolism can be classified by several different categories. The enzymes can either be localized in the cytosol (cytosolic) or the endoplasmic reticulum (ER) membrane (microsomal) portion of the cell. A general classification of enzymatic processes based on the type of reactions involved includes **phase I** and **phase II**.

A. **Phase I metabolism** is characterized as a **functionalization reaction**. Phase I reactions add or reveal a polar functional group on a substrate by oxidation, reduction, or hydrolysis. The addition of the polar group **increases** the overall **polarity** of the metabolites to increase water solubility and facilitate excretion in the urine. Many phase I metabolites are substrates for phase II reactions (see II.B).

1. **Oxidation** is the most common phase I reaction. Several phase I oxidation reactions are further described later and illustrated in *Table 8-1*.

Figure 8-4. Examples of metabolism of active drugs to toxic metabolites. **A.** Halothane, a general anesthetic, is metabolized to a reactive metabolite associated with hepatotoxicity. **B.** Acetaminophen, an antipyretic, is metabolized to the reactive metabolite, NAPQI, associated with hepatotoxicity.

Table 8-1   COMMON OXIDATION REACTIONS

Reaction (Enzyme)	Examples
Aliphatic hydroxylation (CYP450)	Tolbutamide
Allylic hydroxylation (CYP450)	
Benzylic hydroxylation (CYP450)	Tolbutamide
Aromatic hydroxylation (CYP450)	Phenytoin
Epoxidation (CYP450)	Carbamazepine
O-Dealkylation (CYP450)	Codeine to morphine (see *Figure 8-2A*)
S-Dealkylation (CYP450)	
S-Oxidation (CYP450 or FMO)	Ranitidine
N-Dealkylation (CYP450)	Imipramine to desipramine (see *Figure 8-2B*)
N-Oxidation (FMO or CYP450)	Nicotine
Deamination (CYP450 or monoamine oxidase)	Amphetamine
Dehalogenation (CYP450)	Halothane (see *Figure 8-4A*)
Alcohol oxidation (*1*) (alcohol dehydrogenase) Aldehyde oxidation (*2*) (aldehyde dehydrogenase)	Ethanol Acetaldehyde Acetic Acid
Oxidation (xanthine oxidase)	6-Mercaptopurine

FMO, Flavin-containing monooxygenase; *CYP450,* Cytochrome P450s.

2. **Cytochrome P450** (CYP450) is a superfamily of mixed function oxidases that are responsible for the majority of oxidation reactions.

   a. CYP450 is classified as a **microsomal enzyme** and in the cell is bound to the ER. CYP450 is found in very **high concentrations in the liver** and to a lesser extent in the intestinal mucosa, lungs, and kidneys. CYP450 is dependent on the porphyrin prosthetic group, commonly called the heme group, and NADPH to metabolize a wide array of substrates to numerous metabolites. Common CYP450 reactions are illustrated in *Table 8-1*.

   b. There are **several isoforms of CYP450** responsible for drug metabolism, which gives wide substrate specificity to the family of CYP450 enzymes. Each isoform has different substrate specificities based on the size and amino acid composition of the CYP450 active site. The **nomenclature** for the CYP450 enzymes is based on **amino acid homology** and divides the CYP450's into **families** designated by an Arabic number, **subfamilies** designated by a letter, and individual genes designated by an Arabic number preceded by "CYP." For example, CYP3A4 is an example where the family is 3, the subfamily is A, and the individual gene is 4. The CYP450 families most responsible for drug metabolism include CYP1, CYP2, CYP3, and CYP4 with subfamilies CYP2C, CYP2D, and CYP3A metabolizing most drugs. CYP families CYP7, CYP11, CYP17, CYP19, CYP21, and CYP27 contribute to steroid and bile acid synthesis and metabolism required for homeostasis.

3. **Flavin-containing monooxygenase** (FMO) is a family of **microsomal phase I** drug-metabolizing enzymes responsible for the oxidation of N- and S-containing soft nucleophile substrates with metabolites similar to CYP450 metabolites (see *Table 8-1*).

4. **Alcohol dehydrogenase** is a **cytosolic** enzyme that oxidizes alcohols into aldehydes (from primary alcohols) or ketones (from secondary alcohols). This oxidation is reversible and is frequently observed in primary alcohols where the aldehyde can be further oxidized to a carboxylic acid (see Aldehyde Dehydrogenase, III.A.5).

5. **Aldehyde dehydrogenase** is a general name for a group of enzymes expressed both in the mitochondria and the cytosol that is responsible for oxidizing an aldehyde to a carboxylic acid. A common reaction performed by an aldehyde dehydrogenase and aldehyde oxidase is the conversion of acetaldehyde to acetic acid in the metabolism of ethanol.

6. **Xanthine oxidase** and **xanthine dehydrogenase** are the two forms of the same gene product that are responsible for the breakdown of **endogenous purines**. Xanthine oxidase is a cytosolic enzyme that contributes to the metabolism of the purine anticancer drugs (i.e., 6-mercaptopurine) and other xanthines including caffeine and theophylline. Xanthine oxidase is also inhibited by antigout drugs like allopurinol (Zyloprim) to slow the production of uric acid from purines.

7. **Monoamine** and **diamine oxidase** are mitochondrial enzymes that metabolize amines to aldehydes through an **oxidative deamination** process. Monoamine oxidase is responsible for the metabolic inactivation of catecholamines in neurons and the hepatic inactivation of biogenic amines absorbed from the GI tract. Monoamine oxidase is also a target for inhibition in the treatment of depression (i.e., monoamine oxidase inhibitors including phenelzine [Nardil]).

8. **Reduction reactions** are less common than oxidation but are still **phase I** reactions that add or reveal a functional group to increase the water solubility of the molecule to facilitate elimination. There are several reductase enzymes and even CYP450 may have reductase activity. Common reduction reactions include the reduction of disulfide bonds, carbonyls, and nitro or azo functional groups.

   a. A common reduction reaction is the **reduction of disulfide bonds** commonly found between cysteine residues in proteins. Other sulfhydryl-containing molecules can form disulfides that may be reduced back to the free sulfhydryls, or disulfide-containing drugs can be reduced like disulfiram (*Table 8-2*).

   b. **Aldo-keto reductases** reduce a carbonyl-containing compound back to an alcohol in a process opposite the oxidation performed by the alcohol dehydrogenases (*Table 8-2*; see also III.A.4).

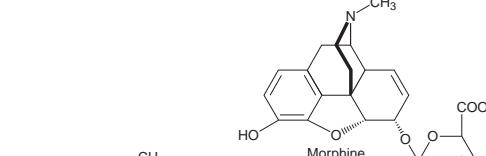
   c. **Reduction** of the **aromatic nitro** (NO_2) group and the **azo** (N=N) group is performed by a class of enzymes generically called nitroreductases and azoreductases, respectively, to produce free aromatic amines. Example reactions are included in *Table 8-2*. The liver contains these reductases both in the cytosol and the microsomal cellular fraction. Additionally, gut bacteria have significant reductase activity for both nitro and azo groups.

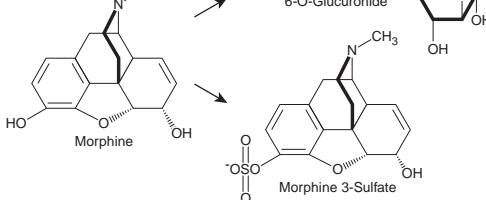
| Table 8-2 | COMMON REDUCTION REACTIONS |

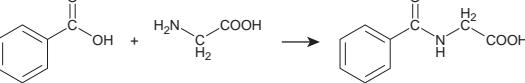
Reaction (Enzyme)	Examples
Reduction of disulfide bond	Disulfiram
Aldehyde and/or keto reduction	Methadone
Nitro (—NO$_2$) reductions	Chloramphenicol
Azo reductions (—N=N—)	Sulfasalazine → Sulfapyridine + 5-Aminosalicylic Acid

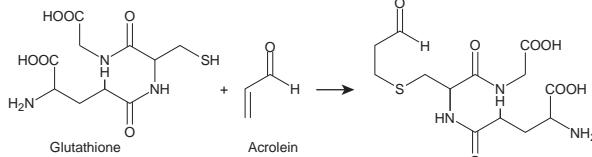
9. **Hydrolysis** reactions add water across a bond to produce a more water-soluble metabolite. Common hydrolysis reactions include ester hydrolysis, amide hydrolysis, and epoxide hydrolysis.

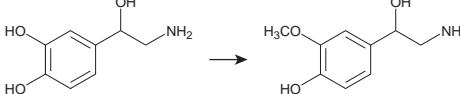
   a. **Ester hydrolysis** is commonly performed by the ubiquitous **esterase** enzymes found throughout the body. There is a significant esterase activity in the plasma that is responsible for the hydrolysis of an ester into a more water-soluble alcohol and carboxylic acid. This metabolic process can be an inactivating or activating (see Prodrugs, V) reaction. A **lactone**, like found in erythromycin, is a cyclic ester that can also be metabolized by esterase enzymes.
   b. **Amide hydrolysis** is performed by **amidase** enzymes that are generally expressed in the liver. Analogous to the ester hydrolysis reaction, the products of amide hydrolysis are an amine and a carboxylic acid (*Table 8-3*). A cyclic amide is called a **lactam** and is the key structural feature for the β-lactam antibiotics.

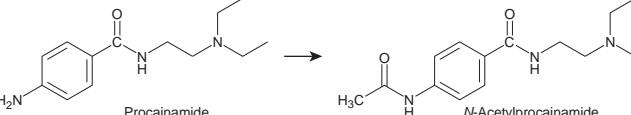
   c. **Epoxide hydrolase** converts epoxides into diols, which can be targets for conjugation reactions to facilitate elimination of xenobiotics (*Table 8-3*). There is both a microsomal and cytosolic form of epoxide hydrolase.






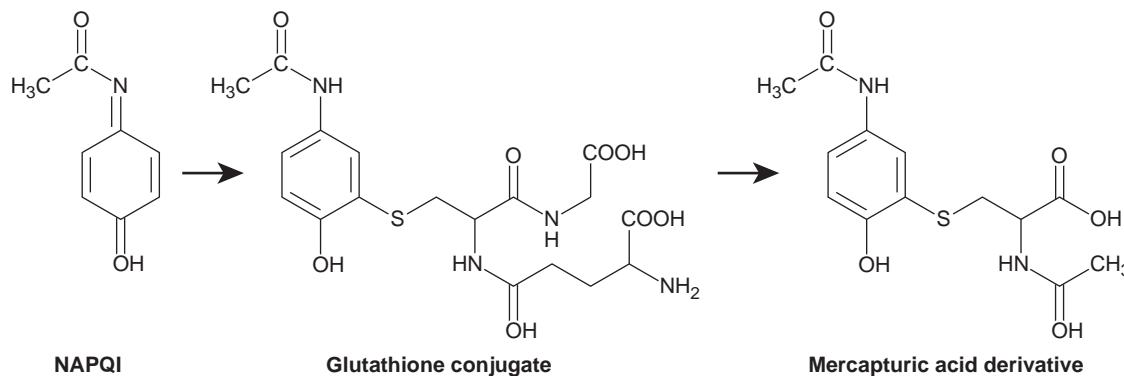






B. **Phase II reactions** are commonly called **conjugation reactions** because they use a functional group on the xenobiotic (either from phase I metabolism or part of the xenobiotic itself) to add or conjugate a biomolecule that usually increases the polarity of the xenobiotic and facilitates elimination from the body. These conjugation reactions require an enzyme generally termed as **transferase** that transfers a high-energy molecule called the **cofactor** or **cosubstrate** to the xenobiotic. The transferred cofactor is usually large and very polar-forming inactive metabolites. There are exceptions like methylation (see later discussion) that do not increase polarity but do generally form inactive metabolites. Common phase II reactions are discussed later and examples are included in *Table 8-4*.

   1. **Glucuronidation** is the most common phase II reaction. **Glucuronosyltransferase** is the microsomal enzyme that uses uridine diphosphate glucuronic acid (UDP-GA) as the cofactor to transfer the glucuronic acid to several different functional groups, including hydroxyl groups, carboxylic acid groups, hydroxylamines, and sulfonamides. The glucuronic acid adds a significant amount of hydrophilicity to the molecule and facilities its elimination in the urine. High-molecular-weight glucuronides (MW > 500 Da) are secreted into the bile, which ends up in the intestines.

Table 8-3	COMMON HYDROLYSIS REACTIONS


Reaction	Examples
Ester hydrolysis (esterase)	See *Figure 8-3A*
Amide hydrolysis (amidase; peptidase)	Lidocaine
Epoxide hydrolysis (epoxide hydrolase)	Carbamazepine epoxide

Table 8-4	COMMON PHASE II REACTIONS

Reaction	Enzyme	Cofactor	Examples
Glucuronidation	Glucuronosyltransferase	UDP-GA	
Sulfation	Sulfotransferase	PAPS	Morphine → Morphine 6-O-Glucuronide, Morphine 3-Sulfate
Amino acid conjugation	*N*-Acyltransferase	Glycine and/ or glutamine	
Glutathione conjugation	Glutathione-S-transferase	Glutathione	Glutathione + Acrolein
Methylation	Methyltransferase	SAM	
Acetylation	*N*-Acetyltransferase	Acetyl-CoA	Procainamide → *N*-Acetylprocainamide

UDP-GA, uridine diphosphate glucuronic acid; *PAPS*, 3'-phosphoadenosine-5'-phosphosulfate; *SAM, S*-adenosylmethionine; *Acetyl-CoA*, acetyl coenzyme A.

2. **Sulfation** is less common than glucuronidation but is also a phase II reaction that increases the polarity of the parent drug by conjugating an endogenous molecule to the xenobiotic. **Sulfotransferase** is the enzyme that uses the cofactor 3′-phosphoadenosine-5′-phosphosulfate (PAPS) to add a sulfate to hydroxyl groups, arylamines, and *N*-hydroxyl compounds. The sulfate conjugate is ionized and highly polar to dramatically increase water solubility and excretion of the xenobiotic.

3. The **amino acid conjugation** reaction adds either a glycine or a glutamine to a carboxylic acid of the parent drug to form an amide. Coenzyme A forms an intermediate with the carboxylic acid of the parent drug called the acyl coenzyme A intermediate. **N-Acyltransferase** then catalyzes the reaction of the activated xenobiotic (acyl coenzyme A) with the amino acid to form the amide-containing metabolite. In this case, the carboxylic acid target is activated into a high-energy intermediate (acyl coenzyme A) that interacts with the amino acid.

4. **Glutathione conjugation** results from the addition of a glutathione molecule (a tripeptide including glycine, cysteine, and glutamic acid) to an electrophilic substrate. Electrophilic compounds react with nucleophiles and the nucleophile on glutathione (the cysteine sulfhydryl) generally acts to detoxify electrophiles. **Glutathione-S-transferase** is the enzyme responsible for the reaction of glutathione with electrophiles, including epoxides and halides to name a few. After glutathione is conjugated to the electrophile, the tripeptide is further processed by amide hydrolysis and *N*-acetyltransferase to the **mercapturic acid metabolite** (*Table 8-4* and *Figure 8-5*). This is a common metabolite excreted in the urine after glutathione conjugation.

5. **Methylation** depends on the cofactor *S*-adenosylmethionine (SAM) and the enzyme **methyltransferase** to add a methyl group to oxygen-, nitrogen-, or sulfur-containing functional groups. The result of this reaction is generally less polar molecules that can inactivate compounds like the catechol-containing neurotransmitters including norepinephrine (*Table 8-4*). More commonly, methylation is responsible for biosynthesis of endogenous compounds like epinephrine through the *N*-methylation of norepinephrine.

6. **Acetylation** depends on the cofactor acetyl coenzyme A (acetyl-CoA) and the enzyme **N-acetyltransferase** to add an acetyl group to primary amines, hydrazines, sulfonamides, and occasionally amides (*Table 8-4*). The *N*-acetyl metabolites are less polar than the parent drug and may retain pharmacological activity, both of which are unusual for a phase II reaction.

C. **Extrahepatic metabolism**, or drug biotransformation outside of the liver, is also an important process in determining the metabolic rate of xenobiotics. Sites with significant metabolic capacity are located at the portals of entry (e.g., GI mucosa, nasal passages, lungs) and the portals of excretion (e.g., kidneys), but other tissues also contain various drug-metabolizing enzymes.

1. The **intestinal mucosa** is a significant site of metabolism for drugs that are administered orally and contributes to the observed **first-pass effect** or **presystemic metabolism**. Several metabolic processes have been identified in the intestinal mucosa, including microsomal oxidation

NAPQI   **Glutathione conjugate**   **Mercapturic acid derivative**

Figure 8-5. Conjugation of NAPQI with glutathione and the processing to the ultimate metabolite, the mercapturic acid derivative.

(e.g., CYP450 and FMO), glucuronidation, sulfation, and ester hydrolysis. Conversion in the intestinal mucosa of a lipophilic xenobiotic into a more hydrophilic and potentially inactivated metabolite prevents the pharmacologically active compound from entering the systemic circulation (i.e., **presystemic metabolism**).

2. The **intestinal flora** is also responsible for producing many **reductase** and **β-glucuronidase enzymes**.

   a. **Reductases**, including nitroreductase and azoreductase, reduce aromatic nitro and azo functional groups into amines (see previous discussion). One example of an azoreductase activity is the reduction of the azo bond in sulfasalazine (Azulfidine) to release the anti-inflammatory aminosalicylic acid and the antibacterial sulfapyridine (*Table 8-2*).

   b. The **β-glucuronidase** enzymes are responsible for the hydrolysis of the polar glucuronide conjugates in the bile to release the free, deglucuronidated drug, which is free for reabsorption. This process of glucuronide conjugates secretion into the GI tract with the bile, being hydrolyzed by β-glucuronidases, and then being reabsorbed is called **enterohepatic circulation**. Estrogen is an example of a drug that demonstrates enterohepatic circulation.

   c. Changes in the number or population of intestinal flora can influence the activity of a drug. Conditions such as diarrhea, intestinal diseases, or antibiotic treatment all alter the intestinal flora and therefore may result in changes in drug activity.

3. The **nasal mucosa**, like the GI mucosa, is considered a portal of entry and contains a high level of CYP450 activity as well as some FMO, esterase, and conjugation activity. This provides a protective mechanism for the exposure to xenobiotics in the air but may also activate some xenobiotics to toxic metabolites. Many compounds administered nasally also undergo significant nasal metabolism to decrease the systemic effects. Examples include topical decongestants, anesthetics, nicotine, and cocaine.

4. The **lungs** express many CYP450s, FMO, epoxide hydrolase, and conjugation pathways and therefore contribute to the metabolism of many xenobiotics that either enter the body through the lungs or via the circulation. The lungs are the site of first-pass metabolism for drugs administered intravenously, intramuscularly, transdermally, or subcutaneously and the site of second-pass metabolism for xenobiotics that leave the liver.

5. Plasma contains **esterases** that hydrolyze esters to either inactive ester-containing drugs (e.g., procaine [Novocain] and succinylcholine [Anectine]) or activate ester prodrugs (e.g., enalapril [Vasotec]).

6. The **placenta** has very limited drug-metabolizing capacity. Drugs that are easily absorbed are usually capable of crossing the placenta. Placentas of mothers that smoke tobacco have a significant increase in the expression of the CYP1A subfamily. This is of concern because it may result in increased exposure of the fetus to reactive metabolites that may have detrimental effects.

7. The extent of **fetal metabolism** is dependent on the age of the fetus. CYP450 activity is present early in gestation but glucuronidation is deficient until after birth. This lack of glucuronidation results in gray baby syndrome after chloramphenicol administration and neonatal hyperbilirubinemia.

8. The **kidney** expresses CYP450s that are mostly involved in the hydroxylation of steroids, arachidonic acid, and 25-hydroxycholecalciferol.

9. **Nonenzymatic degradation** of drugs can occur in the body, but the acidic environment of the stomach can cause the degradation of a number of drug molecules, including penicillin G, erythromycin, tetracycline, and peptides like insulin.

IV. FACTORS THAT INFLUENCE DRUG METABOLISM

A. The **chemical structure** of a xenobiotic has one of the largest influences on the metabolism of a compound. The presence or absence of certain functional groups will determine the necessity, route, and extent of metabolism.

B. **Genetic difference**, or **polymorphisms**, can influence the activity or the extent of expression of the drug-metabolizing enzymes. Section VII will explore these differences in more detail. The rate of acetylation is one example that depends on the amount of *N*-acetyltransferase that is expressed. Individuals can be divided into fast or slow acetylators based on the expression of *N*-acetyltransferase. Many CYP450s also have genetic polymorphisms that influence their activity. CYP2D6 is a highly

polymorphic enzyme that results in the division of individuals into ultrarapid, intermediate, or poor metabolizers of substrates like debrisoquine and dextromethorphan.

C. **Gender**. Metabolic differences between the sexes have been observed for a number of compounds, suggesting that androgen, estrogen, and/or adrenocorticoid activity might affect the activity of certain CYP450 enzyme isozymes.

1. Metabolism of diazepam (Valium), prednisolone (Orapred), caffeine, and acetaminophen (Tylenol) is slightly faster in women.
2. Metabolism of propranolol (Inderal), chlordiazepoxide (Librium), lidocaine (Xylocaine), and some steroids is faster in men than in women.

D. **Age**
1. The **fetus** and the **neonate** do not have fully developed drug-metabolizing enzymes, particularly phase II glucuronidation. As a result, smaller doses are often required to avoid drug accumulation and adverse effects during the first 6 to 8 weeks of life.
2. The **elderly patient** shows a **decrease in the drug-metabolizing capacity** compared to young adults. This may be related to changes in hepatic blood flow, body mass, and/or other disease states. Drug clearance is therefore generally slower and blood concentrations are higher, increasing the potential for toxicity.

E. **Circadian rhythms**. The nocturnal plasma levels of drugs, such as theophylline (Theochron, Uniphyl) and diazepam (Valium), are lower than the diurnal plasma levels.

F. Various **disease states** that influence the function of the liver, the major site of drug metabolism, can affect a drug's hepatic clearance. Alterations in liver blood flow, loss of functional hepatocytes, and changes in albumin production can influence the extent of drug metabolism and toxicity and therefore require caution when administering a drug that requires hepatic biotransformation for detoxification or elimination.

G. The **nutritional status** of an individual can also influence the activity of drug-metabolizing enzymes by altering the amount of conjugating agents, protein, essential fatty acids, minerals, and/or vitamins available for use. Various alterations in drug-metabolizing activity have been identified for each category listed previously.

H. **Interacting substances**. Xenobiotics, whether they are drugs or not, can influence the activity of drug-metabolizing enzymes in a variety of ways.

1. **Inducers** are xenobiotics that cause an increase in the drug-metabolizing activity of a target enzyme, usually by increasing the concentration of the enzyme in the liver or other tissue. Several **CYP450 enzymes** and **glucuronosyltransferases** are known to be inducible. In the case of drug–drug interactions, the compound causing the induction is called the **precipitant drug,** whereas the drug that is being affected is called the **object drug**. The consequence of induction is dependent on the extent of induction by the precipitant drug and the pharmacological characteristics of the object drug. For example, if the object drug is metabolized to a toxic metabolite, then induction by the precipitant drug may result in greater toxicity as a result of the increased drug-metabolizing activity.

2. **Inhibitors** are opposite of inducers in that they **decrease** the metabolizing activity of a target enzyme, usually by competing with the object drug for the enzyme and preventing its metabolism. The extent of inhibition is dependent on the affinity of the inhibitor, the availability of **alternate metabolic pathways** of the object, and the **pharmacologic characteristics** of the object drug. For example, if the object drug has a narrow margin of safety and one metabolic route of elimination, the addition of an inhibitor to that pathway could result in accumulation of the object drug and ultimately toxicity.

3. The extent of **protein binding** can be altered by the administration of another compound that is also highly protein bound. Two drugs that compete for similar binding sites on plasma proteins can result in the displacement of (usually) the agent with the lower affinity. As a result, there is an **increase in the free fraction** of one or both drugs that can lead to increased receptor interactions, metabolism, or toxicity of the displaced drug.

4. **Antibiotic therapy** may also influence the metabolic rate of a drug that is dependent on the gut microflora for its metabolism or **enterohepatic circulation** (see III.C.2.b).

I. **Route of administration** can dramatically influence the metabolic rate of a drug.
1. **Orally administered drugs** are subject to **first-pass metabolism in the liver** through the portal circulation or **presystemic metabolism in the gut**. This first-pass or presystemic metabolism can

significantly reduce the amount of drug that enters the systemic circulation. Often, this problem can be overcome by administering more drug orally so that the systemic concentration is sufficient for pharmacologic activity.

    2. Intravenous administration (IV) bypasses any barriers to GI absorption and first-pass metabolism and generally requires a smaller dose for the same effect. For example, oral morphine undergoes significant first-pass metabolism so an equivalent IV dose is approximately one-sixth that of an oral dose. **Sublingual** and **buccal administrations** also bypass the first-pass metabolism because they are not part of the portal circulation. **Rectal administration** is more variable but also bypasses first-pass metabolism to a significant extent.

J. The **dose** can also influence the extent of metabolism. There is a finite amount of drug-metabolizing enzymes, so higher doses can result in **saturation** of a particular metabolic pathway. When this occurs, an alternate pathway may contribute to the metabolism of the drug. For example, acetaminophen (Tylenol) given at therapeutic doses is metabolized almost exclusively by glucuronidation and sulfation but toxic doses saturate these processes, leading to increased metabolism by CYP2E1 to the proposed toxic metabolite NAPQI causing hepatotoxicity.

V. PRODRUGS.
These drugs are molecules that are either inactive or very weakly active and require in vivo **biotransformation** to produce the pharmacologically active drug. The phase I metabolic processes discussed previously activate prodrugs. There are a variety of advantages to using a prodrug instead of the active form of the drug.

A. An **increase in water solubility** is useful for the preparation of ophthalmic and parenteral formulations. Sodium succinate esters and sodium phosphate esters have been used to make a number of water-soluble steroid prodrugs.

B. An **increase in lipid solubility** is useful for a variety of reasons.

    1. Increased oral absorption is obtained by converting carboxylic acid groups to esters. These esters can then be rapidly converted to the active acids by plasma esterases. Enalaprilat is a potent angiotensin-converting enzyme (ACE) inhibitor that is used for parenteral administration, but, due to its high polarity, it is orally inactive. Its monoethyl ester, enalapril (Vasotec), is considerably more lipophilic and, thus, provides good oral absorption. This strategy has been successfully used for a variety of other compounds, including additional ACE inhibitors, fibric acid derivatives, ampicillin, and several cephalosporins.

    2. Increased duration of action. Lipid-soluble esters of estradiol, such as benzoate, valerate, and cypionate, are used to prolong estrogenic activity. IM injections of these esters in oil result in a deposit of drug that is slowly released and hydrolyzed to free estradiol over a prolonged period (see section VI.A.3).

    3. Increased topical absorption of steroids is obtained by masking hydroxyl groups with less polar functional groups such as esters or acetonides. This decrease in polarity allows for increased dermal permeability to treat inflammatory, allergic, and pruritic skin conditions. Examples include triamcinolone acetonide (Kenalog), diflorasone diacetate (ApexiCon), and betamethasone valerate (Betaderm).

    4. Increased palatability. Antibiotics such as sulfisoxazole have a bitter taste and are not suitable for administration to children who are unable to swallow tablets or capsules. Esterification to produce sulfisoxazole acetyl decreases the water solubility of the antibiotic and, thus, decreases its interaction with bitter taste receptors on the tongue. This compound is marketed as a flavored suspension with erythromycin ethylsuccinate. Similar strategies have been used to mask the bitter taste of chloramphenicol and other antibiotics.

C. A **decrease in GI irritation**. NSAIDs produce gastric irritation and ulceration via two mechanisms: a direct irritant effect of the acidic molecule and inhibition of gastroprotective prostaglandin production. The prodrugs sulindac (Clinoril) and nabumetone (Relafen) produce less GI irritation because the gastric and intestinal mucosa are not exposed to high concentrations of active drug during oral administration. Additionally, nabumetone is a ketone, not an acid, and lacks any direct irritant effects.

D. Site specificity is useful for increasing the concentration of the drug at the active site and for decreasing side effects.

    1. Methyldopa (Aldomet) is a prodrug that is structurally similar to ʟ-dopa. As a result, methyldopa is transported into the central nervous system (CNS) and metabolized to the active

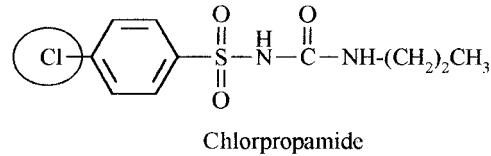
compound, α-methylnorepinephrine, via the same path used for the synthesis of norepinephrine. This allows a significant amount of α-methylnorepinephrine to activate central α_2-adrenergic receptors.

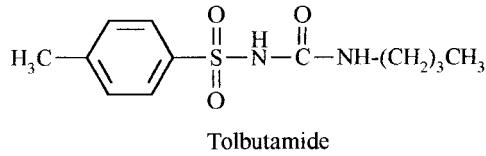
2. Omeprazole (Prilosec) is used to treat gastric ulcers and other hypersecretory disorders. After oral absorption, it is selectively activated at the acidic pH levels (pH less than 1) seen in gastric parietal cells. This allows the active form of the drug to be produced in proximity to the enzyme H^+/K^+-ATPase (proton pump), resulting in irreversible inhibition of the enzyme and a decrease in gastric acid secretion. Activation in the stomach prior to absorption can be prevented by the use of enteric-coated formulations.

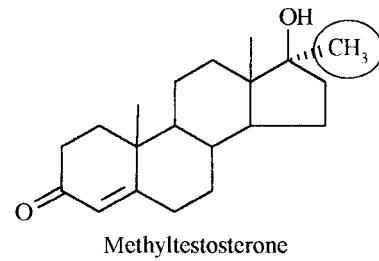
3. Formaldehyde is an effective urinary tract antiseptic; however, oral administration results in significant toxicity. To avoid this problem, the prodrug methenamine (Hiprex, Urex) is administered instead. Methenamine is stable and nontoxic at normal physiological pH but is selectively hydrolyzed to formaldehyde and ammonium ions in the acidic urine (pH less than 5.5). As with omeprazole, activation before absorption can be prevented by the use of enteric-coated formulations.

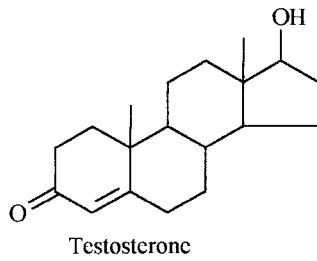
4. Olsalazine (Dipentum) is a highly polar dimer of 5-aminosalicylic acid that is poorly absorbed after oral administration. On reaching the large intestine, colonic bacteria cleave the azo bond and liberate the active anti-inflammatory agent. Olsalazine and a related compound, sulfasalazine, are useful in treating inflammatory bowel disease.

E. **Increased shelf life** of both solids and parenteral admixtures can be obtained by the use of prodrugs. Cyclophosphamide (Cytoxan) is a prodrug that requires in vivo oxidation, followed by nonenzymatic decomposition, to produce the active phosphoramide mustard. As a result, aqueous solutions of cyclophosphamide are much more stable than those of other nitrogen mustards (i.e., mechlorethamine). Mechlorethamine (Mustargen) is highly reactive, does not require in vivo activation, and can rapidly decompose in aqueous environments before administration.

VI. STRATEGIES TO MANAGE DRUG METABOLISM.
A variety of methods have been used to circumvent the rapid metabolism of certain drugs. These methods seek to improve drug therapy by decreasing the overall extent of metabolism and increasing the duration of action. In some instances, these methods have provided increased site specificity.








A. **Pharmaceutical strategies** involve the use of different **dosage forms** to either avoid or compensate for rapid metabolism.

1. **Sublingual tablets** are useful for delivering drugs directly into the systemic circulation and avoiding hepatic first-pass metabolism. **Nitroglycerin**, a rapidly acting antianginal agent, is essentially ineffective when administered orally due to an extremely high first-pass effect but is very effective in treating acute attacks of angina if given sublingually.

2. **Transdermal patches** and **ointment formulations** provide a continuous supply of drug over an extended period and are useful for rapidly metabolized compounds such as nitroglycerin. These delivery systems, although not suited to treat acute anginal symptoms, are effective in providing prophylactic concentrations of nitroglycerin.

3. **Intramuscular depot injections** also provide a continuous supply of drug over an extended period. Highly lipid-soluble esters of **estradiol** and **testosterone** (e.g., estradiol benzoate, testosterone enanthate) are slowly absorbed from their administration site. Hydrolysis of these prodrugs (see section V) produces a steady supply of these rapidly metabolized hormones.

4. **Enteric-coated formulations** can protect acid-sensitive drugs as they pass through the acidic environment of the stomach. **Methenamine**, **erythromycin**, and **omeprazole** are examples of acid-sensitive agents that are available as enteric-coated preparations.

5. **Nasal administration** allows for the delivery of peptides such as **calcitonin salmon**, which have very low (if any) oral bioavailability. Characteristics of the mucosa make it ideal for the administration of peptides. Aerosolized drugs only need to penetrate a thin epithelial layer to reach abundant capillary beds.

6. **Inhalation** as a route of administration is most commonly used for local activity but can bypass gastric or hepatic metabolism for systemic administration. This is a viable route of administration for peptides because the lungs contain protease inhibitors that allow for greater stability. Inhaled insulin is effective but was removed from the market because of adverse effects on the lungs.

B. **Pharmacological strategies** involve the concurrent use of enzyme inhibitors to decrease drug metabolism. In some instances, the concurrent use of an additional agent does not prevent metabolism but rather prevents the toxicity caused by metabolites of the therapeutic agent.

   1. **Levodopa** (L-dopa), the amino acid precursor of dopamine, is used in the treatment of parkinsonism. Unlike dopamine, L-dopa can penetrate the blood–brain barrier and reach the CNS. Once in the brain, it is decarboxylated to dopamine. To ensure that adequate concentrations of L-dopa reach the CNS, peripheral metabolism of the drug must be blocked. The concurrent administration of **carbidopa**, a dopa decarboxylase inhibitor that cannot penetrate the blood–brain barrier, prevents peripheral conversion of L-dopa to catecholamines and allows enhanced delivery of L-dopa to the CNS.

   2. **β-Lactam antibiotics**. The antibacterial activity of a number of β-lactam antibiotics is reduced by microorganisms capable of secreting the enzyme β-lactamase. This enzyme hydrolyzes the β-lactam ring and inactivates the antibiotic. To counter this resistance mechanism, a β-lactamase inhibitor, such as **clavulanic acid**, is used in conjunction with a penicillin, such as **amoxicillin**, to successfully treat infections caused by β-lactamase–producing bacteria.

   3. **Ifosfamide** is an alkylating agent that must undergo in vivo metabolism to produce an active nitrogen mustard. In the process of this metabolic activation, significant concentrations of **acrolein** are produced. These acrolein molecules react with nucleophiles on renal proteins and produce hemorrhagic cystitis. To prevent this toxicity, ifosfamide is always coadministered with **mesna**, a sulfhydryl-containing compound that reacts with and neutralizes any acrolein that is present in the kidney.

   4. **HIV protease inhibitors** are extensively metabolized by CYP3A isozymes but they also inhibit these same isozymes in the process. This latter action has been used to optimize therapy. **Ritonavir** is an HIV protease inhibitor with very high affinity for CYP3A isozymes, whereas **lopinavir** is rapidly oxidized and inactivated by the same enzyme. A combination of low dose ritonavir with a therapeutic dose of lopinavir results in an inhibition of CYP3A, the establishment of adequate plasma levels of lopinavir, and therapeutic efficacy without hepatotoxicity.

C. **Chemical strategies** involve the addition, deletion, or isosteric modification of key functional groups. These molecular modifications hinder or completely eliminate metabolic transformations (*Figure 8-6*).

   1. **Testosterone** is not orally active due to rapid oxidation of its 17-hydroxyl group to a ketone. Addition of a 17α-methyl group converts the labile secondary alcohol to a stable tertiary alcohol. The resulting compound, **methyltestosterone**, is only half as potent as testosterone; however, it is

Figure 8-6. Selected examples of chemical modification that eliminate metabolic transformations. Methylation of testosterone blocks the rapid oxidation of the 17-hydroxyl group and allows oral activity, whereas replacement of the metabolically labile *para*-methyl group on tolbutamide with a chloro group allows for a much longer duration of action.

not subject to rapid first-pass metabolism and can be used orally. A similar strategy has been used to make orally active estradiol analogues.

2. **Tolbutamide** is an oral hypoglycemic with a short duration of action. This sulfonylurea rapidly undergoes oxidation of its para-methyl group. A structurally similar compound, **chlorpropamide**, has a nonmetabolizable para-chloro group and, as a result, has a much longer duration of action.

3. **Isoproterenol** is a potent β-adrenergic agonist used for the relief of bronchospasm associated with bronchial asthma. Because it is a catechol (i.e., 3,4-dihydroxy–substituted benzene ring), isoproterenol is subject to rapid metabolism by catechol-*O*-methyltransferase (COMT) and, thus, has poor oral activity. Alteration of the 3,4-dihydroxy substitution to a 3,5-dihydroxy substitution produces **metaproterenol**, a bronchodilator that is not susceptible to COMT, is orally active, and has a longer duration of action than isoproterenol.

4. **Octreotide** is a synthetic octapeptide used to suppress or inhibit severe diarrhea associated with certain tumors. Octreotide mimics the actions of **somatostatin**, a naturally occurring, 14–amino acid peptide. Somatostatin undergoes rapid proteolysis, has a half-life of 1 to 3 mins, and must be administered as a continuous intravenous infusion. Octreotide contains the amino acids essential for clinical efficacy but replaces two of the amino acids with their D-enantiomers. These unnatural D–amino acids are more resistant to hydrolysis. As a result, octreotide has an increased half-life and can be administered as a subcutaneous injection.

VII. PHARMACOGENETICS is the study of the **genetic basis for variation in drug response**.
Because genes code for the proteins involved in drug absorption, distribution, metabolism, elimination, and receptors, it is clear that gene changes will alter the response to drugs. In this chapter, we will focus on the genetic basis for variation in drug response with some emphasis on drug metabolism.

A. **Phenotypic description of variability**. Historically, genetic variation related to drug metabolism has been described in terms of phenotypic observations such as fast or slow metabolizers of a particular compound. Now that the genetics behind the phenotype is often understood, an observed effect or a phenotype can be connected to the gene sequence or **genotype**. With this knowledge, the phenotype can be predicted regardless of the medication in question. The ability to predict drug response as it relates to drug metabolism or other factors is critical in providing truly personalized medicine, the ultimate goal of pharmacogenetics.

B. **Genetics review**. A review of the vocabulary of genetics will help with the understanding of the genetic basis of variation in drug response and metabolism.

1. **Genes** are defined as a **segment of DNA** that can be replicated for cell division and direct the biosynthesis of specific proteins that include receptors, enzymes, and structural proteins.

2. An **allele** is **one of several variants of a gene**. An individual has two alleles, one allele from each parent, of each gene. In polymorphic genes, the wild-type or most common allele is indicated as the *1 allele and the variant alleles are numbered based on discovery. For example, CYP2D6*1 is the most common allele of cytochrome P450 2D6 but other variants include CYP2D6*3 and CYP2D6*4, both of which lack drug-metabolizing activity.

3. **Promoters** are segments of DNA that aid or direct the transcription of a particular gene.

4. **Transcription** is the process of **copying genes from DNA into complementary RNA called messenger RNA (mRNA)**. This is the first step in the process of expressing a gene as a protein.

5. **Splicing** is the **processing of mRNA** to remove the **introns** (noncoding RNA) and join together **exons** (coding mRNA) to make mature mRNA that encodes for the desired protein.

6. **Translation** is the process of converting the processed or mature **mRNA into protein**. Translation occurs on the **ribosomes** using transfer RNA (tRNA) to read the mRNA and produce a chain of amino acids. The amino acids are connected by peptide, or amide, bonds to make a protein.

7. **Polymorphism** is defined as the existence of two or more variants of a gene that occur in the population with a population frequency of at least 1% for the less common variant.

C. **Genetic variation** in the DNA sequence can cause certain populations of individuals to be more likely to develop specific disease states, to be more likely to follow a specific path of disease progression, to

be more likely to respond to specific drug therapy, and/or to be more likely to develop certain adverse drug effects. It is estimated that individuals differ from one another by one nucleotide, or SNP, every 300–1000 nucleotides in the genome.

1. The most common type of genetic variation is the **single nucleotide polymorphism** (SNP). The consequence of a SNP depends on its location and the change itself.

   a. SNP, pronounced "snip," is a single base pair change in the DNA sequence at a particular point compared with the "common" or "wild-type" gene sequence.

   b. A **synonymous SNP** in the coding region does not result in a change in the amino acid sequence compared to the common or wild-type sequence and therefore generally has no discernible effects.

   c. A **nonsynonymous SNP** in the coding region results in a change in the amino acid sequence compared to the common or wild-type gene. This change can have negligible effects if the new amino acid has similar properties as compared to the original amino acid (e.g., aspartic acid replaced with a glutamic acid) or can have significant effects if the properties change sufficiently (e.g., aspartic acid replaced with lysine). As an example of a significant, nonsynonymous SNP, a mutation from A to C at position 3023 of the CYP2D6 gene results in histidine 324 in the native protein being replaced by a proline ($H_{324}P$). This change produces the allele identified as CYP2D6*7, which has no drug-metabolizing activity.

   d. SNPs outside of the coding region may not influence the amino acid composition of the protein but can have significant effects on the expression of a protein. SNPs in a **promoter** can alter the transcription rate of the target protein, resulting in either more or less of the protein being expressed. SNPs in a **splicing control** region may result in alternative splicing, creating either a novel protein or a nonsense codon that terminates that translation of the protein. In each of these examples, expression and activity of the gene is altered. Vitamin K epoxide reductase complex 1 (VKORC1) is an example of a protein where SNPs in the promoter region result in various levels of protein expression. This is important because VKORC1 is the molecular target for the anticoagulant warfarin. The efficacy of warfarin varies widely across the population and about 25% of this dose variation can be explained by variability in the expression of VKORC1.

2. Other common genetic variations, which may be SNPs, are **insertions** and **deletions**. Just as the name sounds, nucleotides are either inserted or deleted from the sequence of the gene. Recall that nucleotides are translated into amino acids using a three-nucleotide codon, so adding or deleting one nucleotide can result in the significant changes to the gene. The CYP2D6*3 allele is the result of a deletion of one nucleotide (A_{2637}), which causes a reading frameshift in translation. This change results in CYP2D6 with no activity.

3. **Copy number variations** are also a possible genetic variation. In this case, large segments of DNA are duplicated, deleted, or inverted. In duplications, the gene of interest is repeated in the genome multiple times. A deletion is a complete absence of the functional gene, and inversions may disrupt gene function by changing the location of the gene and its promoters. CYP2D6 is one drug-metabolizing enzyme identified to have multiple copies (CYP2D6xN where N is between 2 and 12 copies) of the functional CYP2D6 gene. These multiple copies result in a very high expression of functional CYP2D6. These patients are ultrarapid metabolizers of CYP2D6 substrates.

D. **Clinical pharmacogenetic assays**

1. The goal of a clinical pharmacogenetic assay is to provide the best patient care possible to prevent adverse effects while gaining the best response possible. Ideally, a useful clinical pharmacogenetic assay will place patients into one of four categories.

   a. Individuals who are most likely to respond and are at a low risk for adverse effects.

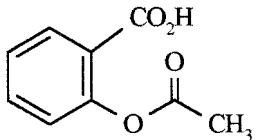
   b. Individuals who are most likely to respond and are at a high risk for adverse effects.

   c. Individuals who are less likely to respond and are at low risk for adverse effects.

   d. Individuals who are less likely to respond and are at a high risk for adverse effects.

2. There are several known genetic variations that affect specific drug efficacy and safety. These variations are related to alterations in drug-metabolizing enzymes, targets, or side effects.

   a. **Warfarin** (Coumadin). Patients demonstrate significant variation in the effective dose of warfarin, which requires careful monitoring and a personalized dose. Part of this variability can be explained by the variation in the drug-metabolizing enzyme CYP2C9. Polymorphisms in

CYP2C9 result in slower clearance of warfarin that translates into drug accumulation and increased risk for bleeding at average doses. Of particular concern are the patients that carry the CYP2C9*2 or CYP2C9*3 allele, which encode for CYP2C9 protein with greatly reduced enzymatic activity. As a result, the metabolism of warfarin is dramatically diminished and the risk for drug accumulation and bleeding is significant. More of the variation can be explained by the variable expression of vitamin K epoxidase (VKORC1), the molecular target for warfarin. This variation is dependent on a SNP in the promoter region of VKORC1. Genetic tests for both CYP2C9 and VKORC1 are recommended in the warfarin labeling as tests that will provide guidance in induction and final therapeutic dose for individuals with specific CYP2C9 and VKORC1 alleles.


b. **6-Mercaptopurine** (Purinethol) and **azathioprine** (Imuran), which is initially bioactivated to 6-mercaptopurine, are inactivated by the drug-metabolizing enzyme **thiopurine methyltransferase** (TPMT). Genetic variations in TPMT, including the TPMT*2, TPMT*3A, and TPMT*3C alleles, are known to result in decreased metabolizing capacity and increased bone marrow toxicity as 6-mercaptopurine accumulates in the body. Although the genotypes for TPMT are known, phenotyping of red blood cells is more commonly used to evaluate TPMT activity.

c. **Procainamide** (Pronestyl), **hydralazine** (Apresoline), and **isoniazid** (Stanozide) are metabolized by *N*-acetyltransferase, a polymorphic drug-metabolizing enzyme. Each of these drugs listed here has a different adverse effect profile based on the ability of variants of *N*-acetyltransferase to metabolize the targets. A slow acetylator taking these drugs is likely to accumulate the drug and develop symptoms of overdose, including hypotension and lupus-like syndrome for procainamide and hydralazine and peripheral neuropathy for isoniazid. Although genetic tests are commercially available, there is currently no recommendation for testing.

d. **Salmeterol** (Serevent Diskus) and **albuterol** (Proventil or Ventolin) are **β_2-adrenergic receptor agonists** used to treat **asthma**. Genetic variations in the β_2-adrenergic receptor yield different responses to these agonists, which results in differences in efficacy in the treatment of asthma. Currently, the labeling for the β_2-agonists does not include a recommendation for genetic testing.

e. **Maraviroc** (Selzentry) is an HIV drug that is only active against HIV infections that require the **CCR5 coreceptor** to penetrate cells. Maraviroc works by antagonizing the CCR5 receptor, but if the HIV does not require CCR5 to penetrate the cell, it will not be effective in the treatment of HIV infections. To determine the HIV-1 tropism, a DNA test of the virus in a patient's blood, called a Trofile DNA, can be performed. A phenotypic assay can also be performed if there is a significant viral load detected called Trofile.

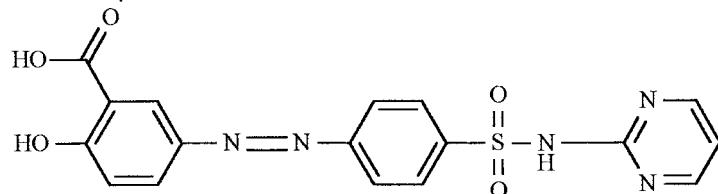
f. **Abacavir** (Ziagen) is an HIV drug that is associated with a serious **hypersensitivity reaction** associated with a particular variation in the major histocompatibility complex, class I, B allele (i.e., HLA-B*5701). Patients with the HLA-B*5701 allele are about 15 times more likely to develop abacavir hypersensitivity when compared to patients without the HLA-B*5701 allele. Genetic screening for the HLA-B*5701 allele is recommended prior to abacavir treatment but does not eliminate the risk for serious abacavir hypersensitivity.

g. **Codeine** is a mild analgesic that is **metabolized by CYP2D6** to morphine, a much more potent analgesic. **CYP2D6 is highly polymorphic**, including a potential for multiple copies of the gene resulting in an ultrametabolizer phenotype. This can lead to increased metabolism to morphine and increases in morphine-related toxicity, including constipation and respiratory depression. CYP2D6 also contributes to the metabolism of several selective serotonin reuptake inhibitors (i.e., fluoxetine [Prozac]), tricyclic antidepressants (i.e., amitriptyline [Elavil]), antipsychotics (i.e., clozapine [Clozaril]), and beta-blockers (i.e., propranolol [Inderal]). In these cases, the CYP2D6 alleles, CYP2D6*3, *4, *5, or *6, that are associated with poor metabolizers result in drug accumulation and toxicity. Genetic testing for CYP2D6 is commercially available, and the consequences of polymorphisms are mentioned in the drug labeling of several agents, but genetic testing is not widely recommended.

Study Questions

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the one lettered answer or completion that is **best** in each case.

1. Which of the following statements concerning drug metabolism is true?

    (A) Generally, a single metabolite is excreted for each drug administered.
    (B) Often, a drug may undergo a phase II reaction followed by a phase I reaction.
    (C) Drug-metabolizing enzymes are found only in the liver.
    (D) All metabolites are less active pharmacologically than their parent drugs.
    (E) Phase I metabolites more likely are able to cross cellular membranes than phase II metabolites.


2. Which of the following metabolites would be the least likely excretion product of orally administered aspirin (see structure below)?
    (A) Glycine conjugate
    (B) Ester glucuronide
    (C) Unchanged drug
    (D) Ether glucuronide
    (E) Hydroxylated metabolite

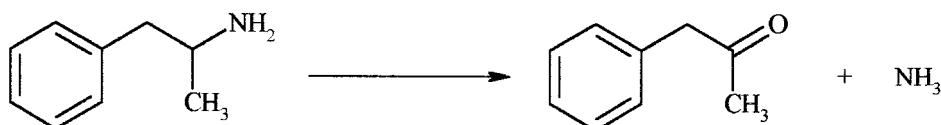
3. Sulfasalazine (see structure below) is a prodrug that is activated in the intestine by bacterial enzymes. The enzyme most likely responsible is

    (A) azoreductase.
    (B) pseudocholinesterase.
    (C) N-acetyltransferase.
    (D) β-glucuronidase.
    (E) methyltransferase.

4. Chloramphenicol (see structure below) is considered to be toxic in infants (gray baby syndrome). This is due to tissue accumulation of unchanged chloramphenicol, resulting from an immature metabolic pathway. Which of the following enzymes would most likely be deficient?

    (A) Pseudocholinesterase
    (B) Glucuronyltransferase
    (C) N-Acetyltransferase
    (D) Azoreductase
    (E) Methyltransferase

5. Which of the following therapeutic advantages cannot be obtained by the use of prodrugs?

    (A) oral absorption
    (B) water solubility
    (C) duration of action
    (D) potency
    (E) palatability


6. Which of the following routes of administration would be subject to first-pass metabolism in the liver?

   (A) IV (intravenous)
   (B) Inhalation
   (C) Sublingual
   (D) IM (intramuscular)
   (E) Oral

7. A compound that slows the metabolism of a xenobiotic is called a(n)

   (A) inducer.
   (B) epimer.
   (C) reductase.
   (D) inhibitor.
   (E) object.

8. Which family of drug-metabolizing enzymes is characterized as a microsomal enzyme that contains a porphyrin prosthetic group?

   (A) Glucuronosyltransferases
   (B) Cytochrome P450s
   (C) Flavin-containing monooxygenases
   (D) Esterases
   (E) *N*-Acetyltransferases

9. The most common type of genetic variation is a(n)

   (A) copy number variation.
   (B) insertion.
   (C) deletion.
   (D) frameshift.
   (E) single nucleotide polymorphism.

10. Which polymorphic enzyme is responsible for the conversion of codeine to morphine?

   (A) TPMT
   (B) *N*-Acetyltransferase
   (C) CYP2D6
   (D) CYP2C9
   (E) CCR5 coreceptor

Directions: Each question in this section contains three suggested answers, of which **one or more** is correct. Choose the answer.
   A if **I only** is correct
   B if **III only** is correct
   C if **I and II** are correct
   D if **II and III** are correct
   E if **I, II, and III** are correct

11. Terms that may be used to describe the following metabolic reaction include

   I. *N*-oxidation.
   II. oxidative deamination.
   III. phase I metabolism.

12. Which of the following reactions can be classified as phase II metabolism?

I.

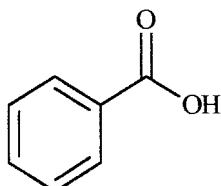
II.

III.

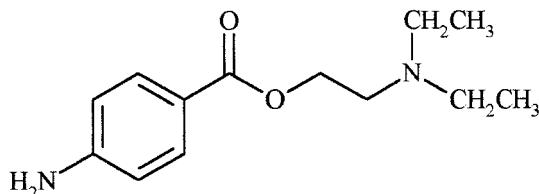
13. Conditions that tend to increase the action of an orally administered drug that undergoes phase II metabolism include
    I. enterohepatic circulation.
    II. enzyme saturation.
    III. first-pass effect.

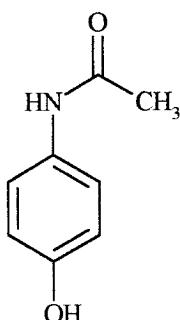
14. Which of the following statements concerning CYP450 are correct?
    I. The CYP7, CYP11, and CYP27 subfamilies are involved in steroid and bile acid synthesis and metabolism.
    II. A single drug may be metabolized by multiple isoforms of CYP450.
    III. The majority of xenobiotics, or drugs, are metabolized by the CYP4B and CYP1A subfamilies.

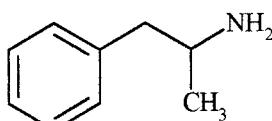
15. Which of the following are genetic contributors to variation in the therapeutic dose of warfarin among patients?
    I. CYP2C9
    II. VKORC1
    III. CYP2D6

16. Examples of phase II enzymes include
    I. CYP450.
    II. *N*-acetyltransferase.
    III. sulfotransferase.


Directions: The group of items in this section consists of lettered options followed by a set of numbered items. For each item, select the **one** lettered option that is most closely associated with it. Each lettered option may be selected once, more than once, or not at all.

Questions 17–20


For each drug, select its most likely metabolic pathway.
- (A) Ether glucuronidation
- (B) Ester glucuronidation
- (C) Nitroreduction
- (D) Oxidative deamination
- (E) Ester hydrolysis


17. Benzoic acid


18. Procaine

19. Acetaminophen

20. Amphetamine

Answers and Explanations

1. The answer is E *[see III.A; III.B]*.
Phase I metabolites are often somewhat more polar than their parents. With the exception of acetylated and methylated metabolites, phase II metabolites are much more polar than their parents. Thus, phase I metabolites are more likely to retain some lipid solubility and are more likely to cross cellular membranes.

It is unusual for a single metabolite to be excreted for a given drug. Most drugs yield a mixture of metabolites. Because of the high polarity and subsequent high excretion of phase II metabolites, they are not likely to undergo further metabolism. Phase I metabolites, on the other hand, are less polar and are very likely to undergo further phase II metabolic reactions.

Whereas the major site of metabolism is the liver, there are many extrahepatic sites that secrete drug-metabolizing enzymes. Although many metabolites are less pharmacologically active than their parents, there are many drugs whose metabolites have equal or greater pharmacological activity and sometimes greater toxicity as well. Prodrugs (i.e., drugs inactive in the form administered) always form at least one active metabolite.

2. The answer is C *[see III.B.1; III.B.3; Table 8-1]*.
Because of the types of functional groups present, aspirin may undergo a number of different metabolic reactions. These include hydroxylation of the aromatic nucleus, conjugation of the carboxyl group with glycine,

conjugation of the carboxyl group with glucuronic acid with the formation of an ester glucuronide, hydrolysis of the acetate ester, and conjugation of the phenol group (resulting from hydrolysis of the acetate ester) with glucuronic acid to form an ether glucuronide.

Because the acetate ester is a simple ester, aspirin is susceptible to hydrolysis in the acid media of the stomach before absorption takes place. In addition, any acetylated molecules that are absorbed are subjected to hydrolysis and are catalyzed by the many esterases present in the circulation. Any acetylated molecules not hydrolyzed in the circulation are subject to hydrolysis in the liver. All of these processes occur before the drug reaches the glomerular filtrate; therefore, excretion of the unchanged acetylated drug is highly unlikely.

3. **The answer is A** *[see III.A.8.c; Table 8-2]*.
Sulfasalazine has both anti-inflammatory and antibacterial activity when converted to aminosalicylic acid and sulfapyridine in the body. This reaction occurs by reductive cleavage of the "azo" linkage contained in the sulfasalazine molecule and is catalyzed in the intestine by bacterial azoreductase. This is a form of site-specific delivery because the intact drug is not absorbed from the stomach or upper intestine and reaches the colon, where it is metabolized. Sulfasalazine is one of a few drugs that are effective for the treatment of ulcerative colitis.

4. **The answer is B** *[see IV.D.1; Table 8-4]*.
The chloramphenicol molecule contains an aromatic nucleus, which would be subject to hydroxylation; a nitro group that is subject to reduction; an amide group that is subject to liver hydrolysis; and alcohol groups that are subject to glucuronidation. Of all the enzyme systems responsible for these reactions, the system responsible for glucuronidation is developed poorly in premature infants and infants up to approximately 6 to 8 weeks of age.

5. **The answer is D** *[see V]*.
By definition, prodrugs are inactive or very weakly active molecules that require in vivo activation to the parent molecule. Thus, conversion of a drug molecule to a prodrug does not increase potency because the original molecule, with whatever potency it contains, is produced after administration. A variety of advantages, including increased water solubility, duration of action, oral absorption, and palatability, can be obtained through the use of prodrugs, but none of these advantages results in an increase in potency of the parent molecule.

6. **The answer is E** *[see IV.I.1–2]*.
First-pass metabolism in the liver refers to biotransformation of a xenobiotic after absorption from the GI tract before it reaches the systemic circulation. Orally administered drugs that are absorbed from the GI tract enter the portal circulation and pass through the liver where they are metabolized. Routes of administration that bypass the first-pass metabolism in the liver include IV, IM, sublingual, buccal, rectal, and inhalation. These routes of administration allow for absorption either outside of the GI tract or in regions of the GI tract that are not part of portal circulation.

7. **The answer is D** *[see IV.H.2]*.
An inhibitor, also called the precipitant drug, is a substance that blocks the metabolism of another drug called the *object drug*. An inducer is a compound that increases the expression of drug-metabolizing enzymes. Both inhibitors and inducers alter drug metabolism that may cause toxicity or lack of efficacy depending on the metabolic consequence of the object drug.

8. **The answer is B** *[see II.A.2.a]*.
The family of cytochrome P450 enzymes are microsomal proteins that contain a porphyrin prosthetic group. Glucuronosyltransferases and flavin-containing monooxygenases are both microsomal enzymes, but they do not contain the porphyrin group.

9. **The answer is E** *[see VII.C.1–3]*.
The most common genetic variation is a single nucleotide polymorphism (SNP), which may be an insertion or deletion that causes a frameshift. These polymorphisms can be called a synonymous SNP if the amino acid expressed is not changed or a nonsynonymous SNP if the amino acid expressed is different. These polymorphisms may also influence the promoter region or the splicing sites for proteins that would not result differences in the amino acids expressed. Multiple copies of a gene, as reported with CYP2D6, are called copy number variations.

10. **The answer is C** *[see VII.D.2.a–c, e, & g]*.
CYP2D6 is a highly polymorphic drug-metabolizing enzyme that is responsible for the conversion of codeine to morphine. TPMT, *N*-acetyltransferase, and CYP2C9 are polymorphic drug-metabolizing enzymes but are not responsible for the conversion codeine to morphine. The CCR5 coreceptor is not a drug-metabolizing enzyme but is involved in the cellular penetration of HIV.

11. The answer is D (II, III) *[see III.A; Table 8-1]*.
The reaction shown in the question involves the conversion of one functional group to another (amine to carbonyl); thus, it is classified as a phase I reaction. The introduction of oxygen into the molecule indicates oxidation, and the loss of the amino group signifies deamination; thus, the reaction also can be classified as oxidative deamination. *N*-Oxidation reactions by CYP450 or FMO are observed but result in the addition of an oxygen to the nitrogen. In this case, no oxygen has been added to the nitrogen; therefore, this is not an *N*-oxidation reaction.

12. The answer is C (I, II) *[see III.A–B; Table 8-4]*.
Phase II metabolic reactions involve masking an existing functional group with a natural endogenous constituent. The formulas shown in choices I and II represent this type of reaction, with choice I being an acetylation reaction and choice II a glycine conjugation reaction. Choice III represents a change in an existing functional group and, thus, represents a phase I reaction. It is an oxidative deamination reaction.

13. The answer is C (I, II) *[see III.C.2.b; IV.I.1; IV.J]*.
Enterohepatic circulation refers to the process by which glucuronides, which are secreted into the intestine with the bile, are hydrolyzed by intestinal bacterial β-glucuronidase. The hydrolyzed free drug, which is no longer polar, becomes available for intestinal reabsorption into the system and subsequent penetration to its active site.

If an enzyme system becomes saturated, then the active drug cannot be inactivated by that pathway. If the drug cannot undergo an alternative pathway, the increased plasma levels of an unchanged active drug can result in increased activity or toxicity.

The first-pass effect results in metabolism of a drug by the liver before the drug reaches its site of action, resulting in an overall decrease in its activity. Drugs that undergo first-pass metabolism generally are effective in much smaller intravenous doses as compared to oral doses.

14. The answer is C (I, II) *[see I; III.A.2.b]*.
There are six mammalian families involved in steroid and bile acid metabolism. These are CYP7, CYP11, CYP17, CYP19, CYP21, and CYP27. Because cholesterol is the common intermediate for the biosynthesis of all endogenous steroids, some of these enzymes are directly involved in cholesterol metabolism. The families listed, CYP7, CYP11, and CYP27, all metabolize cholesterol, whereas the other three families catalyze additional oxidations of the initial metabolites.

There are multiple enzymes and paths that are possible for a single xenobiotic, so it is common that multiple metabolites with varying properties are possible and observed. The cytochrome P450 subfamilies responsible for the majority of the biotransformations are CYP2C, CYP2D, and CYP3A.

15. The answer is C (I, II) *[see VII.D.2.a]*.
Some of the individual variability in dosing is related to the metabolism of warfarin by CYP2C9 and by the level of expression of the warfarin target, VKORC1. With CYP2C9, the variability is related to differences in the metabolic efficiency of the different alleles, whereas differences in the promoter region of VKORC1 result in different levels of expression of the enzyme inhibited by warfarin. CYP2D6, although highly polymorphic, does not contribute to the variability of warfarin dosing.

16. The answer is D (II, III) *[see III.A.2; III.B.2 & 5]*.
Phase II drug-metabolizing enzymes are commonly called transferase enzymes because they transfer a biomolecule from an activated cofactor to a target functional group. Phase II enzymes include glucuronosyltransferase, sulfotransferase, *N*-acyltransferase, glutathione-S-transferase, *N*-acetyltransferase, and methyltransferase. CYP450 is the most common phase I enzyme.

17–20. The answers are 17-B *[see III.B.1]*, **18-E** *[see III.A.9.a]*, **19-A** *[see III.B.1]*, **20-D** *[see Table 8-1]*.
Benzoic acid contains a carboxylic acid, a functional group that commonly undergoes conjugation with glucuronic acid. The resulting conjugation produces an ester. Carboxylic acids can also undergo conjugation with the amino acids glycine and glutamine. Additionally, benzoic acid can undergo aromatic hydroxylation, a common phase I pathway for drugs containing unsubstituted aromatic rings. Of these options, ester glucuronidation is the only answer available here.

Procaine is an ester-containing local anesthetic. Due to the wide physiological distribution of esterase enzymes, it is extremely susceptible to in vivo hydrolysis. This susceptibility to hydrolysis is the major reason why ester-containing local anesthetics have shorter durations of action as compared to those in other chemical classes.

One of the principal functional groups in acetaminophen is the phenol group. Similar to the carboxylic acid in benzoic acid, the phenol commonly undergoes glucuronide conjugation. The one difference is that a phenol (or an alcohol) produces an **ether** glucuronide, whereas a carboxylic acid produces an **ester** glucuronide. Phenols also commonly undergo sulfate conjugation reactions and occasionally undergo O-methylation reactions.

The principal functional group in amphetamine is its primary amine. Oxidative deamination is a very common metabolic path for primary amines. Occasionally, primary amines undergo phase II acetylation; however, this is a less common pathway. Aromatic hydroxylation, similar to that discussed previously for benzoic acid, is also possible for amphetamine.

Pharmacology and Medicinal Chemistry of Drugs Affecting the Nervous System

9

S. THOMAS ABRAHAM, MICHAEL L. ADAMS

I. INTRODUCTION. Drugs affecting the nervous system can modulate neurotransmission in the **central nervous system (CNS) or peripheral nervous system (PNS)**. The CNS consists of the brain and the spinal cord, whereas the PNS is further divided into the **autonomic nervous system (ANS)** and the **somatic nervous system**. The ANS is composed of **sympathetic** and **parasympathetic** divisions that regulate several involuntary actions of the body, whereas the somatic nervous system innervates the skeletal muscles. Agents acting in the ANS include adrenergic agonists and antagonists, cholinergic agonists and antagonists, and indirectly acting agents that could affect one or the other system. These drugs are useful for treating various ailments, including blood pressure disturbances, bronchial asthma, cardiac dysfunctions, anaphylactic reactions, nasal congestion, and skeletal muscle spasticity. Drugs affecting the CNS produce anesthesia and sedation, relieve pain and anxiety, suppress movement disorders and epileptic seizures, and treat psychotic and affective disorders. Drugs acting on the nervous system achieve their pharmacologic effects by modifying the synaptic concentrations or receptor actions of neurotransmitters. Other drugs modulate the intracellular pathways by which neurotransmitter actions are conveyed to yield the ultimate physiological response.

II. DRUGS AFFECTING THE PERIPHERAL NERVOUS SYSTEM

A. The sympathetic nervous system produces global changes in multiple organs such as the heart, liver, kidneys, lungs, etc., to deal with a stressful (fight or flight) situation.

1. Activation of the sympathetic system is accomplished by the stimulation of preganglionic sympathetic nerves in the thoracic and lumbar portions of the spinal cord by input from higher brain centers (e.g., solitary tract nucleus, hypothalamus, the limbic/neostriatal/cortical axis).

2. Most preganglionic fibers synapse with postsynaptic sympathetic fibers in structures known as the paravertebral or chain ganglia. Postganglionic fibers innervate specific organs such as the heart, lungs, and liver, and alter their function by releasing the adrenergic neurotransmitter **norepinephrine (NE)**.

3. Preganglionic sympathetic nerves also stimulate the adrenal medulla to release **epinephrine (Epi)**, which is transported via the blood to the organs of the body. These catecholamines (NE, Epi) activate either **α- or β-adrenergic receptors** on various tissues to initiate specific biochemical signaling events (see Chapter 58), and thereby alter organ function.

4. *Table 9-1* lists the effects of the sympathetic nervous system on various organs as well as the predominant receptors that mediate these effects.

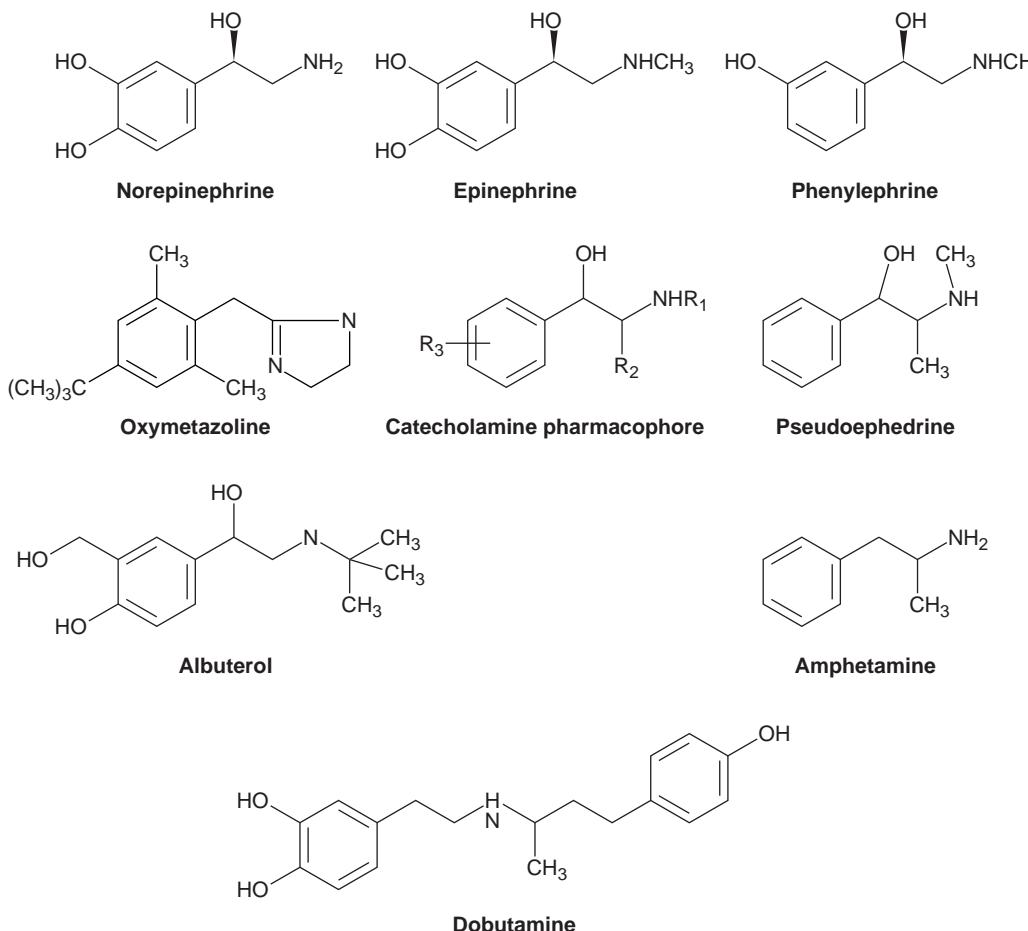
165


Table 9-1　ADRENERGIC RECEPTORS AND THEIR PREDOMINANT PHYSIOLOGICAL EFFECTS

Organ/Tissue	Adrenergic Receptor	Major Effect
Eye		
Iris radial muscle	$\alpha 1$	Pupillary dilation
Ciliary muscle	β_2	Relaxation for far vision
Heart		
Sinoatrial, atrioventricular nodes	β_1, β_2	Increased spontaneous depolarization
His-Purkinje system	β_1, β_2	Increased conduction velocity
Atria, ventricles	β_1, β_2	Increased contractility
Blood vessels		
Arteries, arterioles	$\alpha_1, \alpha_2, \beta_2$	Constriction via α_1, α_2; dilation via β_2
Veins, venules	$\alpha_1, \alpha_2, \beta_2$	Constriction via α_1, α_2; dilation via β_2
Lungs		
Tracheal, bronchial muscle	β_2	Relaxation of smooth muscle
Bronchial glands	α_1, β_2	Decreased secretions
GI tract		
Salivary glands	α_1	Decreased secretions
Stomach	$\alpha_1, \alpha_2, \beta_2$	Decreased motility; decreased secretions
Intestines	α_1, β_2	Decreased motility
Urinary bladder		
Detrusor	β_2	Relaxation, increased capacity
Trigone, sphincter	α_1	Contraction
Sex organs	α_1	Ejaculation
Skeletal muscle	β_2	Increased contractility; glycogenolysis
Liver	α_1, β_2	Increased glycogenolysis
Pancreas	β_2	Increased insulin release
Fat cells	$\beta_1, \beta_2, \beta_3$	Lipolysis
Kidneys	α_1, β_1	Increased renin release

5. The release of NE by postganglionic sympathetic nerves is regulated by the rate of action potentials reaching the nerve ending and also by several receptors on the nerve terminal membranes. The presynaptic α_2, adenosine, neuropeptide Y, and muscarinic M_2-receptors reduce neurotransmitter released by the nerve, whereas nicotinic-N_N, angiotensin AT1, and β_2-receptors enhance NE release.

6. The actions of NE and Epi on adrenergic receptors are terminated by uptake into postganglionic nerve endings via a **norepinephrine transporter (NET)** or the postsynaptic tissue by the extraneuronal transporter. Tricyclic antidepressants (e.g., imipramine) and cocaine are efficient inhibitors of NET function and thereby prolong NE actions at the receptor.

7. NE uptake into the nerve terminal may result in uptake into synaptic vesicles or metabolism by **monoamine oxidases (MAO)** and catechol-*O*-methyltransferases (COMT).

B. **Pharmacology and medicinal chemistry of sympathomimetics**

1. **Nonselective adrenergic agonists**, such as norepinephrine and epinephrine, interact directly with adrenergic receptors to elicit a response. Thus, pharmacological application of these agents results in the activation of α- and β-adrenoceptors throughout the body, resulting in the diverse actions listed in *Table 9-1*.

a. The ethylamine chain common to these agonists is essential to their adrenergic activity, and the general pharmacophore is a primary or secondary amine two carbon atoms away from a substituted benzene ring (*Figure 9-1*).

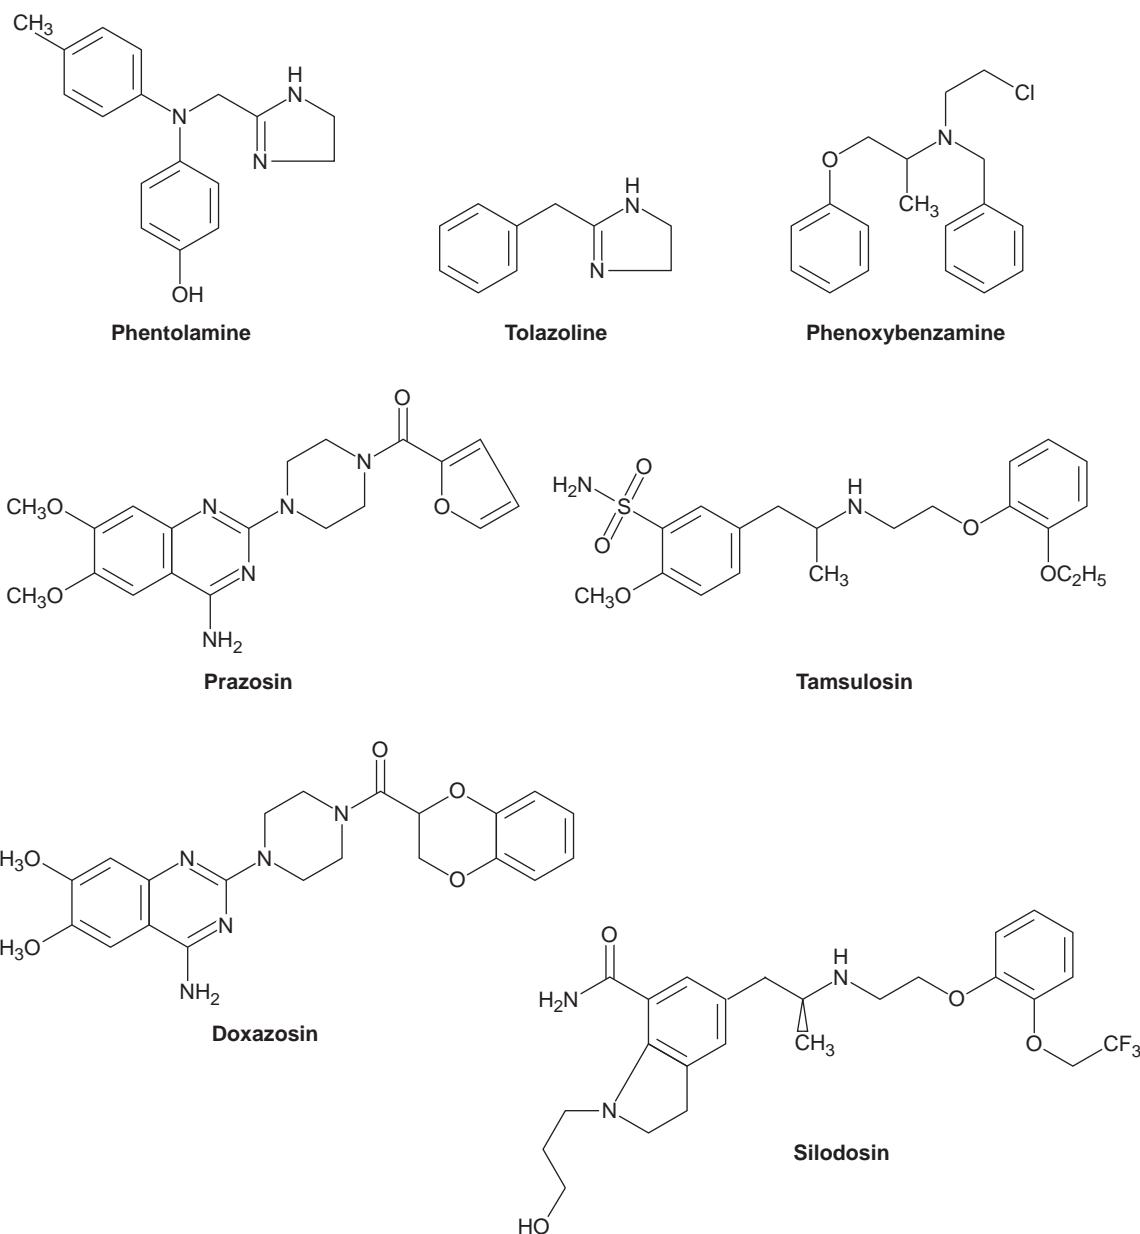
b. Intravenous epinephrine is used to treat cardiac arrest and hypotensive crisis (e.g., during anaphylactic reactions) due to its vasoconstrictor and positive ionotropic/chronotropic effects. Epinephrine is also mixed with local anesthetics, such as lidocaine, to produce localized vasoconstriction to prolong the duration of action and minimize the systemic effects of the latter.


Figure 9-1. Structural formulas of the catecholamine pharmacophore with nonselective (epinephrine, norepinephrine), α_1-selective (phenylephrine), α-nonselective (oxymetazoline), β_1-selective (dobutamine), and β_2-selective (albuterol) agonists. Pseudoephedrine is a mixed α-agonist and indirect (NE releasing) agent, whereas amphetamine only releases catecholamines from sympathetic nerves (indirect action).

    c. Dipivefrin (Propine®), the catechol diester prodrug of epinephrine, is used to treat open-angle glaucoma. Tissue esterases presumably cleave the ester bonds to regenerate epinephrine, which activates α_2-receptors on the ciliary body to decrease aqueous humor production.

2. Selective α-adrenergic agonists. To date, α_{1A}-, α_{1B}-, α_{1D}-, α_{2A}-, α_{2B}-, and α_{2C}-adrenergic receptors have been identified via pharmacological and molecular cloning methods.

    a. Methoxamine, phenylephrine, and clonidine, in general, have increased selectivity for α-versus β-receptors. Removal of the *para* hydroxyl group or substitution of the *meta* hydroxyl of Epi with a methoxy group increases α_1-receptor activity, as seen with phenylephrine (*Figure 9-1*) or methoxamine.

    b. Phenylephrine is useful as a topical (Neo-Synephrine®) or systemic (Sudafed-PE®) nasal decongestant. Intravenous administration of phenylephrine and methoxamine can be used to maintain systemic blood pressure in hypotensive conditions.

    c. Imidazoline derivatives such as oxymetazoline and clonidine have both α_1- and α_2-agonist activities with bulky *para* or *meta* substitutions on the benzene ring, generally increasing $\alpha1$-selectivity (oxymetazoline; *Figure 9-1*). Oxymetazoline (Afrin®) is used as a topical nasal decongestant due to its direct vasoconstrictor action in the nasal mucosa. Clonidine (Catapres®) reduces tonic sympathetic output from the CNS by activating central α_2-adrenoceptors and is an effective antihypertensive agent.

    d. Derivatives of clonidine such as apraclonidine (Iopidine®)and brimonidine (Alphagan-P®) are used topically to selectively activate α_2-receptors in the eye to treat open-angle glaucoma.

e. The predominant adverse effect of imidazoline nasal decongestants is rebound congestion, whereas topical phenylephrine is less likely to produce this effect. Systemic clonidine administration can be associated with bradycardia, hypotension, sedation, and dry mouth. Sudden withdrawal of clonidine can result in enhanced central sympathetic outflow characterized by hypertension, sweating, tachycardia, and tremors.

3. Selective β-adrenergic agonists. To date, three distinct β-adrenergic receptors with unique functions (*Table 9-1*) have been identified; however, β_1- and β_2-receptors are the primary targets of pharmacological intervention.

    a. N-Substitutions of the catecholamine pharmacophore with isopropyl groups or aryl-alkyl groups, as in the case of albuterol (Ventolin®) or dobutamine (Dobutrex®; *Figure 9-1*), respectively, improve β-receptor selectivity over α-receptors. The bulky N-substitution of dobutamine confers some increased selectivity of the drug for β_1- relative to β_2-receptors.

    b. On the other hand, alteration of the *meta* hydroxyl on the benzene ring to a methoxy group (albuterol) or the catechol ring to a resorcinol (e.g., terbutaline) increases the selectivity of these agents for β_2- versus β_1-receptors.

    c. β_2-Selective agonists (albuterol, terbutaline, metaproterenol) are used as rescue bronchodilators in asthma or obstructive pulmonary disease and are often administered via metered-dose inhalers. By activating β_2-receptors, these agents elevate bronchial smooth muscle cAMP leading to decreased intracellular calcium and prompt bronchodilation.

    d. Terbutaline and ritodrine administered systemically have found use in slowing down premature labor.

    e. Dobutamine is used in acute heart failure for its positive ionotropic actions on the myocardium via β_1-receptor stimulation. Receptor stimulation leads to increased myocardial cAMP; however, in this case, the consequence is increased opening of L-type calcium channels and intracellular calcium, followed by enhanced contractility.

    f. Adverse effects such as tachycardia, muscle tremors, and insomnia with β_2-agonist use are generally due to their actions at cardiac and other β-receptors because their selectivity is not absolute. Dobutamine has been associated with tachyarrhythmias and ischemia during use.

4. Indirect acting sympathomimetics

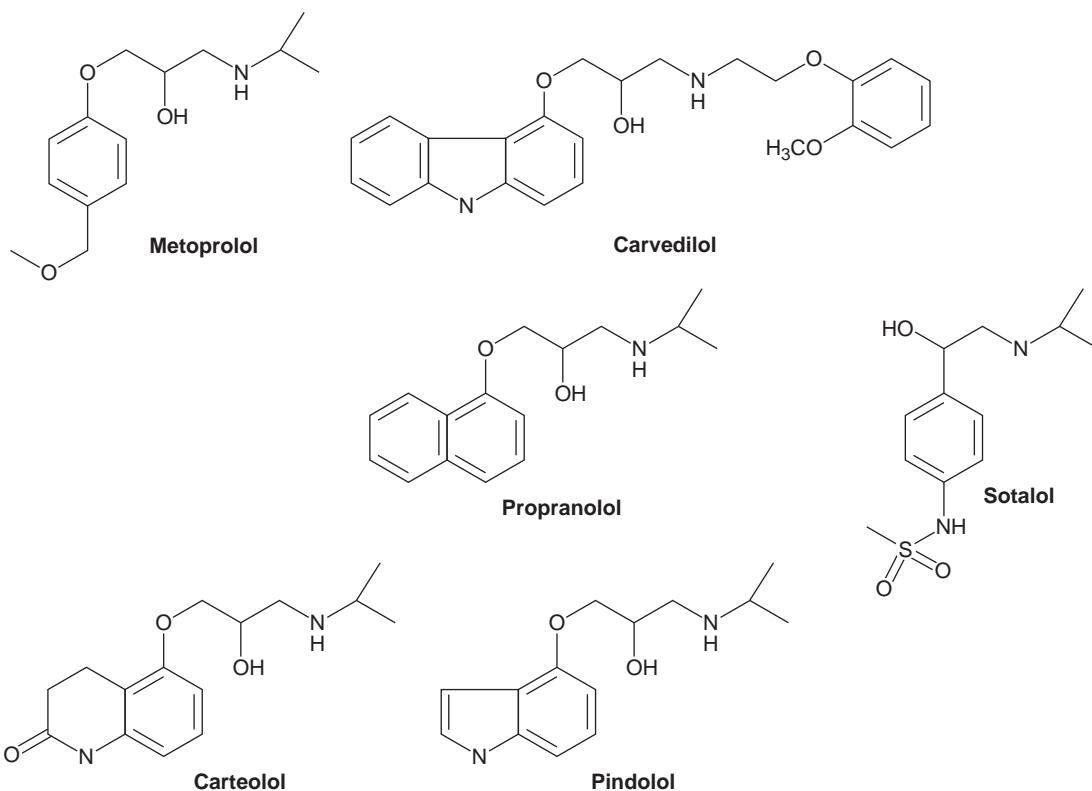
    a. Removal of the hydroxyls on the catechol ring and addition of a α-methyl group partially reduce direct receptor agonist activity but increase indirect activity. Thus, ephedrine and pseudoephedrine (*Figure 9-1*) have the ability to activate α-adrenergic receptors and be taken up into the nerve terminal (via NET) and cause NE release from neurotransmitter vesicles.

    b. The lack of catechol hydroxyls also reduces metabolism by COMT and increases CNS penetration of these phenylethanolamines.

    c. Ephedrine and pseudoephedrine are used systemically to reduce nasal congestion, and their predominant adverse effects are insomnia, appetite suppression, and hypertension.

    d. Amphetamine (Adderall®; *Figure 9-1*), methamphetamine (Desoxyn®), and methylphenidate (Ritalin®) have little or no direct receptor action but enhance catecholamine release in the CNS.

    e. They are primarily used to treat attention deficit hyperactivity disorders, narcolepsy, and to suppress appetite. Adverse events related to their use are multiple and include dizziness, tremors, euphoria, confusion, aggressiveness, anorexia, sweating, convulsions, and coma.

C. Pharmacology and medicinal chemistry of adrenergic antagonists


1. Selective α-adrenergic antagonists. Antagonists of the α-adrenergic receptors are primarily imidazoline or quinazoline derivatives.

    a. The imidazoline antagonists are represented by phentolamine (Regitine®) and tolazoline (not marketed), having a similar structure to imidazoline α-agonists but lacking the lipophilic substitutions on the aromatic ring (*Figure 9-2*). They are unable to activate α-receptors and behave as competitive antagonists of both α_1- and α_2-adrenergic receptors.

    b. Blockade of α_1- and α_2-adrenergic receptors on the arteriolar beds leads to reduced peripheral vascular tone and systemic blood pressure and can be used to treat hypertension. They are also used to manage the hypertensive crisis resulting from catecholamine released by pheochromocytomas.

    c. Due to their actions to block inhibitory **presynaptic α_2-receptors** (see I.A.1), they often produce marked tachycardias as a result of increased NE release from cardiac sympathetic nerves. This can progress to cardiac ischemia, myocardial infarction (MI), or arrhythmias in susceptible individuals.

Figure 9-2. Structural formulas of the nonselective α-adrenergic antagonists phentolamine, tolazoline, and phenoxybenzamine. The α_1-selective antagonists are represented by prazosin and doxazosin, whereas tamsulosin and silodosin are α_{1A}-selective antagonists.

    d. Blockade of α-receptors on veins increases venous pooling of blood and can result in **orthostatic or postural hypotension**. Additionally, blockade of gastrointestinal (GI) α-receptors can result in abdominal cramping, nausea, and exacerbation of peptic ulcers.

    e. The β-haloalkylamine phenoxybenzamine (Dibenzyline®) is unique among α-antagonists in that the tertiary amine undergoes cyclization (with the loss of the chlorine atom, *Figure 9-2*) to form a reactive aziridinium intermediate. Cleavage of this ring results in the formation of a highly reactive carbonium ion that alkylates sulfhydryl, carboxyl, and amino groups on proteins. The covalent interaction of the drug with α-receptors results in irreversible inactivation of the receptor, which cannot be overcome even with very high catecholamine levels.

    f. Phenoxybenzamine is used to manage metastatic pheochromocytoma, where high catecholamine levels would displace reversible antagonists such as phentolamine. Clinical doses of phenoxybenzamine probably antagonize both α_1- and α_2-receptors.

g. Prazosin (Minipress®), doxazosin (Cardura®; *Figure 9-2*), and terazosin (Hytrin®) belong to the quinazoline class and show increased selectivity for the α_1- versus α_2-receptors. Vasodilation of arteriolar beds results from antagonism of α-receptors that are tonically driven by innervating sympathetic nerves, with reduction in peripheral vascular resistance. A similar mechanism leads to venodilation, which reduces venous return to the heart and, in a sequential manner, decreases end-diastolic filling, myocardial contractility, and eventually cardiac output. Because both peripheral vascular resistance and cardiac output contribute to systemic blood pressure, a reduction of either parameter will decrease systemic blood pressure.

h. Quinazoline antagonists are important in the management of essential hypertension but are also used to manage **benign prostatic hyperplasia**, especially terazosin.

i. Adverse effects often seen with the use of prazosin and congeners are postural hypotension especially after the first dose, pupil constriction, nasal congestion, and impaired ejaculation.

j. Newer α-antagonists tamsulosin (Flomax®) and silodosin (Rapaflo®) have increased affinity for the α_{1A}-receptors of the prostate as compared to the α_{1B}-receptors of the vasculature, relaxing the prostate and the neck of the bladder without affecting systemic blood pressure.

k. Yohimbine (Yocon®) is the only clinically relevant α_2-selective antagonist currently on the market and is used to treat erectile dysfunction. It appears to improve this condition by blockade of α_2-receptors in the penile cavernosum, resulting in vasodilation and increased blood pooling.

2. **β-Adrenergic receptor antagonists.** Although all the drugs in this class are β-receptor antagonists, they are heterogeneous with regard to additional actions such as sodium/potassium channel blockade, having inverse or partial agonist activity and blockade of α-receptors.

a. Propranolol (Inderal®), the prototypical drug in this class, is an aryloxypropanolamine (*Figure 9-3*), derived from modifications of earlier antagonists such as dichloroisoproterenol and pronethalol. Generally, an arylethylamino or similar large hydrophobic group, without phenolic hydroxyls, is required for antagonistic activity at both β_1- and β_2-receptors, for example, timolol (Timoptic®), nadolol (Corgard®), and carteolol (Ocupress®) (*Figure 9-3*).

Figure 9-3. Propranolol and carteolol are β-nonselective antagonists, whereas metoprolol is β_1-selective. Pindolol is a β-nonselective partial agonist; carvedilol is also β-nonselective and blocks α_1-receptors as well. Sotalol is a β-nonselective antagonist with prominent K^+ channel blocking activity.

| Table 9-2 | SELECTIVE AND NONSELECTIVE β-RECEPTOR ANTAGONISTS | | |

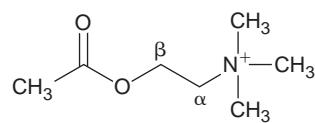
β–Antagonist	Partial Agonist Activity	Local Anesthetic Activity	Other Activity
Subtype nonselective			
Propranolol	No	Yes	
Nadolol	No	No	
Pindolol	Yes	Yes	
Sotalol	No	No	K^+ channel blocker
Timolol	No	No	
Carvedilol	No	No	α_1-Blocker
Carteolol	Yes	No	
Labetalol	Yes	Yes	α_1-Blocker
β_1-Selective			
Acebutolol	Yes	Yes	
Atenolol	No	No	
Betaxolol	No	Low	
Esmolol	No	No	
Metoprolol	No	Yes	

    b. Substitutions *para* to the phenoxy position increase the relative β_1-selectivity of these agents, for example, metoprolol (Toprol-XL®; *Figure 9-3*), atenolol (Tenormin®), and acebutolol (Sectral®). Pindolol (Visken®) and carteolol possess significant agonistic activity at β-receptors and are more appropriately partial agonists than antagonists. The S-isomers of labetalol (Trandate®) and carvedilol (Coreg®; *Figure 9-3*) appear to have significant α_1-receptor antagonist activity in addition to β-blocking actions.

    c. Propranolol and carvedilol have the ability to block voltage-dependent sodium channels, whereas sotalol (Betapace®) is primarily used for its potassium-channel blocking/antiarrhythmic actions rather than its β-blocking activity.

    d. β-Receptor antagonists are used to manage several diverse conditions such as hypertension, post-MI cardiac arrhythmias, angina, congestive heart failure (CHF), stage fright, hand tremors, and glaucoma. Their use in hypertension has been largely supplanted by more effective agents; however, they have been shown to be effective in preventing a second MI, slow down the progression of CHF, and decrease the incidence of stable angina.

    e. For the most part, there appears to be no clinical benefit of using β_1-selective agents over nonselective antagonists except in special populations: β_1-selective agents (e.g., metoprolol) may be less likely to cause bronchospasms in asthmatic patients; partial agonists (e.g., pindolol) may be better tolerated in bradycardic conditions. *Table 9-2* summarizes several important pharmacological actions of β-receptor antagonists.

  3. **The parasympathetic nervous system** is able to produce discreet changes in specific organs to mediate processes such as lacrimation, salivation, or emptying of the bladder. These functions are initiated by preganglionic parasympathetic nerves originating from the tectal brainstem or sacral portions of the spinal cord and end in ganglia close to the innervated organ. Postganglionic nerves from these structures innervate relevant organs and modify their functions by activating **muscarinic-cholinergic (M)** receptors through the release of acetylcholine (ACh). The actions of released ACh are terminated by **acetylcholinesterase (AChE)** found in the synaptic space. *Table 9-3* summarizes the organs innervated by the parasympathetic nerves, the receptors activated, and the resulting biological effects.


D. **Pharmacology and medicinal chemistry of cholinomimetic agents**

  1. **Direct-acting cholinergic agonists.** ACh is considered the prototypical cholinergic agonist having actions at all muscarinic and nicotinic receptor subtypes (*Figure 9-4*).

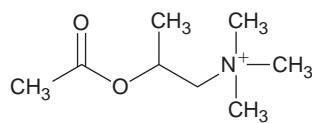
    a. Agonist activity is tightly constrained and requires that there be no more than five atoms between the nitrogen and terminal hydrogen on the acyloxy group (*Figure 9-4*). Substitution of


Table 9-3   CHOLINERGIC RECEPTORS AND THEIR MAJOR PHYSIOLOGICAL EFFECTS

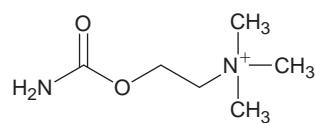
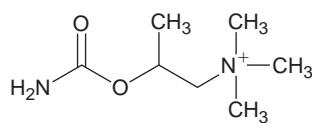
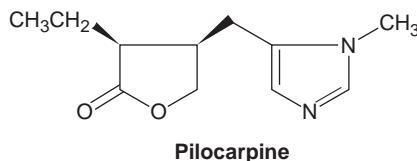
Organ/Tissue	Cholinergic Receptor	Major Effect
Eye		
Iris radial muscle	M_3	Pupillary constriction
Ciliary muscle	M_3	Contraction for near vision
Heart		
Sinoatrial, atrioventricular nodes	M_2	Decreased spontaneous depolarization
His-Purkinje system	M_2	Little effect
Atria, ventricles	M_2	Decreased contractility in atria
Blood vessels		
Arteries, arterioles	M_3	Increased NO release and vasodilation
Veins, venules	—	Little effect
Lungs		
Tracheal, bronchial muscle	M_3	Bronchoconstriction
Bronchial glands	M_2, M_3	Increased secretions
GI tract		
Salivary glands	M_2, M_3	Increased secretions
Stomach	M_2, M_3	Increased motility and secretions
Intestines	M_2, M_3	Increased motility
Kidneys	—	—
Urinary bladder		
Detrusor	M_3	Contraction, decreased capacity
Trigone, sphincter	M_2	Relaxation
Sex organs	M_3	Erection
Skeletal muscle	N_M	Muscle contraction
Liver	—	—
Pancreas	M_3, M_2	Increased digestive enzyme release
Fat cells	—	—


NO, nitric oxide.




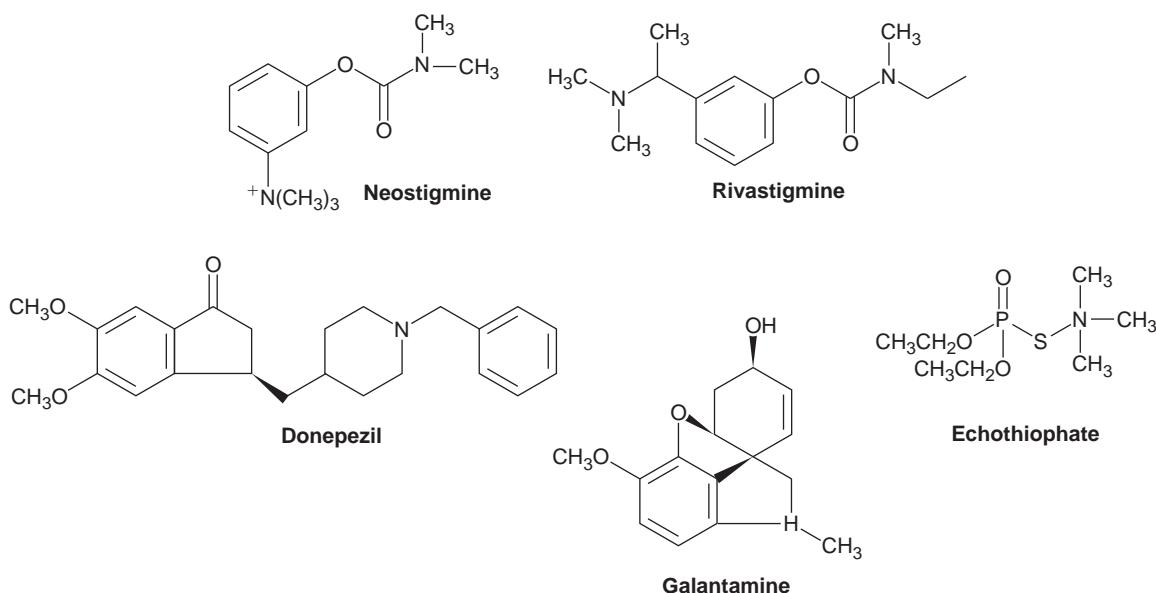


Figure 9-4. The structural formulas of the naturally occurring (acetylcholine, pilocarpine) and synthetic (methacholine, carbachol, bethanechol) muscarinic agonists.

the quaternary nitrogen with S or P usually reduces activity, but the positive charge is required for activity. If more than one of the methyl groups on the amine is altered by a larger alkyl substitution, marked reduction in activity is observed. Generally, the addition of a methyl group on the β-carbon results in increased selectivity for muscarinic versus nicotinic receptors (e.g., methacholine [Provocholine®; *Figure 9-4*]). This also reduces susceptibility to metabolism by cholinesterases, prolonging the duration of action.

   b. The substitution of the methyl group on the acyloxy to an amino group (carbamate) provides additional resistance to cholinesterase metabolism for carbachol (Miostat®) and bethanechol (Urecholine®; *Figure 9-4*). Thus, the susceptibility to metabolism of the four agents follows the trend: ACh > methacholine > carbachol > bethanechol. Only bethanechol has significant oral activity, and the others have to be applied parenterally or topically for pharmacological action.

   c. ACh and carbachol are applied as drops to produce brief miosis during eye surgery, and carbachol is also able to control increases in intraocular pressure after surgery. Inhaled methacholine has been used to assess bronchial hyperactivity in patients who do not exhibit clinical asthma. Bethanechol is indicated for urinary retention that occurs postoperative or postpartum and due to neurogenic atony of the bladder. By contracting the detrusor and relaxing the trigonal and sphincter muscle of the bladder, bethanechol is able to increase voiding action. As indicated in *Table 9-3*, the contractile effects are most likely mediated by M_3-receptors on the bladder wall, whereas the relaxant effects are due to the activation of M_2-receptors on the sphincters. Bethanechol has also been used to increase GI motility in postsurgical distention of the abdomen.

   d. Pilocarpine (Ocusert Pilo-20®) applied topically is used to treat open-angle glaucoma and oral administration has been used to treat dry mouth resulting from head/neck radiation or due to Sjögren syndrome. Pilocarpine relieves glaucoma symptoms by activating muscarinic receptors on iris sphincter and longitudinal ciliary muscles, along with relaxing the suspensory ligaments on the lens, and allows for improved drainage of aqueous humor through the canal of Schlemm.

   e. Because ACh and carbachol are applied topically, they are generally accompanied by relatively few systemic effects. Methacholine has caused profound bronchoconstriction in susceptible individuals when used as a diagnostic agent. The systemic use of bethanechol or pilocarpine may be associated with pupillary constriction, sweating, bradycardia, difficulty focusing the eyes, hypotension, and excessive salivation.

2. Indirect-acting cholinomimetics. Inhibition of AChE in the cholinergic synapse results in enhanced ACh levels in the synapse and increased muscarinic or nicotinic receptor activation. Thus, inhibition of ACh metabolism in the synapse mimics the stimulation of cholinergic nerves.

   a. AChE inhibitors interact with the catalytic site of the enzyme in a reversible or irreversible manner and prevent the access of ACh to the same site. Agents such as tacrine (Cognex®), donepezil (Aricept®), and galantamine (Razadyne®) have high affinity for the AChE active site but interact via noncovalent bonds and can theoretically be displaced by excess ACh.

   b. Carbamate derivatives of AChE inhibitors such as neostigmine (Prostigmin®), pyridostigmine (Mestinon®), and rivastigmine (Exelon®; *Figure 9-5*) form covalent, carbamoylated intermediates with a serine residue in the AChE active site. These inhibitors are often termed "suicide" inhibitors because they are destroyed in the process of covalently modifying AChE. These intermediates are only slowly hydrolyzed to regenerate the active site serine to metabolize ACh again.

   c. The polar nature of quaternary amines (e.g., neostigmine, pyridostigmine) prevents them from crossing the blood–brain barrier and having CNS effects, whereas the tertiary amines (e.g., rivastigmine, donepezil, tacrine, and galantamine) have improved CNS penetration and activity.

   d. The organophosphate inhibitors of AChE, such as echothiophate (Phospholine®; *Figure 9-5*), form much more stable phosphoester bonds with the serine residue and are extremely slowly hydrolyzed. Loss of one or both ethyloxy groups from echothiophate (a process known as aging) increases the stability of the phosphoester bond, and the enzyme is permanently inactivated.

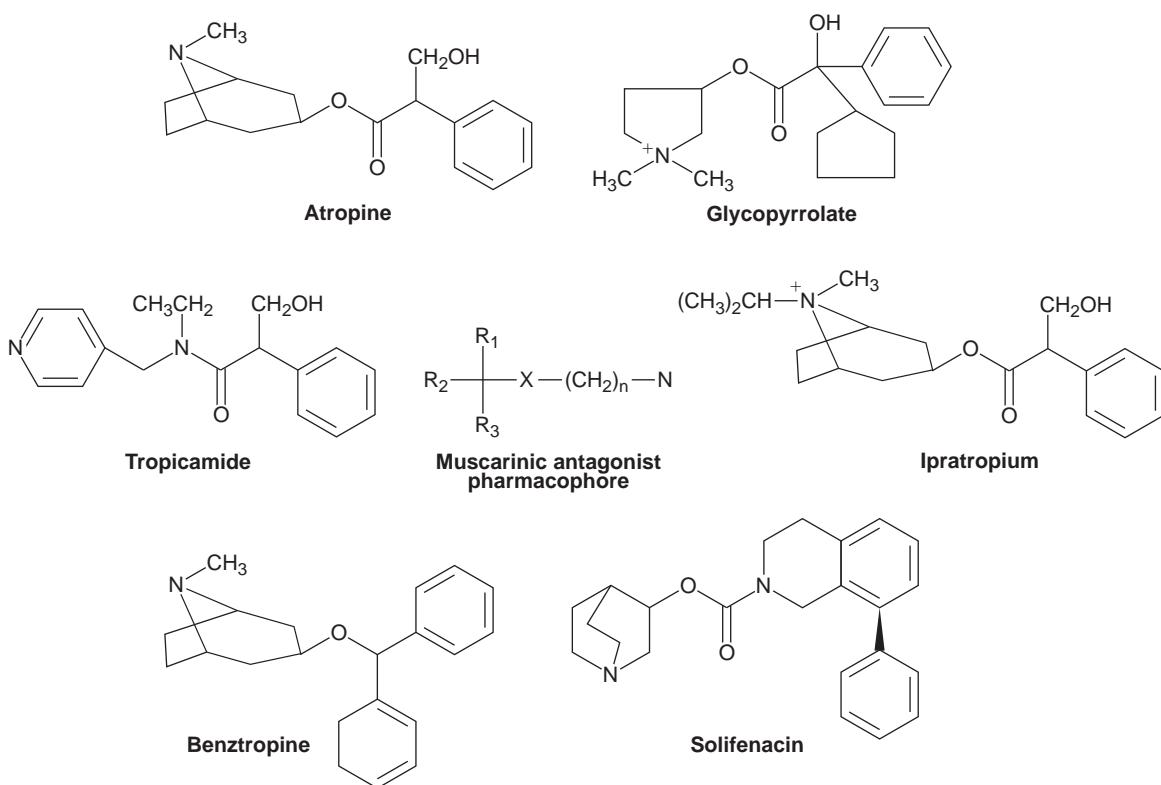
   e. The quaternary amine AChE inhibitors (e.g., neostigmine, pyridostigmine) are used to improve GI motility (e.g., after surgery) by increasing muscarinic stimulation on smooth muscle. They are also used to treat myasthenia gravis, where autoimmune reactions cause a marked loss


Figure 9-5. The structural formula of the carbamate (neostigmine, rivastigmine) and organophosphate (echothiophate) AChE inhibitors. Donepezil and galantamine do not covalently interact with AChE to inhibit its activity.

in nicotinic receptors at the motor end plate with resultant muscle weakness. Inhibition of AChE in the neuromuscular junction elevates ACh levels at the remaining nicotinic receptors to increase skeletal muscle contractions. Topical application of echothiophate and physostigmine can improve the drainage of aqueous humor in patients with open-angle glaucoma via indirect stimulation of muscarinic receptors. The carbamate AChE inhibitors have been used to reverse the poisoning by muscarinic antagonists such as atropine by indirectly elevating synaptic ACh. The tertiary amine inhibitors (e.g., rivastigmine, donepezil, galantamine) are primarily used to block AChE in the CNS to increase synaptic ACh and treat conditions such as Alzheimer dementia.

    f. Systemic application of AChE inhibitors mimics generalized parasympathetic nervous system stimulation with patients experiencing pupillary miosis, loss of far vision, increased salivation and GI motility, and bradycardia.

E. Pharmacology and medicinal chemistry of cholinergic antagonists

    1. Selective muscarinic antagonists. The prototypical muscarinic antagonist, atropine, was originally identified in extracts of the belladonna plant and is an ester of tropic acid and an organic base such as tropine (*Figure 9-6*).

        a. The pharmacophoric structure indicated in *Figure 9-6* represents the wide variety of muscarinic antagonists (naturally occurring and synthetic) and can be grouped into amino alcohols, amino alcohol esters, amino ethers, and amino amides. Cyclic or heterocyclic rings at the R_1 and R_2 positions increase muscarinic receptor binding, whereas R_3 may be -H, -OH, or -CH$_2$OH. Position X may be an ester or ether (ester is more potent) group, whereas increased substitution of the terminal nitrogen improves receptor affinity such that the quaternary amine is most potent.

        b. Most of the these agents are nonselective for the five muscarinic receptors found in the body; however, newer agents such as solifenacin (VESIcare®; *Figure 9-6*) and darifenacin (Enablex®) have some selectivity for M_3-receptors relative to M_1-and M_2-receptors.

        c. Muscarinic antagonists are used to treat several conditions where receptor stimulation via the parasympathetic system needs to be decreased. Atropine and glycopyrrolate (Robinul®) are used to decrease the effects of vagal reflexes during surgery (bronchial secretions, bradycardia), whereas scopolamine is used to induce sedation and decrease motion sickness.

        d. Atropine in preparations such as Lomotil® reduces GI motility associated with diarrhea.

Figure 9-6. Structural formulas of muscarinic antagonist pharmacophore and the nonselective M-antagonists atropine, glycopyrrolate, tropicamide, benztropine, and ipratropium. Solifenacin has selectivity for the M_3-receptor.
    e. Tropicamide (Mydriacyl®) applied topically is used most often to produce pupillary dilation during eye exams, whereas ipratropium (Atrovent®; *Figure 9-6*) and tiotropium (Spiriva®) are applied via metered-dose inhalers for the management of asthma and chronic obstructive pulmonary disease.

    f. Blockade of M_3-receptors on the bladder decreases intravesicular pressure, increases bladder capacity, and reduces the frequency of spasms to effectively manage symptoms of overactive bladders. Oxybutynin (Ditropan®), trospium (Sanctura®), tolterodine (Detrol®), solifenacin, and darifenacin are the primary agents used to manage this condition.

    g. Muscarinic antagonists are used to control movement disorders related to Parkinson disease or antipsychotic drug therapy (e.g., benztropine [Cogentin®] and trihexyphenidyl HCl [Artane®]).

    h. The primary adverse effects related to the systemic use of muscarinic antagonists are dry mouth, tachycardia, constipation, mydriasis/photophobia, loss of accommodation, urinary retention, and CNS excitation. Ocular application of muscarinic antagonists can cause loss of accommodation and increased intraocular pressure.

III. DRUGS AFFECTING THE SOMATIC NERVOUS SYSTEM.

The somatic nerves that produce voluntary movement originate in the spinal cord and project their myelinated axons via the dorsal root to specific muscle bundles. These axons release ACh at the neuromuscular junction to activate **nicotinic–cholinergic (N)** receptors, causing the depolarization and contraction of muscle fibers. The actions of ACh at the nicotinic receptor are terminated by synaptic AChE and result in relaxation of the muscle fiber.

    A. Drugs affecting the neuromuscular junction. The motor end plate of the neuromuscular junction contains cholinergic–nicotinic receptors (N_N subtype) that are voltage-gated sodium channels. Binding of ACh to these receptors opens the channel's gating mechanism, allowing a rapid influx

of Na$^+$ ions that depolarize the end plate. This depolarization spreads longitudinal along the muscle fiber to open T-type calcium channels in the T tubule to allow a secondary calcium influx that triggers further calcium release from the sarcoplasmic reticulum to mediate muscle contraction. The N_N receptor is a pentamer of 2α, β, γ, and δ subunits arranged in the plasma membrane to form an ion channel. The binding of an ACh molecule to each α-subunit is thought to be necessary for optimal channel activation.

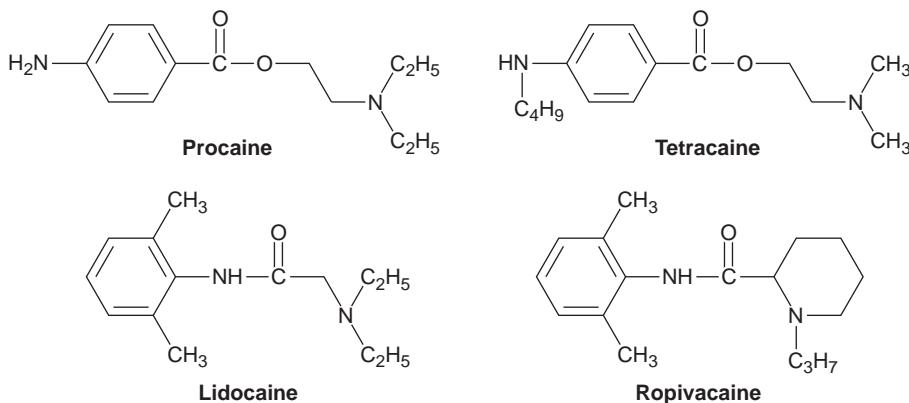
1. All the drugs in this class also appear to bind to the same sites on the α-subunits and can thus be classified as competitive ligands. Nicotinic antagonists are primarily divided into **nondepolarizing** and **depolarizing** agents, depending on whether they activate the ion channel to cause depolarization of the motor end plate or not. Nondepolarizing agents such as tubocurarine, atracurium (Tracrium®), pancuronium, and rocuronium (Zemuron®) (*Figure 9-7*) prevent the binding of ACh to the α-subunits of N_N receptor to prevent depolarization of the end plate, and a rapid paralysis ensues. Thus, these agents possess no inherent ability to activate ion conductance.


Figure 9-7. Structural formulas of the nondepolarizing (tubocurarine, atracurium, pancuronium, rocuronium) and depolarizing (succinylcholine) nicotinic antagonists.

2. Nondepolarizing antagonists can be subdivided into isoquinoline (e.g., tubocurarine, atracurium) or steroid (e.g., pancuronium, rocuronium) chemical classes; however, they all possess one or two quaternary amines, which mimic that on ACh and are required for binding to the receptor.

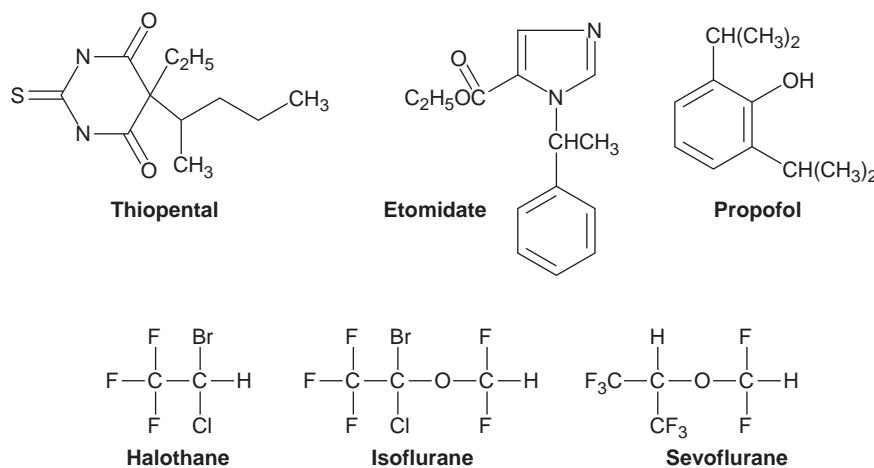
3. The depolarizing blocker succinylcholine (Anectine®; *Figure 9-7*) is essentially two ACh molecules attached at their acyloxy group. The drug binds to the same site as ACh to cause motor end plate depolarization and some muscle contraction initially. The inability of synaptic AChE to rapidly metabolize succinylcholine results in prolonged end plate depolarization and inactivation of the ion channel. Consequently, initial depolarization and muscle contraction is followed by a prolonged flaccid paralysis of muscle as the N-receptor is unable to reset and respond to subsequent agonist stimulation. Any ACh that binds to the receptors tends to further the depolarization/inactivation cycle to promote greater paralysis.

4. Application of an AChE inhibitor (neostigmine) can be used to reverse the paralysis induced by nondepolarizing agents, whereas the paralysis induced by succinylcholine will only be exacerbated by this strategy.

5. Nondepolarizing agents are used to produce prolonged skeletal muscle relaxation during surgery, whereas succinylcholine is used to induce short-term paralysis in procedures such as intubations, resetting of a fracture, and endoscopic investigations.

6. The major adverse effects observed with these agents are histamine release, hypotension, tachycardia, cardiopulmonary collapse, and malignant hyperthermia. Succinylcholine is also associated with hyperkalemia secondary to excessive K^+ release from skeletal muscle.

IV. DRUGS AFFECTING THE CENTRAL NERVOUS SYSTEM

A. **Local anesthetic drugs affecting sensory nerves**


1. The afferent sensory nerve fibers that transmit pain sensations to the CNS are located in the periphery, but secondary afferent neurons found in the spinal cord would also be involved in transmitting those signals to the brain.

2. Noxious stimuli initiate depolarizing currents at the sensory nerve ending that are transmitted up the axon by action potentials regulated by the sequential opening of voltage-gated sodium and potassium channels.

3. This action potential propagates up the axon carrying the sensory signal to the secondary afferent in the spinal cord. Local anesthetics can have actions on the primary or secondary sensory afferents, depending on where the drugs are applied.

4. The general chemical characteristics of local anesthetics are an aromatic ring connected to an ionizable tertiary amine via an ester or amide linkage (*Figure 9-8*). Examples of ester local anesthetics are procaine (Novocaine®) and benzocaine, whereas lidocaine (Xylocaine®) and ropivacaine (Naropin®) are examples of amides.

5. Due to the actions of tissue esterases, amide local anesthetics generally have longer durations of action when compared to esters. Although the uncharged form of these drugs penetrates through

Figure 9-8. Formulas of the ester (procaine, tetracaine) and amide (lidocaine, ropivacaine) local anesthetics.

the plasma membrane, the inhibition of voltage-gated sodium channels on axons requires protonation of the tertiary amines.

6. During action potential propagation, sodium channels cycle between closed, open, and inactive states, and local anesthetics bind preferentially to the open and inactive states and stabilize the channel in the inactive state. Thus, local anesthetics display a use-dependent effect, whereby rapidly depolarizing axons are more readily blocked by the drug.

7. These agents are usually injected into the dermis surrounding sensory nerves to produce decreased nociception during procedures such as wound care, dental manipulation, and placement of sutures. However, they can also be administered at the site of nerve trunks or via intravenous route for regional anesthesia. Epinephrine is often coadministered with local anesthetic agents to produce a vasoconstriction that prolongs the duration of action and reduces systemic effects. Administration of local anesthetics into the epidural or subarachnoid space of the spinal cord is used for pain control during labor or C-section.

8. Systemic adverse effects may occur with high doses or repeated administrations of local anesthetic and include allergic reactions (especially to esters), cardiac arrhythmias, hypotension, methemoglobinemia, CNS depression, nystagmus, convulsions, and coma.

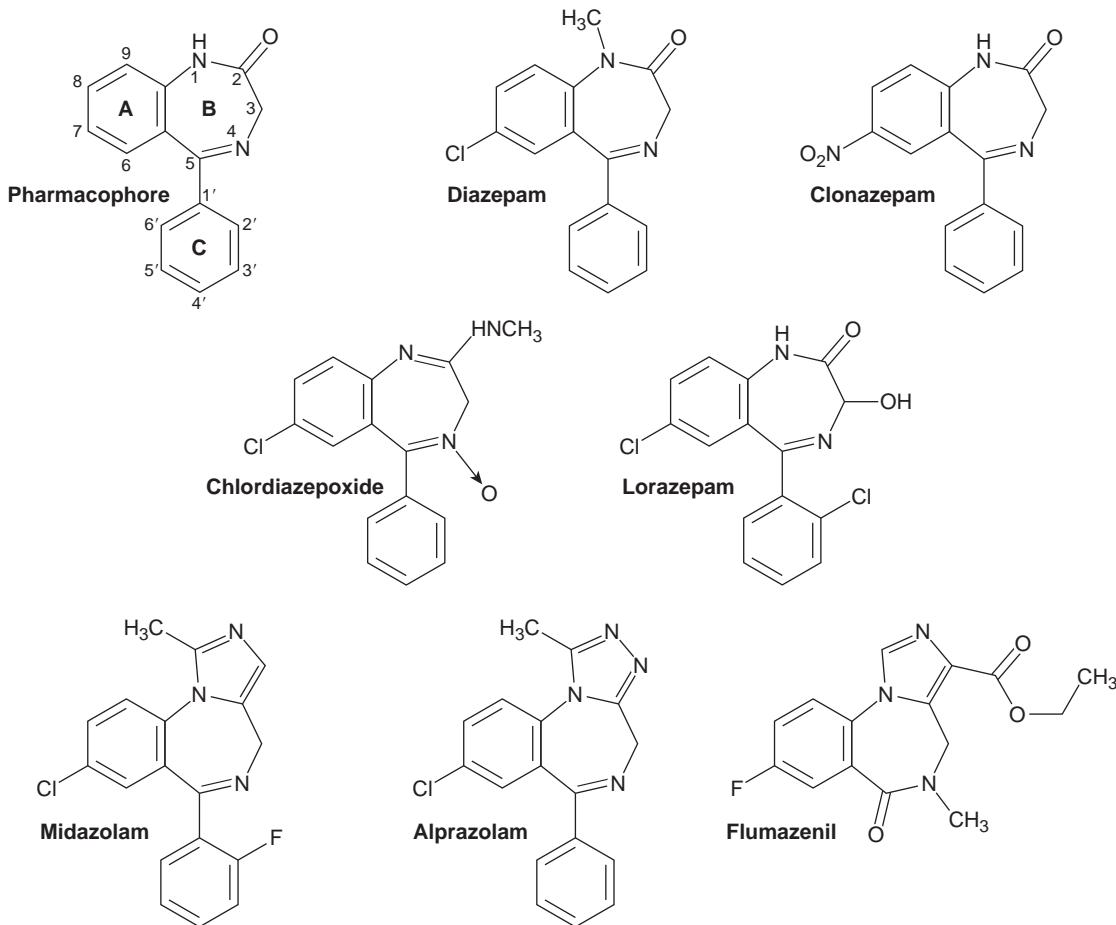
B. **General anesthetics.** Volatile and nonvolatile general anesthetics are used to induce analgesia, amnesia, loss of consciousness, and skeletal muscle relaxation during surgical procedures. Usually, anesthesia is accomplished by preoperative benzodiazepine (BDZ), induction of anesthesia by an intravenous agent, and maintenance of anesthesia by a combination of inhaled and intravenous agents.

1. **Intravenous general anesthetics** are a diverse group of agents used for induction and maintenance of anesthesia. This group includes barbiturates such as thiopental, BDZs such as midazolam (Versed®), phenols such as propofol (Diprivan®), opioids such as fentanyl (Sublimaze®), and carboxylated imidazoles such as etomidate (Amidate®). Thiopental, propofol, and etomidate (*Figure 9-9*) are able to produce a smoother and more rapid anesthesia as compared to inhaled agents and thus are often used for induction. In short-term procedures, these agents may also be used to maintain anesthesia without the addition of an inhaled agent. Opioids and BDZs are generally used as adjuvants for their antinociceptive and amnesic properties.

2. **Volatile or inhalation anesthetics** are drugs inhaled as gases or vapors. These diverse drugs are relatively simple lipophilic molecules.

   a. They include the inorganic agent nitrous oxide (N_2O) and the nonflammable halogenated hydrocarbons (e.g., halothane [Fluothane®]) and ethers (e.g., isoflurane [Forane®], desflurane [Suprane®], sevoflurane [Ultane®]; *Figure 9-9*). These agents produce a reversible loss in consciousness and skeletal muscle relaxation when administered via the inhalational route.

   b. The absorption of these agents from the lungs depends on their blood:gas partition coefficient such that the more water-soluble agents equilibrate much slower in the blood and thus

Figure 9-9. Structural formulas of the intravenous (thiopental, etomidate, propofol) and inhalational (halothane, isoflurane, sevoflurane) general anesthetics.


partition out of the blood into the CNS at slower rates. This chemical characteristic generally results in both induction and recovery from anesthesia to be slow.

  c. It was previously thought that inhaled anesthetics altered membrane fluidity to produce anesthesia, but currently, it is understood that these agents modify GABA$_A$ channel function on neurons. Interaction of these agents with the transmembrane domains of the channel subunits leads to increased chloride conductance, membrane hyperpolarization, and decreased neuronal activity.

  d. The adverse effects experienced during the use of volatile anesthetics have led to the greater reliance on the combination with intravenous agents. These effects include hepatotoxicity (especially with halothane), malignant hyperthermia, respiratory depression, cardiac arrhythmias, and hypotension.

C. Sedative hypnotics and anxiolytic agents. The ideal sedative would produce adequate CNS depression to reduce activity, decrease excitement, and generally have a calming effect. Hypnotic agents are used to produce drowsiness and initiate and maintain sleep. In many cases, a single agent can produce sedative effects at lower doses and hypnotic effects at successively higher doses. It is important to note that, for the most part, these agents do not produce CNS depression to the extent that leads to respiratory depression and death unless used in combination with other CNS depressants.

  1. **Benzodiazepines.** The pharmacophore structure of the BDZ class of drugs is represented by 5-phenyl-1,4-benzodiazepine-2-one (*Figure 9-10*).
  a. Pharmacological activity depends on ring A on the drug being aromatic, and this is further increased by having an electron-withdrawing group (Cl or nitro) at position 7 as in the case

Figure 9-10. The benzodiazepine pharmacophore and representative agents in the class (diazepam, chlordiazepoxide, clonazepam, midazolam, lorazepam, alprazolam). Flumazenil is a selective benzodiazepine antagonist.

of diazepam (Valium®) and clonazepam (Klonopin®). Although the carbonyl group at position 2 is most often seen, this can be substituted with other proton-bond acceptors such as aminomethyl group as in the case of chlordiazepoxide (Librium®), a fused imidazole group at position 1 and 2 for midazolam (Versed®), or a fused triazole group at the position 1 and 2 as seen in alprazolam (Xanax®). Substitutions at position 1 or 3 may increase lipophilicity as in the case of diazepam or hydrophilicity as with lorazepam (Ativan®). Substitutions on ring C are only allowed at position 2 and are electron-withdrawing Cl or F (lorazepam, midazolam).
   b. Removal of ring C results in loss of agonist activity, although high-affinity binding to the BDZ site on the GABA$_A$ receptor is maintained (flumazenil [Romazicon®]). The chemical structures of the BDZs discussed earlier are shown in *Figure 9-10*.

   c. BDZs appear to produce their pharmacological effects by enhancing the binding of the neurotransmitter γ-aminobutyric acid (GABA) to the GABA$_A$ receptor, a multimeric, ligand-gated chloride channel. BDZs bind to a unique site on the receptor and require the presence of GABA to produce a biological effect; they can be regarded as modulators of GABA functions. The increased GABA-mediated chloride current into neurons of the spinal cord, hypothalamus, hippocampus, substantia nigra, and cortex causes generalized CNS depression leading to anxiolytic, sedative/hypnotic, and muscle relaxant effects. Other uses for BDZs include the emergency treatment of seizures (e.g., status epilepticus) and, as discussed earlier, midazolam is primarily used as a preanesthetic due to its rapid metabolism. They are also used to treat symptoms due to alcohol withdrawal.

   d. With prolonged use, some dependence on the BDZs may result, and sudden withdrawal will result in a temporary increase in the symptoms such as insomnia or anxiety.

   e. The antagonist flumazenil has no direct effect on GABA function and competes with BDZs for binding to the BDZ site on the channel. It is used in cases of BDZ overdose and to reverse the sedative effects of BDZs after a surgical or therapeutic procedure. Adverse effects with the use of BDZs include daytime sleepiness, mental confusion, amnesia, headache, blurred vision, nausea, vomiting, and diarrhea.

2. Barbiturates. Includes phenobarbital (Luminal®), secobarbital (Seconal®), and pentobarbital (Nembutal®). Historically, this class of drugs was used most often to treat anxiety and insomnia but has largely been replaced by the BDZs.

   a. The pharmacophoric structure of barbiturates is shown in *Figure 9-11*, with barbituric acid having hydrogen at position 5. The electron-withdrawing nature of the carbonyl groups allows

Figure 9-11. Chemical structure of barbituric acid and representative agents in the class.

the amines to behave as weak acids rather than bases, and alkyl or aryl substitutions at the C-5 position increases lipophilicity and duration of action (*Figure 9-11*).
    b. At low doses, barbiturates appear to enhance GABA binding to its receptor and enhance chloride conductance into neurons. They also have inhibitory effects at AMPA-type glutamate receptors. These two effects combined are responsible for depression of nerve activity throughout the CNS to cause sedation and anxiolytic benefits. At higher doses, barbiturates appear to have direct actions to increase chloride conductance (even in the absence of GABA) and to block sodium and potassium channels. Thus, overdoses can have marked CNS depression leading to coma and death. Experimental data suggest that barbiturates interact with the GABA$_A$ receptor at a site distinct from that of BDZs.

    c. With chronic use of barbiturates, tolerance to the sedative and anxiolytic effects can result. Pharmacokinetic tolerance develops quickly and is due to the induction of several cytochrome P450 enzymes responsible for barbiturate metabolism. Pharmacodynamic tolerance may continue to develop for several months and provides cross-tolerance to other CNS-depressant drugs.

    d. Apart from anxiety and insomnia, barbiturates are also used to treat convulsions in emergencies such as those due to tetanus, eclampsia, convulsant drug overdose, and status epilepticus.

    e. Adverse effects associated with barbiturate use include drowsiness, excitement or restlessness in elderly patients, allergic reactions, apnea, and hypotension.

  3. **Miscellaneous anxiolytic/sedative hypnotics.** Drugs in this category are structurally diverse and may have distinct mechanisms of action.

    a. Zolpidem (Ambien CR®), zaleplon (Sonata®), and eszopiclone (Lunesta®) have a similar mechanism of action as the BDZs and their actions can be blocked by flumazenil. These newer BDZ receptor agonists are used primarily to treat sleep disorders and appear less likely to cause dependency or rebound withdrawal symptoms.

    b. Buspirone (BuSpar®) may exert its effects by behaving as a partial agonist at serotonin 5-HT$_{1A}$-receptors but may also interact with central dopamine D$_2$-receptors. It is not associated with rebound anxiety and insomnia upon abrupt withdrawal, but its therapeutic effects may be delayed for 1 to 2 weeks.

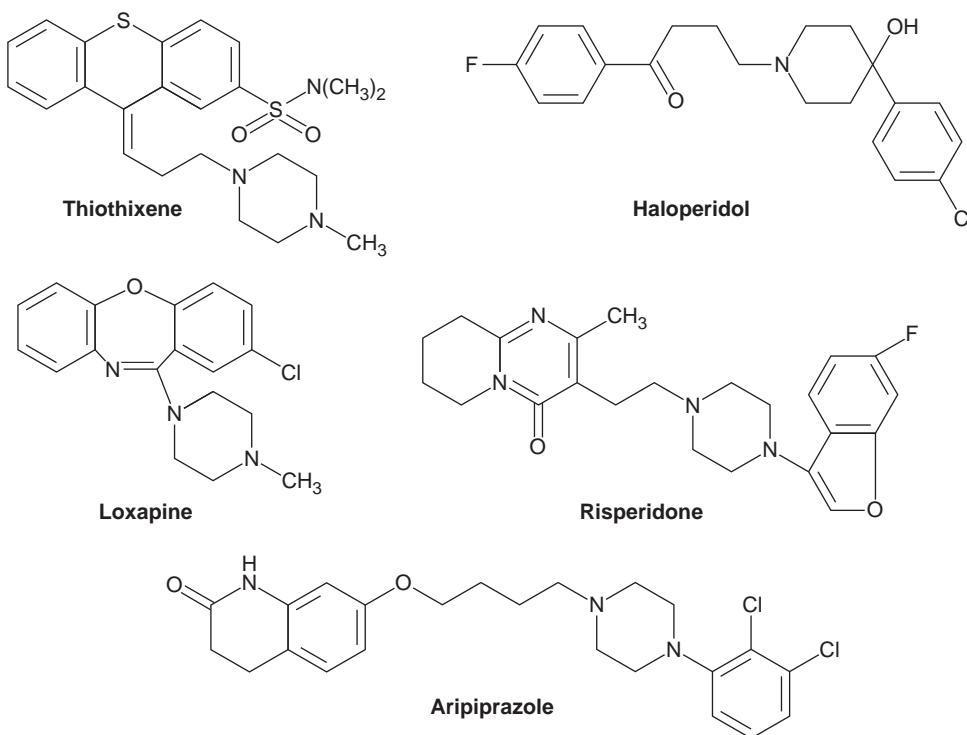
    c. Ramelteon (Rozerem®) is an agonist at the melatonin MT$_1$- and MT$_2$-receptors in the suprachiasmatic nucleus of the brain. It does not have the same abuse potential as BDZs and is used to treat generalized anxiety states and sleep disorders. The chemical structures of these agents are found on *Figure 9-12*.


Figure 9-12. Structural formulas of miscellaneous anxiolytic/sedative-hypnotic agents.

D. Drugs to manage psychosis and mania. Drugs may be used to manage patients exhibiting several conditions such as schizophrenia, bipolar disorder (manic phase), psychotic depression, senile psychosis, and drug-induced psychosis. Psychotic conditions are usually characterized by delusions and auditory or visual hallucinations with some types (e.g., schizophrenia) having a genetic link. Currently, it is thought that altered serotonin, dopamine, and glutamate signaling in the brain are responsible for most symptoms displayed in psychotic behavior. The major antipsychotic drug classes that will be discussed are the phenothiazines, thioxanthenes, butyrophenones, dibenzapines, and benzamides.

1. **Phenothiazines.** This class of drugs is subdivided into aliphatic (e.g., chlorpromazine [Thorazine®]), piperidine (e.g., thioridazine [Mellaril®]), and piperazine (e.g., trifluoperazine [Stelazine®], fluphenazine [Prolixin®]) derivatives, depending on the type of substitution found at the R position on the phenothiazine nucleus (*Figure 9-13*).

   a. The tertiary amine of these substitutions is required for activity, and electron-withdrawing substitutions at the X position further enhance potency.

   b. All these agents have their therapeutic effect through the blockade of dopamine D_2-receptors of the mesolimbic and mesocortical pathways in the brain. However, their interaction with α-adrenergic, muscarinic, histamine, and 5-HT_2-receptors may be responsible for some of the beneficial effects and many adverse effects seen during treatment.

2. **Thioxanthenes.** This class of drugs has a similar tricyclic structure to the phenothiazines; however, only thiothixene (Navane®; *Figure 9-14*) is marketed in the United States. This agent displays high extrapyramidal effects but low sedative and autonomic effects.

3. **Butyrophenones.** This class of antipsychotics is represented by haloperidol (Haldol®; *Figure 9-14*) and pimozide (Orap®), which are thought to act via D_2-receptors to modify psychotic behavior. The tertiary amino group of the piperidine is required for binding to D_2-receptors, as is an aromatic ring para to the piperidine ring. The butyrophenone group (haloperidol) can be substituted with a diphenylbutyl (pimozide) and still have high selectivity for the receptor. These agents have low sedative and autonomic effects but high extrapyramidal effects.

4. **Dibenzapines.** This class contains clozapine (Clozaril®), loxapine (Loxitane®; *Figure 9-14*), olanzapine (Zyprexa®), and quetiapine (Seroquel®). These agents display relatively low extrapyramidal effects but can be sedating and have autonomic effects. They are considered atypical

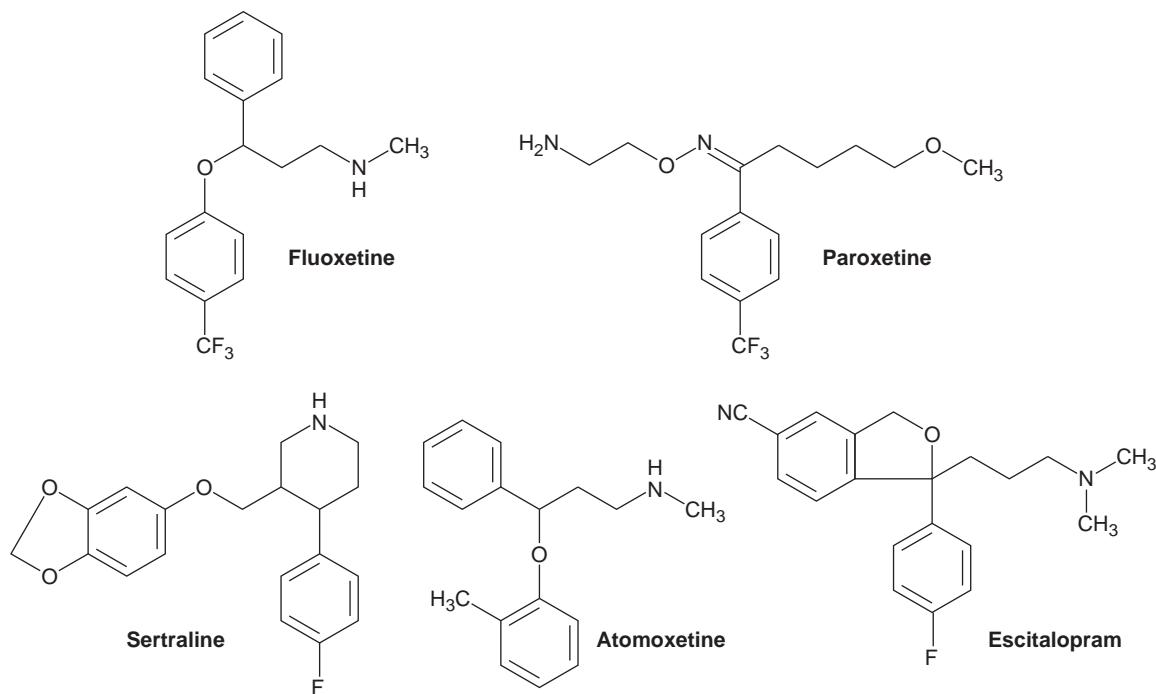
Figure 9-13. Structural formulas of the phenothiazine antipsychotic agents.


Figure 9-14. Structural formulas of thioxanthene (thiothixene), butyrophenone (haloperidol), and benzamide (risperidone, aripiprazole) antipsychotic agents.

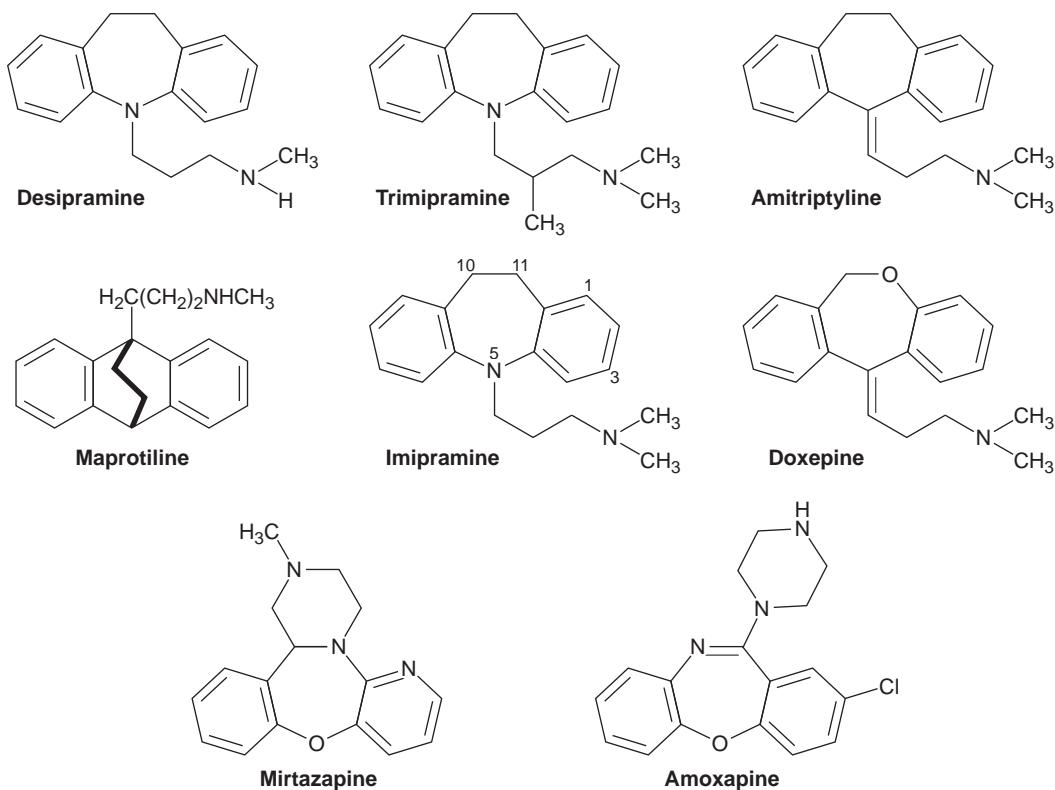
to phenothiazines in their antipsychotic mechanism of action. They have CYP1A2 induction action, which can be a source of drug interactions; quetiapine dosing has to be increased in smokers because cigarettes also induce CYP1A2 expression. Clozapine is likely to cause leucopenia and eosinophilia, which may progress to agranulocytosis, requiring frequent monitoring with blood tests.


5. **Benzamides.** These are also considered atypical in the pharmacological action and are represented by remoxipride (Roxiam®), risperidone (Risperdal®; *Figure 9-14*), paliperidone (Invega®), ziprasidone (Geodon®), and aripiprazole (Abilify®; *Figure 9-14*).

   a. Although phenothiazines, thioxanthenes, and butyrophenones appear to produce their effects primarily by blocking D_2-receptors, the atypical agents appear to have more prominent effects as partial agonists at the $5-HT_{1A}$-receptors. Thus, they tend to exhibit lower extrapyramidal effects but still have sedative (blockade of central M receptors) and autonomic (blockade of central α-adrenergic receptors) effects.

   b. Apart from schizophrenia, these agents are used to treat manic phases of bipolar disorder, Tourette syndrome, and psychotic depression.

   c. The major adverse effects seen with the use of these agents (especially the typical agents) are tardive dyskinesia, sedation, autonomic dysfunction (hypotension, orthostatic hypotension, decreased blood pressure), failure to ejaculate, hepatotoxicity, photosensitivity, and blurred vision.

   d. The atypical agents show less extrapyramidal effects but can cause weight gain and prolong the QT interval of the heart.

6. **Lithium in bipolar disorder.** Bipolar disorder is characterized by a manic phase where the patient is highly excitable, hyperactive, impulsive, requires little sleep, and has cognitive impairment. This manic phase is usually followed by a depressive phase similar to major depression.

   a. Lithium carbonate (Eskalith®) is used to manage the disorder (especially manic phase), but its popularity has decreased due to the introduction of valproate, aripiprazole, and benzamide antipsychotics. Usually, an antidepressant is used to treat the depressive phase of the disorder but has been associated with inducing the manic phase.

   b. Lithium may have its mood-stabilizing effects by blocking inositol phosphate phosphatases to elevate inositol phosphates or reducing glycogen synthase kinase-3 activity in neuronal cells, but the precise mechanisms are unknown.

   c. The primary adverse effects seen with the use of lithium are tremors, decreased thyroid function, nephrogenic diabetes insipidus (polyuria, polydipsia due to loss of sensitivity to antidiuretic hormone), edema, and bradycardia.

E. Drugs used to treat depression. Major depressive disorder is characterized by loss of interest or pleasure in daily activities most of the time for up to 2 weeks and usually exhibits as sleep and appetite disturbance, low energy levels, and decreased cognition. The causes of depression are not entirely clear but may include a decrease in monoamines (serotonin, norepinephrine) as well as neurotrophic and endocrine factors, such as brain-derived neurotrophic factor, in the brain. The primary classes of agents used to treat depression are selective serotonin reuptake inhibitors (SSRIs), serotonin–norepinephrine reuptake inhibitors (selective and tricyclic antidepressants), 5-HT$_2$-antagonists, MAO inhibitors, and several miscellaneous agents.

   1. Selective serotonin reuptake inhibitors. The serotonin transporter (SERT) is glycoprotein inserted into the membrane of axon terminals of neurons that release serotonin (5-HT). Binding of 5-HT to SERT results in transport of the amine Na$^+$ and Cl$^-$ into the nerve terminal with the 5-HT being released in the cytoplasmic side.

   a. SSRIs allosterically interact with SERT at a distinct extracellular site to 5-HT to inhibit the reuptake of the amine into nerve terminals. Presumably, this leads to a buildup of 5-HT in the synaptic space and greater activation of the complementary receptor on the postsynaptic nerve. The overall outcome of this action is a progressive inhibition of the central dopamine system. There is no evidence for the interaction of SSRIs with the NET or other transporters and receptors.

   b. The SSRIs are represented by a diverse group agents such as fluoxetine (Prozac®), paroxetine (Paxil®), sertraline (Zoloft®), atomoxetine (Strattera®), and escitalopram (Lexapro®), with chemical structures shown in *Figure 9-15*.

   c. SSRIs are used to manage major depression; anxiety disorders such as posttraumatic stress disorder (PTSD), panic disorder, and obsessive–compulsive disorder (OCD); premenstrual dysphoric disorder; and bulimia.

Figure 9-15. Structural formulas of the selective serotonin reuptake inhibitors (SSRIs).
   d. The most frequent adverse events experienced by patients on SSRIs include nausea, GI upset, diarrhea, decreased sexual function, headaches, insomnia, and weight gain. Sudden discontinuation of SSRIs may result in a syndrome of effects such as dizziness and paresthesias.

2. Serotonin–norepinephrine reuptake inhibitors (SNRIs). These agents comprise the tricyclic antidepressants and selective SNRIs.

   a. The tricyclic antidepressants were the mainstay of depression therapy for the decades preceding the introduction of SSRIs and include imipramine (Tofranil®), amitriptyline (Elavil®), amoxapine, doxepin (Sinequan®), and trimipramine (Surmontil®).

   b. These agents have multiple pharmacological effects via the interaction with SERT, NET, α1- and α2-adrenergic, muscarinic, and histamine receptors; however, the mood-elevating effects may be attributed to increased α1- and 5-HT-receptor stimulation, secondary to buildup of NE and 5-HT in the synaptic space.

   c. Imipramine serves as the prototypical tertiary amine tricyclic (*Figure 9-16*), which can be modified in several ways to retain antidepressant activity. Modifications of the propylamine at position 5 to a secondary amine (desipramine) or isobutylamine (trimipramine) produce drugs that have increased selectivity for the NET versus the SERT and reduced anticholinergic effects. Loss of the propylamino modification also retains more NET activity as in the case of amoxapine.

   d. There is considerable flexibility for the composition of the seven-member ring where the N at position 5 can be replaced by a carbon (amitriptyline) or oxygen (amoxapine), and the carbon at position 10 or 11 can be replaced by nitrogen (amoxapine) or oxygen (doxepine). The fusion of a piperidine ring to position 10 and 11 also improves NET interaction (maprotiline [Ludiomil®]). Mirtazapine (Remeron®) lacks the propylamino modification and contains a fused tetracyclic ring (*Figure 9-16*) that retains bioamine reuptake blocking activity but increases α_2 and 5-HT-receptor blocking activity as well.

   e. The nontricyclic agents with somewhat greater selectivity for the SERT versus NET are represented by venlafaxine (Effexor®), desvenlafaxine (Pristiq®), and duloxetine (Cymbalta®).

Figure 9-16. Structural formulas of the serotonin–norepinephrine reuptake inhibitors (SNRIs).

These drugs are chemically unrelated and have the advantage of having relatively few interactions with adrenergic, muscarinic, histaminic, and serotonergic receptors.

 f. Adverse effects related to therapy with SNRIs include those with SSRIs (previously discussed) as well as increased blood pressure, heart rate, insomnia, anxiety, and agitation. Tricyclic agents have additional antimuscarinic effects (dry mouth, constipation, urinary retention), as well as orthostatic hypotension due to peripheral α_1-blockade. Most of the SNRIs are also associated with a serotonin-withdrawal syndrome as seen with SSRIs.

3. **Monoamine oxidase inhibitors (MAOIs).** MAOIs were some of the first pharmacological agents developed to treat major depression, but their use has decreased significantly due to the advent of newer agents (previously discussed) with better therapeutic and safety profiles.

 a. MAOIs are reserved for depression that is refractory to other agents, and currently, hydrazine (isocarboxazid [Marplan®], phenelzine [Nardil®]) and phenylcyclopropylamine (selegiline [Emsam®], tranylcypromine [Parnate®]) are marketed in the United States.

 b. These agents bind irreversibly to MAO-A and MAO-B isoforms in aminergic nerve terminals to prevent the metabolism of biogenic amines dopamine, norepinephrine, and serotonin. It is believed that this action leads to elevation of central biogenic amine neurotransmission to improve depressive mood disorders; however, this outcome usually takes several weeks to develop.

 c. Orthostatic hypotension, weight gain, sexual dysfunction, insomnia or sedation, restlessness, and confusion are some of the most common adverse effects experienced while on MAOIs.

 d. The consumption of tyramine-containing foods (cheese, beer, sausage, etc.) while on MAOIs can result in drastic increases in blood pressure, leading to stroke or myocardial infarction. Sudden withdrawal of MAOIs results in delirium, psychosis, and mental confusion.

4. **Miscellaneous antidepressants.** Serotonin 5-HT$_2$-receptor antagonists nefazodone and trazodone (Desyrel®) are rarely used to treat depression and have found use as sedatives. Bupropion (Wellbutrin®) may have NET-inhibiting activity but also appears to enhance catecholamine release from adrenergic nerves. It has little effect on the SERT or 5-HT-receptor systems.

F. **Drugs used to treat seizures.** Epilepsy is a complex of symptoms characterized by recurrent seizures due to abnormal discharge of electrical activity in the brain. The causes of seizures are myriad, from infection, head injury, or neoplastic disease; however, chronic seizures unrelated to these events may be due to genetic defects in neuronal voltage-dependent ion channels. Generally, the type of drug used to treat seizures is based on the type of disease displayed and may be localized to the cerebral cortex (partial seizures) or more generalized with sequential firing of neurons between the cortex and thalamus. Seizures can be of the convulsive and absence (nonconvulsive) types, with the convulsive form usually involving both hemispheres of the brain and resulting in loss of consciousness and often muscle spasms (myoclonic, tonic, tonic-clonic, etc.). Absence seizures are usually brief (< 20 secs), with loss of consciousness and rapid onset and cessation but with no muscle spasms.

1. **Agents for partial and generalized tonic-clonic seizures.** There are no common structural characteristics of these agents that account for their activity as antiseizure drugs and are composed primarily of sodium channel blockers and drugs modulating GABA and glutamate function.

 a. Phenytoin (Dilantin®) binds to sodium channels, stabilizes its inactive conformation, and reduces the excitability of neurons. The action is both voltage and use dependent because a greater proportion of the channels are in the inactive state. The resulting therapeutic benefit is the reduction in the tonic phase of seizures while the clonic phase may be enhanced.

 b. Adverse effects seen with phenytoin are cardiac arrhythmias, CNS depression, gingival hyperplasia, hirsutism, and hypersensitivity reactions.

 c. Carbamazepine (Tegretol®), lamotrigine (Lamictal®), lacosamide (Vimpat®), and topiramate (Topamax®) are all sodium channel blockers with a similar mechanism to phenytoin (*Figure 9-17*).

 d. Carbamazepine has additional actions to reduce synaptic transmission that may be responsible for the anticonvulsant effect of the drug. Its use has been associated with drowsiness, ataxia, blurred vision, aplastic anemia, and hypersensitivity reactions.

 e. Lamotrigine may also block N/P types of calcium channels and decrease glutamate release from excitatory nerves. Chronic use of lamotrigine can be accompanied by dizziness, ataxia, blurred vision, and rash.

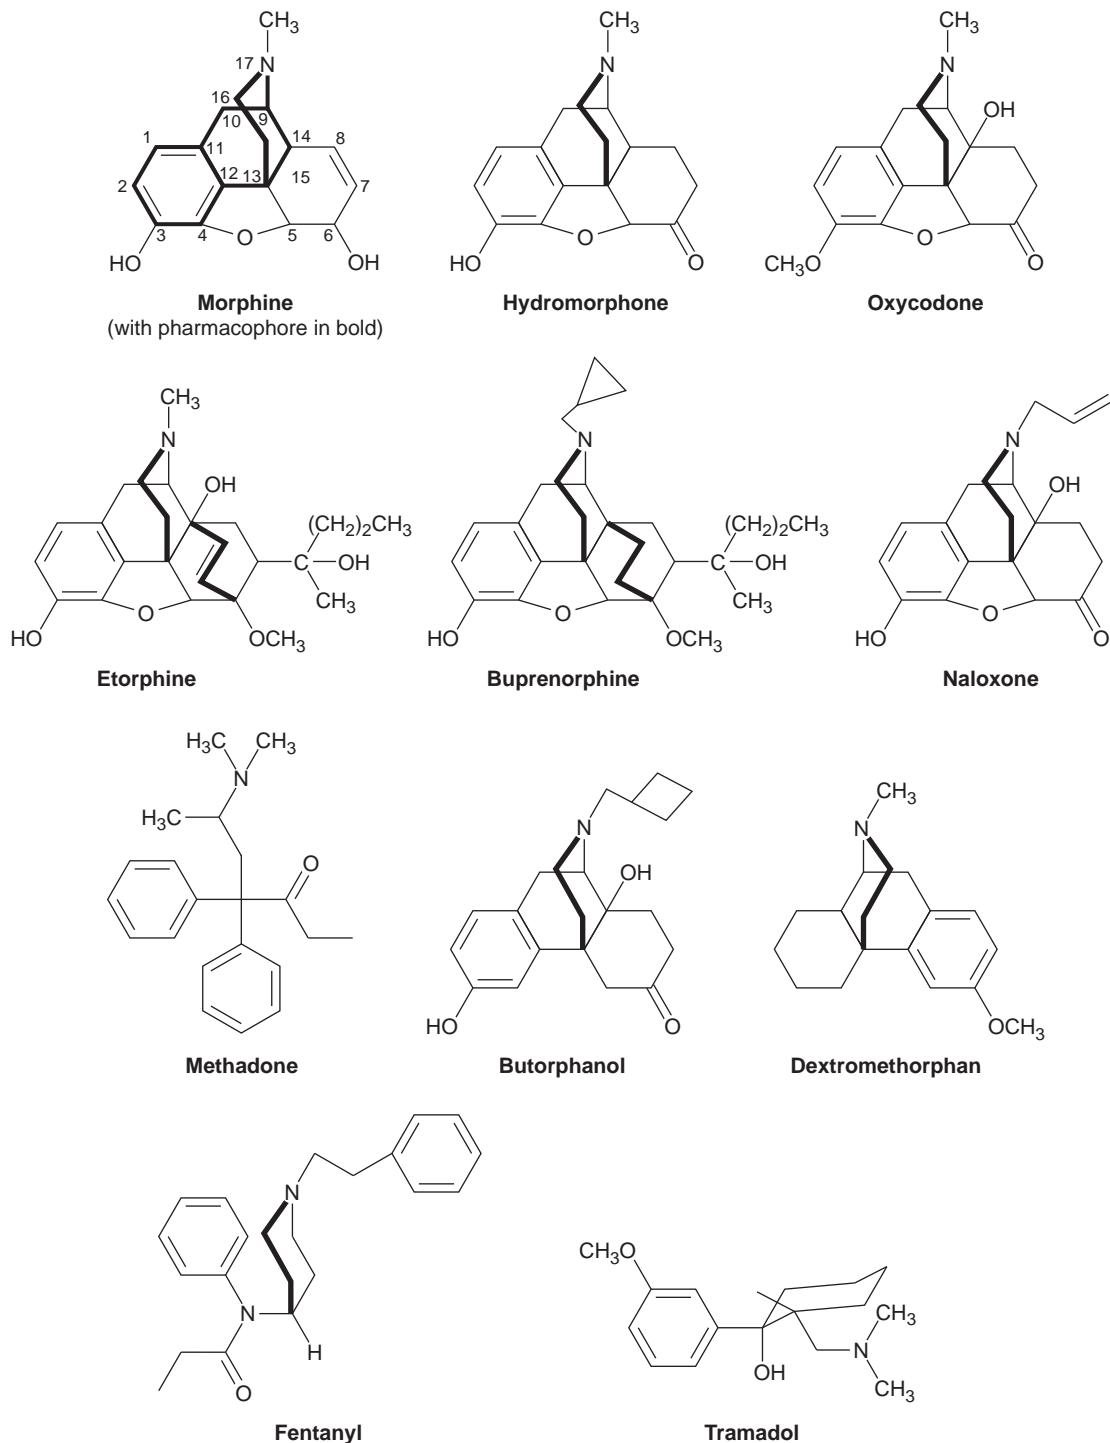
 f. Lacosamide may also interfere with the function of neurotrophic factors such as brain-derived neurotrophic factor (BDNF) and NT3 on axonal/dendritic growth. Suicidal ideation is probably the adverse effect of most concern with the use of this drug.


Figure 9-17. Structural formulas of several drugs used to treat seizure activity.

    g. Apart from sodium channel blockade, topiramate may also potentiate GABA-induced chloride conductance and block kainate action on glutamate receptors. Drowsiness, fatigue, weight loss, and nervousness are the most common adverse effects reported with topiramate use. The chemical structures of these agents are shown in *Figure 9-16*.

    h. Tiagabine (Gabitril®), gabapentin (Neurontin®), and vigabatrin (Sabril®) interfere with GABA neurotransmission to modify seizure activity (*Figure 9-17*).

    i. Tiagabine was rationally designed to block GABA uptake into neurons to enhance its postsynaptic effect on GABA$_A$ receptors and consequent increase in chloride current. The most frequent adverse effects seen with tiagabine are somnolence, dizziness, and tremors.

    j. Gabapentin is structurally similar to GABA and appears to increase GABA release into nerve synapses as well as block N-type calcium channels to decrease glutamate release. Gabapentin is also used to treat chronic pain, migraines, and bipolar disorder. Fatigue, dizziness, drowsiness, and ataxia are the most common adverse effects seen with gabapentin use.

    k. Vigabatrin has the unique mechanism of action of irreversibly inhibiting the aminotransferase that degrades GABA. This results in maintained synaptic GABA levels to enhance receptor activation and tonic inhibition of neuronal activity. The primary adverse effects observed with vigabatrin use are drowsiness, dizziness, weight gain, mental confusion, and psychosis.

    l. Levetiracetam (Keppra®; *Figure 9-17*) has an unknown mechanism of action but has been effective against generalized tonic-clonic seizures and juvenile myoclonic seizures. As with many other drugs in this category, ataxia, somnolence, dizziness, and agitation are its most common adverse effects.

2. Drugs used to manage other generalized seizures

    a. Ethosuximide (Zarontin®) is a cyclic ureide that blocks low-threshold T-type calcium channels. Thalamic pacemaker currents that give rise to absence seizures can be depressed by T-channel blockers. Adverse effects with the use of ethosuximide are nausea, gastric pain, vomiting, lethargy, headache, and euphoria.

b. Valproic acid (Depakene®) may have actions on sodium channels (similar to phenytoin), as well as block *N*-methyl-ᴅ-aspartate (NMDA)-type glutamate ion channels. Additionally, it appears to increase GABA levels in the brain by a poorly defined mechanism and alters neuronal gene expression by inhibiting histone deacetylase. Valproate can be used to effectively manage absence seizures especially when the patient also exhibits generalized tonic-clonic seizures. The most common adverse effects seen with the use of valproate are nausea, vomiting, abdominal pain, weight gain, and hair loss. The agent also increases the risk of spina bifida in infants born to women who took valproate during pregnancy. The chemical structures of several antiseizure drugs discussed in this section are shown on *Figure 9-17*.

G. Drugs to treat Parkinson disease and other movement disorders. Parkinson disease is characterized by the loss of dopaminergic neurons that project from the substantia nigra into the corpus striatum due to poorly defined mechanisms. The consequence of this type of neuronal death is decreased inhibition of GABA-ergic neurons in the corpus striatum, leaving positive cholinergic input on GABA neurons unopposed. This imbalance leads to tremors of the extremities and with progression of the disease, rigidity, postural instability, slowed movement, and cognitive decline. Other movement disorders may be due to drug-induced toxicities (antipsychotics), other toxins (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine [MPTP]), or neuronal injuries. The general strategy of treating Parkinson-type disorder is to attempt the restoration of the balance of dopaminergic and cholinergic inputs on GABA-ergic neurons in the corpus striatum.

   1. Agents modifying the dopaminergic system

   a. Levodopa (Dopar®) is a dopamine precursor that is actively taken into the CNS via the amino acid transporter and converted by dopa decarboxylase to dopamine in neurons expressing the enzyme. Levodopa is often coadministered with carbidopa (Sinemet®), an inhibitor of peripheral dopa decarboxylase that ensures high blood levels of levodopa for CNS uptake.

   b. Catechol-*O*-methyltransferase (COMT) is another enzyme that metabolizes levodopa, and its inhibition with agents such as tolcapone (Tasmar®) and entacapone (Comtan®) also potentiates levodopa activity. Levodopa ameliorates many of the symptoms of Parkinson disease, particularly the diminished or slowed movements.

   c. The major adverse effects experienced by patients on levodopa are nausea and vomiting (especially when taken without carbidopa), cardiac arrhythmias, dyskinesias, depression, hallucinations, confusion, mydriasis, and glaucoma.

   d. Dopamine receptor agonists used to directly modulate striatal GABA neuronal activity have also proven useful in managing Parkinson disease symptoms and are often better tolerated than levodopa. Bromocriptine (Parlodel®) and ropinirole (Requip®) are relatively selective dopamine D_2-receptor agonists that ameliorate Parkinson disease symptoms. Pergolide (Permax®) is both a D_1- and D_2–agonist, whereas pramipexole (Mirapex®) appears to have greater activity at the D_3-receptor. Ropinirole and pramipexole have also found use in the treatment of restless leg syndrome.

   e. The potent dopamine agonist apomorphine (Apokyn®) is only used temporarily for the "off-periods" of patients on dopamine agonist therapy. The primary adverse effects of dopamine agonists are anorexia, nausea, vomiting, constipation, dyspepsia, acid reflux, postural hypotension, cardiac arrhythmias, dyskinesias, hallucinations, delusions, poor impulse control, and narcolepsy.

   2. Anticholinergic agents for Parkinson disease. The mechanism of action of these agents has been discussed previously in the muscarinic antagonist section. They essentially reduce cholinergic input onto GABA-ergic neurons in the basal ganglia.

H. Opioid agonists and antagonists. Opioid alkaloids from *Papaver somniferum* have been known for their analgesic properties for thousands of years, and the principle agent in the extract, morphine, is considered the prototypical analgesic opiate. The pharmacology of opiates led to the discovery of the endogenous opioid peptides that specifically interacted with opioid receptors in the periphery as well as the CNS. These peptides, endorphins, enkephalins, and dynorphins, interact selectively with μ-, δ-, and κ-opioid receptors, respectively. These receptors are located on primary sensory afferent fibers as well as dendrites of the secondary afferent neurons in the spinal cord and on multiple afferent neurons along the pain sensory pathway that ends in the cerebral cortex. The opioid peptides are thought to be released during stressful periods to activate μ, δ, or κ receptors to increase the threshold for pain sensory transmission and thereby decrease pain sensation by the cortex.

1. **Chemistry.** Morphine's phenolic hydroxyl group is extremely important for activity; however, analgesic activity appears to depend on a *p*-phenyl-*N*-alkylpiperidine moiety (in bold, *Figure 9-18*), in which the piperidine ring is in the chair form and is perpendicular to the aromatic ring. The alkyl group at position 17 is usually methyl. The **morphine molecule** can be altered in various ways to retain analgesic activity, and related compounds also can be synthesized from other starting materials.

Figure 9-18. Structural formulas of the morphine (with pharmacophore in bold) and other opioid ligands. Naloxone has only antagonist activity at the opioid receptors.

a. **Natural or synthetic opioids** may be classified into four chemical groups (*Figure 9-18*):

   (1) *Phenanthrenes* such as morphine (MS-Contin®), hydromorphone (Dilaudid®), codeine, and hydrocodone (Vicodin®) are considered full agonists at the μ-receptor although their analgesic potencies vary. Methylation of the phenolic 3-hydroxyl group with or without modification of the 6-hydroxyl group of morphine yields agents with reduced agonist potency but enhanced oral bioavailability (e.g., codeine, hydrocodone, oxycodone [OxyContin®]). Cyclopropylmethyl or cyclobutylmethyl substitutions at the amine as well as large substitutions at position 7 produce opioids that are partial agonists at the μ-receptor (e.g., nalbuphine [Nubain®], buprenorphine [Buprenex®]).

   (2) *Phenylheptylamines*, represented by methadone (Dolophine®), is a bisphenyl derivative of heptylamine that has strong high agonist potency and excellent oral bioavailability.

   (3) *Phenylpiperidines*, which include meperidine (Demerol®), fentanyl (Sublimaze®), and sufentanil (Sufenta®), are potent parenteral μ-agonists. This class also includes diphenoxylate (in Lomotil®) and loperamide (Imodium®) that have lower affinity for opioid receptors, have poor CNS penetration, and thus have lower abuse potential.

   (4) *Morphinans* such as levorphanol (Levo Dromoran®) and butorphanol (Stadol®) lack the oxygen bridge between C4 and C5. This results in agonists with increased potency versus morphine, high oral bioavailability, and increased activity at κ-receptors.

b. *Opioid antagonists* are derived by replacing the methyl group on the nitrogen atom with more bulky substitutions. Therefore, cyclopropylmethyl or allyl substitutions at the amine, along with alterations of the 6-OH to carbonyl or methylene groups, result in pure μ-antagonists such as naltrexone (Revia®), naloxone (Narcan®), and nalmefene hydrochloride (Revex®).

c. Agents having both a free phenolic hydroxyl group and a tertiary amine function (e.g., morphine and nalbuphine) are chemically amphoteric. Amphotericity probably accounts for the erratic absorption of morphine when administered orally.

d. The newer opioid analgesic agent, **tramadol** (Ultram®), may be considered an open-ring codeine analog with weak μ-opioid agonist activity but increased activity as a SERT blocker.

2. **Pharmacology of opioid drugs.** Most of the opioid drugs on the market appear to produce their pharmacological effects through the activation of μ-opioid receptors in the pain sensory pathway. Exceptions to this paradigm are partial agonists (at μ-receptors) with higher affinity for κ-receptors (e.g., pentazocine [Talwin®]). Additionally, butorphanol and nalbuphine have antagonist activity at μ-receptors but maintain agonist activity at κ-receptors. Tramadol and tapentadol (Nucynta®) have low to modest μ-receptor agonist activity but enhanced blockade of SERT and NET, respectively. These agents appear to have low abuse potential and, in fact, the latter is not a controlled substance.

   a. Opioid drugs are primarily used for the following:

      (1) Constant chronic pain after surgical procedures or due to acute biliary or renal colic and cancer-related disease.

      (2) Obstetric pain, although respiratory depression in the neonate may be of concern because these agents can cross the placenta.

      (3) Acute pulmonary edema accompanying MI when respiratory depression is not of concern.

      (4) Suppression of cough is achieved at codeine doses lower than that required for analgesia. Over-the-counter preparations of the opioid derivative dextromethorphan are effective antitussives with no analgesic activity and little abuse potential.

      (5) Most cases of diarrhea can be managed with various preparations containing diphenoxylate and loperamide.

      (6) Analgesia, anti-anxiety and sedative effects can be produced by fentanyl and its derivatives when used as adjuncts to anesthesia. They have also been used as regional analgesics when applied to the epidural space of the spinal cord (e.g., management of the obstetric or postsurgical patient).

   b. The primary concern with opioid use during surgical procedures and overdose is the potential for significant respiratory and CNS depression leading to coma; this can be managed by the administration of opioid antagonists such as naloxone.

   c. A psychological dependence characterized by euphoria, sedation, and high tolerance to stimuli can develop in susceptible individuals, and this may be reinforced by a physical dependence on the drug.

    d. Chronic opioid use may lead to tolerance (requiring higher doses to produce adequate analgesia) and physical dependence that is characterized by tearing, piloerection, hyperventilation, vomiting, diarrhea, anxiety, and hostility upon withdrawal of the drug. Administration of antagonists (e.g., naloxone) or partial agonists (e.g., pentazocine) in a physically dependent patient can suddenly precipitate these symptoms.

    e. Opioid analgesics are associated with the following adverse effects:

        (1) CNS effects, including CNS depression, miosis, dizziness, sedation, confusion, disorientation, and coma

        (2) GI effects, including nausea, vomiting, constipation, biliary spasm, and increased biliary tract pressure

        (3) Cardiovascular effects, such as orthostatic hypotension, peripheral circulatory collapse, dysrhythmias, and cardiac arrest

        (4) Bronchoconstriction

        (5) Psychiatric effects, such as euphoria, dysphoria, and hallucinations

        (6) Abuse potential and dependence

        (7) Classic opioid analgesics can also prompt the release of histamine, causing intense pruritus, vasodilation, and bronchoconstriction, which can be confused with a true allergic reaction.

        (8) Tramadol appears to have significantly fewer respiratory depressant effects than the classic opioids. It also does not appear to cause the release of histamine. It has fewer cardiovascular effects with the exception of orthostatic hypotension, which is produced. Tramadol does possess the typical μ-receptor–mediated side effects of constipation, nausea, vomiting, and sedation.

Study Questions

Directions for questions 1–14: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following drugs would most likely be used in the treatment of bronchospasm that is associated with chronic obstructive pulmonary disease?

    (A) edrophonium (Tensilon)
    (B) ipratropium (Atrovent)
    (C) rocuronium (Zemuron)
    (D) propantheline (Pro-Banthine)
    (E) homatropine

2. All of the following adverse effects are manifestations of cholinergic agonists *except*

    (A) bradycardia.
    (B) bronchoconstriction.
    (C) xerostomia.
    (D) lacrimation.
    (E) myopic accommodation.

3. Which of the following drugs is considered to be the agent of choice for anaphylactic reactions?

    (A) clonidine (Catapres)
    (B) isoproterenol (Inderal)
    (C) epinephrine
    (D) phenylephrine
    (E) terbutaline (Brethine)

4. Which of the following neuromuscular blocking agents can cause muscarinic responses such as bradycardia and increased glandular secretions?

    (A) tubocurarine
    (B) succinylcholine (Anectine)
    (C) pancuronium
    (D) decamethonium
    (E) gallamine

5. Which of the following agents would *not* be appropriate in the treatment of glaucoma?

    (A) atropine
    (B) pilocarpine
    (C) physostigmine
    (D) timolol (Timoptic)
    (E) epinephrine

6. Adverse reactions to atropine include all of the following *except*

   (A) photophobia.
   (B) dry mouth.
   (C) sedation.
   (D) diarrhea.
   (E) tachycardia.

7. Which of the following drugs is a volatile substance that is administered by inhalation?

   (A) thiopental (Pentothal)
   (B) halothane
   (C) alprazolam (Xanax)
   (D) buspirone (Buspar)
   (E) phenytoin (Dilantin)

8. Which of the following agents is used to treat anxiety?

   (A) chlordiazepoxide (Librium)
   (B) thioridazine
   (C) alprazolam (Xanax)
   (D) buspirone (Buspar)
   (E) pentobarbital

9. Which of the following best describes the mechanism of diazepam to cause a sedative effect?

   (A) The drug blocks glutamate receptor to decrease neuronal excitability.
   (B) The drug blocks the uptake of GABA into the nerve to increase its action at the receptor.
   (C) It increases the ability of GABA to produce chloride conductance into neurons.
   (D) It prevents the metabolism of catecholamines by blocking monoamine oxidases.
   (E) It blocks inositol phosphate metabolism in neurons.

10. Which of the following mechanisms of action is true and most likely contributes to the treatment of parkinsonism?

    (A) The direct-acting dopaminergic agonist bromocriptine (Parlodel) mimics the activity of striatal dopamine.
    (B) The antimuscarinic activity of entacapone (Comtan) contributes to the restoration of striatal dopaminergic–cholinergic neurotransmitter balance.
    (C) Striatal H_1-receptors are blocked by levodopa.
    (D) The ergoline bromocriptine stimulates the release of striatal dopamine from intact terminals.
    (E) The ability of dopamine to cross the blood–brain barrier allows it to restore striatal dopaminergic–cholinergic neurotransmitter balance.

11. All of the following adverse effects are associated with the use of levodopa *except*

    (A) increased intraocular pressure.
    (B) orthostatic hypotension.
    (C) delusions and confusion.
    (D) dyskinesia.
    (E) agranulocytosis.

12. The activity of which of the following drugs depends on a *p*-phenyl-*N*-alkylpiperidine moiety?

    (A) phenobarbital
    (B) chlorpromazine
    (C) diazepam (Valium)
    (D) imipramine (Tofranil)
    (E) meperidine (Demerol)

13. Opioids are used for all the following conditions *except*

    (A) cough.
    (B) severe chronic pain.
    (C) arthritis.
    (D) severe diarrhea.
    (E) preanesthetic.

14. Which of the following agents would *not* be an alternative to phenytoin in the treatment of tonic-clonic seizure?

    (A) levetiracetam (Keppra)
    (B) gabapentin (Neurontin)
    (C) ethosuximide (Zarontin)
    (D) lamotrigine (Lamictal)
    (E) carbamazepine (Tegretol)

Directions for questions 15–19: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

   A if **I only** is correct
   B if **III only** is correct
   C if **I and II** are correct
   D if **II and III** are correct
   E if **I, II, and III** are correct

15. Cholinesterase inhibitors can be used therapeutically

    I. as miotic agents in the treatment of glaucoma.
    II. to increase skeletal muscle tone in the treatment of myasthenia gravis.
    III. to decrease gastrointestinal (GI) and urinary bladder smooth muscle tone.

16. Antimuscarinic agents are used in the treatment of Parkinson disease and in the control of some neuroleptic-induced extrapyramidal disorders. These agents include

    I. ipratropium (Atrovent).
    II. benztropine.
    III. trihexyphenidyl.

17. Certain drugs are sometimes incorporated into local anesthetic solutions to prolong their activity and reduce their systemic toxicity. These drugs include

    I. dobutamine.
    II. phenoxybenzamine.
    III. epinephrine.

18. Improper administration of local anesthetics can cause toxic plasma concentrations that may result in

    I. seizures and central nervous system (CNS) depression.

    II. respiratory and myocardial depression.

    III. circulatory collapse.

19. In addition to their anxiolytic properties, benzodiazepines are indicated for use

    I. as preanesthetic medications.

    II. as anticonvulsants.

    III. during acute withdrawal from alcohol.

For questions 20–23: A 58-year-old white male who has a history of essential hypertension and bronchial asthma has recently been diagnosed with prostatic hypertrophy. His medication history includes the following drugs:

    (A) propranolol (Inderal), for hypertension

    (B) ipratropium (Atrovent), for asthma

    (C) metaproterenol, for asthma

    (D) finasteride (Proscar), for prostatic hypertrophy

    (E) prazosin (Minipress), for hypertension

Directions: The following questions can be answered by **one** of the listed drugs. Choose the **best** answer, **A–E**.

20. Tamsulosin (Flomax) may replace this agent on the list.

21. Which agent would be most likely to cause postural hypotension?

22. Which agent acts selectively at β_2-receptors?

23. Which of the agents on the list would be counterproductive or inappropriate in a patient taking metaproterenol?

For questions 24–27: A 55-year-old black female has a history of moderate hypertension, glaucoma, and mild osteoarthritis. Her medication history includes the following drugs:

    (A) metoprolol (Lopressor), for hypertension

    (B) pilocarpine gel, for glaucoma

    (C) dipivefrin (Propine) drops, for glaucoma

    (D) echothiophate, for glaucoma

    (E) timolol (Timoptic), for glaucoma

Directions: The following questions can be answered by **one or more** of the listed drugs. Choose the **best** answers, **A–E**.

24. Which of her glaucoma medicines acts via an indirect mechanism?

25. Which two agents could have an additive effect to produce excessive bradycardia?

26. Which two glaucoma agents could lessen the effects of the other?

27. Which of the aforementioned agents is a prodrug that is metabolized to its active form?

Directions for questions 28–31: Each statement in this section describes **one** of the following drugs. Choose the **best** answer, **A–E**.
    (A) tranylcypromine (Parnate)

    (B) imipramine (Tofranil)

    (C) buspirone (Buspar)

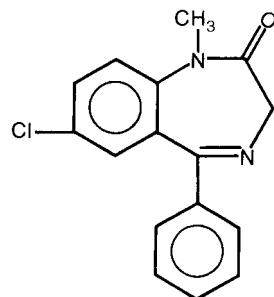
    (D) fluoxetine (Prozac)

    (E) phenelzine (Nardil)

28. An anxiolytic drug that does not possess either hypnotic or anticonvulsant properties.

29. A prototype tricyclic antidepressant with significant antimuscarinic properties.

30. An antidepressant that inhibits serotonin reuptake and may cause adverse effects such as insomnia, sexual dysfunction, and GI distress.

31. Tyramine-containing foods may cause dangerous hypertension in patients on this agent.


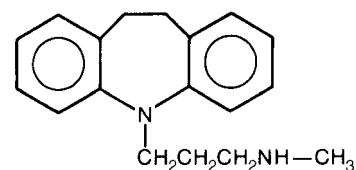
Directions for questions 32–34: Each structure in this section can be described by **one** of the following pharmacological categories. Choose the **best** answer.

    (A) general anesthetic

    (B) local anesthetic

    (C) antidepressant

    (D) anxiolytic

    (E) opioid antagonist


32.

33.

34.

For questions 35–37: A 38-year-old man has a history of affective disorders, including schizophrenia, depression, obsessive–compulsive disorder, and situational anxiety. His past medications include thiothixene, chlorpromazine, amitriptyline, and diazepam. His current medication profile includes the following drugs:

(A) clozapine (Clozaril)
(B) fluoxetine (Prozac)
(C) buspirone (Buspar)
(D) amoxapine

Directions: The following questions can be answered by **one** of the listed drugs. Choose the **best** answer, **A–D.**

35. Which agent is most likely being used to treat his schizophrenic psychosis?

36. Which agent is most likely being used to treat depression and obsessive–compulsive disorder?

37. Which of these agents is able to selectively block the actions of the serotonin transporter?

Directions for questions 38–44: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

38. Amphetamine exemplifies the pharmacologic mechanism of
    (A) ganglionic blockade.
    (B) inhibition of transmitter release.
    (C) facilitation of transmitter release.
    (D) interference with vesicular storage.
    (E) blockade of transmitter reuptake.

39. Considering the general chemical structures of sympathomimetic amines, modification of the meta-hydroxyl group on the phenyl ring of norepinephrine would likely produce
    (A) increased α-receptor potency.
    (B) increased β-receptor potency.
    (C) indirect sympathomimetic activity.
    (D) decreased transport through the blood–brain barrier.
    (E) loss of any biological activity in the nervous system.

40. Sometimes, combination treatment of Parkinson disease is warranted. Which of the following drug combinations could work cooperatively to enhance a clinical anti-parkinsonian response?
    (A) amphetamine (Adderall) and reserpine
    (B) levodopa and carbidopa
    (C) carbidopa and tolcapone (Tasmar)
    (D) amantadine (Symmetrel) and haloperidol (Haldol)
    (E) dopamine and tyramine

41. Terazosin is able to facilitate micturition when used in the treatment of benign prostatic hypertrophy (BPH) because the drug
    (A) relaxes the prostate gland.
    (B) constricts the neck of the bladder.
    (C) prevents penile erections associated with BPH.
    (D) blocks seminal fluid production.
    (E) blocks prostate cell growth.

42. BRL37344 is a β_3-agonist. It might be of interest to develop this agent into a clinically usable drug because of the expectation that β_3-agonists would
    (A) constrict blood vessels and increase blood pressure in shock patients.
    (B) induce lipolysis and decrease adipose cell mass in obese patients.
    (C) increase glycogenolysis and prevent glycogen storage in liver cirrhosis.
    (D) enhance renal vasodilation and increase urinary elimination of ethanol in alcoholics.
    (E) cause bronchodilation and counteract the negative effects of asthma treatment agents.

43. The pharmacologic profile of carvedilol is most similar to that of
    (A) esmolol.
    (B) labetalol (Trandate).
    (C) metoprolol (Lopressor).
    (D) nadolol (Corgard).
    (E) timolol (Timoptic).

44. The CNS and respiratory depression due to morphine overdose can be reversed by
    (A) methadone (Dolophine).
    (B) meperidine (Demerol).
    (C) propranolol (Inderal).
    (D) flumazenil (Romazicon).
    (E) naloxone (Narcan).

Answers and Explanations

1. **The answer is B** *[see II.B.2.b]*.
   Ipratropium is an approved antimuscarinic agent used to treat bronchospasm. Propantheline and homatropine are antimuscarinic agents used as a gastrointestinal (GI) antispasmodic and as a mydriatic, respectively. Edrophonium and ambenonium are indirect-acting cholinergic agonists and, as such, would be expected to induce bronchospasm.

2. **The answer is C** *[see II.B.1]*.
   Xerostomia, or dry mouth, results from reduced salivary secretions and, therefore, is not a manifestation of cholinergic agonist activity. All of the other effects listed in the question are extensions of therapeutic effects of cholinergic agonists to the point of being adverse effects.

3. **The answer is C** *[see II.A.8.a]*.
   Of the adrenergic agonists listed in the question, only epinephrine, because of its broad, nonselective α- and β-activity, is an agent of choice for anaphylactic reactions. Epinephrine improves circulatory and respiratory function and counteracts the vascular effects of histamine-related anaphylaxis.

4. **The answer is B** *[see II.C.1.f]*.
   Neuromuscular blocking agents interact with nicotinic receptors at the skeletal neuromuscular junction. Succinylcholine is also capable of eliciting K^+ release from skeletal muscle due to muscle contractions.

5. **The answer is A** *[see II.B.1.a,b]*.
   Both direct-acting (e.g., pilocarpine) and indirect-acting (e.g., physostigmine) cholinergics may be used in glaucoma to increase cholinergic activity and facilitate outflow of aqueous humor. Similarly, both β-agonists (e.g., epinephrine) and antagonists (e.g., timolol) may be used, respectively, to increase outflow and decrease production of aqueous humor. Atropine is contraindicated in glaucoma because its anticholinergic effects can block the outflow of aqueous humor and, consequently, increase intraocular pressure.

6. **The answer is D** *[see II.B.2.a]*.
   Classic signs and symptoms of muscarinic blockade, as with atropine, include mydriasis, which may cause light sensitivity (photophobia); dry mouth and constipation by decreasing secretory activity and motility in the GI tract; and tachycardia by inhibiting the normal inhibitory cholinergic control of the cardiac system. Diarrhea is one of the common signs of cholinergic agonists (others signs include salivation, lacrimation and urination).

7. **The answer is B** *[see III.B.2.a]*.
   The general anesthetics are divided into two major classes of drugs: those that are gases or volatile liquids, which are administered by inhalation, and those that are nonvolatile salts, which are administered as intravenous solutions. Halothane is a halogenated hydrocarbon, which belongs to the former class. It has the advantage over older volatile anesthetics (e.g., ethyl ether, cyclopropane) of being nonflammable. Thiopental sodium, alprazolam, buspirone, and phenytoin are all nonvolatile substances that are administered orally or parenterally. Thiopental is a general anesthetic and is sometimes referred to as a basal anesthetic because it does not produce significant third-stage surgical anesthesia. Alprazolam and buspirone are anxiolytics, whereas phenytoin is an anticonvulsant.

8. **The answer is B** *[see III.C]*.
   Chlordiazepoxide, alprazolam, buspirone, and phenobarbital are all used as anxiolytic agents, whereas thioridazine is a phenothiazine antipsychotic.

9. **The answer is C** *[see III.C.1.c]*.
   Benzodiazepines like diazepam enhance the actions of GABA on the $GABA_A$ receptor to enhance chloride influx into neurons. Topiramate and valproate are able to decrease epileptic activity by blocking glutamate receptors, whereas tiagabine prevents GABA uptake into the nerve terminal. Diazepam is not a MAOI and does not block the metabolism of inositol phosphates like lithium.

10. **The answer is A** *[see III.G.1.d]*.
    Entacapone blocks peripheral COMT to enhance CNS penetration of levodopa, which is metabolized to dopamine but has no H_1-receptor activity. Bromocriptine directly stimulates dopamine receptors in the striatum to restore the balance between GABA-ergic and cholinergic neurons in Parkinson disease.

11. **The answer is E** *[see III.G.1.c]*.
    Levodopa is not associated with agranulocytosis.

12. **The answer is E** *[see III.H.1; Figure 9-17]*.
    The *p*-phenyl-*N*-alkylpiperidine moiety is common to the structurally specific opioid analgesics. Meperidine is an opioid analgesic and is an *N*-methyl-*p*-phenylpiperidine derivative. Its chemical name is ethyl 1-methyl-4-phenylpiperidine-4-carboxylate. Phenobarbital is a barbiturate sedative. Chlorpromazine is a phenothiazine antipsychotic. Diazepam is a benzodiazepine anxiolytic. Imipramine is a tricyclic dibenzazepine antidepressant.

13. The answer is C *[see III.H.2]*.

Opioids are used to treat all the following conditions except arthritis, which is often treated with nonsteroidal anti-inflammatory drugs (NSAIDs) and immunosuppressants, depending on the type of disease and severity.

14. The answer is C *[see III.F.1]*.

All these agents are used to treat partial or generalized tonic-clonic seizures except ethosuximide, which is more effective against absence seizures.

15. The answer is C *[see II.B.2.b]*.

Cholinesterase inhibitors are indirect-acting cholinergic agonists useful in treating myasthenia gravis and glaucoma. Their effects on GI and urinary bladder smooth muscle would be to increase smooth-muscle tone, not decrease it.

16. The answer is D *[see II.B.2]*.

All three compounds listed in the question are antimuscarinic agents; however, only benztropine and trihexyphenidyl are used to control parkinsonism and some neuroleptic-induced extrapyramidal disorders. Ipratropium is an approved agent for the treatment of bronchospasm.

17. The answer is B *[see II.A.8.c]*.

Dobutamine is a β_1-selective adrenergic agonist. It would be inappropriate to use dobutamine to decrease blood flow at the site of local anesthetic administration. Epinephrine is a nonselective α- and β-agonist that can be used to limit the systemic absorption of local anesthetics and prolong their activity. Phenoxybenzamine is an α-selective antagonist that will only enhance the loss of the local anesthetic away from the site of application.

18. The answer is E *[see III.A.4]*.

Careful administration of a local anesthetic by a knowledgeable practitioner is essential to prevent systemic absorption and consequent toxicity. This is especially important when the patient has cardiovascular disease, poorly controlled diabetes, thyrotoxicosis, or peripheral vascular disease.

19. The answer is E *[see III.C.1.c]*.

Benzodiazepines can serve as induction agents for general anesthesia; they also have anxiolytic properties. In addition, intravenous diazepam is used to treat status epilepticus, whereas clonazepam is used orally for myoclonic and absence (petit mal) seizures. Benzodiazepines also diminish alcohol withdrawal symptoms.

20. The answer is D *[see II.A.9.a]*.

Tamsulosin is an α_{1A}-selective antagonist that may be used in place of finasteride to treat benign prostatic hypertrophy (BPH).

21. The answer is E *[see II.A.9.a]*.

Due to venodilatory actions, prazosin is associated with postural or orthostatic hypotension.

22. The answer is C *[see II.A.8.c]*.

Of all of the agents, only metaproterenol is an agonist at the β_2-receptors.

23. The answer is A *[see II.A.9.b]*.

The administration of propranolol, a nonselective antagonist of β-receptors, will antagonize β_2-receptors in the bronchioles of the patient to prevent the ability of metaproterenol to dilate the airways.

24. The answer is D *[see II.B.2.a]*.

Pilocarpine acts directly at the muscarinic receptor, whereas dipivefrin eventually activates α_2-receptors. Timolol blocks β-receptors. Echothiophate inhibits the metabolism of ACh, indirectly increasing levels of the endogenous neurotransmitter.

25. The answers are A and E *[see II.A.9.b]*.

Metoprolol, a β_1-selective agent, can cause bradycardia alone. The addition of topical timolol, while limiting systemic absorption, could have an additive β-blocking effect to decrease heart rate (negative chronotropy) and hypotension.

26. The answers are C and E *[see II.A.9.b; II.B.1.a,b]*.

Pilocarpine and echothiophate cause the stimulation of muscarinic receptors (pilocarpine directly and echothiophate indirectly), so applying them together would not produce any additional benefit. However, dipivefrin (once activated, below) can compete with timolol for β-receptors on the ciliary body, reducing the effectiveness of timolol.

27. The answer is C *[see II.A.8.a]*.

Dipivefrin is diacetylated epinephrine, which is readily metabolized to epinephrine to activate α_2-receptors on the ciliary body to reduce the production of aqueous humor.

28–31. The answers are: 28-C *[see III.C.3]*, **29-B** *[see III.E.2.e]*, **30-D** *[see III.E.1.d]*, **31-E** *[see III.E.3.d]*.

Buspirone's mechanism of anxiolytic action is unknown. Unlike the benzodiazepines, buspirone lacks hypnotic and anticonvulsant properties. The tricyclic antidepressant imipramine is useful in the treatment of enuresis because the compound blocks muscarinic receptors mediating micturition. Fluoxetine is the serotonin uptake blocker and has the adverse effects listed. Phenelzine is a MAOI that enhances catecholamine content in the nerve terminal, and foods containing tyramine (e.g., cheese) would elicit greater catecholamine release to potentially cause hypertension.

32–34.   The answers are: 32-B *[see Figure 9-8]*, **33-D** *[see Figure 9-10]*, **34-C** *[see Figure 9-15]*.

The structure shown in question 29 is that of procaine, which is a diethylaminoethyl *p*-aminobenzoate ester. It contains a hydrophilic amino group in the alcohol portion of the molecule and a lipophilic aromatic acid connected by the ester linkage. The procaine molecule is typical of ester-type local anesthetics.

The structure in question 30 is that of diazepam, which has a benzo-1,4-diazepine as its base nucleus. The widely used benzo-1,4-diazepine derivatives have significant anxiolytic, hypnotic, and anticonvulsant activities.

The structure in question 31 is that of desipramine, which has a dibenzazepine as its base nucleus. Dibenzazepine derivatives that have a methyl- or dimethylaminopropyl group attached to the ring nitrogen have significant antidepressant activity. Similarly, substituted dibenzocycloheptadienes also have antidepressant activity. Together, these two chemical classes make up most of the tricyclic antidepressants.

35.   The answer is A *[see III.D.4]*.

Clozapine, although therapeutically defined as a general antipsychotic, is used almost exclusively in the treatment of schizophrenia.

36.   The answer is B *[see III.E.1]*.

Fluoxetine is most likely being used in this patient in an attempt to treat depression and obsessive–compulsive disorder with the same drug. Clinical trials have shown fluoxetine to improve both conditions. The use of a single agent for both conditions will minimize the risk of drug–drug interactions, as well as reduce the chances of adverse effects.

37.   The answer is B *[see III.E.1]*.

Fluoxetine produces its antidepressant actions by selectively blocking the SERT to enhance serotonin levels in the synapse.

38.   The answer is C *[see II.A.8.d]*.

Amphetamine is an indirectly acting sympathomimetic that enters the nerve terminal and displaces norepinephrine from the storage vesicles, thus increasing quanta of the transmitter released.

39.   The answer is A *[see II.A.8.b]*.

Both aromatic hydroxyl functions are important for both α- and β-receptor binding; however, modification of the meta-hydroxyl to a methoxy derivative increases α- versus β-receptor selectivity.

40.   The answer is B *[see III.G.1.a]*.

Although levodopa can cross the blood–brain barrier to gain access into the brain, a significant portion of an orally administered dose is converted into dopamine and norepinephrine at peripheral sites, leading to peripheral side effects and decreased brain bioavailability. Carbidopa, a dopa decarboxylase inhibitor that does not cross the blood–brain barrier, is coadministered with levodopa to decrease its peripheral conversion and increase central delivery of the drug and, hence, the therapeutic response.

41.   The answer is A *[see II.A.9.a]*.

Terazosin blocks α-receptors on the prostate gland to cause a relaxant effect, which reduces the pressure exerted by the prostate on the urethra, thus easing urinary voidance.

42.   The answer is B *[see Table 9-1]*.

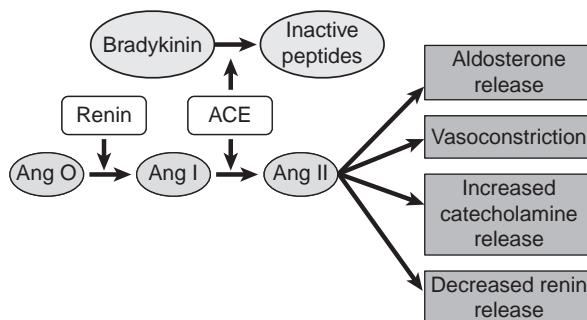
Stimulation of β_3-receptors induces the metabolic breakdown of fat stores into free fatty acids that can be further catabolized by the body. The hope is that this category of pharmacologic agents could, with repeated use, lead to a decrease in the content and number of fat cells, and, hence, an antiobesity effect.

43.   The answer is B *[see II.A.9.b; Table 9-2]*.

Like labetalol, carvedilol is a nonselective α- and β-receptor antagonist used in the treatment of hypertension. Blockade of vascular α (alpha-1)-receptors would cause vasodilatation and decreased peripheral vascular resistance, whereas blockade of myocardial β (beta-1)-receptors would decrease cardiac contractility. The resultant decrease in cardiac output would produce a fall in blood pressure (blood pressure = cardiac output × peripheral resistance).

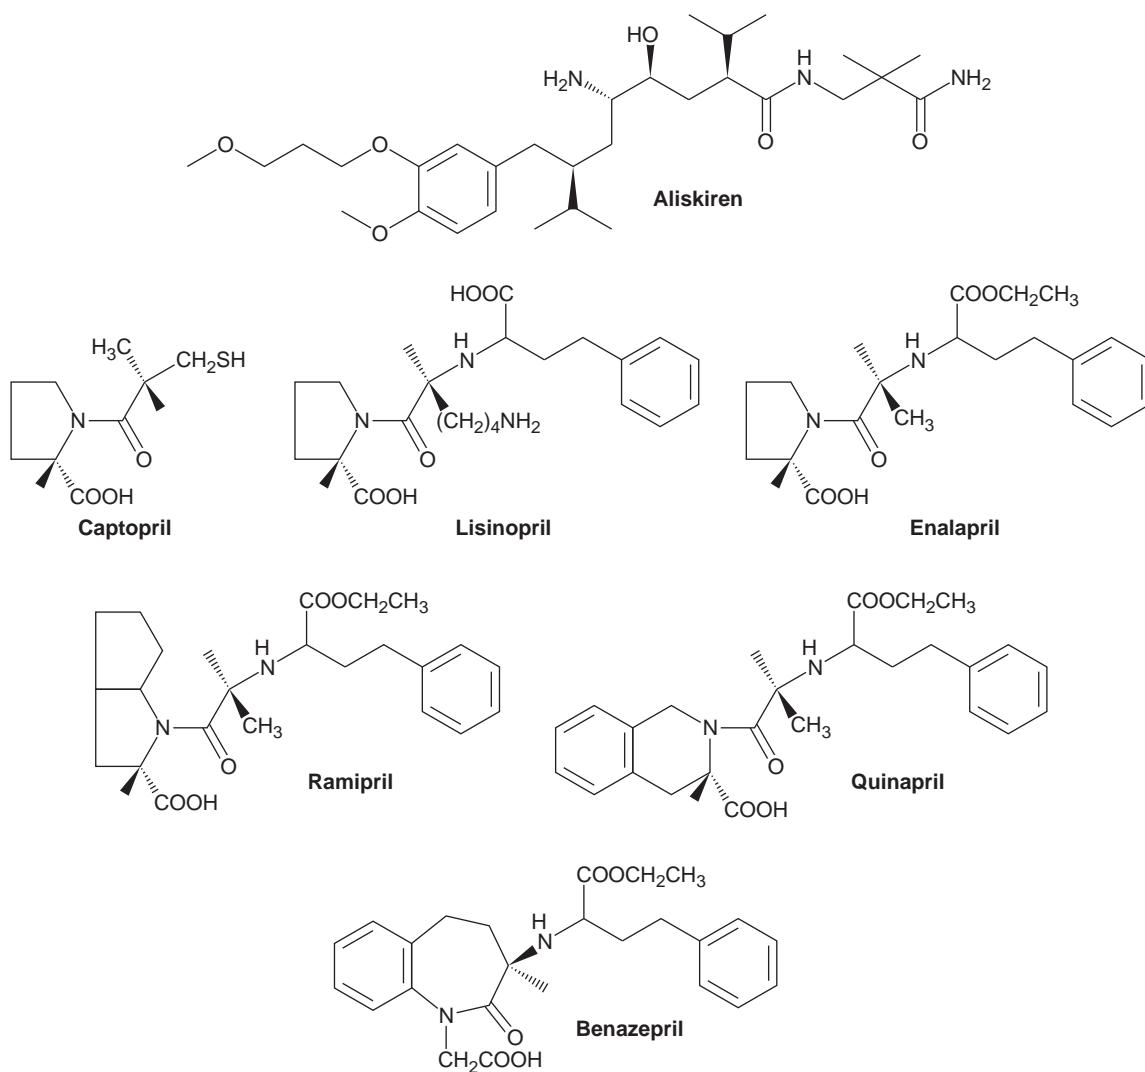
44.   The answer is E *[see III.H.1.b]*.

Only naloxone is able to effectively compete with morphine binding to central μ-opioid receptors to reverse the depressant effects of the opiate. Meperidine may have additive suppressive effects in this condition.

Pharmacology and Medicinal Chemistry of Cardiovascular and Diuretic Drugs


S. THOMAS ABRAHAM, MICHAEL L. ADAMS

I. INTRODUCTION. Cardiovascular diseases such as coronary heart disease (CHD), heart failure, and hypertension are some of the most widespread causes of mortality and morbidity in the world. CHD is more appropriately a disease of the coronary vasculature that can be exacerbated by thrombotic events to precipitate an acute myocardial infarction. Survivors of myocardial infarctions are often susceptible to heart failure and sudden cardiac death due to ventricular arrhythmias. Uncontrolled hypertension can also lead to CHD, heart failure, and stroke. Thus, several significant cardiovascular diseases have multiple causes, and patients are often treated for multiple, interconnected diseases using an array of agents.

II. ANTIHYPERTENSIVE AGENTS. Some of the drugs used to treat hypertension have been discussed in Chapter 9 and will not be addressed here in any detail. Antagonists of α_1- and β-adrenergic receptors (e.g., prazosin, propranolol, respectively) and α_2-agonists (clonidine) are examples of some these agents. The other classes of drugs used to treat systemic hypertension include angiotensin-converting enzyme (ACE) inhibitors, renin inhibitors, angiotensin receptor antagonists, diuretics, calcium-channel blockers, and direct vasodilators. Pulmonary hypertension is managed by endothelin antagonists and PDE5 inhibitors.


A. Drugs that modify the renin-angiotensin-aldosterone system

1. The renin-angiotensin system is an important regulator of systemic blood pressure and may be a contributing factor in about one-third of the cases of essential hypertension. In response to low renal tubular sodium or sympathetic nervous system stimulation, the renal juxtaglomerular cells release renin into the afferent arterioles.

2. Renin converts circulating angiotensinogen to angiotensin I, which is rapidly converted to angiotensin II by endothelial ACE, primarily in the pulmonary circulation (*Figure 10-1*). ACE is also responsible for the inactivation of the vasoactive peptide bradykinin.

Figure 10-1. The renin-angiotensin-aldosterone system with sites for pharmacological intervention. *Ang 0*, angiotensinogen; *Ang I*, angiotensin I; *Ang II*, angiotensin II; *ACE*, angiotensin-converting enzyme.

3. Angiotensin II is a potent vasoconstrictor; it releases aldosterone from the adrenal cortex and increases catecholamine release from sympathetic nerves. Aldosterone increases sodium and water reabsorption from the renal tubules and has vasoconstrictor effects as well. These direct and indirect effects of angiotensin II increase peripheral vascular resistance and blood volume that eventually increases systemic blood pressure.

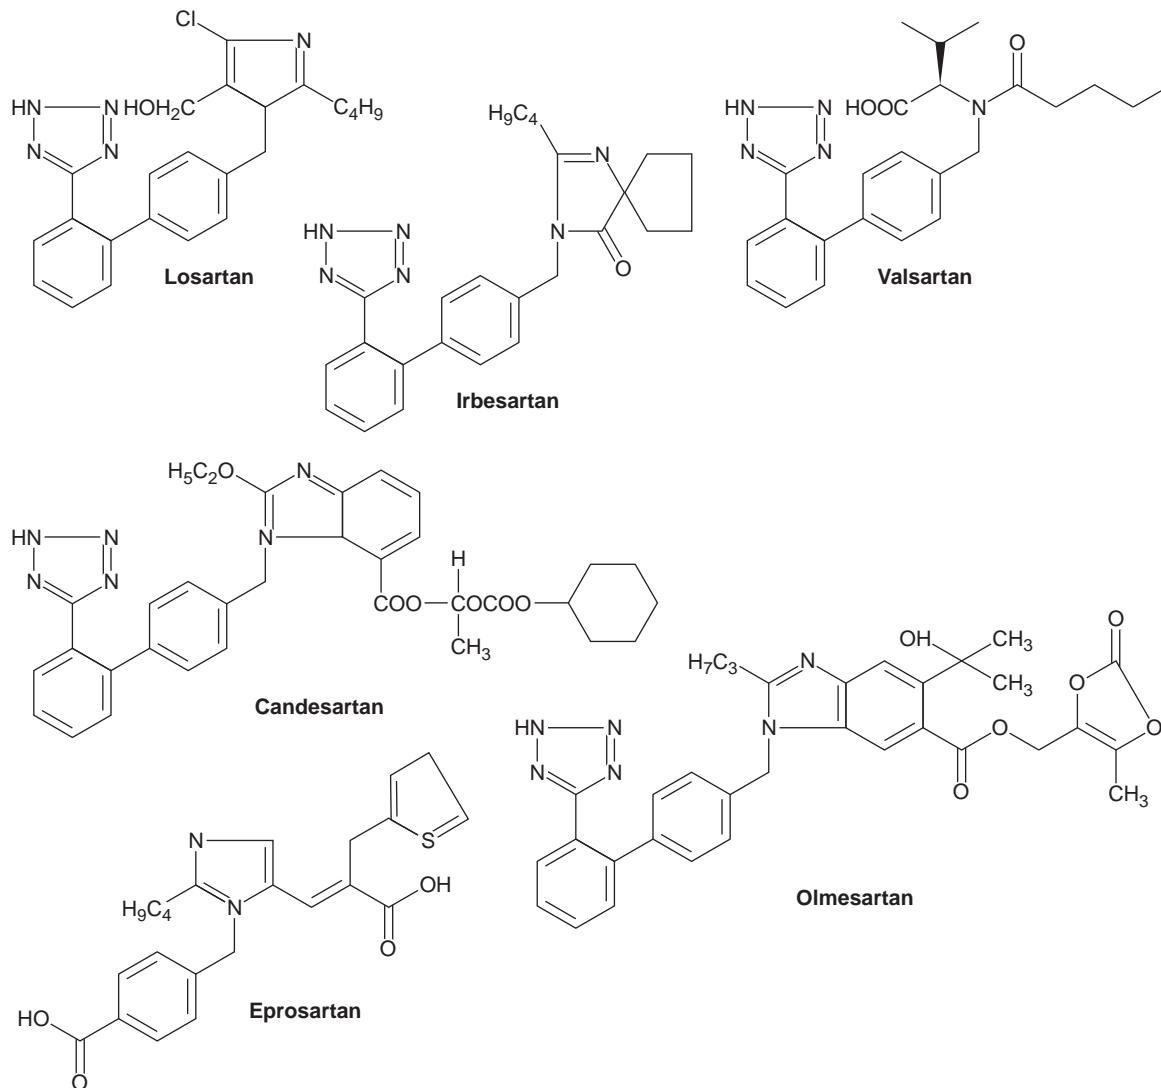
4. **Renin inhibitors** are represented by aliskiren (Tekturna®). Renin is an aspartate protease that catalyzes the rate-limiting conversion of angiotensinogen to angiotensin I (*Figure 10-1*). Aliskiren (*Figure 10-2*) is considered a peptidomimetic amide hydrolysis transition state analog that results in a high affinity interaction with renin. Its actions on preventing the production of angiotensin I cause a decrease in circulating angiotensin II and subsequent lowering in aldosterone. The loss of both aldosterone and angiotensin II leads to significant decreases in peripheral vascular resistance and systemic blood pressure. Currently, aliskiren is used as a second-line therapy for the management of hypertension.

5. **Angiotensin-converting enzyme inhibitors (ACEIs)**

    a. These agents are also transition-state analogs with the general structure shown in *Figure 10-2*. Binding to ACE requires a nitrogen-containing heterocyclic ring that also has a carboxylate group, as well as zinc-binding domain that may be a sulfhydryl, carboxylate, or a phosphinic acid.

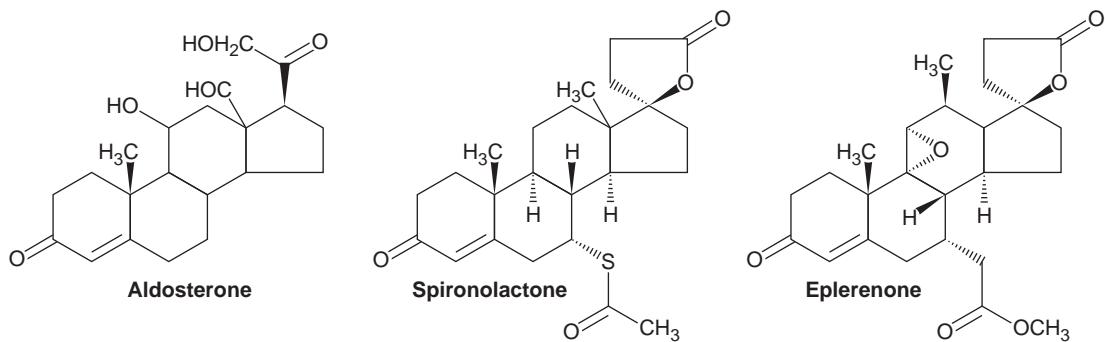
    b. Generally, the esterification of this carboxylate or phospho group improves oral activity but requires hydrolysis to the acid form for inhibitory action. Captopril (Capoten®; *Figure 10-2*) is an

Figure 10-2. Structural formulas of aliskiren (a renin inhibitor) and the ACE inhibitors captopril, enalapril, lisinopril, benazepril, ramipril, and quinapril.

example of sulfhydryl-containing drug with not only high affinity for ACE but also increased incidence of skin rash and dysgeusia due to this moiety. Lisinopril (Zestril®) and enalapril (Vasotec®) are carboxylate variant of ACEIs with enalapril being hydrolyzed by esterases to the active form enalaprilat. Other carboxylate derivatives of ACEIs are trandolapril (Mavik®), benazepril (Lotensin®), moexipril (Univasc®), perindopril (Aceon®), quinapril (Accupril®), and ramipril (Altace®). The phosphoester fosinopril (Monopril®; *Figure 10-2*) is converted by ester hydrolysis to fosinoprilat.


c. Inhibition of ACE activity systemically leads to reduced circulating angiotensin II with the consequent reductions in blood pressure. Inhibition of ACE and reduction in circulating angiotensin II and aldosterone also ameliorate cardiac and vascular remodeling and hypertrophy seen in hypertension and cardiomyopathies. ACEIs are used to treat hypertension, especially those prone to diabetic nephropathy, congestive heart failure, dilated cardiomyopathy, and the postmyocardial infarction patient.

d. Adverse effects of the ACEIs include cough and angioedema that are associated with an accumulation of bradykinin, which is also metabolized by ACE. Other adverse effects include hypotension, hyperkalemia, and acute renal failure.

6. Angiotensin receptor blockers


a. The angiotensin AT1 receptor is the predominant mediator angiotensin II's effects with regard to aldosterone release, vasoconstriction, catecholamine release, etc. Thus, blocking this receptor effectively reduces the untoward effects of this vasoactive peptide.

b. These drugs (losartan [Cozaar®], valsartan [Diovan®], telmisartan [Micardis®], azilsartan [Edarbi®], irbesartan [Avapro®], olmesartan [Benicar®], and candesartan [Atacand®]) are all biphenylmethyl derivatives except for eprosartan (Teveten®), which is a thienylmethylacrylate (*Figure 10-3*). The angiotensin receptor blockers (ARBs) are nonpeptide molecules that mimic the pharmacophore of angiotensin II to allow for AT1 receptor binding with no agonist activity. The ARBs have an acidic group that mimics either the carboxy terminal or the acidic tyrosine of angiotensin II. In the biphenyl compounds, the acidic functional group is either a carboxylic acid or a tetrazole in the ortho position on the second phenyl ring. The acidic group of the nonbiphenyl ARB eprosartan is attached in the para position of the only phenyl ring. The imidazole ring, or the amide bond in valsartan, mimics the histadine ring of angiotensin II, and the lipophilic substituents provide additional AT1 affinity.

c. Generally, these receptor antagonists interact with the receptor with a very slow off rate such that they behave as pseudo-irreversible antagonists. This has advantages in situations where a dose or two may be missed with no immediate reversal in hypotensive effect. Additionally, the buildup of angiotensin II due to the lack of negative feedback on the juxtaglomerular cells will be unable to effectively displace the antagonist.

d. The major pharmacological effect of these receptor antagonists is a lowering in systemic blood pressure without affecting cardiac output or initiating a baroreceptor reflex. Receptor antagonists also reduce smooth and cardiac muscle hypertrophy and decrease the progression of renal disease in diabetics. They have similar therapeutic use profile to the ACEIs and may be used in cases where the latter are poorly tolerated.

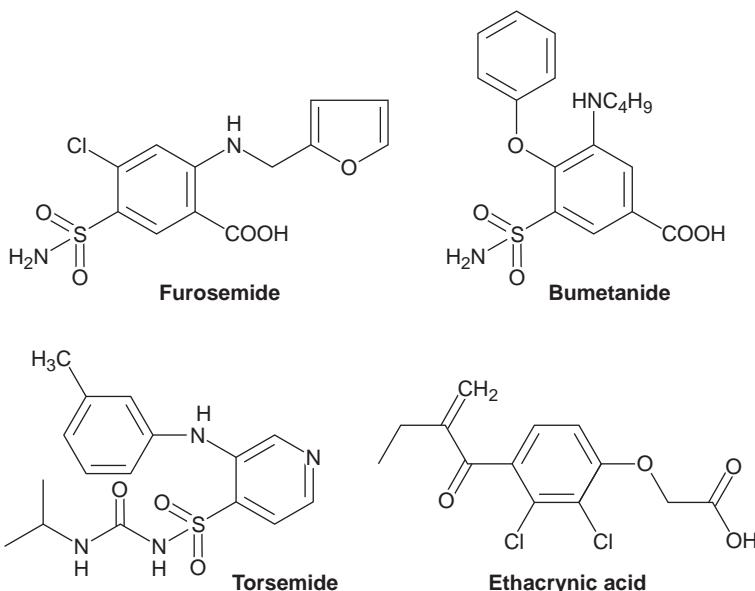
e. The major adverse effect of renin inhibitors, ACEIs, and angiotensin antagonists is first-dose hypotension, especially in patients with high plasma renin activity or are hypovolemic. Other prominent effects include acute renal failure in patients with renal artery stenosis, birth defects if taken during second/third trimesters, hyperkalemia, and liver toxicity. Additionally, angiotensin receptor antagonists are less likely to cause life-threatening angioedema and unproductive cough than ACEIs due to the inhibition of bradykinin metabolism observed with ACEIs (*Figure 10-1*).

7. Aldosterone antagonists

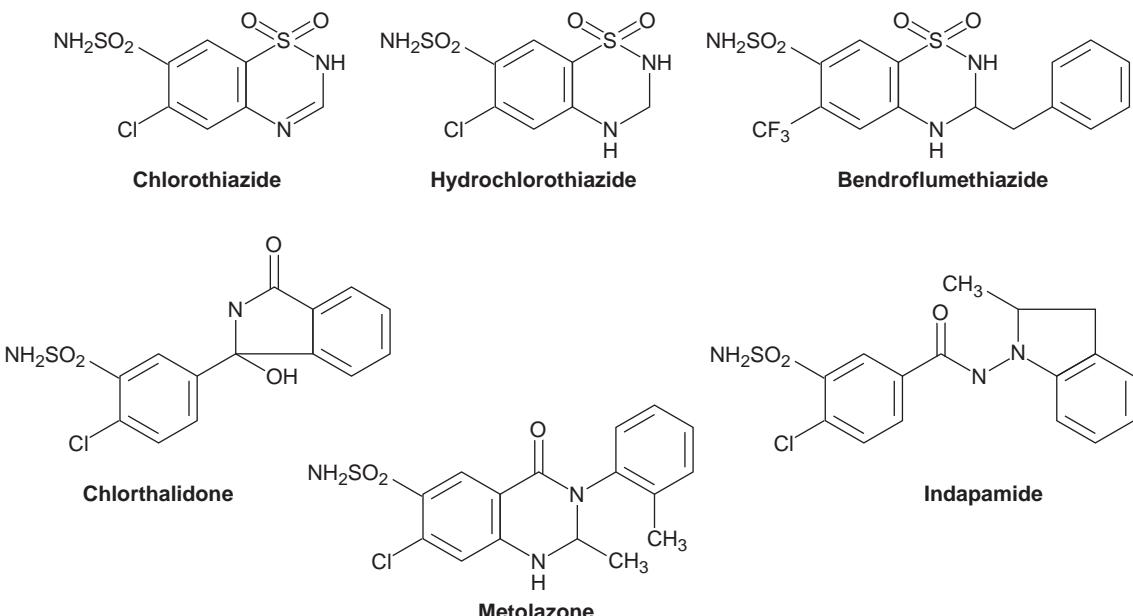
a. Although aldosterone antagonists have been historically grouped with the diuretics, their nondiuretic effects are more often relied upon to produce therapeutic benefit. Aldosterone is the primary mineralocorticoid released by the adrenal cortex in response to angiotensin II and high potassium levels. It functions in the renal collecting tubules to increase sodium and water reabsorption via the mineralocorticoid receptor (MR).

b. The antagonists spironolactone (Aldactone®) and eplerenone (Inspra®) are structurally analogous to aldosterone (*Figure 10-4*) and compete with it for the MR to prevent salt and water reabsorption. The result is a modest diuresis without concomitant wasting of potassium. This

Figure 10-3. Structural formulas of the angiotensin receptor antagonists losartan, valsartan, candesartan, irbesartan, olmesartan, and eprosartan.

Figure 10-4. Structural formulas of the mineralocorticoid aldosterone and antagonists for its receptor spironolactone and eplerenone.


effect, coupled with a significant vasodilator effect on the arteriolar vascular beds, produces significant lowering in systemic blood pressure. Additionally, spironolactone and eplerenone have been found to reduce the cardiac and renal remodeling in congestive heart failure and diabetes. These agents are primarily used to treat heart failure patients, hyperaldosteronism, and diabetic nephropathy.

    c. The adverse effects related to aldosterone antagonists are hyperkalemia, which may be proarrhythmic, and metabolic acidosis. Spironolactone is also likely to cause gynecomastia, menstrual irregularities, impotence, and benign prostatic hyperplasia due to its interactions with androgen and progesterone receptors.


B. Diuretic agents. The kidneys regulate salt and water balance to maintain systemic blood pressure and acid–base balance. Diuretic agents alter salt reabsorption in the renal tubules to modify the concomitant water reabsorption. The majority ($> 60\%$) of sodium and chloride, the primary osmotic ions in the glomerular filtrate, are reabsorbed in the proximal convoluted tubules, whereas the remainder is taken up in the thick ascending loop of Henle (TAL, ~25%), the distal convoluted tubule (~10%), and collecting tubules (~5%). The most efficacious and therapeutically relevant diuretics function at sites distal to the proximal tubules.

    1. Loop diuretics

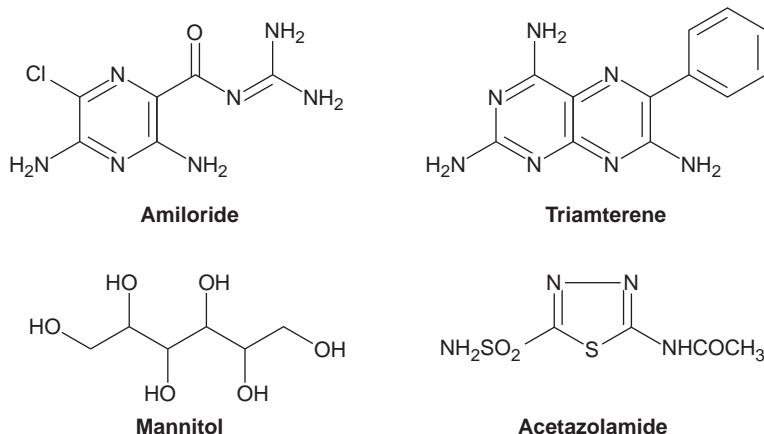
        a. Loop diuretics are anthranilic acid derivatives with a sulfonamide substituent (furosemide [Lasix®]; bumetanide [Bumex®]; torsemide [Demadex®]) or an aryloxyacetic acid without a sulfonamide substituent (ethacrynic acid [Edecrin®]; *Figure 10-5*).

        b. These agents are secreted via the organic acid transporter into the proximal tubule and block the functions of the Na/K/2Cl-transport system in the TAL from the luminal side. This prevents the reabsorption of a large quantity of Na^+ and Cl^- in the TAL and most of this is lost along with water in the urine. The loop diuretics also induce cyclooxygenase expression that leads to PGE2-mediated inhibition of salt transport in the TAL. Prostaglandin production may also be responsible for the vasodilator effects of loop diuretic and decreases in peripheral resistance.

        c. Loop diuretics are used when a large, rapid diuresis is required, as in the case of pulmonary congestion due to heart failure, other edematous diseases, hyperkalemia, hypercalcemia, acute renal failure, and fluoride/iodide overdose.

        d. Loop diuretics tend to cause large losses in K^+ as the collecting tubules attempt to recover some of the sodium load through the actions of aldosterone. This potassium-wasting effect can lead to hypokalemia and potential arrhythmogenic activity. Loss of magnesium absorption in the TAL due to diuretic action can result in hypomagnesemia. Ethacrynic acid is associated

Figure 10-5. Structural formulas of the loop or high ceiling diuretics.

Figure 10-6. Structural formulas of the thiazide (chlorothiazide, hydrochlorothiazide, and bendroflumethiazide) and thiazide-like (chlorthalidone, metolazone, and indapamide) diuretics.


with ototoxicity, especially when combined with aminoglycoside antibiotics. The sulfonamide moiety of loop diuretics (except ethacrynic acid) may result in allergic reactions in susceptible patients.

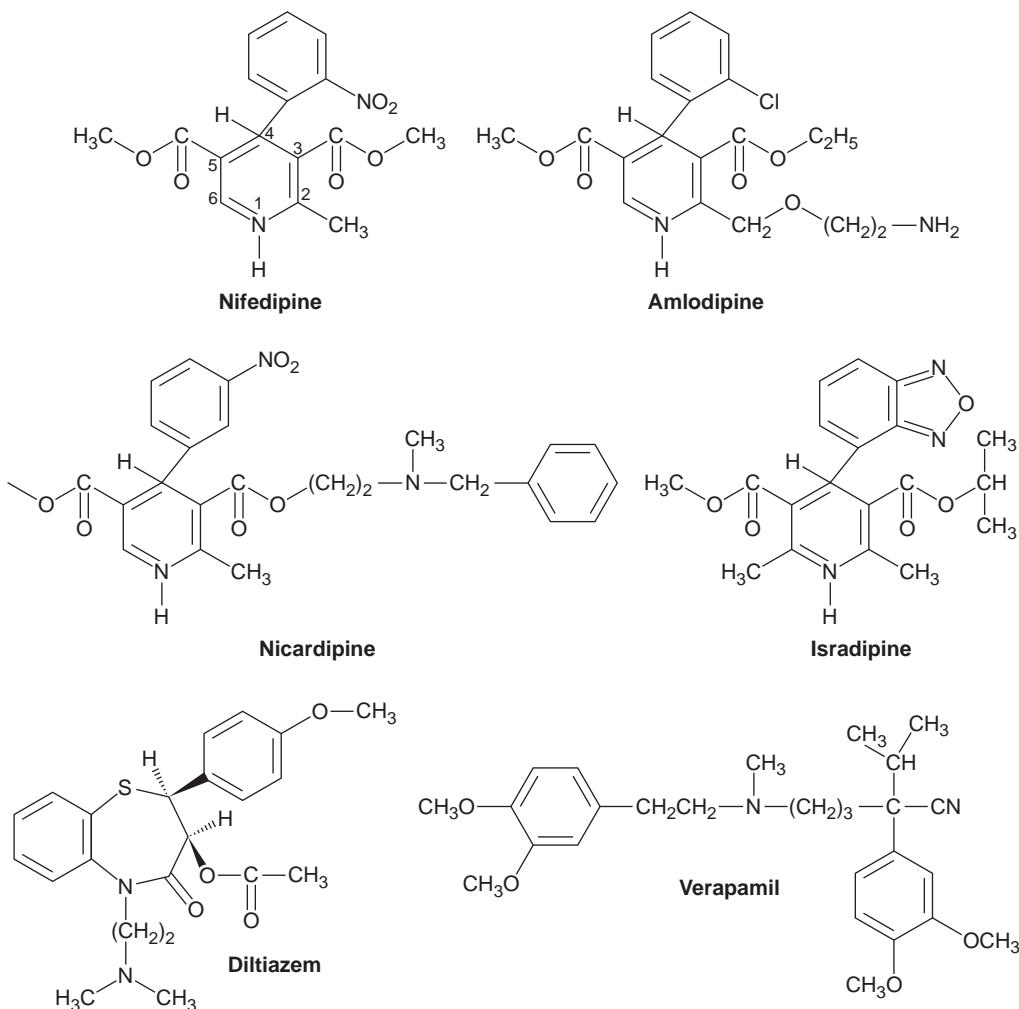
2. **Thiazide and thiazide-like agents**
   a. These agents are substituted benzothiadiazines with the general structure shown in *Figure 10-5* and represented by chlorothiazide (Diuril®), hydrochlorothiazide (HydroDIURIL®), bendroflumethiazide (Naturetin®; *Figure 10-6*), and methylchlorothiazide (Enduron®). These agents require an unsubstituted sulfonamide at position 7 as well as an electron-withdrawing group at position 6 for activity. Additionally, the saturation of the C3–C4 bond, lipophilic substitutions on C3, and alkylation of the nitrogen at position 2 improve the potency and duration of action.
   b. The thiazide-like agents are structurally similar except that the cyclic sulfonamide is replaced by an amide (e.g., chlorthalidone [Thalitone®], metolazone [Mykrox®], indapamide [Lozol®]; *Figure 10-6*).
   c. The agents in this class are organic acids that are secreted into the proximal tubular lumen to eventually inhibit the actions of the Na^+/Cl^- symporter in the early distal convoluted tubule (DCT). Inhibition of the symporter reduces salt reabsorption at this location and osmotically draws water with it as it is eliminated in the urine. Loss of water in the renal filtrate lowers blood volume, which ultimately decreases systemic blood pressure. Thiazide diuretics are a mainstay in the treatment of hypertension and congestive heart failure, calcium renal stones, and nephrogenic diabetes insipidus.
   d. The decrease in intracellular Na^+ increases Ca^{2+} reabsorption at the DCT to potentially cause hypercalcemia. As with the loop diuretics, the delivery of high Na^+ to the collecting tubules can cause excessive K^+ loss as aldosterone-stimulated Na^+ reabsorption takes place. Note that the Na^+ reabsorption capacity of the collecting tubules is limited and will not significantly counter the natriuresis seen with loop or thiazide diuretics.
   e. Apart from the hypokalemia, thiazides can cause hyponatremia, hypercalcemia, and sulfonamide-related sensitivity reactions. Hyperglycemia may be seen in diabetic patients and some increases in low density lipoprotein (LDL) levels may be observed.
3. **Potassium-sparing diuretics**
   a. These include the structurally dissimilar amiloride (Midamor®), triamterene (Dyrenium®; *Figure 10-7*), and spironolactone and eplerenone (see II.A.4 for discussion).


Figure 10-7. Structural formulas of the potassium-sparing diuretics (amiloride and triamterene), osmotic diuretic (mannitol), and the carbonic anhydrase inhibitor (acetazolamide).

    b. Amiloride and triamterene block the Na^+ channel through which the ion is absorbed into the principal cells of the collecting tubule leading to a small natriuresis and diuresis. Normally, Na^+ reabsorption here is electrically coupled to K^+ elimination, but these agents are able to produce a natriuresis without K^+ wasting, hence their designation as "K^+-sparing". Amiloride and triamterene are used to minimize K^+-wasting induced by loop and thiazide diuretics, reduce symptoms of cystic fibrosis, and treat Liddle syndrome and lithium-induced diabetes insipidus.

    c. These agents can cause hyperkalemia (and consequent arrhythmias), metabolic acidosis, and precipitate acute renal failure.

  4. Miscellaneous diuretics

    a. The osmotic diuretic mannitol (Osmitrol®; *Figure 10-7*) is freely filtered into the renal tubules to produce an osmotic pressure resulting in a rapid diuresis. This agent is use to rapidly reduce intracranial or intraocular pressure in emergency situations.

    b. The carbonic anhydrase inhibitor acetazolamide (Diamox®; *Figure 10-7*) reduces Na^+ reabsorption in the proximal convoluted tubules but has low efficacy because the amount of natriuresis produced is marginal and short-lived. The primary use of acetazolamide is to reduce aqueous humor production to treat glaucoma, metabolic alkalosis, and acute altitude sickness.

C. Calcium-channel blockers and other vasodilators

  1. Calcium is a fundamental signaling molecule in biological processes and is necessary for the orderly contraction of smooth, cardiac, and skeletal muscle. The activation of α-adrenergic receptors on vascular smooth muscle cells (*Table 9-1*) initiates an influx of calcium, through voltage-dependent calcium channels, that promotes contractile response. Cardiac conduction cells and muscle also contain similar calcium channels and are most often designated as L-type channels. These channels participate in spontaneous depolarization of the sinoatrial (SA) and atrioventricular (AV) nodes and provide the trigger calcium for sarcoplasmic calcium release and contraction of myocardial cells.

  2. The major use of all the aforementioned calcium-channel blockers (CCBs) is in the therapy of hypertension, angina, and Raynaud syndrome. Verapamil and diltiazem are also used to treat supraventricular arrhythmias.

  3. CCBs belong to the dihydropyridine, phenylalkylamine, and benzothiazepine classes.

    a. Dihydropyridines contain a 1,4-dihydropyridine (DHP) ring that is required for channel blocking activity, and generally ester groups at the C3 and C5 positions improve activity (e.g., nifedipine [Procardia®], amlodipine [Norvasc®], nicardipine [Cardene®]; *Figure 10-8*). Additionally, electron-withdrawing ortho or meta substitutions on the phenyl ring improve channel blocking activity. DHPs interact preferentially with the inactive form of the calcium channel and maintain that conformation to prevent its opening during membrane depolarization. At therapeutic doses, DHPs preferentially inactivate vascular versus cardiac calcium channels to produce greater vasodilation than negative ionotropic and chronotropic effects. The drop in blood pressure can elicit a baroreceptor reflex increase in heart rate and contractility that can lead to angina attacks.

    b. Phenylalkylamines are represented by verapamil (Calan®; *Figure 10-8*). Verapamil diffuses through the plasma membrane and interacts on the cytoplasmic domain of the calcium

Figure 10-8. Structural formulas of the dihydropyridine (nifedipine, nicardipine, amlodipine, and isradipine), phenylalkylamine (verapamil), and benzothiazepine (diltiazem) calcium-channel blockers.

      channel. Verapamil has equivalent actions on vascular and cardiac calcium channels to produce vasodilation and decreased cardiac output to decrease blood pressure.

    c. **Benzothiazepines** are represented by diltiazem (Cardizem CD®; *Figure 10-8*). Diltiazem has a similar mechanism of action as verapamil to reduce blood pressure.

  4. Adverse effects related to the use of CCBs are hypotension, headache, peripheral edema, constipation, cough, and wheezing. Verapamil and diltiazem are also prone to cause bradycardia, AV block, and transient sinus arrest.

  5. **Miscellaneous vasodilators** are a diverse group of agents with distinct vasodilator or hypotensive actions.

    a. Nitroprusside (Nitropress®) is an intravenous agent for the rapid reduction in blood pressure. Nitroprusside is a potent nitric oxide (NO) donor that relaxes vascular smooth muscle cells to decrease systemic blood pressure.

    b. Hydralazine (Apresoline®) is a direct vasodilator that may be administered parenterally or orally to manage hypertension that is not responsive to other agents.

    c. Minoxidil (Loniten®) is metabolized to a glucuronide conjugate that is a potent K^+ATP channel activator. This action results in hyperpolarization of smooth muscle membranes, reduced calcium influx, and vasodilation. Minoxidil is used to treat hypertension resistant to standard therapy and also increases hair growth when applied topically (Rogaine®).

    d. These agents can also be used to manage the congestive heart failure patient.

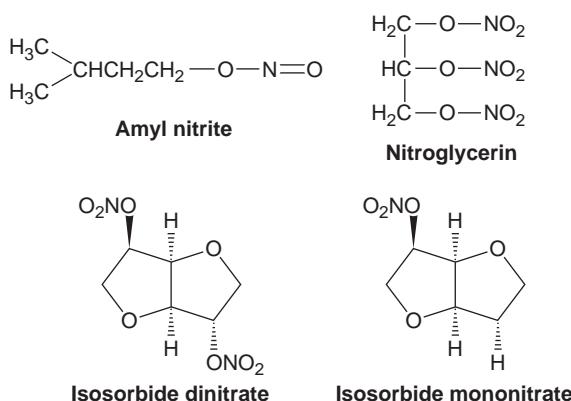
e. All three agents may cause edema, tachycardia, angina, and hypotension. Hydralazine is also associated with lupus-like sensitivity reactions, whereas minoxidil may also increase pulmonary artery pressure and hirsutism. Nitroprusside may also cause lactic acidosis secondary to cyanosis with sustained use.

D. Agents used to treat pulmonary arterial hypertension (PAH)

Pulmonary hypertension is characterized by elevated pulmonary artery pressure leading to dyspnea, dizziness, fatigue, right ventricular failure, and edema.

1. The potent vasoactive protein endothelin appears to be elevated in the pulmonary circulation of patients with PAH. Endothelin activates its receptors (ET_A and ET_B) on pulmonary vascular cells to cause vasoconstriction and subsequent hypertension. The endothelin receptor antagonists bosentan (Tracleer®) and ambrisentan (Letairis®) are able to prevent endothelin's actions and the result is arterial vasodilation. These agents have little effect on systemic blood pressure but have been associated with hepatotoxicity and fetal death if taken by pregnant women. Less serious adverse effects include nasal congestion, flushing, edema, headaches, and gastric cramps.

2. The **type 5A phosphodiesterase (PDE5A)** is the target for sildenafil (Revatio®) and tadalafil (Adcirca®), which are also used to treat PAH. Guanylyl cyclase in vascular smooth muscle cells of the pulmonary circulation convert guanosine triphosphate to cyclic guanosine monophosphate that reduces intracellular calcium and leads to vasodilation (details discussed later in this chapter). The PDE5A inhibitors prevent the metabolism of cGMP; maintain its intracellular concentrations; and, thus, preserve its vasodilatory actions on smooth muscle. Sildenafil and tadalafil are also used to treat erectile dysfunction, so priapism is a potential adverse effect and other effects may include headache, nausea, mild hypotension, visual disturbances, and flushing of the skin.

3. Prostanoids such as epoprostenol (Flolan®), iloprost (Ventavis®), and treprostinil (Remodulin®) are also used to treat PAH and are discussed in more detail in Chapter 11.


III. AGENTS USED TO MANAGE ANGINA.
Angina is characterized by chest pain either upon exertion (stable angina) or even at rest (unstable or vasospastic form). The symptoms are due to the lack of myocardial oxygenation secondary to atherosclerotic disease of the coronary vasculature (stable), spontaneous vasoconstriction of the coronary vessels (vasospastic), and episodic thrombotic events in the cardiac vessels (unstable). The general strategy for the treatment of acute or chronic angina is to increase oxygen supply or reduce myocardial oxygen demand.

A. Nitrate vasodilators are polyol esters of nitric acid nitrite (amyl nitrite) or nitrate (isosorbide dinitrate [Isordil®], nitroglycerin [Nitro-Dur®], isosorbide mononitrate [Ismo®]; *Figure 10-9*).

1. The fully nitrated polyols are nonpolar and lipid soluble, allowing rapid absorption from inhalational, dermal, sublingual, and oral routes. These routes (except for the oral) avoid first-pass metabolism to produce rapid antianginal effects, especially nasal and sublingual administration.

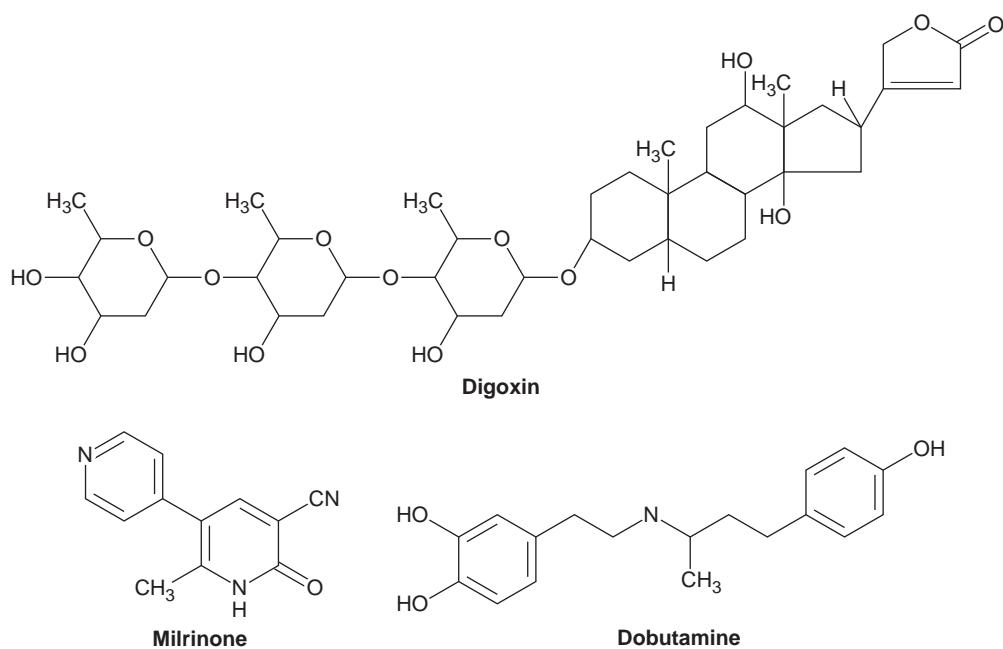
2. The systemic actions of these agents occur after a reductase-catalyzed (glutathione functioning as cofactor) production of nitric oxide (NO) in the vasculature. The potency and duration of action of these agents increase with the number of reducible nitrate groups found on the molecule. Higher reductase activity in veins than arteries is thought to produce greater venous rather than arterial effects of usual doses of nitrate derivatives.


Figure 10-9. Structural formulas of the nitrite (amyl nitrite) and nitrate (nitroglycerin, isosorbide dinitrate, and isosorbide mononitrate) vasodilators.

3. NO produced in vascular smooth muscle cells activates soluble guanylyl cyclase that converts GTP to cGMP, which in turn activates protein kinase G (PKG). PKG is thought to reduce smooth muscle contraction by reducing cytoplasmic calcium levels and decreasing actin-myosin interactions.

4. Venodilation results in reduced venous return and decreased myocardial filling, which ultimately decreases myocardial work and oxygen demand. Reduced end-diastolic pressure also has the ability to improve subendocardial blood flow to increase oxygen supply to ischemic regions. Modest arterial dilation produced at these doses may also contribute to these two mechanisms.

5. Tolerance to nitrates occurs with chronic use and may be due to depletion of vascular glutathione; a withdrawal period is often required to restore sensitivity.

6. The most frequent adverse effects associated with nitrate use are flushing, headache, orthostatic hypotension, tachycardia, and dizziness.

B. **Ranolazine (Ranexa®)** is a relatively new agent used in the treatment of angina due to ischemic disease. Its mechanism of action is not entirely clear but may reduce myocardial contractility (and consequently oxygen demand) by blocking the late sodium current. The most common adverse events related to its use are dizziness, nausea, constipation, headache, and bradycardia.

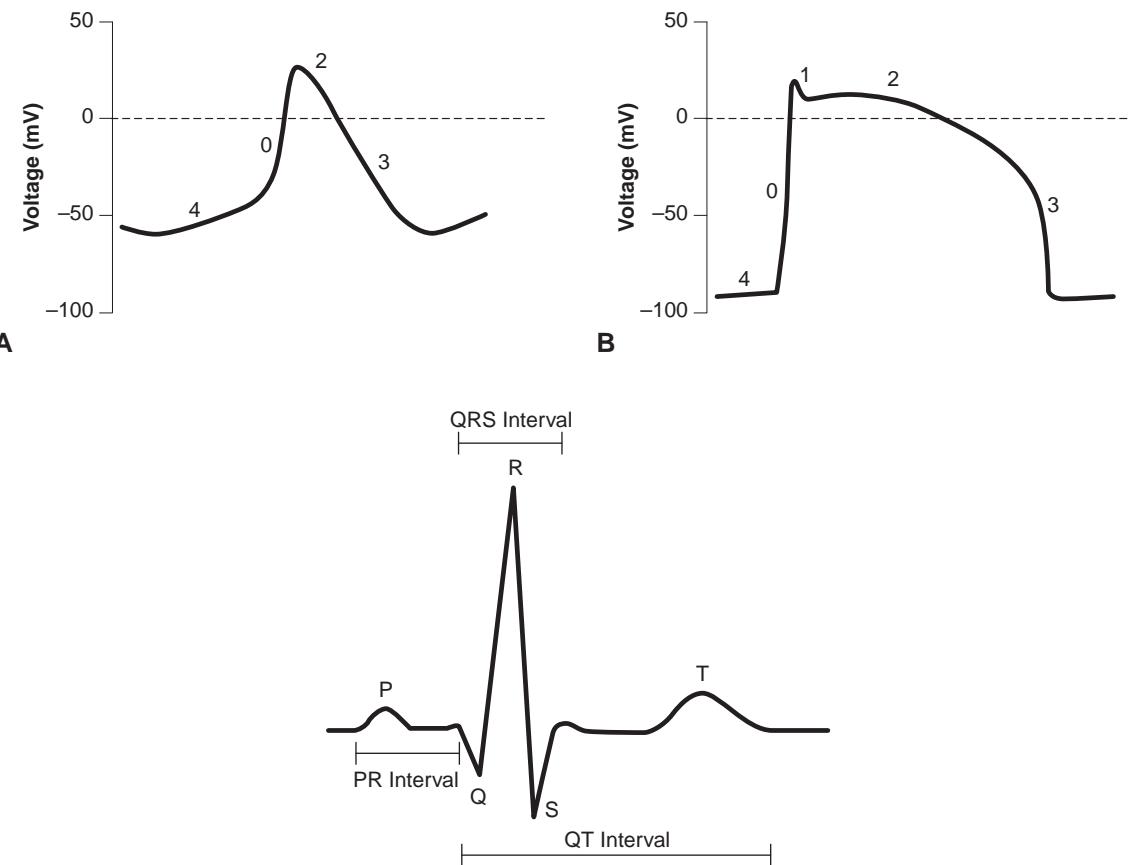
C. **CCBs** prevent vasospastic angina by dilating coronary vessels to improve blood supply to the ischemic myocardium. The CCBs have been discussed in the previous section (see II.C).

D. **β-Adrenergic antagonists** reduce myocardial work by decreasing catecholamine-induced changes in heart rate and contractility. These agents primarily reduce myocardial oxygen demand and have been discussed in Chapter 9 (see II.B.3).

E. **Antiplatelet agents** reduce thrombotic events in the coronary circulation to prevent episodic reductions in myocardial blood flow and thus improve oxygen supply. These agents are discussed in the succeeding antiplatelet section.

IV. AGENTS FOR THE TREATMENT OF CONGESTIVE HEART FAILURE.
Congestive heart failure (CHF) is the reduction in cardiac output at normal filling pressures and may be secondary to a myocardial infarction or uncontrolled hypertension but may be the result of underlying myopathies of cardiac tissue. Generally, the treatment strategy is to alleviate the pulmonary and peripheral congestion due to edema and enhance cardiac pump function. Thus, diuretics and positive ionotropic agents are critical to CHF management; however, other agents that reduce cardiac remodeling and lower the work of the myocardium have also been found to be useful.

A. **Positive ionotropic agents** include several diverse agents used to manage acute and chronic pump failure.
   1. Digoxin (Lanoxin®)
      a. Digoxin belongs to the cardiac glycoside family of positive ionotropic agents and is composed of a steroidal nucleus, an unsaturated lactone ring, and three sugars attached via glycosidic linkage (*Figure 10-10*). The glycoside portion is required for function, and bacterial cleavage of the glycosidic bond in the gastrointestinal (GI) tract reduces efficacy in about 10% of the population.
      b. Digoxin inhibits the actions of the electrogenic Na^+/K^+-ATPase resulting in increased intracellular Na^+ and consequent increase in intracellular calcium via actions of the coupled Na^+-Ca^{2+} exchanger. This intracellular calcium is stored in the sarcoplasmic reticulum until myocardial depolarization produces greater calcium-induced calcium release, which produces enhanced cardiac contractility.
      c. Improved cardiac contractility leads to increased cardiac output, better tissue perfusion, and enhanced renal function and urine output. This promotes greater water loss and reduces pulmonary congestion and edema of the extremities.
   2. Infusions of dopamine or dobutamine (*Figure 10-10*) are used to manage acute heart failure via the activation of $β_1$-adrenergic receptors on the myocardium (discussed in Chapter 9). Activation of $β_1$-adrenergic receptors initiates the cAMP-protein kinase A (PKA) pathway (*Figure 58-1*) to increase myocardial calcium levels and subsequent increases in contractility and cardiac output. Dopamine also improves renal blood flow to enhance urine output and reduce edema.
   3. The bipyridine phosphodiesterase type 3 (PDE3) inhibitors, milrinone (Primacor®; *Figure 10-10*) and inamrinone (Inocor®; not currently marketed), are also used intermittently in acute heart failure (*Figure 10-10*). Inhibition of PDE3 prevents the metabolism of cAMP to AMP that results

Figure 10-10. Structural formulas of the positive ionotropic agents digoxin, milrinone, and dobutamine.


in greater PKA activation and an ionotropic effect. Elevated cAMP-PKA in vascular smooth muscle also results in vasodilation and reduced systemic pressure to improve cardiac output.

4. A common adverse effect of all these positive ionotropic agents is the possibility of inducing ventricular arrhythmias during treatment. Nausea, vomiting, and visual disturbances are seen with digoxin, whereas PDE3 inhibitors are associated with thrombocytopenia and liver toxicity.

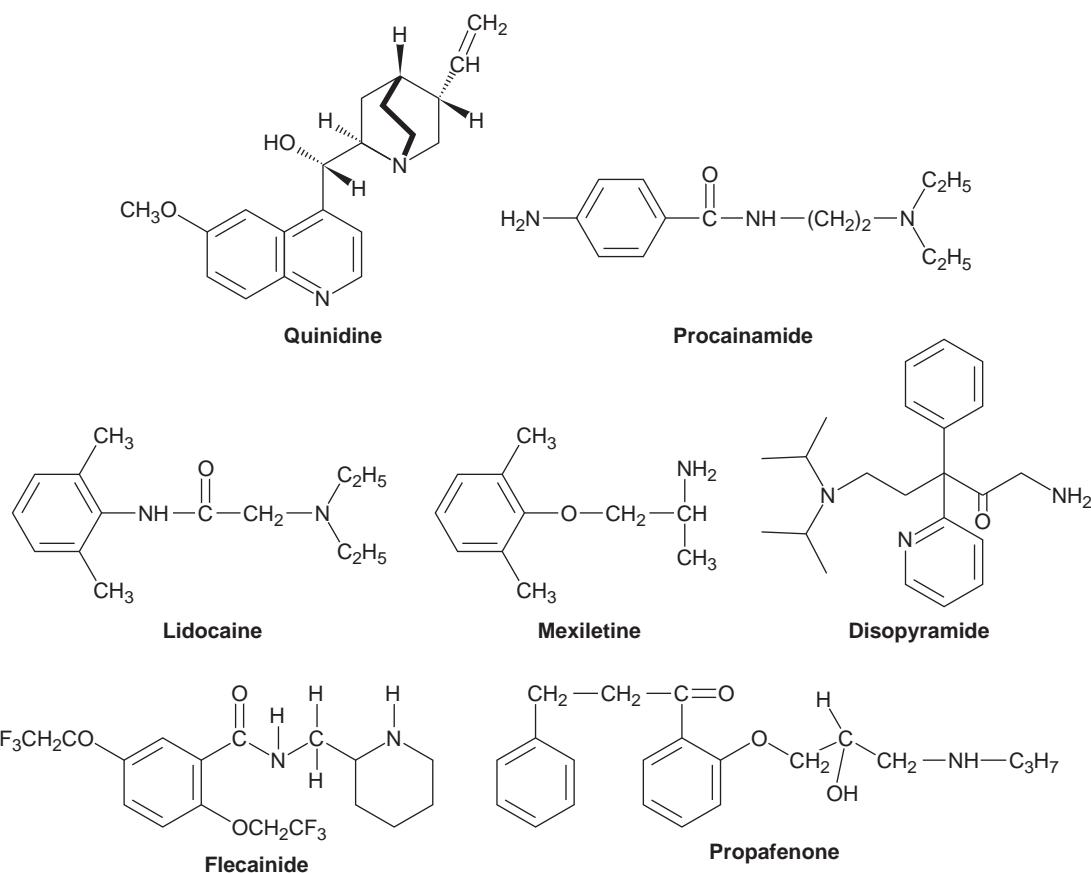
B. **β-Receptor antagonists.** In an apparently paradoxical manner, these drugs can be used to effectively manage chronic heart failure if they are carefully titrated. Blocking the β₁-receptors on the myocardium agents such as metoprolol, atenolol, and carvedilol can reduce the sympathetically driven heart rate and myocardial remodeling seen in CHF patients. Reduction in heart rate coupled with the lowering in peripheral resistance allows for better ventricular filling and improved ejection fraction to diminish the congestive symptoms.

C. **Inhibitors of renin-angiotensin-aldosterone system.** The high blood pressures seen in compensated heart failure and chronic cardiac remodeling can be reduced by ACEIs, ARBs, and aldosterone antagonists (e.g., eplerenone). The mechanisms for these effects are discussed in the previous section.

D. **Vasodilators.** Agents such as hydralazine and isosorbide dinitrate can reduce systemic blood pressure in the CHF patient to improve ventricular ejection and reduce pulmonary congestion. The combination of these two drugs (BiDil®) has been found to be beneficial in patients of African origin.

E. **Diuretics.** The extensive pulmonary congestion and peripheral edema experienced by CHF patients can be managed by the use of thiazide (e.g., hydrochlorothiazide) and loop (e.g., furosemide) diuretics.

F. **Nesiritide (Natrecor®)** is a recombinant form of brain natriuretic peptide that activates guanylyl cyclase A receptors on vascular smooth muscle cells to produce vasodilation and improve natriuresis and diuresis in the kidneys. Infusions of nesiritide are used to manage congestive symptoms in advanced heart failure.

V. ANTIARRHYTHMIC AGENTS.
Cardiac arrhythmias are often the result of underlying organic disease secondary to myocardial infarction or genetic mutations in the specific ion channels responsible for cardiac electrical activity.


A. The orderly movement of electrical activity from the SA node, through the atrial body to the AV node, and through the His-Purkinje system to the myocardium, is responsible for the organized contraction of the heart.

1. Arrhythmias result in uncoordinated atrial and ventricular contractions that reduce cardiac output and systemic blood pressure.

2. SA nodal pacemaker cells are able to spontaneously depolarize due to the leakiness of these cells to Na^+ (via the I_f channel) and Ca^{2+} (via L-type channels), producing a characteristic action potential (*Figure 10-11*). AV nodal cells are also leaky to Na^+/Ca^{2+} ions to spontaneously depolarize, but more often, they conduct atrial impulses through the His-Purkinje system.

3. Atrial, His-Purkinje, and ventricular myocardial cells are much less permeable to cations and are triggered to depolarize by electrical impulses from the SA nodes or AV nodes, respectively. Once triggered, voltage-dependent Na^+ channels open to depolarize the cells (phase 0), which is followed by rapid opening of outward K^+ channels (phase 1) and slower inward L-type (Ca^{2+}) currents to produce the phase 2 portion of the action potential (*Figure 10-11*). These cells are repolarized by the opening of delayed rectifier K^+ channels in phase 3 to reset the voltage-dependent Na^+ channels from inactive to the closed state in preparation for depolarization.

4. Generally, L-type channel blockers will preferentially affect SA and AV nodal cells due to their dependence on calcium currents for depolarization, whereas sodium channel blockers will decrease the activity of atrial and ventricular myocardial cells as well as those of the His-Purkinje conduction system. Potassium channel blockers decrease the rate of repolarization of all cells in the heart and can affect myocardial and conduction system cells.

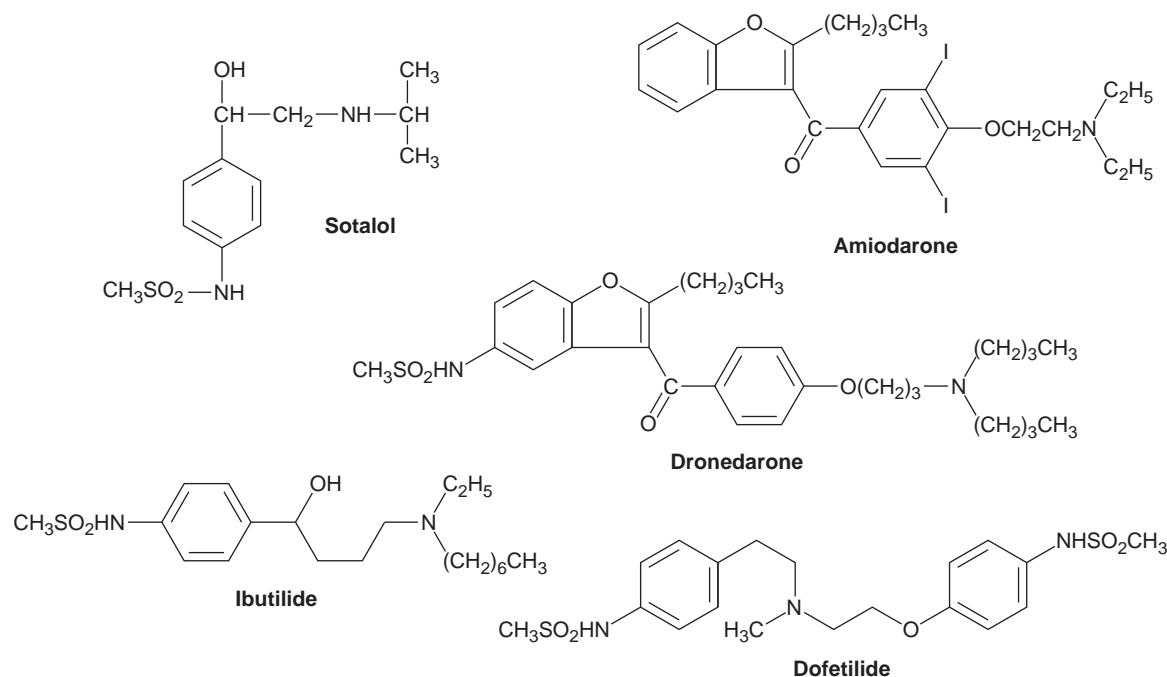
5. Cardiac electrical activity is assessed by the use of surface chest electrodes connected to an amplification system that generates the recognizable electrocardiogram (ECG). The components of the ECG that are important for diagnosis of disease, as well as efficacy of antiarrhythmic drugs, are the P wave, PR interval, R wave, QRS interval, T wave, and QT intervals (*Figure 10-11*).


Figure 10-11. A. Action potential of an SA nodal cell with slow depolarization (phase 4), rapid depolarization (phase 0), plateau (phase 2), and rapid depolarization (phase 3). **B.** Action potential of a myocardial Purkinje cell with slow depolarization (phase 4), rapid depolarization (phase 0), rapid repolarization (phase 1), plateau (phase 2), and slow repolarization (phase 3). **C.** A typical electrocardiogram indicating atrial depolarization (P wave), ventricular depolarization (QRS wave), and ventricular repolarization (T wave).

a. The P wave is indicative of the depolarization of the atria, whereas the PR interval is the time taken for the impulses to travel through the atria to the ventricles.

b. The electrical activity of the AV node is the largest contributor to the PR interval, and drugs that affect the excitability of the AV node would tend to widen the PR interval (e.g., CCBs).

c. The QRS interval indicates the time taken for electrical impulses to travel through the His-Purkinje and ventricular cells, whereas the QT interval represents the cardiac repolarization time. Drugs that affect Na^+ channels would slow electrical conduction through the His-Purkinje–ventricular pathway to prolong the QRS interval.

d. Agents that slow down repolarization by interacting with K^+ channels have the effect of prolonging the PR, QRS, and QT intervals by increasing the refractory period of Ca^{2+} or Na^+ channels.

e. Most antiarrhythmic agents are Na^+, Ca^{2+}, or K^+ channel blockers that reduce the excitability of various cells of the cardiac conduction system. β-Adrenoreceptor antagonists are the fourth class of antiarrhythmic agents used to reduce the impact of the sympathetic nervous system on aberrant electrical activity.

6. Arrhythmias are due to defects in action potential initiation such as sinus bradycardia or premature ventricular beat, or defects in the conduction of electrical activity through the heart (e.g., reentrant supraventricular arrhythmias or torsades de pointes).

B. Sodium channel blocking antiarrhythmics

1. Quinidine, procainamide (Pronestyl®), and disopyramide (Norpace®; *Figure 10-12*) have dissimilar structures but similar Na^+ channel blocking activity to reduce excitability in atrial fibrillation and flutter, and also to decrease the recurrence of ventricular arrhythmias. Quinidine also has significant K^+ channel blocking activity as well as α-adrenergic blocking activity. Procainamide is metabolized to *N*-acetyl procainamide that has more prominent K^+-channel blocking activity, whereas disopyramide has the ability to block K^+-channels and depress cardiac contractility. The K^+-channel blocking activity of these three agents can predispose to torsades de pointes type of arrhythmias, whereas quinidine is associated with hypotension and syncope and disopyramide may precipitate heart failure. Procainamide is associated with lupus-like reactions, especially in patients who are unable to acetylate the drug effectively.

2. Lidocaine (Xylocaine®) and mexiletine (Mexitil®; *Figure 10-12*) have much more selective Na^+ channel blocking activity than the agents discussed in (V.B.1) above. The chemistry of lidocaine with respect to Na^+ channel interaction has been addressed in Chapter 9. Intravenous lidocaine can be used for the treatment of ventricular fibrillation, especially rapidly paced arrhythmias. Due to its high affinity for Na^+ channels in the inactive state, it binds preferentially to the channels on arrhythmic tissues but dissociates readily as the channels transition to the closed state. Thus, lidocaine has less effect on normal myocardial cells and, thus, only small changes in the overall ECG are seen with its use. Mexiletine is an oral derivative of lidocaine that can be used to prevent the occurrence of ventricular arrhythmias. Adverse effects related to the use of these agents are seizures, tremors, nystagmus, and heart block.

3. Flecainide (Tambocor®) and propafenone (Rhythmol®; *Figure 10-12*) are less selective Na^+ channel blockers than lidocaine that are used to manage supraventricular tachycardias such as atrial fibrillation and have some activity against ventricular arrhythmias. Both agents may have activity at K^+ channels, and propafenone has some β-adrenoreceptor antagonist activity as well. Adverse effects related to their use are worsening of heart failure symptoms, and flecainide may initiate lethal ventricular arrhythmias in patients with ischemic disease.

C. Potassium channel blockers. Sotalol (Betapace®), amiodarone (Cordarone®), dronedarone (Multaq®), ibutilide (Corvert®), and dofetilide (Tikosyn®; *Figure 10-13*) are generally recognized as K^+ channel blockers; however, they have other significant pharmacological action.

1. The levorotary isomer of sotalol has prominent β-adrenoreceptor antagonist activity, whereas amiodarone is known to also interact with Na^+ and Ca^{2+} channels and may interfere with thyroid hormone function in the myocardium. Ibutilide may activate Na^+ channels.

2. All these agents are used to maintain normal sinus rhythm in patients with atrial fibrillation or flutter, whereas amiodarone may also be useful in treating ventricular arrhythmias.

3. The most significant adverse effect of these agents is the potential to cause torsades de pointes arrhythmias by virtue of their K^+ channel blocking activity. Amiodarone has also caused lethal pulmonary fibrosis, microcrystalline corneal deposits, and photosensitivity. Dronedarone may be associated with hepatotoxicity, whereas amiodarone, dronedarone, and sotalol may also cause heart block and bradycardia and exacerbate heart failure.

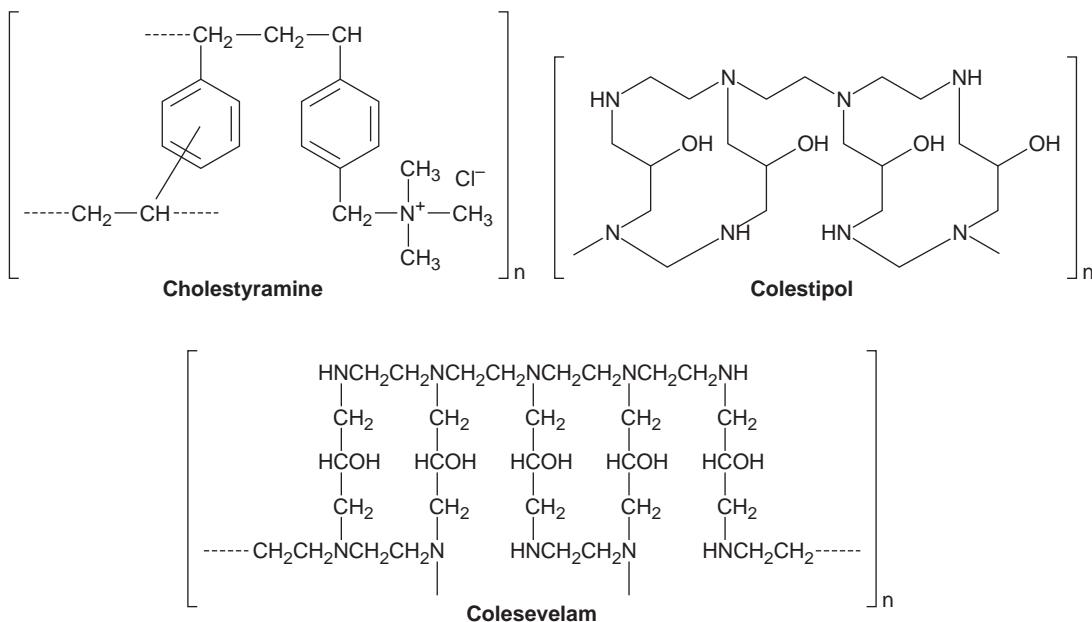
Figure 10-12. Structural formulas of antiarrhythmic agents with predominant Na^+ channel blocking activity.


Figure 10-13. Structural formulas of antiarrhythmic agents with predominant K^+ channel blocking activity.

D. **β-Adrenoceptor antagonists** such as propranolol, metoprolol, and carvedilol have been instrumental in the reduction of sudden cardiac death (due to ventricular arrhythmias) after a myocardial infarction. The sympathetic nervous system promotes the excitability of postinfarct tissues through β-receptor stimulation, and this component is significantly diminished by the antagonists. The sodium channel blocking (membrane-stabilizing) effect of some β-antagonists such as propranolol may have additional benefits in suppressing arrhythmic activity. They have also shown some benefits in managing atrial fibrillation or flutter. Their adverse effects were discussed previously (see Chapter 9, section II.B.3.f).

E. **CCBs** such as verapamil and diltiazem exert inhibitory actions on tissues dependent on Ca^{2+} channels for electrical activity (e.g., SA, AV nodal cells). Thus, they are used to treat supraventricular tachycardias. Their adverse effects were discussed in a previous section (see II.C).

F. **Miscellaneous agents**
   1. Adenosine (Adenocard®) infusion is used to restore sinus rhythm in patients with reentrant supraventricular arrhythmias. The activation of adenosine receptors in AV nodal tissue reduces the resting membrane potential and conduction velocity through this tissue.
   2. Digoxin at low doses activates the parasympathetic nerves supplying the heart and thus stimulates muscarinic receptors on the AV node to hyperpolarize the tissue and reduce electrical conduction. It is used to decrease AV conduction to prevent atrial fibrillation from causing ventricular arrhythmias. It is also used to manage reentrant supraventricular arrhythmias by the same mechanism.
   3. Atropine can block muscarinic M2 receptors in the AV node to enhance AV conduction to treat conditions such as bradycardia due to parasympathetic (vagal) input.

VI. ANTIHYPERLIPIDEMIC AGENTS

A. Coronary heart disease is rapidly becoming the world's most prevalent cause of morbidity and mortality, and the high levels of lipids in the circulation appear to promote the severity of the disease. Dietary and other essential lipids are carried in the circulation, complexed to lipoproteins, to the tissues and organs that require these lipids.

B. Most fatty acids and cholesterol absorbed from the GI tract are associated with chylomicrons that carry it via the lymphatic and circulatory system to the liver. The liver uses acetyl coenzyme A, via the rate-limiting step of HMG-CoA reductase, to synthesize mevalonate and, eventually, cholesterol. Some of this cholesterol is used to produce bile acids for the emulsification and digestion of fat in the GI tract while the rest, along with triglycerides, is packaged into very low density lipoproteins (VLDLs) and secreted into the blood.

C. Tissue lipoprotein lipases hydrolyze the triglycerides from VLDL to release free fatty acids that are taken into adipose, cardiac, and skeletal tissues. Depletion of triglycerides from the VLDL particle results in the formation of an intermediate density lipoprotein that may be taken back into the liver or converted to LDL by a hepatic lipase.

D. Circulating LDL, enriched in cholesterol, is taken into peripheral cells by the LDL receptor to liberate cholesterol for essential functions. LDL may also supply cholesterol to atherosclerotic lesions where the lipid is oxidized and is engulfed by monocytes and vascular smooth muscle cells to produce the pathological foam cells.

E. High density lipoprotein (HDL) is able to acquire cholesterol from peripheral tissues, macrophages, and atherosclerotic lesions and deliver it back to the liver in an esterified form. Thus, LDL is considered proatherogenic, whereas HDL is thought to be antiatherogenic.

F. Total cholesterol should ideally be less than 200 mg/dL, whereas LDL-C should be less than 130 mg/dL and HDL-C should be at least 40 mg/dL. Triglyceridemias are defined by having triglyceride levels greater than 200 mg/dL. Dislipidemias may be the result of excessive dietary intake or genetic factors (e.g., defective LDL receptor) that lead to high levels of LDL or other lipoproteins. The major classes of drugs used to treat hyperlipidemias are bile acid sequestrants, HMG-CoA reductase inhibitors, fibric acid derivatives, ezetimibe, and niacin.

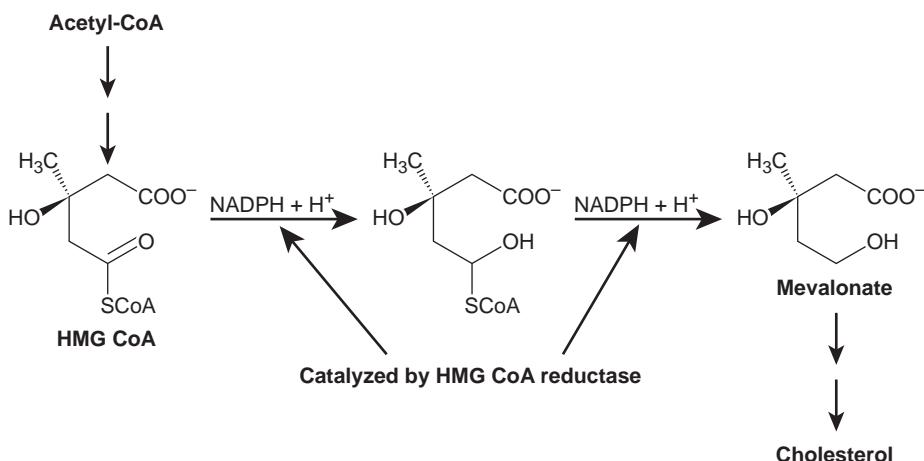
G. **Bile acid sequesterants** include cholestyramine (Questran®), colestipol (Colestid®), and colesevelam (Welchol®). They are hydrophilic, insoluble anion-exchange resins that are ingested in the form of a slurry or as gel formulation.
   1. Cholestyramine is a resin consisting of trimethylbenzylammonium groups in a large copolymer of styrene and divinylbenzene, whereas colestipol is a copolymer of diethylenetriamine and 1-chloro-2,3-epoxypropane in a hygroscopic powder (*Figure 10-14*). Colesevelam


Figure 10-14. Structural formulas of the bile acid–binding resins.

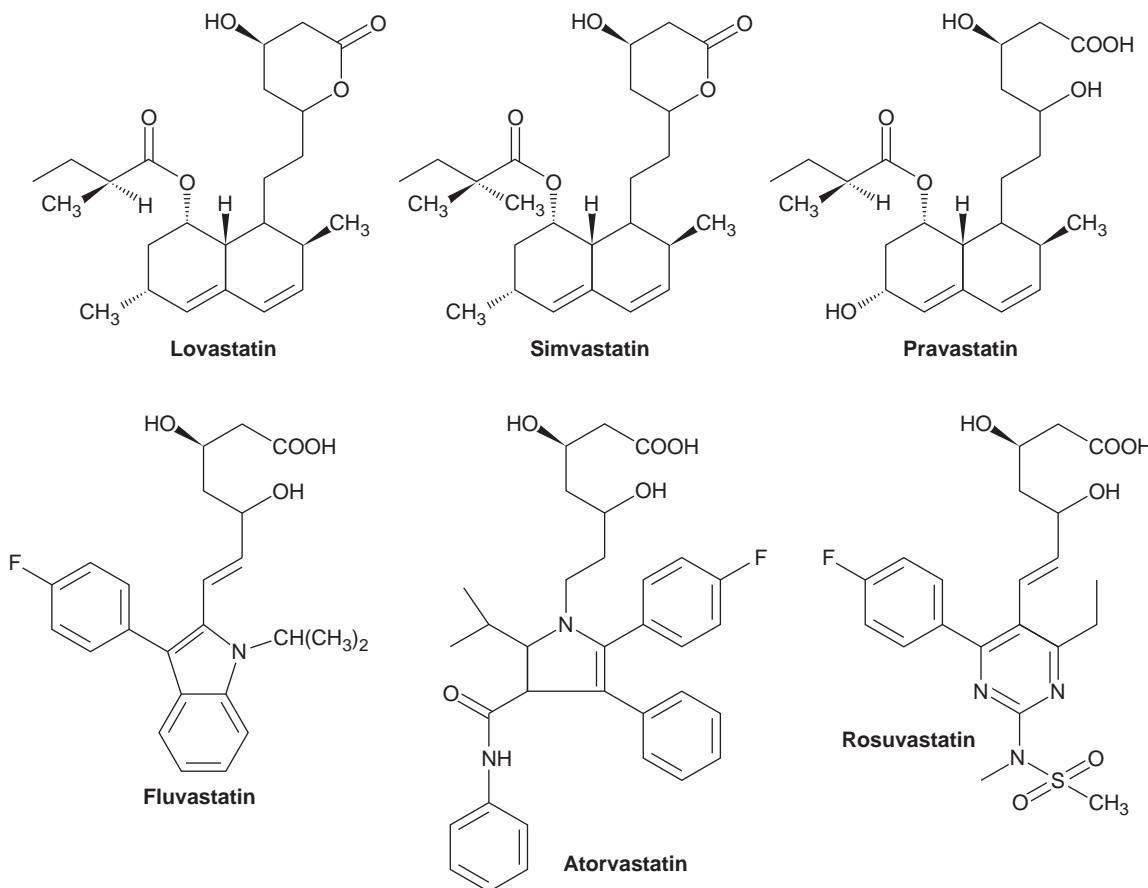
is a polyallylamine cross-linked with epichlorohydrin and alkylated with 1-bromodecane and (6-bromohexyl)-trimethylammonium bromide in a hydrophilic gel (*Figure 10-14*).

2. These resins are positively charged (cholestyramine, colesevelam) or become positively charged (colestipol) in the small intestines to bind negatively charged bile acids. The bile acids that are normally reabsorbed and returned to the liver are eliminated in the fecal matter. This signals the liver to increase the expression of the LDL receptor to capture more LDL from the blood to recover cholesterol for the synthesis of fresh bile acids.

3. Bile acid resins are able to lower circulating LDL levels by 10% to 25%; however, this effect is not usually sustained because of the ability of the liver for de novo cholesterol synthesis.

4. Adverse effects seen with bile acid resin use are gastric distress, bloating, and flatulence. These agents have the ability to reduce the absorption of drugs such as diuretics, thyroxine, warfarin, and statins and have to be administered 1 hr before or 2 hrs after other drug ingestion.

H. **HMG-CoA reductase inhibitors.** The liver is able to synthesize cholesterol from acetyl coenzyme A; the conversion of hydroxymethylglutaryl-CoA to mevalonate being the rate limiting step in this process (*Figure 10-15*).


1. The fungal derivatives lovastatin (Mevacor®) and simvastatin (Zocor®; *Figure 10-16*) are composed of a closed six-membered lactone ring attached to a naphthalene ring via an ethyl bridge. Esterases in the liver convert the lactone conformation to the active, open hydroxy carboxylic acid form that mimics the mevalonate intermediate shown in *Figure 10-15*. The lactone in pravastatin (Pravachol®), fluvastatin (Lescol®), atorvastatin (Lipitor®), and rosuvastatin (Crestor®) is in the open hydroxy acid form and the naphthyl rings in the latter three are replaced by other aromatic derivatives (*Figure 10-16*).

2. The statins, in their active conformation, compete with HMG-CoA for binding to the reductase to prevent the synthesis of mevalonate and, ultimately, cholesterol. The inhibition of hepatic cholesterol synthesis by the statins results in increased expression of hepatic LDL receptor that scavenges LDL particles from the blood. These agents have varying potencies and efficacies but are the most effective means of reducing circulating LDL-cholesterol, and up to 60% lowering can be achieved in some patients (*Figure 10-17*). Based on the desired lipid lowering and the tolerability of individual statins, patients can be titrated with varying agents and doses to produce the appropriate therapeutic outcome (*Figure 10-17*).

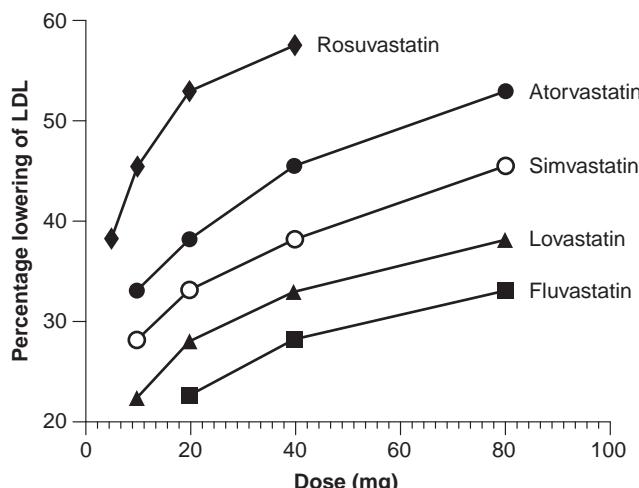
3. A usual consequence to treatment with statins is the upregulation of HMG-CoA reductase by the liver that may require further dose titration to maintain the desired plasma LDL levels.


Figure 10-15. The cholesterol biosynthesis pathway highlighting the rate-limiting steps catalyzed by HMG-CoA reductase.

Some of the statins (e.g., simvastatin, rosuvastatin) are also able to increase plasma HDL levels to produce additional antiatherogenic effects. Combination of statins with other lipid lowering agents (e.g., gemfibrozil, bile acid resins, niacin, ezitimibe) can produce even greater lowering in LDL-cholesterol in patients with more severe lipid abnormalities.

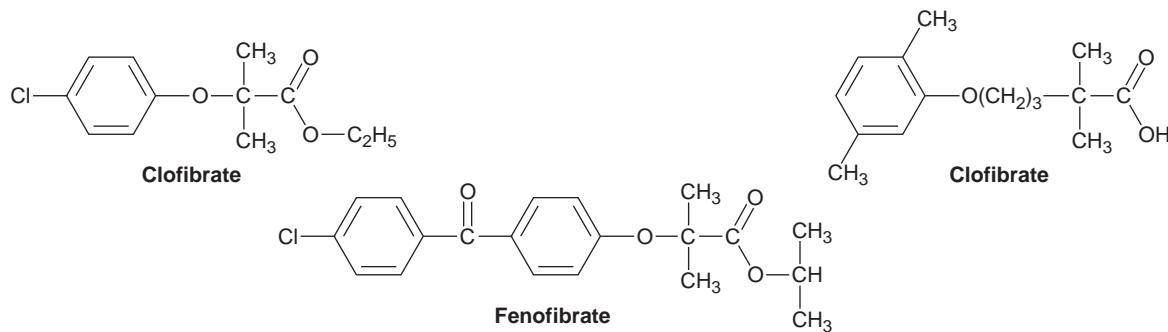
4. Statins are associated with very rare but serious adverse effects: hepatotoxicity, rhabdomyolosis, and potential birth defects if taken by pregnant women.


Figure 10-16. Structural formulas of the HMG-CoA reductase inhibitors ("statins").

Figure 10-17. Dose–response curves of percentage LDL cholesterol lowering seen in patients treated with several HMG-CoA reductase inhibitors.

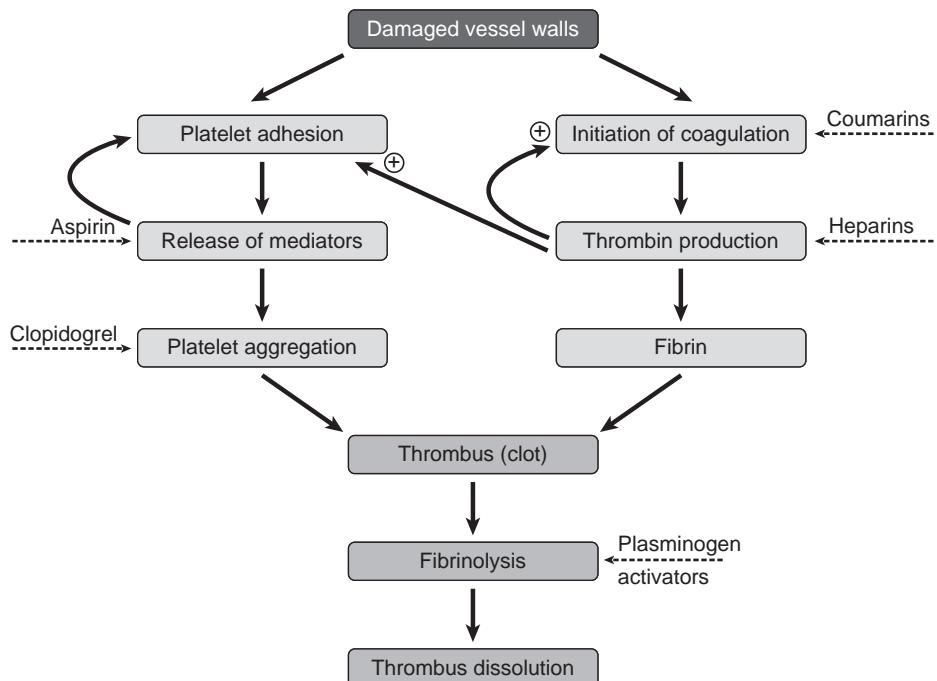
I. **Fibric acid derivatives.** The fibric acid derivatives are represented by clofibrate (Atromid-S®), gemfibrozil (Lopid®), and fenofibrate (Tricor®; *Figure 10-18*).
    1. The esterified drugs (clofibrate, fenofibrate) have to be hydrolyzed to the carboxylic acid form (gemfibrozil) in order to have therapeutic benefit.
    2. These agents are thought to induce lipoprotein lipase to reduce plasma VLDL levels and also induce the production of apolipoprotein AI and AII (via PPARα receptors) to enhance HDL levels. Reduction in VLDL has modest LDL lowering effects, but fibric acid derivatives are more often used to treat triglyceridemias and also to elevate HDL.
    3. Skin rash, GI disturbances, myopathies (especially when combined with statins), hepatotoxicity, arrhythmias, and hypokalemia have been reported with the use of fibrates.
J. **Ezetimibe** (Zetia®) belongs to a new class of inhibitors of GI sterol transporters.
    1. This drug has the ability to reduce dietary cholesterol absorption from the gut to lower the cholesterol component of chylomicrons. The reduced delivery of cholesterol to the liver enhances LDL receptor expression and decreases of up to 20% in plasma LDL may be observed.
    2. In response, the liver increases de novo cholesterol synthesis and ezetimibe–statin combinations may be particularly effective in lowering LDL levels, although clear reductions in cardiovascular end points are less obvious.
    3. Adverse effects with ezetimibe use include upper respiratory infections, diarrhea, and pain in the joints and extremities.
K. **Niacin** (Niaspan®) or nicotinic acid has VLDL and LDL lowering capacity as well as the ability to significantly elevate HDL levels.
    1. Circulating VLDL levels are lowered due to reduced hepatic triglyceride synthesis and increased VLDL uptake by hepatocytes. LDL is reduced secondary to VLDL reduction, whereas HDL is elevated due to reduced clearance of the particle from plasma.


Figure 10-18. Structural formulas of the fibric acid derivatives.
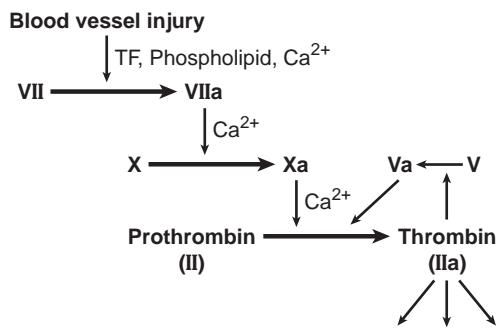


2. Niacin is used to treat patients with hypertriglyceridemia coupled with elevated LDL and lowered HDL.
3. The most common adverse effects of niacin ingestion are flushing, pruritus, dyspepsia, vomiting, gastric ulcers, liver toxicity, and elevated uric acid levels.

VII. ANTICOAGULANT, ANTIPLATELET, AND THROMBOLYTIC AGENTS

A. Damage to the blood vessel wall results in platelet adhesion and the activation of the coagulation cascade that culminates in the formation of a clot or thrombus. During the process, adherent platelets release autocoid mediators (thomboxanes, adenosine diphosphate, etc.) that lead to sustained aggregation of platelets.

B. Activation of the extrinsic coagulation cascade leads to the production of thrombin that processes fibrinogen to fibrin to form a rigid meshwork. The adherence of aggregated, activated platelets to the fibrin strands leads to thrombus formation.

C. As indicated in *Figure 10-19*, injury to the endothelial layer of blood vessels initiates the extrinsic coagulation cascade, which is modulated by several anticoagulant drugs. In the presence of tissue factor, phospholipid and calcium ion factor VII is converted to factor VIIa, which in turn proteolytically processes factor X to Xa in the presence of calcium. Factor Xa cleaves factor II to IIa (thrombin) in the presence of calcium, and thrombin also processes factor V to Va, which promotes additional factor II activation via factor Xa (*Figure 10-20*).

D. The thrombin produced by this proteolytic cascade cleaves soluble fibrinogen to fibrin that rapidly polymerizes to form long strands that entrap platelets and red blood cells to form a thrombus. Thrombin also activates the platelets participating in clot formation, has mitogenic activity for vessel repair, and is a potent vasoconstrictor.

E. After the repair of the injured vessel, the resident clot is eventually degraded by the fibrinolytic pathway to restore blood flow through the region (*Figure 10-19*).

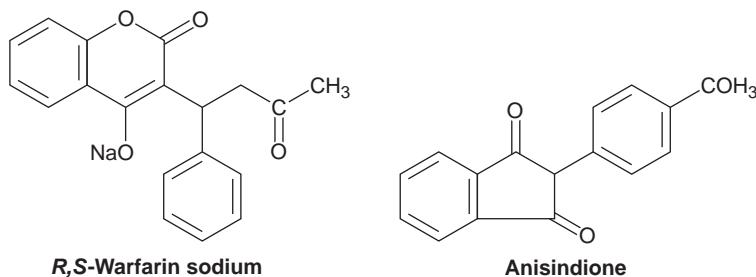
F. The pharmacological agents used to control the formation of clots can be either anticoagulants or antiplatelet drugs, whereas the agents that enhance degradation of formed clots are designated as thrombolytics.


Figure 10-19. The components in the formation of a thrombus (clot) and its eventual resolution. The steps where pharmacological intervention (with specific agents) can modify this process are indicated by the *dashed arrows*.

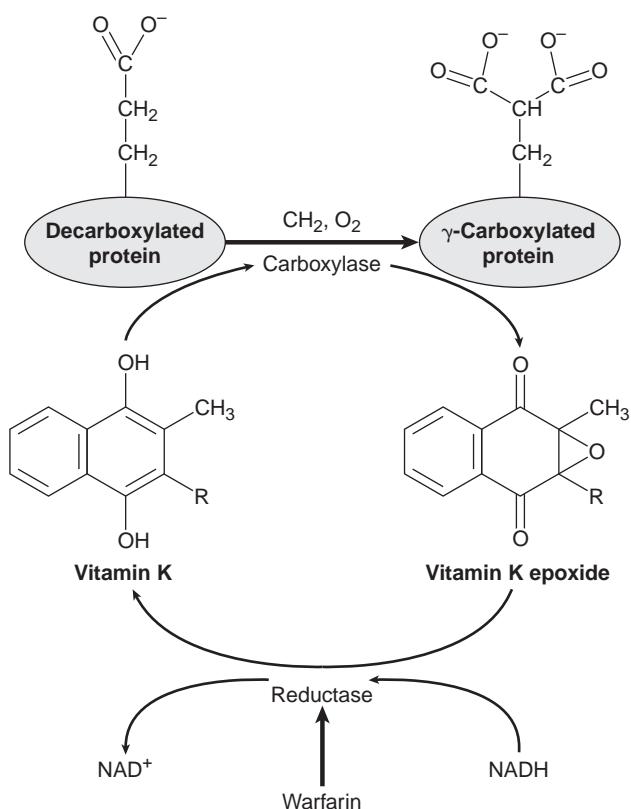
Blood vessel injury


Figure 10-20. Details of the extrinsic coagulation cascade leading to the activation of thrombin (factor II) and the formation of insoluble fibrin strands.

G. Anticoagulant agents

1. Vitamin K reductase inhibitors

   a. This class of anticoagulants is represented by the coumarin derivative warfarin (Coumadin®) or the indandione analog anisindione (Miradon®).

   b. The minimal structural requirements for coumarin activity are substitutions at position 3 and 4 with the potential to form a cyclic hemiketal (*Figure 10-21*). Vitamin K is a cofactor in the γ-carboxylation of nascent clotting factors such as factor VII, X, II, and protein C and S and is converted to the epoxide form in the process (*Figure 10-22*). The epoxide has to be reduced to vitamin K by a hepatic reductase for the posttranslational modification of coagulant proteins to continue, and this step is selectively inhibited by warfarin and anisindione.

   c. By mimicking the epoxide form of vitamin K, these agents are able to compete with oxidized vitamin K for the enzyme, resulting in a depletion of reduced vitamin K in hepatocytes. Loss of reduced hepatic vitamin K decreases the carboxylation of newly synthesized coagulation factors, and their release into the blood replaces competent factors with time. With the decline of competent coagulation factors, the rate of coagulation is slowed, and therapeutic benefits are observed in 3 to 4 days.

   d. Genetic polymorphisms in the level of vitamin K reductase and CYP2C9 (which metabolizes warfarin) may affect the level of warfarin or time taken to establish adequate anticoagulant effects.

   e. Warfarin is used to treat deep vein thrombosis, pulmonary embolism, and clots due to atrial arrhythmias and prosthetic cardiac valves. Adverse effects due to warfarin are many but uncontrolled bleeding is the most likely; skin necrosis, purple toe syndrome, and alopecia are observed; birth defects are likely if taken during pregnancy. Toxicity due to warfarin overdose can be countered with reduced vitamin K (phytonadione), but the reversal of effects may take 1 to 2 days as new, competent clotting factors are produced.

2. Unfractionated and low-molecular-weight heparins.

   a. Unfractionated heparins (UFHs) are mucopolysaccharide polymers (60 to 100 kDa; *Figure 10-23*) extracted from mast cells of bovine lung tissue or porcine intestinal mucosa. Low-molecular-weight (LMWHs, 2 to 10 kDa) are produced by careful fragmentation of UFH and purification by gel filtration to produce agents such as enoxaparin (Lovenox®), tinzaparin (Innohep®), and dalteparin (Fragmin®).

   b. UFHs have high affinity for antithrombin III (AT-III) and catalyze the inactivation of factor Xa and IIa by AT-III, ultimately reducing the amount of fibrin formed. LMWHs also bind to AT-III but preferentially inhibit factor Xa rather than IIa, but the ultimate effect on fibrin levels is much the same.

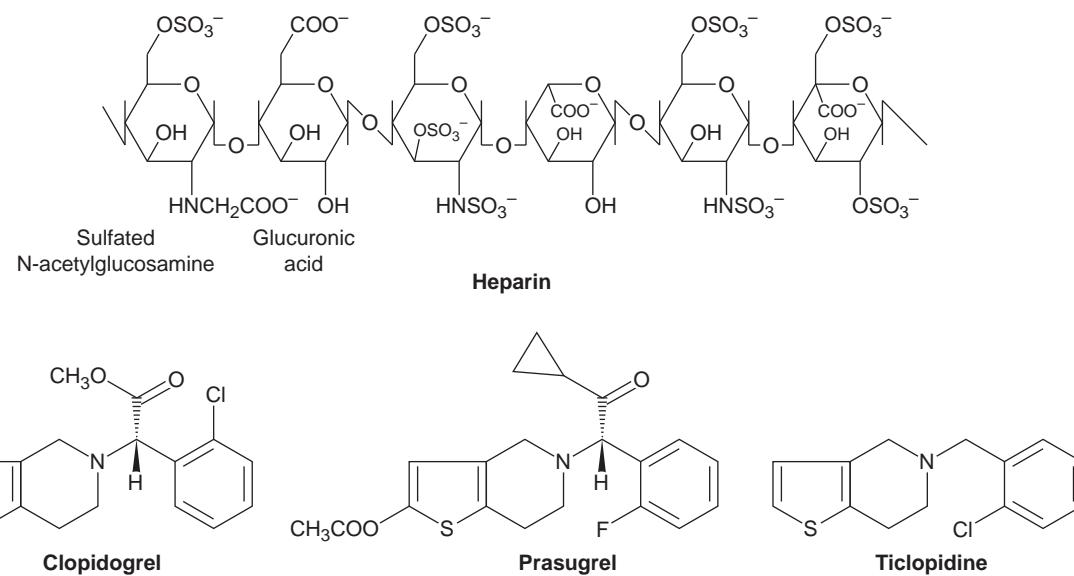
R,S-Warfarin sodium   **Anisindione**


Figure 10-21. Structural formulas of the coumarin derivative warfarin and the indandione anisindione.

Figure 10-22. The posttranslational modification of coagulation factors (γ-carboxylation) requires reduced vitamin K as a cofactor. Vitamin K is oxidized during this reaction and vitamin K reductase regenerates the reduced form to continue the carboxylation reaction. Warfarin inhibits this reductase function.

   c. Both UFHs and LMWHs have to be administered by subcutaneous or intravenous injection, but LMWHs have a more predictable pharmacokinetic profile with longer half-life. These agents are used for pulmonary emboli prophylaxis and to treat venous thromboemboli until transitioned to warfarin.

   d. Fondaparinux (Arixtra®) is a synthetic pentasaccharide that inhibits factor Xa through the action of AT-III. Danaparoid (Orgaran®) is a mixture of heparin sulfate, dermatan sulfate, and

Figure 10-23. Structural formulas of heparin and the thienopyridine platelet inhibitors ticlopidine, clopidogrel, and prasugrel.

chondroitin sulfate extracted from porcine mucosa and having a similar mechanism of action as LMWHs.

  e. Adverse effects related to heparin use are bleeding, heparin-induced thrombocytopenia (HIT), alopecia, and osteoporosis. Overdose with UFH or LMWHs can be treated with parenteral administration of protamine sulfate that neutralizes the polysaccharides via ionic interaction.

3. Direct thrombin inhibitors

  a. These agents are able to inhibit thrombin activity by interacting with the catalytic or substrate recognition site of the protease without the need for AT-III.

  b. Lepirudin (Refludan®) is a 65 amino acid recombinant derivative of hirudin, the anticoagulant found in the saliva of the medicinal leech. Bivalirudin (Angiomax®) is a synthetic 20 amino acid derivative of hirudin.

  c. These agents are administered parenterally to inhibit thrombin activity and reduce the formation of thrombi. Argatroban is also a parenterally administered, direct thrombin inhibitor, and all three of these agents are used to treat HIT. Bivalirudin is also used to prevent thrombosis after coronary angioplasty procedure. Dabigatran (Pradaxa®) is the first orally active direct thrombin inhibitor and is used to prevent stroke in patients with atrial fibrillation.

  d. Adverse effects to these agents are usually bleeding, but dabigatran is also associated with GI disturbances such as esophageal reflux, gastric bleeding, and abdominal pain.

H. Antiplatelet agents

1. Aspirin. This agent has been discussed extensively in Chapter 11 and only its antithrombotic actions will be addressed here. The inhibition of cyclooxygenase by aspirin reduces the amount of thromboxane A2 produced by platelets during the activation process and leads to decreased shape change, aggregation, and release of granules. Aspirin is used for the prophylaxis of myocardial infarctions and, in conjunction with other agents, it decreases thrombosis after coronary stenting.

2. Dipyridamole (Persantine®) and cilostazol (Pletal®) are antiplatelet agents used in stroke prophylaxis in cerebrovascular ischemia or after prosthetic valve replacement. Cilostazol is also used for intermittent claudication. These agents elevate cGMP in platelets by inhibition of phosphodiesterase activity to decrease their activation and aggregation. Headache, dizziness, edema, and GI distress are the most often reported adverse effects with these agents.

3. Thienopyridines

  a. Ticlopidine (Ticlid®), clopidogrel (Plavix®), and prasugrel (Effient®; *Figure 10-23*) belong to this class of antiplatelet agents and have to be bioactivated by hepatic CYP enzymes before they are active.

  b. Thienopyridine metabolites covalently bind to the $P2Y_{12}$ receptors on platelets to prevent ADP-mediated aggregation and adhesion to fibrin. These drugs are used to decrease clot formation after angioplasty and stenting procedures and are often combined with aspirin or GPIIb/IIIa inhibitors.

  c. The following adverse effects are rare but can be serious: thrombocytopenia purpura, aplastic anemia, neutropenia, cholestatic jaundice, fever, rash, and GI distress.

4. Glycoprotein IIb/IIIa inhibitors

  a. This class includes dissimilar agents such as abciximab (ReoPro®), eptifibatide (Integrilin®), and tirofiban (Aggrastat®). These are all parenteral agents that reduce the interaction of platelets via the GPIIb/IIIa receptors to fibrinogen. The result of this action is decreased platelet aggregation during clot formation and reduced thrombus size.

  b. Abciximab is the Fab fragment of a monoclonal antibody directed against GPIIb/IIIa, whereas eptifibatide is a cyclized heptapeptide with high affinity for the fibrinogen receptor. These agents are used after a myocardial infarction or during angioplasty and stent placement.

  c. The most likely adverse effect seen with all these agents is bleeding, but abciximab also causes hypotension, nausea, vomiting, and atrial fibrillation. Tirofiban has caused thrombocytopenia, especially when combined with heparin.

I. Thrombolytic agents are administered to selectively resolve formed pathological clots without initiating wholesale clot resorption and a generalized lytic state.

1. Tissue plasminogen activators (tPAs) are normally released by endothelial cells to activate fibrin-bound plasminogen to plasmin. Plasmin then cleaves fibrin strands to cause the disintegration of the clot.

  a. Human tPA, alteplase (Activase®), is produced by recombinant technology, as is reteplase (Retavase®), a truncated recombinant product with lower fibrin specificity. Tenecteplase (Tnkase®) is also a mutant of tPA designed to have enhanced fibrin selectivity.

     b. These agents are used to resolve clots during myocardial infarction, pulmonary emboli, or cerebral stroke.

     c. Their primary adverse effect is risk of bleeding, and this can be managed by the administration of aminocaproic acid (Amicar®).

  2. Streptokinase (Streptase®) is a 47 kDa protein produced by β-hemolytic streptococcus that combines with plasminogen to produce plasmin.

     a. This agent is less clot-specific because it does not require the presence of fibrin to activate plasminogen. Often, high loading doses are required to overcome antibody immunity in patients who have had previous streptococcal infections.

     b. Streptokinase is used to treat deep vein thrombosis and myocardial infarctions, and some of the adverse effects seen with this use are bleeding, fever, rash, and anaphylaxis.

  3. Urokinase (Abbokinase®) is a serine protease that cleaves plasminogen to plasmin that can then degrade formed clots. The lack of clot-specificity predisposes patients to a systemic lytic state. It is used to clear massive pulmonary emboli as well as treat patients with acute myocardial infarction.

Study Questions

Directions for questions 1–19: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Calcium-channel blockers can have all of the following characteristics *except*

  (A) they block the slow inward current carried by calcium during phase 2 of the cardiac action potential.

  (B) they dilate peripheral arterioles and reduce total peripheral resistance.

  (C) they constrict coronary arteries and arterioles and decrease oxygen delivery to the myocardium.

  (D) they are useful in treating vasospastic angina.

  (E) adverse effects include bradycardia and edema.

2. The termination of heparin activity by protamine sulfate is the result of

  (A) a chelating action.

  (B) the inhibition of gastrointestinal absorption of heparin.

  (C) the displacement of heparin–plasma protein binding.

  (D) an acid–base interaction.

  (E) the prothrombin-like activity of protamine.

3. Which of the following agents is composed of a steroid nucleus, unsaturated lactone, and saccharide units?

  (A) nifedipine

  (B) digoxin

  (C) flecainide

  (D) cholestyramine

  (E) warfarin

4. Digoxin may be useful in treating one of the following conditions:

  (A) AV block

  (B) torsades de pointes

  (C) congestive heart failure

  (D) ventricular tachycardia

  (E) bradycardia

5. Which of the following antiarrhythmic agents is most likely to cause pulmonary fibrosis during therapy?

  (A) procainamide

  (B) sotalol

  (C) amiodarone

  (D) lidocaine

  (E) quinidine

6. The structure shown is characteristic of which of the following agents?

  (A) osmotic diuretics

  (B) carbonic anhydrase inhibitors

  (C) thiazides

  (D) loop diuretics

  (E) potassium-sparing diuretics

7. Much of the reduction in circulating LDL-cholesterol during treatment with simvastatin may be due to

    (A) enhanced uptake of LDL by the liver.
    (B) upregulation of HMG-CoA reductase.
    (C) decreased GI absorption of cholesterol.
    (D) decreased bile acid production.
    (E) decreased VLDL levels.

8. Valsartan is used to treat all the following conditions *except*

    (A) hypertension.
    (B) diabetic nephropathy.
    (C) heart failure.
    (D) post-MI patient.
    (E) supraventricular arrhythmias.

9. Diuretics such as hydrochlorothiazide are first-line therapy for essential hypertension. Which of the following statements best explains the actions of these drugs?

    (A) Loss of sodium in the renal filtrate causes hyponatremia that reduces blood osmolarity.
    (B) Water loss in the urine decreases blood volume that lowers systemic blood pressure.
    (C) Loss of potassium causes water loss to decrease blood pressure.
    (D) They are prominent vasodilators.
    (E) They produce a decrease in heart rate to lower cardiac output and blood pressure.

10. Sildenafil, when used to treat pulmonary arterial hypertension, can cause all of the following adverse effects *except*

    (A) hepatotoxicity.
    (B) priapism.
    (C) visual disturbances.
    (D) headache.
    (E) flushing of the skin.

11. Which of the following agents is not used to treat angina symptoms?

    (A) propranolol
    (B) nitroglycerin
    (C) ranolazine
    (D) digoxin
    (E) verapamil

12. Spontaneous depolarization of the SA node can be reduced by

    (A) verapamil.
    (B) lidocaine.
    (C) milrinone.
    (D) digoxin.
    (E) flecainide.

13. All of the following agents can be used to manage atrial fibrillation *except*

    (A) verapamil.
    (B) lidocaine.
    (C) dronedarone.
    (D) propranolol.
    (E) quinidine.

14. Which of the following is a likely adverse event of heparin therapy?

    (A) purple toe syndrome
    (B) thrombocytopenia
    (C) dry cough
    (D) skin necrosis
    (E) hypertension

15. A major use of dabigatran is in

    (A) thrombocytopenia.
    (B) stroke prophylaxis in atrial fibrillation.
    (C) decreasing clotting after stent placement.
    (D) breaking down clots that have formed during myocardial infarction.
    (E) intermittent claudication.

16. Bile acid reabsorption from the GI tract is reduced by

    (A) ezetimibe.
    (B) cholestyramine.
    (C) pravastatin.
    (D) niacin.
    (E) fenofibrate.

17. Alteplase is less likely to cause systemic bleeding than urokinase because

    (A) it only activates thrombin that is associated with a clot.
    (B) it has more specific effects on platelets.
    (C) it is a recombinant protein.
    (D) it only activates plasminogen associated with a clot.
    (E) urokinase is extracted from hemolytic streptococcus that causes bleeding.

18. All of the following agents have actions on blood platelets to modify clot formation *except*

    (A) eptifibatide.
    (B) dabigatran.
    (C) clopidogrel.
    (D) dipyridamole.
    (E) tirofiban.

19. The amount of dietary cholesterol absorbed from the GI tract is reduced by

    (A) niacin.
    (B) rosuvastatin.
    (C) ezetimibe.
    (D) clofibrate.
    (E) colestipol.

Directions for questions 20–25: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

    A   if **I only** is correct
    B   if **III only** is correct
    C   if **I** and **II** are correct
    D   if **II** and **III** are correct
    E   if **I, II**, and **III** are correct

20. The use of milrinone in the treatment of acute heart failure

    I. increases intracellular calcium.
    II. activates protein kinase A.
    III. increases myocardial contractility.

21. Warfarin

    I. increases hepatic vitamin K epoxide.
    II. decreases reduced hepatic vitamin K.
    III. decreases the absorption of dietary vitamin K.

22. Ms. Jane M. was being treated with atorvastatin calcium (20 mg/d) and this produced a lowering in LDL-C, but this effect was not maintained beyond 3 months. Her physician wants to increase the dose of the drug to 40 mg/d and asks you if this strategy will be successful. Which of the following would be part of an appropriate answer?

    I. The patient is becoming desensitized to the 20 mg dose so doubling it will not have any additional benefit.
    II. The patient must have increased her dietary intake of cholesterol and increasing the dose of drug will only cause her to eat more cholesterol-containing foods.
    III. The patient's liver may have upregulated the amount of HMG-CoA reductase and so increasing the drug dose can produce further lowering in LDL-C.

23. The use of lepirudin in heparin-induced thrombocytopenia would indicate that

    I. thrombin is activated during this condition.
    II. increased clotting may occur during this condition.
    III. this is caused by leech saliva.

24. Nitroglycerin, when used to treat stable angina,

    I. decreases myocardial oxygen demand by reducing the tension on the ventricular walls.
    II. increases oxygen supply by allowing ventricular arterioles to remain open for longer periods by reducing ventricular filling.
    III. reduces the amount of blood returning to the heart by causing a venodilation.

25. Which of the following is required for heparin's action on factor Xa?

    I. Antithrombin III
    II. Fibrinogen
    III. Thrombin

Directions for questions 26–30: Each group of adverse effects in this section is most closely related to **one** of the following drug classes. The drug classes may be used more than once or not at all. Choose the **best** answer, **A–E**.

    A   Cardiac glycosides
    B   Calcium-channel blockers
    C   Angiotensin-converting enzyme inhibitors
    D   β-Adrenergic antagonists
    E   Nitrites and nitrates

26. Bradycardia, hypotension, increased airway resistance, and congestive heart failure

27. Visual disturbances (yellow or green vision), confusion, anorexia, vomiting, atrioventricular (AV) block, and ventricular tachycardia

28. Hypotension, acute renal failure, dry cough, and angioedema

29. Birth defects if women take them during early pregnancy

30. Produce a vasodilation by reducing the influx of a cation necessary for contraction

Directions for questions 31–34: Each statement in this group is most closely characterized by **one** of the following drugs. The drugs may be used more than once or not at all. Choose the **best** answer, **A–E**.

    A   Furosemide
    B   Hydrochlorothiazide
    C   Spironolactone
    D   Mannitol
    E   Acetazolamide

31. It interferes with collecting tubular aldosterone-mediated sodium–potassium exchange and may cause hyperkalemia, gynecomastia, and menstrual irregularities.

32. Freely filtered, this drug limits tubular reabsorption of water and is useful in reducing cerebral edema and intracranial pressure.

33. The principal site of action of this drug is on the thick ascending limb of the loop of Henle; it is useful in treating pulmonary edema and ascites.

34. This agent is used to treat mountain or altitude sickness.

Directions for questions 35–38: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

35. Angiotensin-converting enzyme inhibitors (ACEIs) such as enalapril (Vasotec) are prodrugs. What is the purpose of the prodrug formulation of enalapril?

    (A) enhance potency
    (B) enhance oral activity
    (C) mask taste
    (D) enhance water solubility
    (E) increase stability

36. Angiotensin receptor antagonists or blockers (ARBs) are less likely to cause angioedema and cough than the angiotensin-converting enzyme inhibitors (ACEI) because

    (A) ARBs do not contain a sulfhydryl functional group.
    (B) ARBs are not administered as prodrugs.

    (C) ACEIs are more specific for inhibiting the production of angiotensin II.
    (D) ARBs are pseudo-irreversible antagonists.
    (E) ARBs do not inhibit the breakdown of bradykinin.

37. Which of the following diuretics does NOT contain a sulfonamide substituent?

    (A) furosemide (Lasix)
    (B) ethacrynic acid (Edecrin)
    (C) torsemide (Demadex)
    (D) hydrochlorothiazide (HydroDIURIL)
    (E) bumetanide (Bumex)

38. Which of the following anticoagulant agent's dose is influenced by genetic polymorphisms in CYP2C9 and vitamin K reductase?

    (A) enoxaparin (Lovenox)
    (B) fondaparinux (Arixtra)
    (C) warfarin (Coumadin)
    (D) lepirudin (Refludan)
    (E) bivalirudin (Angiomax)

Answers and Explanations

1. **The answer is C** *[see II.B]*.
   By blocking the influx of calcium into vascular smooth muscle (via L-type channels), these agents decrease rather than increase the contractile response of various arterial beds.

2. **The answer is D** *[see VII.G.2]*.
   Heparin is a highly acidic mucopolysaccharide, whereas protamine is a highly basic protein. When administered after heparin, protamine chemically combines with it (presumably by an acid–base interaction) and inactivates its anticoagulant effect. Hence, it is an effective antidote for heparin. Caution must be employed when using protamine because an excess of protamine can cause an anticoagulant effect.

3. **The answer is B** *[see IV.A.1; Figure 10-10]*.
   Digoxin is composed of a steroid nucleus, unsaturated lactone ring, and three sugars attached via a glycosidic bond.

4. **The answer is C** *[see IV.A.1]*.
   Low doses of digoxin activate the vagal reflex to cause AV block and bradycardia, and this action can be beneficial in preventing atrial fibrillations from causing ventricular tachycardias, but the more common use of cardiac glycosides is to increase cardiac contractility in heart failure.

5. **The answer is C** *[see V.C.3]*.
   Of all the drugs on the list, amiodarone is most likely to cause life-threatening pulmonary fibrosis.

6. **The answer is C** *[see II.B.2; Figure 10-5]*.
   The structure is a benzothiadiazine (or thiazide) derivative and, more specifically, it is the diuretic hydrochlorothiazide. Only this class of diuretics contains the benzothiadiazine nucleus even though the sulfonamide moiety is common to others such as the loop diuretics and carbonic anhydrase inhibitors.

7. **The answer is A** *[see VI.H.2]*.
   The HMG-CoA reductase inhibitors such as simvastatin reduce hepatic cholesterol synthesis, but the lipid lowering effects more often occur as hepatocytes increase their expression of the LDL receptor to scavenge LDL-C from the circulation.

8. **The answer is E** *[see II.A.6]*.
   Valsartan has no antiarrhythmic activity and would not be useful in supraventricular arrhythmias, but it is used to treat all the other listed conditions.

9. **The answer is D** *[see II.B.2]*.
   Like all diuretics, hydrochlorothiazide increases Na^+ loss in the renal filtrate, which osmotically draws water with it to cause a diuresis. The water loss decreases blood volume to reduce systemic blood pressure.

10. **The answer is A** *[see II.D.2]*.
    Sildenafil is not associated with hepatotoxicity, although all the other adverse events have been reported with use.

11. The answer is D *[see III]*.

Digoxin would worsen angina symptoms by increasing cardiac contractility and thereby increasing myocardial oxygen demand.

12. The answer is A *[see V.A.2; V.E]*.

SA nodal cells are highly dependent on L-type calcium channels for their spontaneous depolarization and initiation of pacemaker activity. This allows verapamil to have a significant bradycardia effect by blocking these channel activities. The relative specificity of lidocaine and flecainide for Na^+ channels prevents them from having significant effects at the SA node. Milrinone tends to increase heart rate by increasing intracellular cAMP to enhance spontaneous depolarization of the SA node, whereas digoxin has greater effects on the AV node via vagal inputs.

13. The answer is B *[see V.B.1–2; V.C]*.

The relative specificity of lidocaine for Na^+ channels results in little nodal inhibition, so fibrillation due to SA or AV nodal activity would be unaffected. Lidocaine also has little effect on atrial myocardial cell depolarization because its Na^+ channels are only in the inactive state for very brief periods and so would not be effective against ectopic atrial arrhythmias. Overall, lidocaine is not effective in the management of supraventricular arrhythmias, unlike the other agents on the list.

14. The answer is E *[see VII.G.2]*.

All the adverse events listed except for hypertension have been reported with heparin use. However, heparin needs to be used cautiously in uncontrolled hypertension in order to prevent the occurrence of strokes.

15. The answer is B *[see VII.G.3]*.

By virtue of its direct inhibition of thrombin (not requiring antithrombin III), dabigatran is able to reduce the clot formation in patients with atrial fibrillation. It is not approved for decreasing clots after stent placement or in intermittent claudication.

16. The answer is B *[see VI.G]*.

Only the bile acid–binding resins such as cholestyramine reduce the reabsorption of bile acid from the GI tract to reduce plasma LDL-C levels.

17. The answer is D *[see VII.I.1]*.

Alteplase is a recombinant form of tissue plasminogen activator that requires plasminogen to be bound to the fibrin of clots before it can cleave to plasmin. Urokinase is able to catalytically activate free plasminogen to plasmin, which can lead to generalized dissolving of clots and a systemic bleeding or lytic state.

18. The answer is B *[see VII.G.3]*.

Dabigatran does not interact with platelets but rather inhibits thrombin directly to reduce clot formation.

19. The answer is C *[see VI.J]*.

Ezetimibe specifically interacts with the sterol transporter on GI epithelial cells to reduce the absorption of dietary cholesterol.

20. The answer is E (I, II, and III) *[see IV.A.3]*.

Milrinone is a type 3 phosphodiesterase inhibitor that increases cAMP to increase PKA activity. PKA phosphorylates L-type channels to increase calcium influx into myocardial cells to increase contractility.

21. The answer is C (I and II) *[see VII.G.1; Figure 10-22]*.

Warfarin competes with vitamin K epoxide for access to the reductase that converts the epoxide back to the reduced (active) form. This leads to elevation of the epoxide form and a reduction in the reduced form of vitamin K in hepatocytes. Warfarin does not affect the absorption of dietary vitamin K from the GI tract, and in fact, this intake can oppose the activity of warfarin by supplying fresh reduced vitamin K for carboxylation of nascent clotting factors.

22. The answer is B (III) *[see VI.H.3]*.

Inhibition of HMG-CoA reductase activity by statins increases hepatic expression of the enzyme that may require further increases in the dose of the statins to maintain the suppression of the enzyme and low LDL-C.

23. The answer is C (I and II) *[see VII.G.3]*.

HIT appears to be due to an immune reaction following heparin administration and is often accompanied by marked platelet activation and destruction as well as thrombin activation to cause disseminated clotting. Direct thrombin inhibitors such as lepirudin can be used to control thrombin-induced coagulation without perpetuating the immune reaction.

24. The answer is E (I, II, and III) *[see III.A.4]*.

Nitroglycerin liberates NO in venous smooth muscle, leading to venous pooling and reduced blood returning to the heart (preload). Thus, ventricular filling is reduced and this decreases the tension on the ventricular walls to reduce oxygen demand. Reduced wall tension, especially during diastole, also allows subendocardial arteries to remain patent for longer periods to increase blood flow to the heart muscle.

25. The answer is A (I) *[see VII.G.2]*.

Both UFH and LMWHs require antithrombin III as an intermediate to inhibit the actions of factor Xa or II (thrombin).

26. The answer is D *[see chapter 9.I.A.1.b]*.

Nonselective β-adrenergic blockers (e.g., propranolol) produce adverse effects associated with their mechanism of action on the autonomic nervous system. Thus, bronchospasm, lowering of blood pressure, and reduced heart rate result from blockade of autonomic β-adrenergic receptors.

27. The answer is A *[see IV.A.1].*

Visual disturbances (yellow or green vision) are peculiar to cardiac glycoside overdose. AV dissociation and ventricular tachycardia are obviously more significant adverse effects.

28. The answer is C *[see II.A.5].*

ACE inhibitors may cause dry cough, angioedema, hypotension, and acute renal failure.

29. The answer is C *[see II.A.5].*

ACE inhibitors will cause birth defects and fetal demise if taken during the second and third trimesters of pregnancy.

30. The answer is B *[see II.C].*

Calcium influx during arterial smooth muscle contraction is blocked by L-type channel blockers resulting in a rapid vasodilation.

31. The answer is C *[see II.A.7].*

Spironolactone interferes with aldosterone-mediated sodium–potassium exchange, reducing the amount of potassium excreted and is often used with other diuretics that promote the excretion of potassium, such as the benzothiadiazines.

32. The answer is D *[see II.B.4].*

Mannitol increases the osmolarity of the glomerular filtrate because it is reabsorbed poorly. By increasing the osmolarity of the glomerular filtrate, mannitol limits tubular reabsorption of water, thus promoting diuresis. In this way, it reduces cerebral edema and decreases intracranial pressure.

33. The answer is A *[see II.B.1].*

Furosemide is a diuretic of choice for treating acute congestive heart failure and ascites because it promotes a significant, rapid excretion of water and sodium. This is accomplished by inhibiting the actions of the $Na^+/K^+/2Cl^-$ transporter in the thick ascending loop of Henle.

34. The answer is E *[see II.B.4].*

This is one of the few unique uses of carbonic anhydrase inhibitors such as acetazolamide.

35. The answer is B *[II.A.5.b].*

Enalapril has an ethyl ester that covers a required carboxylic acid. After ester hydrolysis, the active drug enalaprilat is released to inhibit ACE. By covering the ionic carboxylic acid functional group with the more lipophilic ethyl ester, the oral bioavailability of enalapril is enhanced. Prodrugs can also be used to mask a foul-tasting drug, enhance water solubility, or increase the stability of a drug, but this is not the case with enalapril.

36. The answer is E *[II.A.6.e; II.A.5.d].*

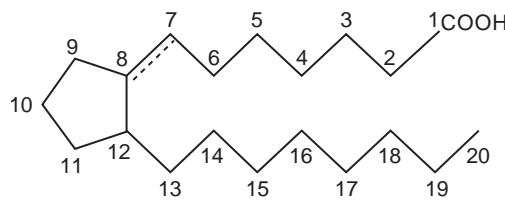
ACEIs inhibit not only the conversion of angiotensin I to angiotensin II but also inhibit the metabolism of bradykinin. The accumulation of bradykinin has been associated with the side effects of nonproductive cough and angioedema observed with the ACEI. The ARBs do not interfere with bradykinin metabolism and therefore have a much lower incidence of these effects than observed with the ACEI. Although the other choices are sometimes true statements, they do not address the question related to the side effects.

37. The answer is B *[II.B.1.a; II.B.2.a; Figure 10-5].*

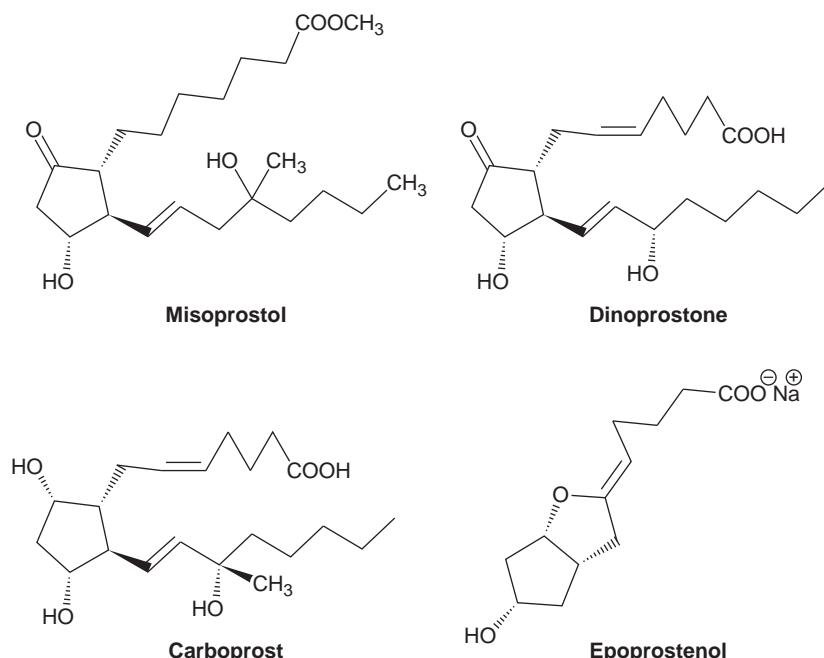
Ethacrynic acid, an aryloxyacetic acid derivative, is the only loop diuretic that does not have a sulfonamide substituent. Furosemide, torsemide, and bumetanide are loop diuretics. The thiazide and thiazide-like diuretics also have a sulfonamide, including hydrochlorothiazide, and also contain a sulfonamide substituent. This may be important in patients with a hypersensitivity to sulfonamides, although cross-reactivity with sulfonamide antibiotics is not always apparent.

38. The answer is C *[VII.G.1.d].*

Polymorphisms of the CYP2C9 gene can result in variant forms of the enzyme with markedly altered capacity for warfarin metabolism. The reduced metabolic capacity of the variants can increase the likelihood of bleeding with usual doses. Specific polymorphisms in the vitamin K reductase gene can lead to altered hepatic levels of the enzyme such that patients with low expression can be more susceptible to anticoagulant effects of standard warfarin doses, again increasing the potential for bleeding.

11


Pharmacology and Medicinal Chemistry of Autacoids, Nonsteroidal Anti-inflammatory Drugs, and Antihistamines

MICHAEL L. ADAMS, S. THOMAS ABRAHAM


I. **AUTACOIDS** are classified as substances that are released at or near their site of action and have a short duration of activity. Autacoids, such as **prostaglandins**, **leukotrienes**, kallidin, bradykinin, **serotonin**, and **histamine**, have varied structures and physiological activities that are modulated by several different drugs. Although some autacoids (histamine and serotonin) function as neurotransmitters, their autacoid functions will be covered here. Currently, there are no agents that specifically modulate the function of bradykinin or kallidin; however, drugs or analogs that mimic, block, or modulate other autacoid functions and/or synthesis have important therapeutic roles.

II. **PROSTAGLANDINS (PGs)** are autacoids with diverse pharmacological activities, including the initiation of inflammation.

A. **PGs** are derivatives of prostanoic acid, a 20-carbon fatty acid containing a 5-carbon ring (*Figure 11-1*). In the body, PGs are principally synthesized from arachidonic acid, which is formed from membrane phospholipids by the action of phospholipase A2. Specifically, PGs are synthesized from arachidonic acid by the enzyme cyclooxygenase (COX). Note that the products of COX are then converted into

Figure 11-1. Structural formula of prostanoic acid, from which the prostaglandins are derived.

Figure 11-2. Prostaglandin analogs including misoprostol (PGE$_1$), dinoprostone (PGE$_2$), carboprost (PGF$_{2\alpha}$), and epoprostenol (PGI$_2$).

either PGs by PG synthase or thromboxanes by thromboxane synthase. The thromboxanes differ from the PGs mainly by the substitution of a tetrahydropyran ring structure for the pentane ring found in PGs. The only clinically relevant thromboxane currently identified is thromboxane A2 (TxA2), which causes platelet aggregation.

B. Classification of PGs as prostaglandin A (PGA), prostaglandin B (PGB), prostaglandin E (PGE), and so forth relates to the presence or absence of keto or hydroxyl groups at positions 9 and 11 (*Figure 11-1*). Subscripts relate to the number and position of double bonds in the aliphatic chains (*Figure 11-2*).

C. PGs produce **diverse physiological and pathological effects** by activating specific PG receptors on relevant tissues. The physiological responses to PGs include **vasodilation** in most vascular beds, although vasoconstriction can occur in some others. In general, PGs increase renal blood flow, promote diuresis, natriuresis, and kaliuresis. The PGs are also important regulators of renin release from juxtaglomerular cells. Specific activities for the individual PGs and their respective receptors are summarized in the following.

  1. **PGEs inhibit platelet aggregation, relax bronchial and gastrointestinal (GI) smooth muscle, contract uterine smooth muscle, and inhibit gastric acid secretion.** Most of these effects are mediated by PGE (EP)-type receptors on smooth muscle and secretory cells.

  2. **PGDs and PGFs contract bronchial, iris sphincter, and GI smooth muscle by activating PGD (DP)- or PGF (FP)-type receptors, respectively.**

  3. **PGI$_2$**, also called prostacyclin, **inhibits platelet aggregation**, **is a potent vasodilator**, and **stimulates gastric release of bicarbonate** and **mucus**. These effects are dependent on the PGI2 (IP)-type PG receptors on vascular smooth muscle, platelets, and gastric mucosal cells.

D. By selectively activating various PG receptors, several PG derivatives are used to manage diverse conditions or disease states.

  1. PGE$_1$ analogs

    a. Alprostadil (PGE$_1$) is the endogenous PG marketed in various forms for different indications (*Figure 11-2*).

      (1) Alprostadil (Prostin VR Pediatric) is used for the **temporary maintenance of a patent ductus arteriosus** until corrective surgery for the congenital heart defect can be performed.

      (2) Alprostadil (Caverject, Edex) and alprostadil (Muse) are marketed as an intracavernosal injection and urethral suppository, respectively, for the **treatment of erectile dysfunction** (*Figure 11-2*).
    b. Misoprostol (Cytotec) is a PGE_1 analog with a longer duration of action than PGE_1 indicated for the **prevention of nonsteroidal anti-inflammatory drug (NSAID)–induced gastric ulcers** in high-risk patients.

    c. Adverse effects associated with PGE_1 and PGE_1 analogs include diarrhea, abdominal pain, facial flushing, hypotension, headache, abortion, and pain associated with administration of the erectile dysfunction agents.

2. PGE_2 analogs

    a. Dinoprostone (PGE_2) (vaginal insert [Cervidil], vaginal gel [Prepidil], vaginal suppository [Prostin E2]) is the endogenous PG that is used as a **cervical ripening agent** in near-term pregnant females to induce labor or as an abortifacient between the 12th and 20th week of gestation (*Figure 11-2*).

    b. Adverse effects associated with PGE_2 are related to effects on gastric and vascular smooth muscle and include nausea, diarrhea, vomiting, headache, and hypotension.

3. $PGF_{2\alpha}$ analogs

    a. Carboprost (Hemabate; *Figure 11-2*) is a $PGF_{2\alpha}$ analog modified for increased stability for intramuscular administration to produce uterine smooth muscle contractions. It is used as an **abortifacient** between the 13th and 20th week of gestation or for the treatment of **postpartum uterine hemorrhage**.

    b. Bimatoprost (Lumigan, Latisse), latanoprost (Xalatan), and travoprost (Travatan Z) are $PGF_{2\alpha}$ analogs applied **topically** to increase aqueous humor outflow and lower intraocular pressure in **glaucoma**. Bimatoprost (Latisse) is also marketed for **hypotrichosis of the eyelashes**.

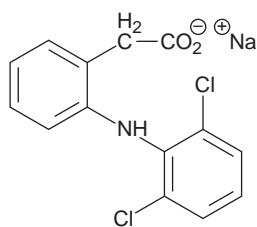
    c. Adverse effects of carboprost are usually related to its **contraction of smooth muscle** (vomiting, diarrhea, and bronchoconstriction); however, elevated body temperature has also been reported. Adverse effects of the topical $PGF_{2\alpha}$ analogs include conjunctival hyperemia, ocular pruritus, and eyelash changes. The eyelash changes include increased length, thickness, pigmentation, and number. Bimatoprost (Latisse) relies on these effects for the treatment of less than normal amounts of hair of the eyelashes.

4. PGI_2 analogs

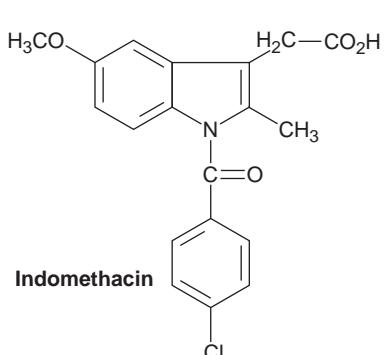
    a. Epoprostenol (PGI_2, PGX, prostacyclin) (Flolan, Veletri) is marketed as an IV form of PGI_2 for the treatment of **pulmonary hypertension** that does not respond to conventional therapies. Due to its short half-life (i.e., 3 to 5 mins), epoprostenol is administered by continuous IV infusion (*Figure 11-2*).

    b. Iloprost (inhalation [Ventavis]) and treprostinil (IV [Remodulin], inhalation [Tyvaso]) are more **stable prostaglandin PGI_2 analogs** with a similar activity and side effect profile compared to epoprostenol. Iloprost has a 30-min half-life and treprostinil has a 4 hr half-life. Both iloprost and treprostinil are available as inhalation products and treprostinil is also available for administration subcutaneously or IV bolus.

    c. The most common adverse effects of the PGI_2 analogs are related to vasodilation and include flushing, hypotension, headache, nausea, and vomiting.

III. NONSTEROIDAL ANTI-INFLAMMATORY DRUGS, OR NSAIDs, as the name implies, are anti-inflammatory agents that are different structurally and mechanistically from the anti-inflammatory steroids (see Chapter 12). The activities of the NSAIDs also include antipyretic and analgesic properties.


A. NSAIDs, except aspirin, exert their anti-inflammatory effect by a **competitive** and **reversible** active site inhibition of COX. Aspirin irreversibly inhibits COX by covalent acetylation of the enzyme. The inhibition of COX reduces the local synthesis of PGs that include pro-inflammatory actions among the diverse physiological role for the PGs (see section II). The PG family is also associated with fever and the perception of pain that accounts for the antipyretic and analgesic effects of the NSAIDs.

    1. COX is a heme-containing enzyme that converts arachidonic acid released from membrane phospholipids to PGs, thromboxanes, and prostacyclin through prostaglandin G2 (PGG2) and PGH2. PGG2 mediates the inflammatory response, whereas both PGG2 and PGH2 mediate pain and vasoconstriction.


2. Two isoforms of COX, COX-1 and COX-2, have been confirmed, whereas the relevance of a human COX-1 splice variant, which is sometimes called COX-3, is debated. COX-1 is constitutively expressed and contributes to normal cellular function, including maintenance of gastric mucosa and renal function. COX-2 is induced by cytokines, growth factors, and other factors and is expressed in inflammatory sites.

3. Classic or traditional NSAIDs are relatively nonselective inhibitors of COX-1 and COX-2, but COX-2 selective inhibitors (see following discussion) have been developed with the goal of preventing the inhibition of COX-1, therefore preventing adverse effects associated with its inhibition.

4. The salicylates also block platelet COX and subsequent formation of thromboxane A2. As a result, the salicylates inhibit platelet aggregation and eventual thrombus formation.

B. The traditional NSAIDs are structurally diverse group of molecules that are acids or acid prodrugs attached to a planar aromatic ring structure. The acidic functional group is responsible for binding to the same cationic site on COX bound by the natural substrate, arachidonic acid. The planar aromatic ring, generally one carbon from the acidic group, is analogous to the conjugated double bonds of arachidonic acid.

1. The **salicylates** are derivatives of salicylic acid, which is found as the glycoside salicin in willow bark. Aspirin is the acetyl ester of salicylic acid that hydrolyzes easily in the presence of water. Other salicylates include diflunisal (Dolobid), magnesium salicylate (Doans Pills or MST600), salsalate (Salflex or Disalcid), and choline magnesium trisalicylate (includes various ratios of choline salicylate and magnesium salicylate) (*Figure 11-3*).

2. The **acetic acid derivatives** include diclofenac (sodium salt [Voltaren] and potassium salt [Cataflam]), indomethacin (Indocin), sulindac (Clinoril), and tolmetin (Tolectin). Etodolac (Lodine) has a significant degree of selectivity for COX-2 inhibition. Nabumetone (Relafen) is a prodrug converted to an active acetic acid derivative in vivo (*Figure 11-4*).

3. The **propionic acid derivatives** have an alpha methyl group added to the acetic acid structure and include fenoprofen (Nalfon), ibuprofen (Motrin), ketorolac (Toradol), ketoprofen (Orudis), naproxen (Anaprox, Naprosyn), and oxaprozin (Daypro) (*Figure 11-5*).

4. The *N*-arylanthranilic acids or **fenamic acids** are bioisosters of the salicylic acid with modest anti-inflammatory properties and include meclofenamate sodium and mefenamic acid (Ponstel) (*Figure 11-6A*).

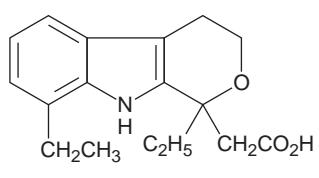
5. The **oxicams** or **enolic acid derivatives** utilize keto-enol tautomerization to form the acidic functional group rather than a carboxylic acid functional group found in the other classes. The enolic acid derivatives include piroxicam (Feldene) and meloxicam (Mobic). Meloxicam has a significant degree of selectivity for COX-2 inhibition (*Figure 11-6B*).


Figure 11-3. Examples of the salicylates based on the prototype salicylic acid. Other salicylates include aspirin, magnesium salicylate, and diflunisal.
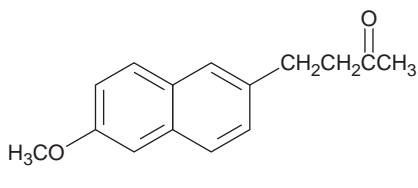

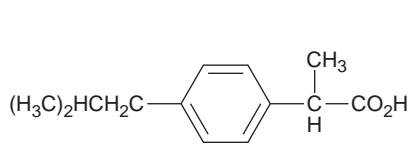

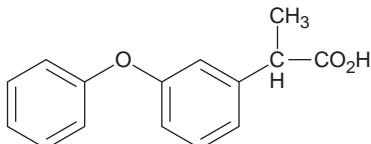

Figure 11-4. The acetic acid derivative NSAIDs including diclofenac, indomethacin, etodolac, and the prodrug nabumetone.
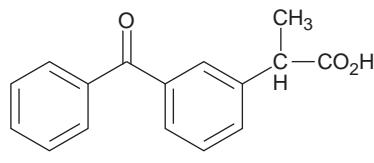

C. NSAIDs are the agents of choice for the treatment of **rheumatoid arthritis**, **osteoarthritis**, and **ankylosing spondylitis**.
   1. NSAIDs may also be used to relieve musculoskeletal pain, headache, and gouty arthritis.
   2. NSAIDs have **antipyretic effects** for the relief of fever. The salicylates should not be used in children with varicella or influenza-type viral infections because of the observed association between salicylate use in these situations and Reye syndrome.
   3. Aspirin is also indicated for prophylaxis and initial treatment of myocardial infarction based on its ability to inhibit platelet aggregation (see Chapter 10).

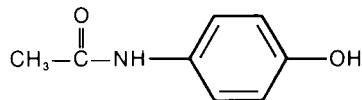
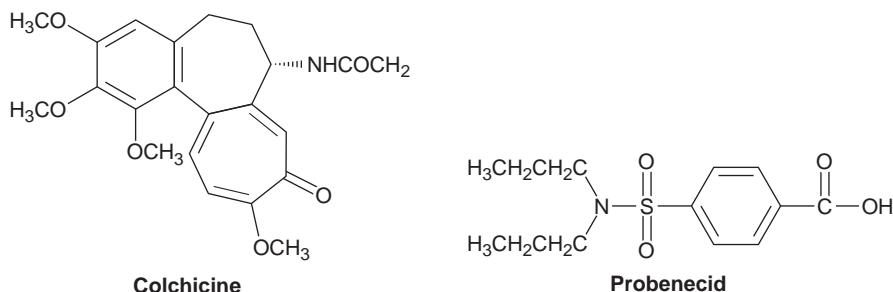
D. NSAIDs are associated to varying degrees, depending on the agent, with the following adverse effects.
  1. **GI effects**, such as GI distress, irritation, erosion of the gastric mucosa, nausea, vomiting, and dyspepsia are the most commonly observed effects and are attributed to the **acidic nature of the molecules** and the **decreased synthesis of gastric mucosa** secondary to inhibition of COX-1. Serious GI toxicity including bleeding and gut perforation is also possible.
  2. **CNS (central nervous system) effects**, such as CNS depression, drowsiness, headache, dizziness, visual disturbances, ototoxicity, and confusion are observed.
  3. **Cardiovascular events** associated with NSAIDs include an increased risk of myocardial infarction and stroke that increases with longer duration of therapy. These risks are addressed in a black box warning on all NSAIDs.
  4. **Hematologic effects** observed include thrombocytopenia, altered platelet function, and prolonged bleeding time, which are commonly called antiplatelet effects.
  5. **Nephrotoxicity** in the form of renal failure, hyperkalemia, and proteinuria are also possible adverse effects.
  6. Other adverse effects include skin rashes, rare liver failure, asthma, and fluid retention.
  7. In addition, the salicylates are associated with increased depth of respirations, excessive bleeding due to inhibition of thromboxane synthesis, and Reye syndrome in children with viral infections. Salicylate overdose is called salicylism and is characterized by tinnitus, nausea, and vomiting.
E. The family of NSAIDs also includes the **COX-2 selective inhibitors**.
  1. The COX-2 inhibitors selectively inhibit the inducible form of COX to reduce PG synthesis associated with the inflammatory response. Their ability to decrease pain and inflammation associated with arthritic diseases is approximately equal to that produced by the nonselective or traditional NSAIDs. The theoretical advantage of this selectivity is to **reduce the GI adverse effects** caused by the inhibition of the constitutive COX-1.
  2. The only compound marketed in the United States as a COX-2 selective inhibitor is celecoxib (Celebrex), a diarylheterocycle containing a sulfonamide (*Figure 11-7*). Rofecoxib (Vioxx) and valdecoxib (Bextra) were removed from the U.S. market after concerns over adverse effects (see III.E.4.).
  3. Celecoxib (Celebrex) is approved for the treatment of acute pain, ankylosing spondylitis, osteoarthritis, rheumatoid arthritis, primary dysmenorrhea, and familial adenomatous polyposis.
  4. Celecoxib does not appear to cause as great an incidence of GI ulceration or antiplatelet effects as the traditional NSAIDs, but **GI upset** and bleeding is still a significant side effect. The risk of adverse GI events increases with increasing dose and duration of therapy. Additionally, **adverse cardiovascular events** observed with the potent COX-2 inhibitors rofecoxib (Vioxx) and valdecoxib (Bextra) resulted in their market withdrawal. These risks included an increased risk of heart attack and stroke in patients taking rofecoxib (Vioxx) and valdecoxib (Bextra) compared to patients taking the traditional NSAIDs.

Celecoxib

Figure 11-7. Structural formula of celecoxib, a COX-2–specific inhibitor.

IV. NONNARCOTIC ANALGESICS AND ANTIPYRETICS lack the anti-inflammatory properties of the NSAIDs but remain useful as analgesics and antipyretics.




A. **Acetaminophen** (paracetamol, Tylenol, and various combination drugs) is a *p*-aminophenol derivative, which is the active metabolite of the older, no longer used agents phenacetin and acetanilide (*Figure 11-8*).

B. Acetaminophen does not significantly inhibit peripheral COX-1 or COX-2; therefore, it is not useful as an anti-inflammatory agent but has a similar antipyretic and analgesic potency when compared to aspirin. These activities of acetaminophen are proposed to be related to inhibition of COX in the CNS and potentially the controversial COX-3 enzyme.

C. Acetaminophen is indicated for use as an **antipyretic** and **mild analgesic** for minor aches and pains. Acetaminophen is the antipyretic of choice in children because there is no association between acetaminophen use in children with viral infections and Reye syndrome.

D. Acetaminophen is usually well tolerated, but the following adverse effects have been reported:
   1. Hypersensitivity, including a rash
   2. Rare methemoglobinemia
   3. Renal dysfunction
   4. **Hepatotoxicity**
      a. **Mild increases in liver function enzymes** may be observed with therapeutic doses, but these elevations are reversible upon drug withdrawal.
      b. **Acute overdose** and **chronic excessive doses** of acetaminophen results in significant **hepatotoxicity** characterized by **centrilobular necrosis** with potential for fulminant hepatic failure requiring a liver transplant.
      c. **Acetaminophen hepatotoxicity** is dependent on the **CYP metabolism** to the reactive metabolite *N*-acetyl-*p*-benzoquinone imine (NAPQI). NAPQI is inactivated by glutathione but covalently binds to cellular proteins as glutathione is depleted.
      d. Acetaminophen hepatotoxicity is treated orally or IV with **N-acetylcysteine** (Mucomyst, Acetadote), which restores the glutathione levels in the hepatocytes (see *Figure 8-5*).

V. GOUT is the result of an inflammatory response to deposition of sodium urate crystals in the joint formed by the breakdown of purine nucleotides from DNA. Treatments for gout reduce plasma uric acid concentration or inhibit the inflammatory response.

A. NSAIDs, except aspirin, salicylates, and tolmetin, are useful in the treatment of gout. Additionally, oxaprozin is a good choice due to its uricosuric properties (i.e., the ability to lower serum uric acid levels).

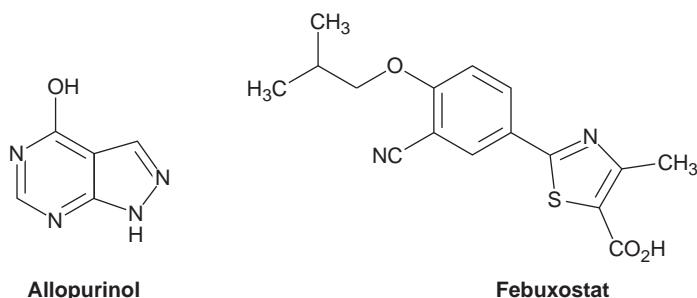
B. **Colchicine** (Colcrys) is an alkaloid isolated from the **autumn crocus plant** and is useful in the treatment of the symptoms of **gouty arthritis** (*Figure 11-9*).
   1. Multiple pharmacological activities for colchicine have been identified, but the presumed mechanism useful in the treatment of gout is related to **inhibition of tubulin polymerization into**


Figure 11-8. Structural formula of acetaminophen, the prototypical *p*-aminophenol derivative.

Figure 11-9. Colchicine and probenecid are both used to treat gout.

> **microtubules**. This process is required for the movement and phagocytosis of uric acid by leukocytes that play a role in the initiation of the inflammatory process. Colchicine also reduces the production of lactic acid by the leukocytes. Lactic acid production lowers the pH and causes more uric acid crystals to precipitate.

2. Colchicine is used for the treatment of **acute gout attacks** and usually provides relief to the pain and inflammation within 24 hrs. Colchicine is also marketed in combination products with probenecid (see section V.C) for the treatment of gout.

3. The majority of the **side effects** of colchicine are **related to the inhibition of tubulin microtubules** required for cell division in rapidly dividing cells.

   a. GI effects including nausea, vomiting, abdominal pain, and diarrhea are the most common side effects and may be the early signs of colchicine toxicity characterized by hemorrhagic gastropathy.

   b. Other serious side effects include agranulocytosis, aplastic anemia, myopathy, hair loss, and peripheral neuritis.

C. The benzoic acid derivative **probenecid** (Benemid, Probalan) is useful in the treatment of chronic gout (*Figure 11-7*).

   1. Probenecid, a uricosuric agent, **inhibits the proximal tubular reabsorption of uric acid**, increasing uric acid excretion, thus reducing plasma uric acid levels.

   2. Probenecid is used to treat **chronic tophaceous gout**. It is also used in smaller doses to prolong the effectiveness of penicillin-type antibiotics by inhibiting their tubular secretion. Probenecid is also marketed in combination products containing colchicine for the treatment of gout.

   3. Side effects for probenecid include GI irritation and less frequently, hemolytic anemia, rash, and renal stones caused by increased excretion of uric acid.

D. **Decreasing the synthesis of uric acid** is another approach to the treatment of gout.

   1. **Allopurinol** (Zyloprim) is an isopurine and **febuxostat** (Uloric) is a nonpurine analog (*Figure 11-10*). Both **inhibit xanthine oxidase** to slow the conversion of the purine metabolites xanthine and hypoxanthine to uric acid.

      a. Allopurinol is a **competitive inhibitor of xanthine oxidase** at low concentration and noncompetitive at high concentration. The active metabolite of allopurinol, oxypurinol, is produced by xanthine oxidase and is a noncompetitive inhibitor of xanthine oxidase.

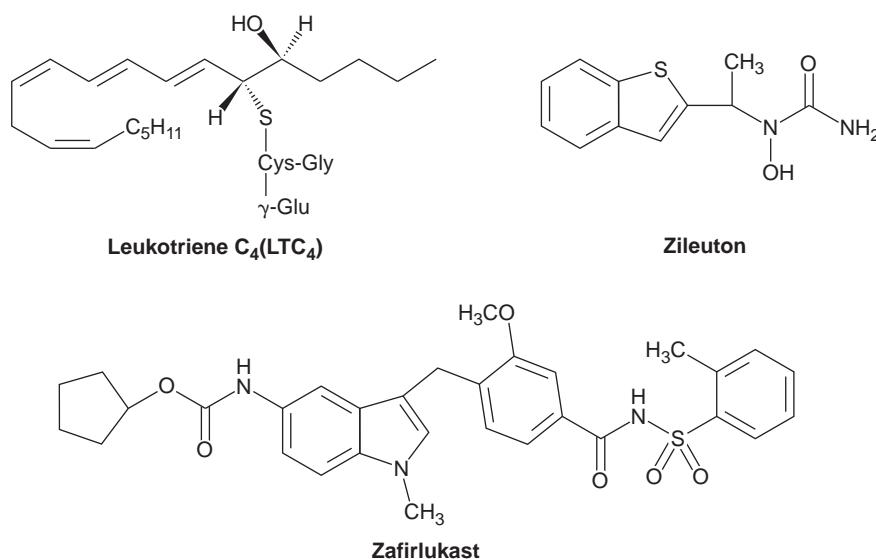
      b. Febuxostat (Uloric) inhibits xanthine oxidase through the formation of a stable complex with xanthine oxidase.


Figure 11-10. Xanthine oxidase (XO) inhibitors allopurinol and febuxostat.

    2. Allopurinol is indicated for **gouty arthritis**, the treatment of tophaceous gout, whereas febuxostat is indicated for patients experiencing **gouty arthritis with hyperuricemia**. Neither agent is indicated for asymptomatic hyperuricemia.

    3. Allopurinol and febuxostat are associated with the following adverse effects, although febuxostat generally has a better adverse effect profile.

        a. Precipitation of an acute gout attack with initiation of therapy due to mobilization of stored urate

        b. GI intolerance, including GI distress, nausea, vomiting, and diarrhea

        c. Rarely, aplastic anemia and hepatotoxicity have been reported.

        d. Peripheral neuritis and necrotizing vasculitis, bone marrow depression, skin rash, and Stevens-Johnson syndrome are also seen in rare instances of allopurinol use.

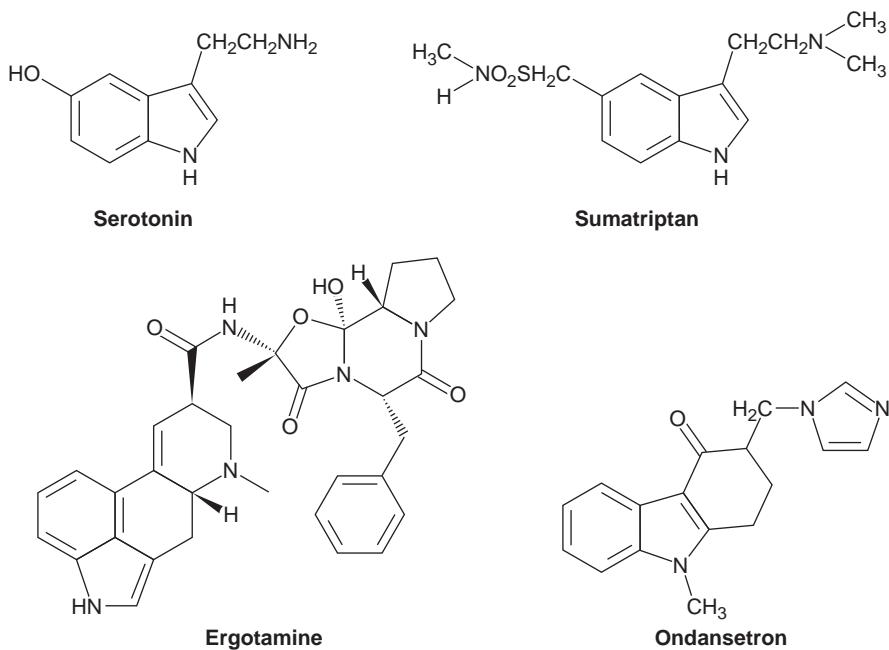
  E. **Pegloticase** (Krystexxa) and **rasburicase** (Elitek) are recombinant uricase or urate-oxidase, enzymes responsible for the final step in the breakdown of purines. Uric acid is converted to allantoin, a more water-soluble metabolite by urate-oxidase. Whereas pegloticase (Krystexxa) is indicated for **gout refractory to conventional therapy**, rasburicase (Elitek) is indicated for the **treatment of hyperuricemia secondary to anticancer therapy** in patients with leukemia, lymphoma, and solid tumor malignancies but is used off-label for refractory, non–malignancy-related gout. Major side effects including anaphylaxis, hemolysis, and methemoglobinemia and excessive cost for these parenterally administered products will most likely limit their use to the treatment of last resort for gout.

VI. LEUKOTRIENES (LTs) are autacoids with diverse pharmacological activities, including **inflammation** and **bronchoconstriction**.

  A. The LTs are **20-carbon derivatives of the fatty acids** that are formed via the enzymatic catalysis of arachidonic acid by **lipoxygenase**. Unlike the PGs, they contain no ring structure and are covalently linked to two or three amino acids. The two most important LTs identified to date (LTC_4 and LTD_4) differ only by the presence of a glutamine residue. The nomenclature of the LTs is similar to that used for the PGs (*Figure 11-11*).

  B. LTs play a role in the immune response to antigen challenge and were initially called the slow-reacting substances of anaphylaxis. Specific actions of the LTs that are targets for pharmacological modulation include their **potent chemotactic** action on neutrophils and eosinophils and significant **bronchoconstriction** and **mucus secretion**. These activities are readily seen in asthmatic patients and are specifically targeted by inhibitors of LT synthesis or antagonists of LT receptors.

Leukotriene C$_4$(LTC$_4$)

Zileuton


Zafirlukast

Figure 11-11. Endogenous leukotriene C$_4$ and two modulators of leukotriene activity. Zileuton inhibits the synthesis of leukotrienes by inhibiting 5-lipoxygenase, and zafirlukast is an antagonist of the cysLT$_1$-receptor that blocks the effects of leukotrienes.

C. Specific **inhibition of LT synthesis** can be achieved to reduce the tissue content of these inflammatory mediators. Zileuton (Zyflo) is an orally administered benzothiophene derivative **inhibitor of lipoxygenase** (*Figure 11-11*).

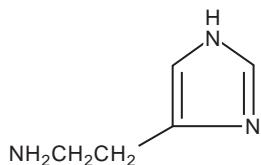
1. The inhibition of lipoxygenase prevents the synthesis of LTs, thereby preventing their contribution to various inflammatory processes. Because the lungs are sensitive to LT-induced bronchoconstriction, zileuton (Zyflo) is indicated for **prophylactic treatment of asthma**. It is not, however, effective in the management of acute asthma attacks.

2. Adverse effects of zileuton include GI effects, including dyspepsia and nausea, and headache. Reports of elevated liver enzymes in the plasma and neuropsychiatric events, including sleep disorders and behavior changes, require continued monitoring with zileuton treatment.

D. Antagonism of LT receptors prevents the consequence of immune-related production of LTs. Zafirlukast (Accolate) and montelukast (Singulair) are nonstructurally related molecules with hydrophobic regions and an acidic functional group (i.e., sulfonamide and carboxylic acid, respectively) required for their **antagonist activity at the leukotriene CysLT$_1$-receptor** (*Figure 11-11*).

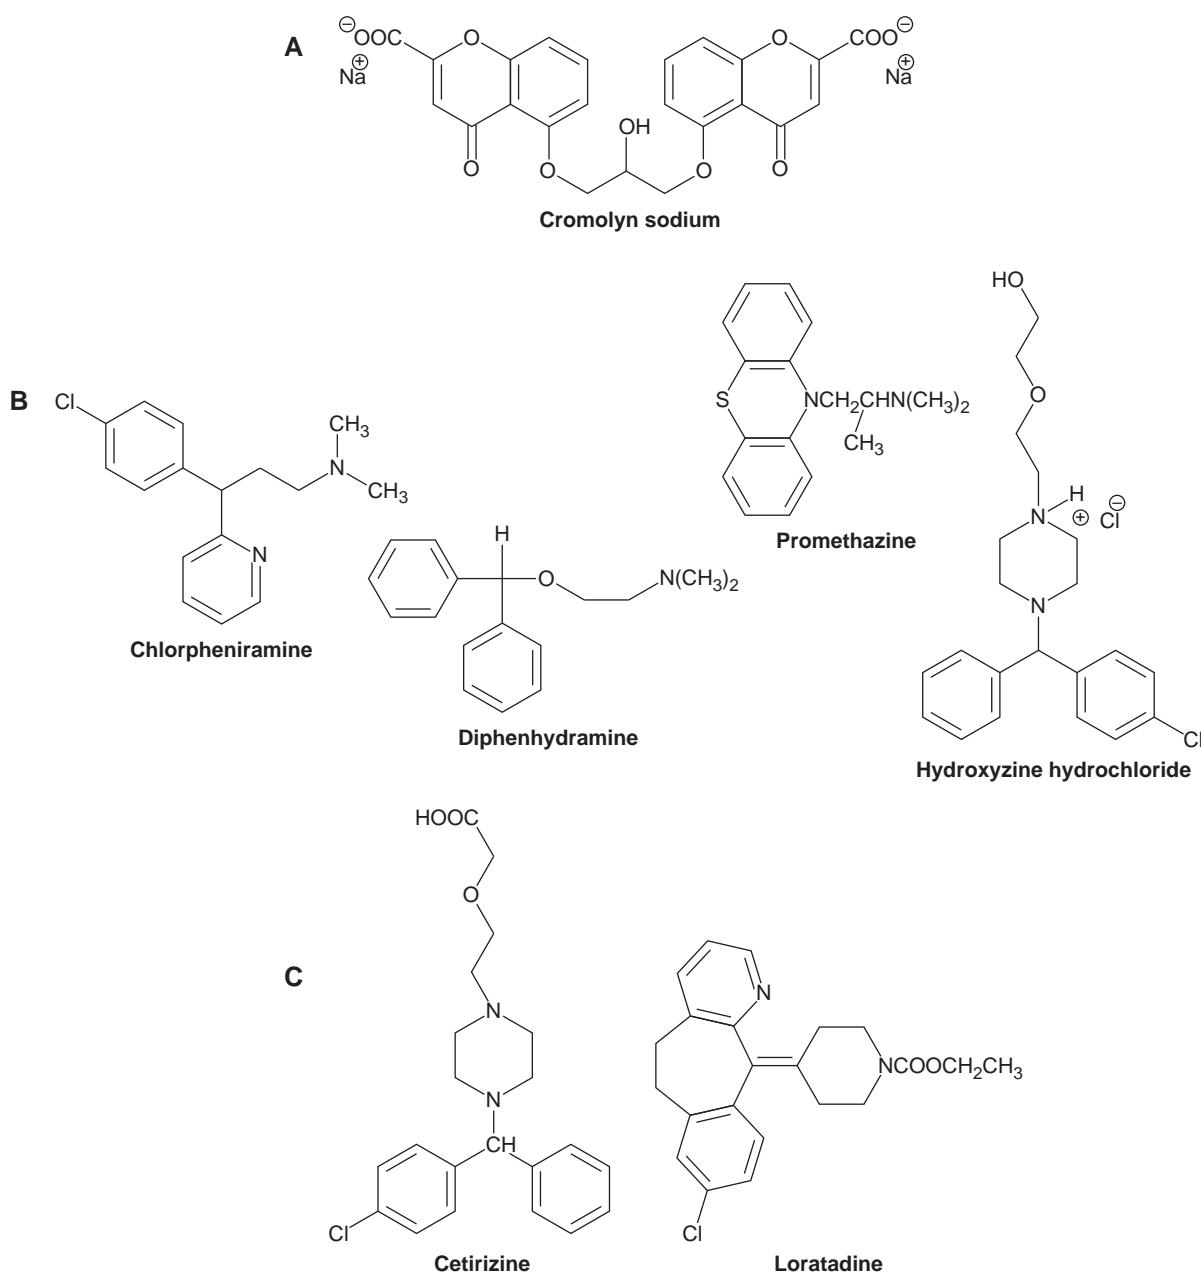
1. By acting as **competitive antagonists**, zafirlukast and montelukast **inhibit bronchoconstriction** and **pulmonary edema** induced by endogenously produced LTs.

2. Zafirlukast may produce GI upset and liver dysfunction but to a lesser extent than zileuton. Zafirlukast is a substrate and an **inhibitor of CYP2C9** and may result in drug–drug interactions. Interactions have been reported with warfarin, erythromycin, and theophylline. Rare cases of **Churg-Strauss syndrome** or eosinophilic vasculitis have been reported in association with reduction of oral steroid therapies.

3. Montelukast has adverse effects similar to zafirlukast without significant reports of hepatotoxicity. CYP450 induction increases the clearance of montelukast leading to the potential for therapeutic failure.


VII. SEROTONIN, in addition to being a neurotransmitter, is also an autacoid with various effects, including **vasoconstriction** and **platelet aggregation**.

A. **Serotonin** (5-hydroxytryptamine, 5-HT) is a bioamine that is synthesized from the amino acid **tryptophan** by a two-step enzymatic process catalyzed by tryptophan hydroxylase and L-amino acid decarboxylase (*Figure 11-12*).

Figure 11-12. Structures of serotonin and representative serotonin agonists sumatriptan, ergotamine, and the serotonin antagonist ondansetron.


B. Serotonin exerts a wide range of effects via a family of seven receptors with several subtypes. Major physiological effects of serotonin include **vasoconstriction** (5-HT$_2$); **platelet aggregations** (5-HT$_2$); **increased release of acetylcholine** in the enteric nervous system (5-HT$_3$, 5-HT$_4$); **nausea/emesis** (5-HT$_3$); and CNS actions that influence anxiety, depression, aggression, impulsivity, and appetite (5-HT$_1$, 5-HT$_2$, 5-HT$_3$). In addition, the 5-HT$_1$-receptor acts presynaptically at both serotonergic and adrenergic neurons to reduce neurotransmitter release. Based on these numerous effects, the serotonergic system is a rich pharmacologic target to modulate. Many **CNS drugs** modulate the **serotonergic system** to treat conditions such as **anxiety** (buspirone [Buspar]) and **depression** (fluoxetine [Prozac]), which are discussed in more detail in Chapter 9.

C. **5-HT$_1$-receptor agonists** are **indole derivatives** with structural similarity to serotonin (*Figure 11-12*) and include sumatriptan (Imitrex), rizatriptan (Maxalt), naratriptan (Amerge), zolmitriptan (Zomig), almotriptan (Axert), eletriptan (Relpax), and frovatriptan (Frova).

    1. **5-HT$_1$-receptor agonists** mimic the actions of serotonin at this receptor to produce **direct vasoconstriction** of cerebral vessels, **decrease the release of inflammatory** and **vasodilating substances** (neurokinin A, substance P), and have **antinociceptive activities**. These actions are thought to contribute to the efficacy of these drugs in the treatment of pain and nausea associated with migraine headaches.

    2. Adverse effects of the 5-HT$_1$-receptor agonists include feeling warm, paresthesias, dizziness, and tightness or heaviness in the chest. Rarely, patients may experience chest pain. Because these agents may cause **coronary vasoconstriction**, they are contraindicated in angina patients and should be used cautiously in patients with hypertension or other risk factors for ischemic heart disease.

D. **Ergot alkaloids** are derived from the *Claviceps purpurea* fungus that infects grains and contains a tetracyclic ergoline nucleus (*Figure 11-12*). The activity of the ergot alkaloids is complex and includes serotonin receptor agonist activity for some alkaloids and serotonin receptor antagonist activity for other alkaloids in addition to mixed activities at the α-adrenergic receptors and the dopamine receptors. The specific pharmacological response depends on the specific alkaloid drug and the animal model.

    1. Ergotamine (Ergomar) and dihydroergotamine (injection [D.H.E. 45], intranasal [Migranal]) are used for the treatment of **migraine headaches** via 5-HT$_1$-receptor and α-adrenoreceptor agonist activity.

    2. Other ergotamine alkaloids including ergonovine (Ergotrate) and methylergonovine (Methergine) are used to **prevent postpartum hemorrhage** through both **vasoconstrictive** and **uterine contractile actions** of 5-HT$_2$ and α-adrenoreceptor activities. Bromocriptine (Parlodel), through its dopaminergic activity, is also used to prevent postpartum breast engorgement.

    3. Adverse effects of the ergot alkaloids include GI upset and cold extremities. With increasing doses, the patient may experience emesis, diarrhea, peripheral pain secondary to local ischemia, and hallucinations or delusions.

E. **5-HT$_3$-antagonists** are indole or indole-like derivatives that block the ligand-gated ion channel, which is the 5-HT$_3$-receptor. This prevents serotonin from causing **nausea** and/or **emesis** both locally at the GI track and centrally in the area postrema. In addition, activation of peripheral 5-HT$_3$-receptors will increase pain, abdominal distention, and motor responses of the intestinal tract.

    1. 5-HT$_3$-antagonists indicated for **nausea and vomiting,** including that due to radiation or **cancer chemotherapy,** are ondansetron (Zofran), dolasteron (Anzemet), granisetron (IV or PO [Kytril], transdermal [Sancuso]), and palonosetron (Aloxi) (*Figure 11-12*).

    2. Alosetron (Lotronex) is also a 5-HT$_3$-antagonist at the peripheral receptors that **slows GI motility**, making it useful in certain cases of **irritable bowel syndrome** (IBS) when diarrhea is predominant.

    3. 5-HT$_3$-antagonists will produce headache, constipation, and dizziness. In addition, granisetron (Kytril) has been reported to produce somnolence and diarrhea. The use of alosetron (Lotronex) in patients with diarrhea-associated IBS has resulted in some cases of ischemic colitis and life-threatening complications from severe constipation. These adverse events have resulted in the development of a risk evaluation and mitigation strategy (REMS) that requires prescribers be specially certified to prescribe alosetron (Lotronex).

Figure 11-13. Structural formula of histamine, an autacoid.

VIII. ANTIHISTAMINES

A. Histamine is a bioamine derived principally from dietary histidine, which is decarboxylated by L-histidine decarboxylase (*Figure 11-13*). Histamine is synthesized throughout the body but is highly concentrated in the granules of basophils and mast cells. The physiological functions of histamine are numerous and include **allergic responses**, **cell proliferation**, **cell differentiation**, **hematopoiesis**, and neurotransmission related to **wakefulness** and **memory**. This wide array of responses to histamine is mediated by different histamine receptor types and their tissue localization.

B. One approach to manage the effects of histamine is to **inhibit the release of histamine from mast cells**. Cromolyn, the prototype for mast cell stabilizers, is marketed as an intranasal (Nasalcrom), ophthalmic (Crolom), and inhalation (Intal) product for the treatment of **allergic rhinitis, allergic conjunctivitis**, and **asthma**, respectively (*Figure 11-14*). Cromolyn is also available in an oral formulation (Gastrocrom) for mastocytosis. Other ophthalmic mast cell stabilizing agents for the treatment of allergic conjunctivitis include lodoxamide (Alomide), nedocromil (Alocril), and pemirolast (Alamast). The adverse effects of the mast cell stabilizers are generally related to the route of administration and include burning or irritation of the tissue.

C. Four different histamine receptors (i.e., H_1, H_2, H_3, and H_4) have been characterized thus far as **G protein couples receptors**. H_1 and H_2 receptors are therapeutically modulated and will be discussed further in the following. The H_3 receptor is found presynaptically in the brain and is thought to act as an autoreceptor to modulated histamine release in the CNS. The H_4 receptor is found on eosinophils, neutrophils, and CD4 T cells and has effects on the chemotactic function of eosinophils and mast cells.

1. The **H_1-receptors** mediate typical **allergic** and **anaphylactic responses** to histamine release, such as **bronchoconstriction**, **vasodilation**, **increased capillary permeability**, and **spasmodic contractions of GI smooth muscle**.

    a. **H_1-receptor antagonists** have been historically believed to competitively antagonize the receptor, but the observation that H_1-receptors have constitutive activity allows for the possibility that some of these agents act as inverse agonists rather than pure antagonists (see Chapter 58). Regardless of this pharmacological distinction, the H_1-receptor antagonists block the physiological response to histamine release, thereby limiting its effects on bronchial smooth muscle, capillaries, and GI smooth muscle. Additionally, the antagonists prevent histamine-induced pain and itching of the skin and mucous membranes; therefore, they are useful in providing **symptomatic relief of allergic symptoms** (i.e., seasonal rhinitis and conjunctivitis) or the common cold caused by **rhinoviral infections**. Their antihistaminic effects also make them useful for symptomatic **relief of urticaria**. Because of the **anticholinergic activities** of several of the H_1-receptor antagonists, some agents have utility as **antiemetics** and **anxiolytics**.

    b. The H_1-receptor antagonists, or antihistamines, are divided into **first-** and **second-generation** agents based on the sedating activities of the agents secondary to CNS access and distribution (*Figure 11-14*).

    (1) The classic, first-generation antihistamines include the chemical classes of

        (a) the **ethanolamines**: carbinoxamine (Arbinoxa, Palgic), clemastine (Tavist), diphenhydramine (Benadryl), and doxylamine (Unisom);

        (b) the **alkylamines**: brompheniramine (Dimetane, Brovex, Lodrane), chlorpheniramine (Chlor-Trimeton), dexbrompheniramine (Drixoral, Ala-Hist IR), dexchlorpheniramine (Polaramine), and triprolidine (Zymine, Actidil, Tripohist);

        (c) the **piperazine**: hydroxyzine (Atarax, Vistaril);

        (d) the **piperidine**: cyproheptadine (Periactin);

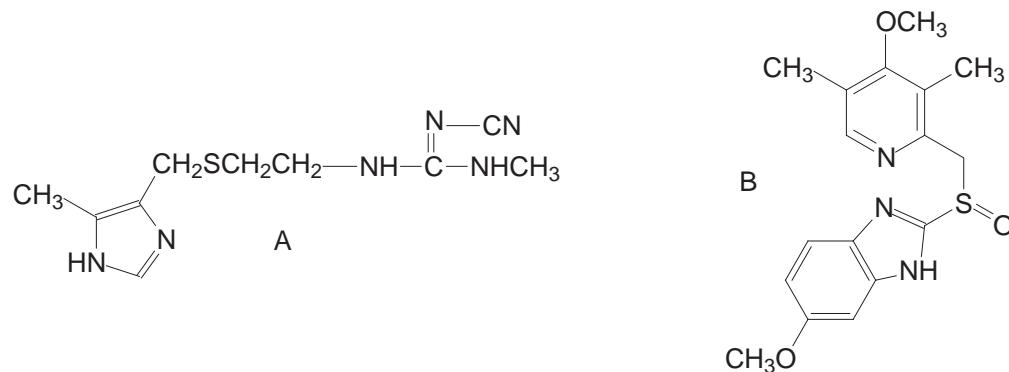
        (e) the **phenothiazine:** promethazine (Phenergan).


Figure 11-14. Modulators of histamine activity include cromolyn sodium (**A**) as a mast cell stabilizer and the antihistamines or histamine receptor blockers. The first-generation antihistamines (**B**) are generally sedating, whereas the second-generation antihistamines (**C**) are nonsedating.

    (2) Many of the first-generation agents are **significantly sedating** and produce **significant anticholinergic activity**. Several of the H_1 antagonists are also used for other indications such as **mild antiemetic** (diphenhydramine, marketed as an alternate salt form called dimenhydrinate [Dramamine]); **antiemetic** (promethazine); **mild anxiolytic** (hydroxyzine pamoate); and **sedating effect** (doxylamine and diphenhydramine).

    (3) The **second-generation** antihistamine include the chemical classes of

        (a) the **piperazines** (cetirizine [Zyrtec], levocetirizine [Xyzal]); and

        (b) the **piperidines** (loratadine [Claritin, Alavert], desloratadine [Clarinex], and fexofenadine [Allegra]).

    (4) These agents are **less or nonsedating** due to their limited ability to cross the blood–brain barrier.

(5) There are also many intranasal or ophthalmic antihistamines that are useful for the relief of allergic rhinitis or allergic conjunctivitis, respectively, that will be reviewed elsewhere (see ophthalmic/topical chapter).

c. The adverse effects of the H_1-receptor antagonists are relatively minor and, as a result, many antihistamines are available over-the-counter (OTC). The common adverse effects include CNS effects, including sedation, fatigue, hallucination, and ataxia mostly observed with the first-generation agents. Other common side effects of the first-generation antihistamines include anticholinergic effects, such as dry mouth, urinary retention, and constipation. The second-generation antihistamines are relatively free of side effects.

2. The **H_2-receptors** mediate the production of **gastric acid secretion**.

a. **H_2-receptor antagonists** competitively block the H_2-receptors, thereby limiting the effects of histamine on gastric secretions. Because of this activity, the H_2-receptor antagonists are used to treat **gastric hypersecretory conditions**, such as **duodenal ulcer** and **Zollinger-Ellison syndrome**. They are effective in reducing pain associated with gastroesophageal reflux disease, but not that they do not prevent actual reflux. OTC versions are indicated for the **treatment of heartburn**.

b. The H_2-receptor antagonists are heterocyclic congeners of histamine and include cimetidine (Tagamet), ranitidine (Zantac), famotidine (Pepcid), and nizatidine (Axid) (*Figure 11-15*).

c. H_2-receptor antagonists are associated with adverse events, including CNS effects (e.g., confusion, dizziness) and hepatic and/or renal dysfunction. **Cimetidine also has androgenic effects with high doses** (i.e., impotence and gynecomastia) and is a significant **inhibitor of CYP450** leading to the potential for serious drug–drug interactions.

IX. PROTON PUMP INHIBITORS (PPIs) are an alternative to the H_2-receptor antagonists in controlling gastric acid secretion. The PPIs are specific inhibitors of the ultimate mediator of gastric acid secretion, the H^+/K^+-ATPase or proton pump.

A. The PPIs **covalently bind to the proton pump** for an **irreversible inhibition of acid secretion**. The extensive and relatively long-term inhibition of gastric acid secretion is useful for the treatment of **gastroesophageal reflux disease**, **duodenal ulcers**, and makes PPIs the drugs of choice for **Zollinger-Ellison syndrome**. Several PPIs are marketed OTC for the treatment and prevention of **heartburn**.

B. The PPIs are benzimidazoles linked to a pyridine ring by a sulfinyl bridge that is required for H^+/K^+-ATPase inhibition. The PPIs include omeprazole (Prilosec), esomeprazole (Nexium), lansoprazole (Prevacid), dexlansoprazole (Dexilant), rabeprazole (AcipHex), and pantoprazole (Protonix) (*Figure 11-15*).

C. The adverse effects of the PPIs include diarrhea, GI pain, and headache. The PPIs, particularly omeprazole, **inhibit CYP450**, specifically CYP2C19, so care should be taken to avoid this interaction with agents such as diazepam (Valium), warfarin (Coumadin), phenytoin (Dilantin), clopidogrel (Plavix), and theophylline.

Figure 11-15. Structural formulas of (**A**) cimetidine, an H_2-receptor antagonist, and (**B**) omeprazole, a proton pump inhibitor.

Study Questions

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A 45-year-old long-haul trucker suffers from seasonal allergies. He asks advice on which over-the counter product is best to relieve his symptoms. Which of the following choices is the best recommendation for this patient?

   (A) diphenhydramine
   (B) promethazine
   (C) clemastine
   (D) chlorpheniramine
   (E) loratadine

2. Which of the following choices would be most appropriate in treating nausea and vomiting associated with motion sickness?

   (A) diphenhydramine
   (B) brompheniramine
   (C) ondansetron
   (D) omeprazole
   (E) ranitidine

3. Omeprazole would *not* be effective in the treatment of

   (A) gastroesophageal reflux disease.
   (B) peptic ulcer disease.
   (C) Zollinger-Ellison syndrome.
   (D) heartburn.
   (E) urticaria.

4. Which of the following antiulcer medications is most likely to cause drug interactions and endocrine side effects?

   (A) ranitidine
   (B) omeprazole
   (C) lansoprazole
   (D) cimetidine
   (E) famotidine

5. A patient has just been diagnosed with recurrent migraine headaches. Which of the following preexisting conditions would preclude the use of sumatriptan for this patient?

   (A) liver disease
   (B) renal failure
   (C) ischemic heart disease
   (D) irritable bowel syndrome (IBS)
   (E) gouty arthritis

6. Aspirin is best described as a(n)

   (A) acetyl ester of salicylic acid.
   (B) acetic acid derivative.
   (C) propionic acid derivative.
   (D) *N*-arylanthranilic acid derivative.
   (E) enolic acid derivative.

7. Which of the following prostaglandin analogs is used specifically for the treatment of glaucoma?

   (A) alprostadil
   (B) latanoprost
   (C) carboprost
   (D) dinoprostone
   (E) epoprostenol

8. The use of misoprostol to prevent nonsteroidal anti-inflammatory drug–induced ulcers could cause all of the following side effects *except*

   (A) fever.
   (B) gastrointestinal cramping.
   (C) hypertension.
   (D) headache/pain.
   (E) diarrhea.

9. Which of the following asthma therapies has been associated with an acute vascular syndrome that is associated with sudden withdrawal of corticosteroid anti-inflammatory drugs?

   (A) zafirlukast
   (B) zileuton
   (C) montelukast
   (D) cetirizine
   (E) ranitidine

10. Which of the following asthma therapies is effective by decreasing the amounts of released leukotrienes?

    (A) zafirlukast
    (B) zileuton
    (C) montelukast
    (D) alprostadil
    (E) bimatoprost

11. Rizatriptan is effective in treating migraine headache by all of the following *except*

    (A) directly vasoconstricting involved blood vessels.
    (B) inhibiting the roles of inflammatory neurotransmitters.
    (C) directly blocking pain transmission.
    (D) inhibiting platelet aggregation.
    (E) inhibiting the release of vasodilating substances.

12. Which of the following drugs, based on its mechanism of action, is effective in treating diarrhea-predominant irritable bowel syndrome (IBS)?

(A) misoprostol
(B) naratriptan
(C) alosetron
(D) cetirizine
(E) rabeprazole

13. The second-generation antihistamines (H_1-receptor antagonists) are generally considered nonsedating because they

(A) are more selective for H_1 receptors than the first-generation agents.
(B) are metabolized faster than the first-generation agents.
(C) actually function as H_1 receptor inverse agonists.
(D) do not cross the blood–brain barrier as easily as the first-generation agents.
(E) are only applied topically and therefore do not enter the systemic circulation.

14. Aspirin exerts its antiplatelet effect by inhibiting

(A) cyclooxygenase (COX) 1.
(B) COX-2.
(C) COX-3.
(D) prostaglandin synthesis.
(E) leukotriene synthesis.

15. Acetaminophen has advantages over aspirin or other nonsteroidal anti-inflammatory drugs by virtue of all of the following *except*

(A) relative lack of antiplatelet effects.
(B) relative lack of gastrointestinal ulcerative effects.
(C) being a safe alternative for children with viral infections.
(D) no hepatotoxicity.
(E) absence of adverse cardiovascular effects.

16. Acetaminophen toxicity is characterized by

(A) profound vasoconstriction and pain.
(B) severe abdominal cramping and diarrhea.
(C) central nervous system stimulation and seizures.
(D) profound liver damage and failure.
(E) tinnitus.

17. Which of the following antigout medications is specifically used in acute attacks?

(A) colchicine
(B) allopurinol
(C) probenecid
(D) pegloticase
(E) febuxostat

18. Which of the following antigout medications acts by decreasing serum levels but increasing urine levels of uric acid, thus increasing the risk of kidney stone development?

(A) colchicine
(B) allopurinol
(C) probenecid
(D) rasburicase
(E) pegloticase

19. The nonsteroidal anti-inflammatory drugs, as a class, are anti-inflammatory primarily through their ability to inhibit

(A) cyclooxygenase (COX) 1.
(B) COX-2.
(C) COX-3.
(D) leukotriene synthesis.
(E) thromboxane synthesis.

20. The selective cyclooxygenase (COX) 2 inhibitors have been associated with which of the following adverse drug reactions?

(A) severe ischemic colitis
(B) torsades de pointes
(C) cardiovascular thrombotic events
(D) acute liver failure
(E) Churg-Strauss syndrome

21. Which of the following antihistamines is used for the treatment of emesis?

(A) fexofenadine
(B) doxylamine
(C) chlorpheniramine
(D) promethazine
(E) desloratadine

22. Which of the following agents would produce a long-term inhibition of reduced gastric acid secretion through an irreversible mechanism?

(A) rabeprazole
(B) cimetidine
(C) famotidine
(D) nizatidine
(E) nedocromil

23. Which of the following is an indole derivative that antagonizes the 5-HT_1-receptor?

(A) ergotamine
(B) sumatriptan
(C) granisetron
(D) buspirone
(E) methylergonovine

24. Each of the following is classified as an NSAID *except*

- **(A)** piroxicam
- **(B)** ketorolac
- **(C)** oxaprozin
- **(D)** acetaminophen
- **(E)** indomethacin

25. Which one of the following side effects is the topic of a black box warning on all NSAIDs?

- **(A)** liver failure
- **(B)** asthma
- **(C)** cardiovascular events
- **(D)** nephrotoxicity
- **(E)** CNS depression

Answers and Explanations

1. The answer is E *[see VIII.C.1.b]*.
Diphenhydramine, promethazine, and clemastine all possess moderate to strong anticholinergic activity. This will increase the risk of sedation, which could prove dangerous in this patient. Chlorpheniramine, although the least sedating of the first-generation drugs, still may cross the blood–brain barrier and cause some sedation. Loratadine, as a second-generation drug that has minimal anticholinergic activity and does not cross the blood–brain barrier (thus producing no central effects), is least likely to cause sedation and thus affect his job.

2. The answer is A *[see VIII.C.1.b.(2)]*.
Although ondansetron is used for nausea associated with chemotherapy and anesthetics, it is not typically used for nausea associated with motion or vertigo. Diphenhydramine, which possesses a high degree of anticholinergic activity, is effective in reducing nausea and vomiting associated with vestibulocochlear activity, vertigo, and motion sickness. None of the other choices directly reduces nausea or vomiting; therefore, diphenhydramine is the best choice.

3. The answer is E *[see IX.A]*.
Because choices A–D are all disease states that represent some action of excessive acid secretion, omeprazole, which also blocks the proton or acid pump, would be effective in reducing the acid-induced pain and damage associated with gastroesophageal reflux disease (GERD), peptic ulcer disease (PUD), Zollinger-Ellison syndrome, and heartburn. Urticaria is best treated with a H$_1$-receptor antagonist.

4. The answer is D *[see VIII.C.2.c]*.
Of the drugs listed, and specifically, of the H$_2$ antagonists, cimetidine is the only drug that inhibits the hepatic microsomal metabolizing system (specifically, the 3A4 isozyme) and the only drug that exhibits weak androgenic activity. The former is responsible for numerous drug interactions and some side effects, whereas the latter is responsible for endocrine (specifically, androgen-like) side effects.

5. The answer is C *[see VII.C.2]*.
Sumatriptan (and other drugs in the class) specifically causes vasoconstriction. This effect, when present in coronary vessels, can cause chest tightness or pain as a normal side effect of the drug. However, in patients with ischemic heart disease, angina, or a risk for coronary artery disease, this action could precipitate attacks of angina or potentially cause myocardial infarction and should not be used in those patients.

6. The answer is A *[see III.B.1–5]*.
Aspirin is the acetyl ester of salicylic acid or a salicylate member of the NSAIDs. Diclofenac is an example of an acetic acid derivative, whereas ibuprofen is an example of a propionic acid. Meclofenamate sodium is an example of an *N*-arylanthranilic acid or fenamic acid. Meloxicam is an example of an enolic acid derivative or an oxicam.

7. The answer is B *[see II.D.3.b]*.
Although most prostaglandin analogs are nonspecific in their sites of action and may produce similar physiological effects, latanoprost is specifically formulated and marketed for use in the treatment of glaucoma. The relative selectivity of latanoprost for the PGF$_2\alpha$ receptor is responsible for its ability to lower intraocular pressure and therefore its benefit in treating glaucoma.

8. The answer is C *[see II.D.1.c]*.
As noted in the answer to question 7, most prostaglandin analogs have activity at receptors throughout the body, causing a prostaglandin-like effect on numerous organ systems. Misoprostol, as a relatively nonselective agonist, would cause contraction of gastrointestinal smooth muscle, stimulate pain fibers, and reset the thermoregulatory center of the CNS, thus causing all the potential side effects listed except hypertension. Hypotension is more commonly observed.

9. **The answer is A** *[see VI.D.2]*.
Zafirlukast is the only drug that has been associated with Churg-Strauss syndrome, a condition of eosinophilic vasculitis that occurs when a patient who is on both zafirlukast and corticosteroid therapy suddenly discontinues the corticosteroid. This effect has not been observed with the pharmacologically similar drug montelukast. Note that slow withdrawal of the corticosteroid (which should be done anyway, to minimize acute adrenal insufficiency) will prevent this adverse drug reaction. Neither ranitidine nor cetirizine are indicated for the treatment of asthma.

10. **The correct answer is B** *[see VI.C.1]*.
Zafirlukast and montelukast exert their effect by blocking leukotrienes at their receptor. Zileuton, which acts by inhibiting lipo-oxygenase, will decrease the synthesis of these inflammatory mediators. Therefore, it is the only drug listed that will decrease the synthesis and, consequently, the release of leukotrienes. Alprostadil and bimatoprost are both prostaglandin analogs.

11. **The answer is D** *[see VII.C.1; II.C.3]*.
Rizatriptan (and other drugs in the class) are 5-HT_1-agonists. This mechanism results in three distinct and beneficial pharmacodynamic effects. First, it causes direct vasoconstriction, which returns the blood vessel to its preheadache diameter. Second, by acting on neuronal receptors, it inhibits the release of additional vasodilating and pain-transmitting substances, such as neurokinin A and substance P. Third, this action has been shown to have a direct antinociceptive action, preventing the firing of pain neurons directly. Therefore A, B, C, and E are correct answers that describe the benefit of rizatriptan. Platelet aggregation is inhibited by PGI and its analogs along with some of the NSAIDs but not by the 5-HT_1-agonists.

12. **The correct answer is C** *[see VII.E.2; II.D.1.b; VIII.C.1.a and b.(2)]*.
Alosetron is the agent useful in treating diarrhea-predominant IBS. By blocking the 5-HT_3-receptor, it inhibits the serotonin-induced increase in intestinal motility, thus slowing peristalsis and gut movement. Naratriptan, acting as a 5-HT_1-agonist, has little effect on GI motility. Misoprostol is a PGE_1 analog that causes diarrhea. Cetirizine is a second-generation antihistamine with minimal anticholinergic activity or effects on GI motility. Rabeprazole is a proton pump inhibitor used to decrease gastric acid secretion that has little effect on GI motility.

13. **The correct answer is D** *[see VIII.C.1.b; VIII.C.1.b.(4)]*.
The division between first- and second-generation antihistamines is the sedating properties of the first-generation agents that are a result of the antagonism of histamine receptors in the CNS. The second-generation agents do not access the CNS as easily as the first-generation agents. The second-generation agents are more selective for the H_1 receptor that reduces the anticholinergic side effects but does not affect sedation.

14. **The correct answer is A** *[see III.A]*.
Recall that in prostaglandin and thromboxane synthesis, COX-1 is responsible for much of the daily production of maintenance eicosanoids. COX-2, while also contributing to daily production of prostaglandins and thromboxanes, is more important in inflammation. COX-3 is the debated splice variant that may be the central source of prostaglandins that contributes to CNS function of the eicosanoids. Also recall that it is thromboxane that specifically has platelet-aggregating ability. Therefore, it is through inhibition of COX-1 and the subsequent decrease in thromboxane (not prostaglandin or leukotriene) synthesis that the antiplatelet effect of aspirin is effected.

15. **The correct answer is D** *[see III.D; IV.D.4]*.
Acetaminophen does not possess any antiplatelet activity or reduce the synthesis of gastric cytoprotective prostaglandins, so it does not interfere with platelet function or other antiplatelet therapies, and it would not be prone to cause gastric ulceration. In addition, the relationship between aspirin and Reye syndrome in children with viral infections does not apparently exist with acetaminophen, making it a safe antipyretic to use in those patients. Acetaminophen does have a significant risk of hepatotoxicity with overdose or chronic use, but, to date, no correlation to increased risk of cardiovascular disease has been identified.

16. **The correct answer is D** *[see IV.D.4]*.
Acetaminophen toxicity is characterized by a profound hepatotoxicity, which is mediated by a reactive intermediary formed on saturation and depletion of the normal metabolic pathways. This does not affect the vasculature (as with the ergot derivatives), thus no vasoconstriction is observed. Neither is severe GI upset evident (although mild GI upset may occur early in toxicity), nor does profound CNS stimulation occur, as it does with aspirin toxicity. Tinnitus is a sign of salicylate overdose. Therefore, answer D is correct.

17. **The correct answer is A** *[see V.B.2]*.
Allopurinol, probenecid, pegloticase, and febuxostat, although effective in preventing attacks of gouty arthritis by lowering circulating levels of uric acid, are not effective in treating the acute inflammatory situation that characterizes an acute attack. Colchicine, by inhibiting the migration of proinflammatory cells into the affected joint, will reduce the inflammatory process, thus alleviating the pain and edema associated with acute attacks of gouty arthritis.

18. **The correct answer is C** *[see V.C.3, D, and E]*.
    Probenecid, as a uricosuric and promoting the excretion of uric acid, will effectively lower plasma concentration of urate. However, it also increases the urinary levels of uric acid. If this concentration exceeds the solubility constant of uric acid in the urine, then it may crystallize and precipitate out, causing stone formation or urinary lithiasis. For this reason, patients taking probenecid should always be counseled to drink copious amounts of water. Pegloticase and rasburicase are recombinant uricase enzymes that metabolize uric acid to allantoin, which is more water soluble.

19. **The correct answer is B** *[see III.A.2]*.
    The roles of COX-1, -2, and -3 are reviewed in the answer to question 14. It is through their inhibition of inflammatory prostaglandin synthesis by inhibiting COX-2 that the NSAIDs exert their anti-inflammatory actions.

20. **The correct answer is C** *[see III.E.4]*.
    The primary side effects that have been associated with the COX-2–specific inhibitors are gastrointestinal bleeding and, more recently, potentially fatal thrombotic events. The latter is thought to reflect a toxicodynamic effect that results from inhibition of vascular COX-2, which contributes to the daily control of platelet and/or vascular function. Severe ischemic colitis has been reported with alosetron; torsades de pointes, with older second-generation antihistaminics and cisapride, which is no longer available for use; acute liver failure, with acetaminophen overdose; and Churg-Strauss syndrome, with zafirlukast and corticosteroid withdrawal. None of these adverse drug reactions has been associated with the COX-2–specific inhibitors.

21. **The correct answer is D** *[see VIII.C.1.b.(2)]*.
    Promethazine (Phenergan) is an H_1-receptor antagonist, which is useful as an antiemetic. Diphenhydramine, marketed as Dramamine, is also used as an antiemetic. Other antihistamines do not have significant antiemetic effects.

22. **The correct answer is A** *[see IX.A; VIII.C.2.a]*.
    Rabeprazole is a proton pump inhibitor that works by covalently binding to the proton pump for an irreversible inhibition of acid secretion. This irreversible inhibition of the proton pump produces a longer term inhibition of gastric acid secretion compared to the H_2-receptor antagonists (i.e., cimetidine, ranitidine, famotidine, and nizatidine). Nedocromil is a mast cell stabilizer used ophthalmically for the treatment of allergic conjunctivitis, not acid reduction.

23. **The correct answer is B** *[see VII.C.1]*.
    Sumatriptan (Imitrex) is a $5\text{-}HT_1$-receptor agonist and indole derivative that causes direct vasoconstriction and decrease in the release of inflammatory and vasodilating substances that contributes to the efficacy of sumatriptan as a migraine headache medication. Both ergotamine and methylergonovine are ergot alkaloids that have $5\text{-}HT_1$-receptor agonist activity as a contributor to its mechanism of action, but the ergotamine derivatives are not indoles. Granisetron (Kytril) is a $5\text{-}HT_3$-receptor antagonist used to manage nausea and vomiting. Buspar is an anxiolytic agent that modulates the CNS serotonergic system but lacks efficacy in the treatment of migraine headaches.

24. **The answer is D** *[see IV; III.B]*.
    Acetaminophen is not an NSAID because it has no anti-inflammatory properties. Acetaminophen does have antipyretic and analgesic activities similar to aspirin, the prototypical NSAID. Each of the other drugs listed are anti-inflammatory agents.

25. **The answer is C** *[see III.D.1–6; III.E.4]*.
    There is an increased risk of cardiovascular events, which may include thrombotic events, myocardial infarction, or stroke, with the use of NSAIDs. This was also observed with the COX-2–specific NSAIDs. Adverse GI effects are also included in a black box warning in the NSAIDs. Each of the other side effects listed are associated with NSAID use but are not specifically addressed in a black box warning.

Pharmacology and Medicinal Chemistry of Endocrine and Related Drugs

MICHAEL L. ADAMS, S. THOMAS ABRAHAM

I. INTRODUCTION. Hormones are substances secreted by specific tissues and transported via the blood to distant tissues where they exert their effects. Hormones can be obtained from natural substances (animal preparations) or they may be synthetic or semisynthetic compounds resembling the natural products. They are often used for replacement therapy (e.g., exogenous insulin for treatment of diabetes mellitus). However, they can also be used for a variety of other therapeutic and diagnostic purposes. Certain drugs (e.g., thyroid hormone inhibitors, oral antidiabetic agents) are not hormones themselves but rather influence the synthesis, secretion, or activity of hormones. Therapeutically important hormones include the pituitary hormones, the gonadal hormones, the adrenocorticosteroids, the thyroid hormones, the parathyroid hormones, and insulin. Some of these hormone systems are modified by antagonists, inhibitors, and release modifiers.

II. PITUITARY HORMONES are synthesized in the pituitary gland. The pituitary gland is divided into two anatomical lobes called the **anterior lobe** (adenohypophysis) and the **posterior lobe** (neurohypophysis).

A. The two **posterior pituitary hormones**, oxytocin (Pitocin) and vasopressin (Pitressin), are closely related nonapeptides that differ only in two of their nine amino acids. Both oxytocin and vasopressin exert their physiological effects through distinct G protein coupled receptors.

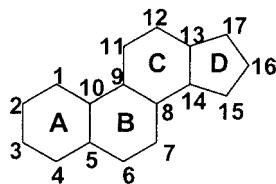
1. **Oxytocin** (Pitocin) **stimulates uterine contraction** and plays an important role in the **induction of labor**. It is used to initiate and maintain uterine contractions in near-term pregnancies and to control postpartum bleeding or hemorrhage. Adverse effects of prolonged and excessive oxytocin administration include uterine hypertonicity with spasms, uterine or placental rupture, fluid retention, hyponatremia, heart failure, and seizures. Fetal effects such as bradycardia, neonatal jaundice, and cardiac arrhythmias have been observed.

2. **Vasopressin** (Pitressin, arginine vasopressin [AVP]) also called **antidiuretic hormone (ADH)** produces most of its effects through V1 and V2 receptors.

   a. Through V1 receptors located on the vasculature, AVP produces a potent vasoconstriction to increase blood pressure. Intravenous infusion of AVP can be useful in hypotensive conditions requiring emergency support (e.g., ventricular arrhythmias or asystole).

   b. AVP and **desmopressin** (DDAVP, Minirin, Stimate) can also activate V2 receptors in the renal collecting tubules to reduce the amount of water lost in the urine (antidiuretic function). DDAVP is a **vasopressin analog** that has been modified at the N-terminal and by the replacement of L-arginine with D-arginine at position 8. These modifications increase the oral and nasal bioavailability, duration of action, and provide selectivity for V2 receptors over

V1 receptors. Both AVP and DDAVP can be used to treat central **diabetes insipidus**, **nocturnal enuresis** (bed wetting), and manage bleeding in hemophilia A patients.

c. The most likely adverse effects of AVP and DDAVP use are headaches, nausea, gastrointestinal (GI) cramps, central nervous system (CNS) agitation, and allergic reactions. AVP may also increase blood pressure and increase the likelihood of cardiovascular events and strokes.


d. The **vasopressin antagonists** conivaptan (Vaprisol) and tolvaptan (Samsca) are used to **manage conditions where excessive AVP** is involved in pathological conditions. Conivaptan is a V1/V2 antagonist that is administered intravenously, whereas tolvaptan is an orally active, selective V2 antagonist. These agents are used primarily to control hyponatremia secondary to hypovolemic states such as congestive heart failure and hepatic cirrhosis. A specific use of these agents is in the management of syndrome of inappropriate ADH where excessive AVP is released by the posterior pituitary.

e. Adverse effects associated with conivaptan and tolvaptan are headache, constipation, diarrhea, thirst, fever, and polyuria. Additionally, conivaptan can cause severe injection site reactions and phlebitis.

B. The **anterior pituitary hormones** are required for the maintenance of **thyroid function**, **adrenal function**, and **ovulation** (gonadotropins).

1. **Adrenocorticotropic hormone** (ACTH) is a 39-amino acid polypeptide that stimulates the adrenal cortex to produce and secrete adrenocorticosteroids (see section IV). The activity of ACTH is mimicked by corticotropin (Acthar HP), which can be used as a diagnostic agent to test adrenocortical function and differentiate between primary and secondary adrenal insufficiency. Adverse effects of corticotropin are rare but include hypersensitivity and corticosteroid excess.

2. **Thyroid-stimulating hormone** (TSH) is a protein with a molecular weight of 28,000 Da that stimulates the thyroid to produce T_4 and T_3 (see section V). Thyrotropin-α (Thyrogen) is human recombinant TSH that is used diagnostically with thyroglobulin and radioiodine imaging to monitor thyroid cancer. Adverse effects are similar to hyperthyroid symptoms.

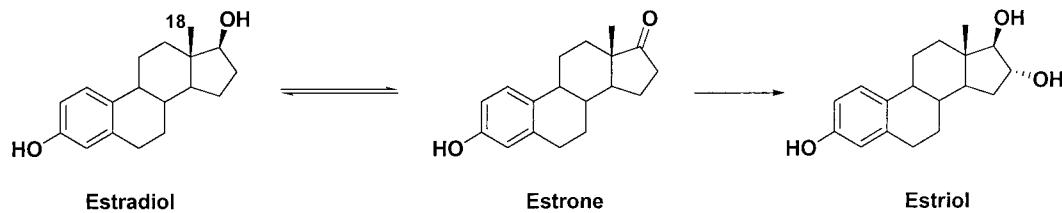
3. **Growth hormone**, also called **somatropin**, is a protein of 191 amino acids that stimulates protein, carbohydrate, and lipid metabolism to promote increased cell, organ, connective tissue, and skeletal growth, causing a rapid increase in the overall rate of linear growth. Somatropin (Genotropin, Humatrope, Norditropin, Nutropin, Omnitrope, Saizen, Serostim, Tev-tropin, Valtropin, Zorbtive) is indicated for long-term treatment of children whose **growth failure** is the result of **lack of endogenous growth hormone secretion**. Adverse effects are limited to the formation of nonbinding antibodies to growth hormone but antibody development does not interfere with continued use.

4. **Anterior pituitary gonadotropins** include **follicle-stimulating hormone** (FSH), **luteinizing hormone** (LH), and **prolactin** or **luteotropic hormone** (LTH). Only recombinant FSH is used therapeutically; however, several related nonpituitary gonadotropins have FSH-like or LH-like actions. These include the following agents that can be used to induce ovulation.

a. **Menotropins** (Menopur, Repronex), also known as human menopausal gonadotropin (hMG), are **high in FSH-like** and **LH-like activity** and are obtained from the urine of postmenopausal women. In men, menotropins are used to induce spermatogenesis.

b. **Urofollitropin** (Bravelle) is obtained from the urine of postmenopausal women and has **significant FSH-like activity**. Two recombinant DNA forms, follitropin alfa (Gonal-f) and follitropin beta (Follistim AQ), are also available. These agents can also **induce spermatogenesis** in men.

c. **Human chorionic gonadotropin** (Novarel, Pregnyl), produced by the placenta, is isolated from the urine of pregnant females, and choriogonadotropin alfa (Ovidrel) is recombinant human chorionic gonadotropin. Human chorionic gonadotropin is indicated for the treatment of some cases of **hypogonadism** in males in addition to **inducing ovulation**. The presence of human chorionic gonadotropin in the urine is the basis for home pregnancy tests.

III. GONADAL HORMONES are hormones produced in the gonads (i.e., ovary or testis). Most natural and synthetic gonadal hormones are derivatives of **cyclopentanoperhydrophenanthrene** with various changes in strategic positions (*Figure 12.1*). The steroid hormones contain this 17-carbon fused-ring system that uses a common numbering system.


A. **Estrogens** are the female sex hormones responsible for the development of female sex organs and secondary sexual characteristics.

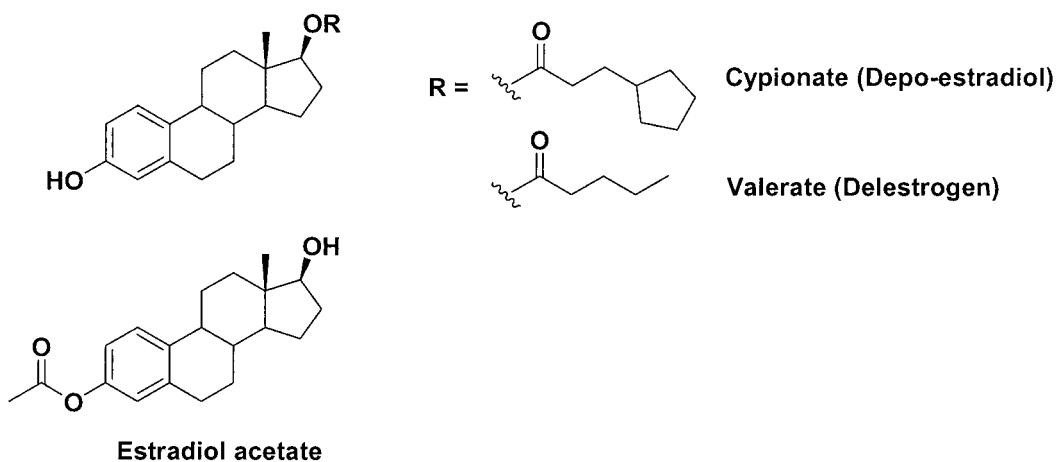
1. Both **natural** and **semisynthetic estrogens** are marketed for clinical use. The basic nucleus of the natural estrogens has a methyl group designated as C-18 on position C-13 of the


Figure 12-1. Structural formula of cyclopentanoperhydrophenanthrene, from which the gonadal hormones are derived. *A–D* rings, which may be modified during subsequent conversions; *1–17*, carbon atom positions on the rings.

cyclopentanoperhydrophenanthrene and is known as estrane. Unlike other steroid hormones, **all estrogens have an aromatic A-ring** (*Figure 12-2*).

   a. **Estradiol**, the principal estrogenic hormone, exists in the body in equilibrium with estrone, which is converted to estriol before excretion (*Figure 12-2*).

   b. The various routes of administration for estradiol include oral (Estrace), vaginal cream (Estrace), vaginal ring (Estring, Femring), vaginal tablet (Vagifem), transdermal patch (Climara, Estraderm, Alora), and topical emulsion (Estrasorb) or gel (Estrogel, Divigel). Estradiol is **only weakly active when administered orally due to extensive first-pass metabolism**.

   c. Several synthetic estradiol esters, such as estradiol cypionate (Depo-Estradiol) and estradiol valerate (Delestrogen) (*Figure 12-3*), are prepared as intramuscular injections in oil to prolong their action. These estradiol esters are slowly absorbed into the circulation, hydrolyzed to estradiol to act on the target tissue. Before hydrolysis, these compounds do not have estrogenic activity and thus are considered to be prodrugs. Another prodrug, estradiol acetate, is available for oral (Femtrace) and vaginal ring (Femtrace) administration.

   d. The addition of a 17 α-ethinyl to estradiol increases resistance to first-pass metabolism and enhances oral effectiveness. The estradiol derivatives, ethinyl estradiol and its 3-methyl ether mestranol, are used principally as the estrogenic components of serial-type oral contraceptives (*Figure 12-4*). Mestranol is a prodrug and is metabolized to ethinyl estradiol after its oral administration.

   e. Conjugated estrogens or esterified estrogens are a mixture of estrogen metabolites, most often estrogen sulfates from plant or animal sources, that can be administered orally. Brand names included in this class are Premarin, Cenestin, Menest, and Enjuvia. Estropipate (Ogen) is a single-component conjugated estrogen sulfate.

2. Estrogens exert their actions through ERα- and ERβ-type **estrogen receptors** in estrogen-responsive tissues (e.g., vagina, uterus, mammary glands, anterior pituitary, hypothalamus). The estrogen receptors are localized in the nucleus bound to stabilizing proteins. When estrogen or an estrogen analog binds to the estrogen receptor, the receptor forms a dimer that increases its affinity for DNA, and increases the expression of specific genes. This ultimately leads to an increase in protein synthesis and a biological response.

3. The **therapeutic indications** for the estrogens vary and include the following:

   a. **Oral contraceptives** (in combination with progestins)

   b. **Treatment of menopausal symptoms** including vasomotor disorder, vaginal dryness, urogenital atrophy, and psychological disorder. It is not recommended to use estrogens, with or without progestins, for the prevention of cardiovascular disease or dementia.

   c. **Acne**

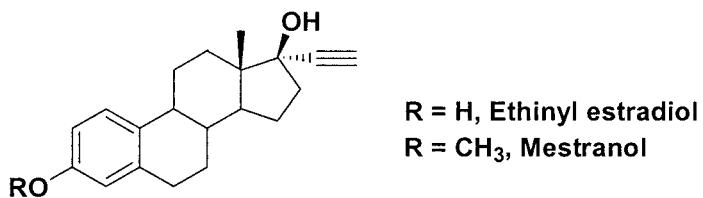
   d. **Osteoporosis**, both senile and postmenopausal osteoporosis


Figure 12-2. Structural formula of estradiol, which exists in the body in equilibrium with estrone, which in turn is converted to estriol before excretion.
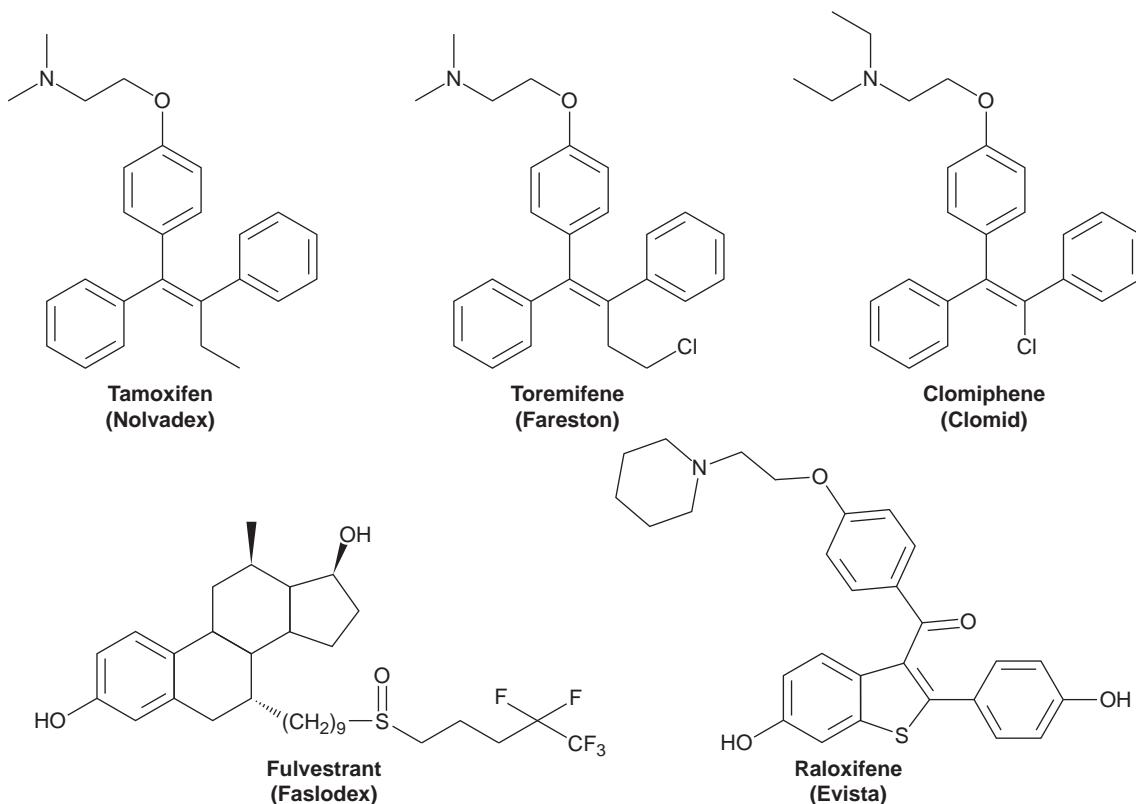

Figure 12-3. Structural formulas of estradiol cypionate (Depo-Estradiol), estradiol valerate (Delestrogen), and estradiol acetate.

    4. The adverse effects from the pharmacological use of estrogens include the following:
      a. **GI effects**, including GI distress, nausea, vomiting, anorexia, and diarrhea.
      b. **Cardiovascular effects**, including hypertension and an increased incidence of thromboembolic diseases, stroke, and myocardial infarction.
      c. **Fluid and electrolyte disturbances**, including increased fluid retention and increased triglyceride levels.
      d. An increased incidence of endometrial cancer and hepatic adenomas (associated with long-term use).
B. **Antiestrogens** antagonize the effects of estrogens at various tissues.
    1. The **nonsteroidal antiestrogens** (i.e., **estrogen antagonists**) clomiphene (Clomid), tamoxifen (Nolvadex), and toremifene (Fareston) are triphenylethylene derivatives with an important basic amine side chain (*Figure 12-5*). These agents are structurally related to nonsteroidal synthetic estrogens with a stilbene-like structure. Raloxifene (Evista) is a benzothiophene with structural similarity to the triphenylethylethylene derivatives and fulvestrant (Faslodex) is a potent steroidal antiestrogen (*Figure 12-5*). Except for fulvestrant, these behave as agonists or antagonists of estrogen response, depending on the site of action and are often called selective estrogen response modifiers. Fulvestrant appears to behave as a pure estrogen receptor antagonist regardless of the tissue or organ.
    2. Pharmacology
      a. **Tamoxifen** and **toremifene** are predominantly **estrogen antagonists** and inhibit the action of estrogens by competitively binding to estrogen receptors in **breast tissue**. These agents have a **weak estrogen agonist effect on the endometrium, bone, and lipid levels**.
      b. **Clomiphene** has **estrogenic and antiestrogenic activity** and **induces ovulation** by causing an increase in the secretion of the pituitary gonadotropins FSH and LH.
      c. **Raloxifene** has estrogenic activities and antiestrogenic activities at certain tissues. Raloxifene is an **agonist in bone** and **antagonist in uterine and breast tissue**.
      d. Fulvestrant inhibits the action of estrogen by competitively binding to estrogen receptors and preventing estrogen-like responses to receptor binding (i.e., changes in gene expression).

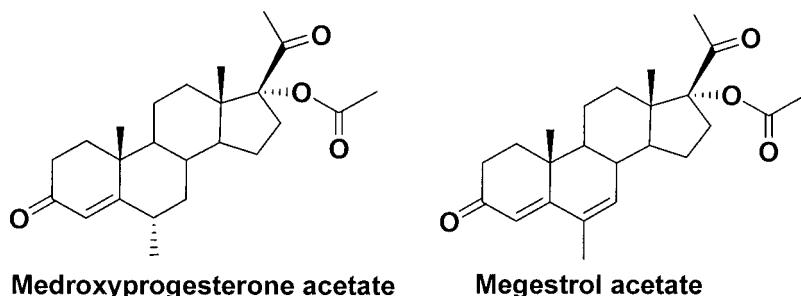
Figure 12-5. Structural formulas of the antiestrogens tamoxifen, toremifene, clomiphene, raloxifene, and fulvestrant. Clomiphene, tamoxifen, toremifene, and raloxifene are structurally similar, whereas fulvestrant is a larger and more lipid-soluble analog of estradiol. Raloxifene is a SERM used to treat osteoporosis.
      3. Therapeutic indications
         a. Tamoxifen, toremifene, and fulvestrant are used to treat **estrogen-dependent breast cancer**.
         b. Clomiphene is used to **induce ovulation** in women who have ovulation failure.
         c. Raloxifen is used to **treat and prevent osteoporosis** in postmenopausal women.
      4. Adverse effects of the antiestrogens include hot flashes, nausea, and vomiting.
  C. **Aromatase inhibitors** decrease endogenous estrogen synthesis. Aromatase, a cytochrome P450 enzyme, is responsible for generating the **aromatic A-ring** that distinguishes estrogen from the progesterones and androgens (e.g., androstenedione and testosterone). Inhibition of aromatase dramatically **decreases the amounts of estrogen in circulation**.
      1. Anastrozole (Arimidex) and letrozole (Femara) are potent and selective triazole containing **nonsteroidal inhibitors of aromatase** (*Figure 12-6*). Exemestane (Aromasin) is the **only steroidal irreversible inhibitor of aromatase**.
      2. Aromatase inhibitors are indicated for the treatment of **advanced estrogen-dependent breast cancer**.
      3. Adverse effects are similar to the antiestrogens, including hot flashes.
  D. **Progestins.** Endogenous progestins are produced by the corpus luteum after normal ovulation to prevent further ovulation and maintain pregnancy if fertilization occurs.
      1. The naturally occurring progestin progesterone is a C-21 steroid. Its basic nucleus is known as pregnane (*Figure 12-7*). The routes of administration for progesterone include oral, vaginal gel, and intramuscular injection. Progesterone has a half-life of 5 to 10 mins because of rapid liver metabolism at C-5 and C-20.
      2. Synthetic steroidal progestins have structural features that hinder metabolism at C-5 and C-20. They consist of three types:
         a. The 17α-hydroxyprogesterone derivatives (e.g., medroxyprogesterone acetate [Provera, Depo-Provera], megestrol acetate [Megace]) typically introduce a methyl group at position


Figure 12-6. Structures of the triazole containing aromatase inhibitors anastrozole and letrozole and the only steroid-based aromatase inhibitor, exemestane.

C-6 of progesterone and an acetoxyl group at position C-17. These substitutions **increase lipid solubility** and **decrease first-pass metabolism**, enhancing oral activity and the progestin effect (*Figure 12-8*).

  b. The second group of progestins is 19-nortestosterone derivatives (17α-ethinylandrogens). They are structurally classified as androgens because they lack the 19-methyl group. Although these compounds have progestational and androgenic activity, their primary activity is progestational.

    (1) The absence of the 19-methyl group increases progestational activity.

    (2) The 17α-ethinylandrogens are **more lipid soluble** than progesterone and undergo **less first-pass metabolism**. The 17α-ethinyl substituent increases progestational activity relative to androgenic activity in addition to **blocking metabolism at C-17** as with ethinyl estradiol.

    (3) These agents, with a **17α-ethinyl group**, have **potent oral activity** and are extensively used as **oral contraceptives** in combination with ethinyl estradiol (*Figure 12-9*). Other orally active 17α-ethinylandrogens include the positional isomer of norethindrone, norethindrone acetate, norethynodrel, its 18-methyl homolog norgestrel, and its 3,17-diacetate analog ethynodiol diacetate. Norgestimate is an orally active 3-oxime prodrug that is metabolically deacetylated and oxidized to norgestrel. Desogestrel is a prodrug that is metabolically oxidized to the 3-ketone.

    (4) Norelgestromin (Ortho-Evra) and etonogestrel (NuvaRing) are also used as contraceptive agents given in combination with ethinyl estradiol (*Figure 12-9*). Norelgestromin is administered as a **transdermal patch** to **avoid first-pass metabolism**, and etonogestrel is formulated in a vaginal ring.

  c. Drospirenone is a progestin that is structurally different from the other progestins in that it is a structural analog of the aldosterone antagonist spironolactone with minimal androgenic activity. Drospirenone is used in the oral contraceptive agents Yasmin and Yaz in combination with ethinyl estradiol or estradiol, respectively (*Figure 12-9*).

 3. The mechanism of action of progestins is similar to estrogen. Progestins bind to nuclear progesterone receptors that dimerize to bind to the DNA in progestin-responsive tissues. The formation of the progestin-receptor complex results in an increase in the synthesis of mRNA and specific enzyme or protein synthesis.

medroxyprogesterone acetate
(Provera) and megestrol acetate
(Megace), synthetic progestins.

4. Progestins have various therapeutic uses.
   a. The progestins are predominantly used as **oral contraceptive agents**. Progestins can be given alone (progestin only such as norethindrone acetate) or in combination with estrogens as monophasic, biphasic, and triphasic combinations. Extended oral contraception (Seasonale, Seasonique) is also available for a 91-day cycle.
   b. Progestins are also used for **emergency contraception** in the form of levonorgestrel (Plan B) and levonorgestrel with ethinyl estradiol (Preven).
   c. **Endometriosis** and **menstrual disorders** including dysfunctional uterine bleeding and dysmenorrhea can also be treated with progestins.
5. Adverse effects of the progestins include irregular menses, breakthrough bleeding, amenorrhea, weight gain, edema, and exacerbation of breast carcinoma.

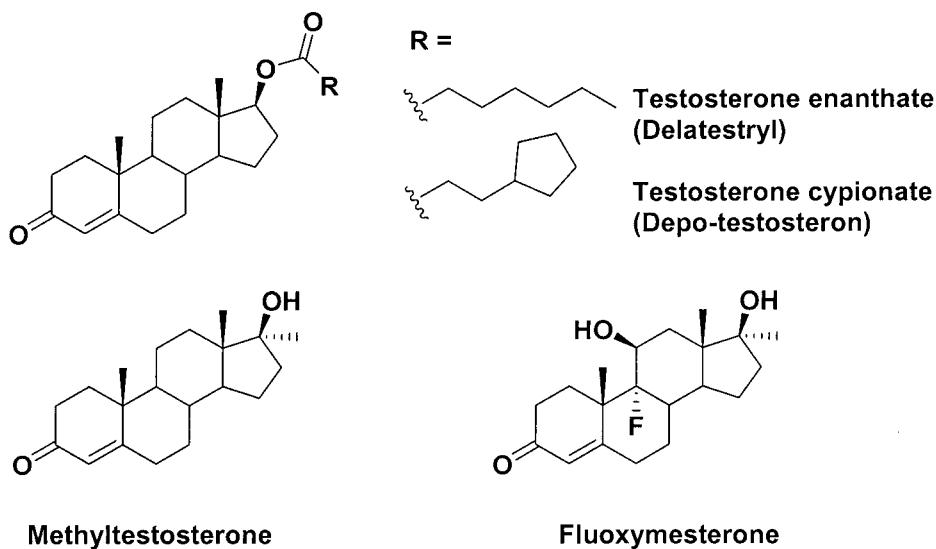
Figure 12-10. Structural formula of the antiprogestin mifepristone (Mifeprex).

E. **Antiprogestins** antagonize the effects of endogenous progestins.
1. Mifepristone (Mifeprex) is a **steroidal progestin receptor antagonist** that can be used to medically terminate pregnancy through 49 days (*Figure 12-10*). At 2 days after administration of mifepristone, a health care provider will administer the prostaglandin E_1 (PGE_1) analog misoprostol.
2. Mifepristone inhibits the action of progestins by competitively binding to progestin receptors. Misoprostol induces uterine contractions. This activity is used to terminate intrauterine pregnancy.
3. Adverse effects include the expected vaginal bleeding and uterine cramping but vaginal bleeding is generally heavier than a menstrual period. Additional adverse effects include nausea, vomiting, and diarrhea.
F. **Androgens and anabolic steroids.** Androgens are responsible for the development and maintenance of the male sex organs and secondary male characteristics including deep voice, and growth of hair on face, arms, legs, and pubic areas. Androgens also have anabolic activities that result in increased tissue growth including bone and muscle. The anabolic steroids have a much greater capacity to increase tissue growth (i.e., muscle) than the natural androgens.
1. The primary natural androgen is **testosterone**, a C-19 steroid with various routes of administration (buccal [Striant], transdermal gel [AndroGel, Fortesta, Testim], transdermal patch [Androderm], subcutaneous pellets [Testopel], intramuscular [Depo-Testosterone]) (*Figure 12-11*). **Testosterone has two physiological effects: androgenic and anabolic effects.**
   a. Compounds used for **androgenic** effects
      (1) Esters of testosterone, such as testosterone 17-enanthate (Delatestryl) and testosterone cypionate (Depo-Testosterone), are prodrugs and provide increased duration of action when administered intramuscularly owing to slow absorption and ester hydrolysis to the active testosterone (*Figure 12-12*).
      (2) Introduction of a 17α-methyl group results in potent, orally active androgens, such as methyltestosterone (Android, Testred) and fluoxymesterone (Androxy) (*Figure 12-12*). The **17α-methyl group decreases first-pass oxidative metabolism** to the 17-ketone.
   b. Compounds used for anabolic effects include drugs resulting from structural modifications of testosterone. These drugs have a **much enhanced anabolic-androgenic activity ratio** and a 17α-methyl group providing **oral activity** (e.g., oxymetholone [Anadrol-50], oxandrolone [oral-Oxandrin]; *Figure 12-13*).


Testosterone

5α-reductase

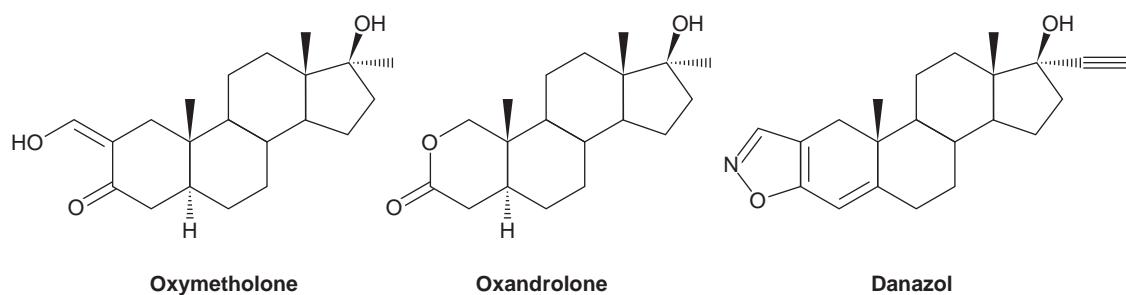
5α–Dihydrotestosterone (DHT)


Figure 12-11. Testosterone is converted to 5α-dihydroxy-testosterone (DHT) by the enzyme 5α-reductase.
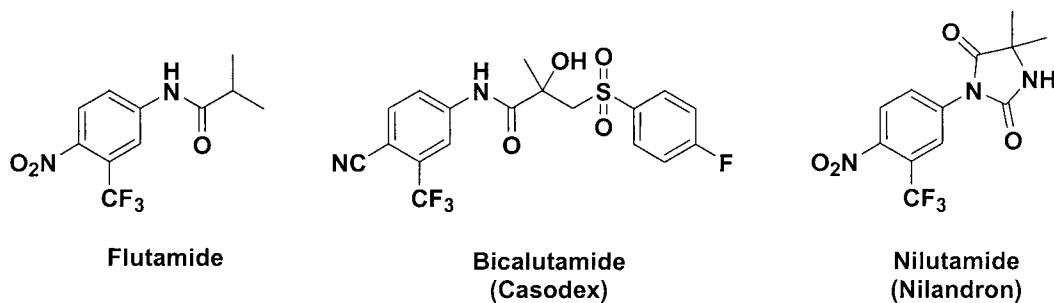

Figure 12-12. Structural formulas of testosterone enanthate, testosterone cypionate, methyltestosterone, and fluoxymesterone.

    c. Danazol (Danocrine), a weak androgen, suppresses the pituitary–ovarian axis (i.e., LH and FSH release) and is used for treatment of **endometriosis** and **fibrocystic breast disease** (*Figure 12-13*). The 17α-ethinyl group provides for **oral bioavailability**.

  2. The mechanism of action of androgens is similar to that of estrogen. Testosterone is converted to **5α-dihydroxytestosterone** (DHT) in the cytoplasm of androgen-responsive tissue by the enzyme **5α-reductase** (*Figure 12-11*). **DHT binds** to the cytoplasmic androgen receptor **with higher affinity** than testosterone and also acts as an agonist. The formation of androgen-receptor complex results in translocation to the nucleus and an increase in the synthesis of mRNA and eventually protein synthesis.

  3. The androgens are used for **androgen-replacement therapy**, **breast cancer**, **endometriosis**, **female hypopituitarism** (with estrogen therapy), **anabolic therapy**, and **anemia**.

  4. The adverse effects of the androgens include fluid retention, increased low density lipoprotein (LDL), decreased high density lipoprotein (HDL), psychological changes, liver disorders, decreased male fertility (i.e., **azoospermia**), and development of masculine features in the female.

G. **Antiandrogens** antagonize the effects of endogenous testosterone or DHT.

  1. Most of the antiandrogens are **nonsteroidal** in nature. They include flutamide (Eulexin), bicalutamide (Casodex), and nilutamide (Nilandron) (*Figure 12-14*).

  2. Flutamide, bicalutamide, and nilutamide inhibit the action of androgens by **competitively binding to the androgen receptors** and acting as **antagonists** in the target tissue.

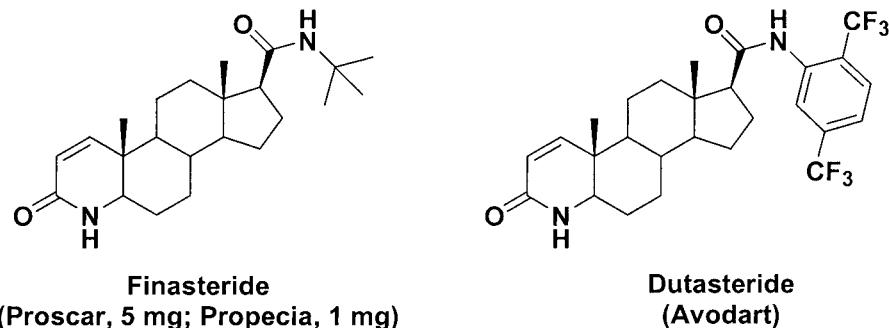
Figure 12-13. Structural formulas of the anabolic steroids oxymetholone, and oxandrolone, and the weak androgen danazol.


Figure 12-14. Structures of the antiandrogens flutamide, bicalutamide, and nilutamide.
   3. The antiandrogens are used to treat **prostate cancer**. Flutamide and bicalutamide are given in combination with luteinizing hormone-releasing hormone (LHRH) agonists.

H. **5α-Reductase inhibitors** decrease the synthesis of the potent tissue androgen DHT.

   1. Finasteride (Proscar, Propecia) and dutasteride (Avodart; *Figure 12-15*) are **competitive inhibitors of the 5α-reductase**, the enzyme in target tissues that converts testosterone to the potent androgen DHT.

   2. The 5α-reductase inhibitors are used to treat **benign prostatic hyperplasia** (BPH). Finasteride, marketed as Propecia, is used for **androgenic alopecia** at one-fifth the dose used in BPH.

IV. ADRENOCORTICOSTEROIDS are synthesized in the adrenal cortex. Adrenocorticosteroids are divided into two classes, **mineralocorticoids** and **glucocorticoids**, based on their physiological activities. Most naturally occurring adrenocorticosteroids have some degree of both mineralocorticoid and glucocorticoid activity. All adrenocorticosteroids are derived from the C-21 pregnane nucleus.

A. **Mineralocorticoids** cause the **retention of sodium** and the **excretion of potassium** in the kidney. **Aldosterone** is the endogenous, prototypical mineralocorticoid, which is formed in the outer (glomerular) layer of the adrenal cortex.

   1. Mineralocorticoids act by binding to **cytoplasmic receptors** that are then translocated to the nucleus to stimulate the production of mineralocorticoid-responsive mRNA to change the expression of target proteins. The mineralocorticoids also act in the feedback regulation of pituitary corticotropin.

   2. **Fludrocortisone** acetate (Florinef) has significant **mineralocorticoid activity** and it is therefore used to treat **Addison's disease** (*Figure 12-16*).

   3. Mineralocorticoid receptor antagonists, **spironolactone** (Aldactone) and **eplerenone** (Inspra), are **steroidal aldosterone-receptor (mineralocorticoid) antagonists** used to treat cardiovascular disorders (see Chapter 10).

Figure 12-16. Structural formula of fludrocortisone acetate, the clinically useful mineralocorticoid.

Fludrocortisone Acetate

B. **Glucocorticoids have anti-inflammatory, protein-catabolic, and immunosuppressant effects**.
   1. **Cortisone** and **hydrocortisone** (Cortisol), the **prototypical glucocorticoids**, are formed in the middle (fascicular) layer of the adrenal cortex (*Figure 12-17*).
      a. The 17β-ketol side chain (-COCH2OH), the 4-ene, and the 3-ketone structures are found in all clinically useful adrenocorticosteroids (*Figure 12-17*).
      b. Many natural, semisynthetic, and synthetic glucocorticoids are available. Modifications of the prototypes cortisone and hydrocortisone represent attempts to **increase glucocorticoid activity** while **decreasing mineralocorticoid activity**.

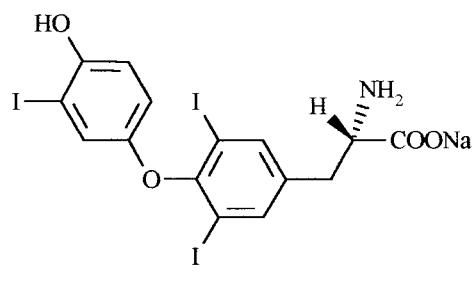
Cortisone

Hydrocortisone

Prednisone

Prednisolone

Triamcinolone acetonide

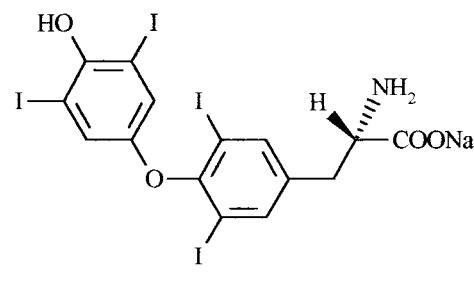
Betamethasone


Dexamethasone

Figure 12-17. Structural formulas of cortisone, hydrocortisone, prednisone, prednisolone, triamcinolone acetonide, betamethasone, and dexamethasone.

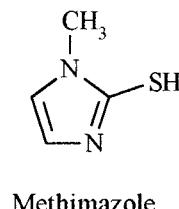
(1) The **oxygen atom at position C-11** is essential for glucocorticoid activity.
(2) A **double bond between positions C-1 and C-2** increases glucocorticoid activity without increasing mineralocorticoid activity as with prednisone (Deltasone) and prednisolone (Delta-Cortef; *Figure 12-17*).
(3) Fluorination at position **C-9 greatly increases both mineralocorticoid** and **glucocorticoid activity**, as with fludrocortisone (*Figure 12-16*); whereas fluorination at position **C-6 increases glucocorticoid activity** with less effect on mineralocorticoid activity (*Figure 12-17*).
(4) A **17α-hydroxyl group** in combination with either a **16α-hydroxyl group** forming an acetonide, as with triamcinolone, or a 16-methyl group, as with betamethasone or dexamethasone, enhances glucocorticoid activity and abolishes mineralocorticoid activity (*Figure 12-17*).

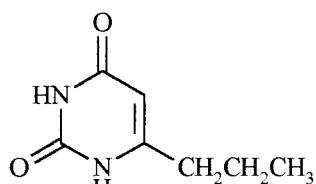
2. The cellular activity of the glucocorticoids is exactly as the mineralocorticoids (see previous section) except they bind to the glucocorticoid receptors. The therapeutic uses of the glucocorticoids include **metabolic**, **anti-inflammatory**, and **immunosuppressive** activities. More specifically, glucocorticoids are useful for the last resort management of severe, disabling arthritis; severe allergic reactions; seasonal allergic rhinitis; bronchial asthma; chronic ulcerative colitis; rheumatic carditis; nephrotic syndrome; collagen vascular disease; cerebral edema; and topically for inflammatory disorders.

3. The adverse effects of the glucocorticoids include **suppression of the pituitary–adrenal axis** that requires dose tapering while withdrawing the drug. **GI effects** are also common adverse effects and may include **peptic ulcer**, **GI hemorrhage**, ulcerative esophagitis, and acute pancreatitis. Characteristic effects of glucocorticoids include **weight gain**, **osteoporosis**, **hyperglycemia**, acne, increased susceptibility to infection, and **cushingoid "moon face"** and **"buffalo hump."** Other adverse effects include headache, vertigo, increased intraocular and intracranial pressures, muscle weakness, psychological disturbances, edema, and hypertension.


V. THYROID HORMONES are responsible for the development and regulation of metabolic homeostasis.

A. **Synthesis** of thyroid hormones is a four-step process beginning with the concentration of iodide in the thyroid gland. The enzyme **iodoperoxidase** then catalyzes steps two and three: iodination of tyrosine residues located on thyroglobulin, a 650,000 Da molecular weight glycoprotein located within the thyroid gland, and coupling of the iodinated tyrosine precursors. Finally, proteolysis of thyroglobulin produces the two naturally occurring thyroid hormones: **thyroxine (levothyroxine; T_4)** and **triiodothyronine (liothyronine; T_3)** in a ratio of 4:1 (*Figure 12-18*).

1. Levothyroxine is **less potent** than liothyronine but possesses a **longer duration of action** (6 to 7 days vs. 1 to 2 days).
2. **Peripheral deiodination** by 5′-deiodinase converts T_4 to T_3.
3. Regulation of thyroid hormone production involves a **hypothalamic-pituitary-thyroid feedback system**. Thyrotropin-releasing hormone (TRH) is secreted by the hypothalamus and stimulates the release of TSH (thyrotropin) from the anterior pituitary. Thyrotropin stimulates the thyroid gland to produce T_4 and T_3. T_3 and T_4 hormones then regulate their own synthesis by binding to specific sites in the anterior pituitary and inhibiting the release of TSH.




Sodium Liothyronine   Sodium Levothyroxine

Figure 12-18. Sodium salt forms of the naturally occurring thyroid hormones, liothyronine (T_3) and levothyroxine (T_4).

B. Various forms of thyroid hormones are used therapeutically including the sodium salts of liothyronine (T_3) and levothyroxine (T_4) either alone or together.

    1. **Thyroid** *USP* or porcine-derived thyroid desiccated (Armour Thyroid) is made from dried, defatted thyroid glands from pigs and is standardized based on iodine content.

    2. **Liotrix** (Thyrolar) is a **4:1 mixture of levothyroxine sodium to liothyronine sodium**, which is equivalent to but offers no advantages over levothyroxine alone.

    3. Administration of **levothyroxine** or T_4 (Synthroid, Levoxyl) alone will produce the natural 4:1 ratio of T_4 to T_3.

    4. **Liothyronine** (T_3, Cytomel, Triostat) has a **rapid onset** and **short duration of action** compared to levothyroxine sodium and may have utility in patients who may be sensitive to the adverse effects of thyroid medication, but the rapid changes in T3 levels may be more of a disadvantage.

C. **Thyroid hormone preparations** mimic the activity of endogenous thyroid hormones. These hormones regulate growth and development, have caloriogenic and metabolic activity, and (through sensitization of the β-adrenergic receptors) have positive inotropic and chronotropic effects on the myocardium. The major indication for the thyroid hormone preparations are **hypothyroidism** (i.e., **myxedema**), myxedema coma, cretinism, and simple goiter. Other indications include endemic goiter and thyrotropin-dependent carcinoma.

D. The adverse effects of the thyroid preparations are rarely observed. An overdose can cause palpitations, nervousness, insomnia, and weight loss.

E. Drug interactions with thyroid hormones

    1. Bile acid sequestrants (BAS), calcium, ferrous sulfate, sucralfate, iron, and aluminum hydroxide antacids **can decrease the absorption of thyroid hormones**. An appropriate solution to this problem is to adequately space the administration of these agents (e.g., take the thyroid hormone 1 hr before or 4 hrs after taking the BAS).

    2. Several drugs, including phenytoin, carbamazepine, and rifampin, accelerate thyroid metabolism. An appropriate solution to this problem is to increase the dose of thyroid hormone.

F. **Thyrotropin** (TSH; Thyrogen) is marketed as a highly purified and lyophilized thyrotropic hormone isolated from bovine anterior pituitary glands and used as an **adjunct in the detection and treatment of thyroid cancer**. Adverse effects associated with thyrotropin include nausea, vomiting, headache, urticaria, anaphylaxis, thyroid gland swelling, transient hypotension, tachycardia, and arrhythmias.

G. **Inhibitors of thyroid function** directly or indirectly interfere with the synthesis of thyroid hormones and have use in the **treatment of hyperthyroid**. These agents include potassium or sodium iodide, radioactive iodine (e.g., $Na^{131}I$ [Hicon]), and the thioamides (e.g., propylthiouracil [PTU; generic], methimazole [Tapazole]; *Figure 12-19*).

    1. **Iodides in high concentrations** (e.g., Lugol's solution) **have profound effects in all aspects of thyroid hormone synthesis, release, and metabolism**. Iodides limit their own transport, inhibit the synthesis of both iodotyrosine and iodothyronine, and most importantly, inhibit the release of thyroid hormones.

        a. **Lugol's solution** is used **before thyroid surgery** to make the thyroid gland firmer and reduce its size.

        b. Adverse effects include **iodism** characterized by increased salivation, brassy taste, sore teeth and gums, swollen eyelids, inflamed larynx and pharynx, frontal headache, skin lesions, and skin eruptions. Hypersensitivity reactions including fever, arthralgia, eosinophilia, and angioedema are also observed. Large doses of iodides given over long periods can cause goiter and hypothyroidism, which can be corrected by the administration of thyroid hormone.

Propylthiouracil (PTU)

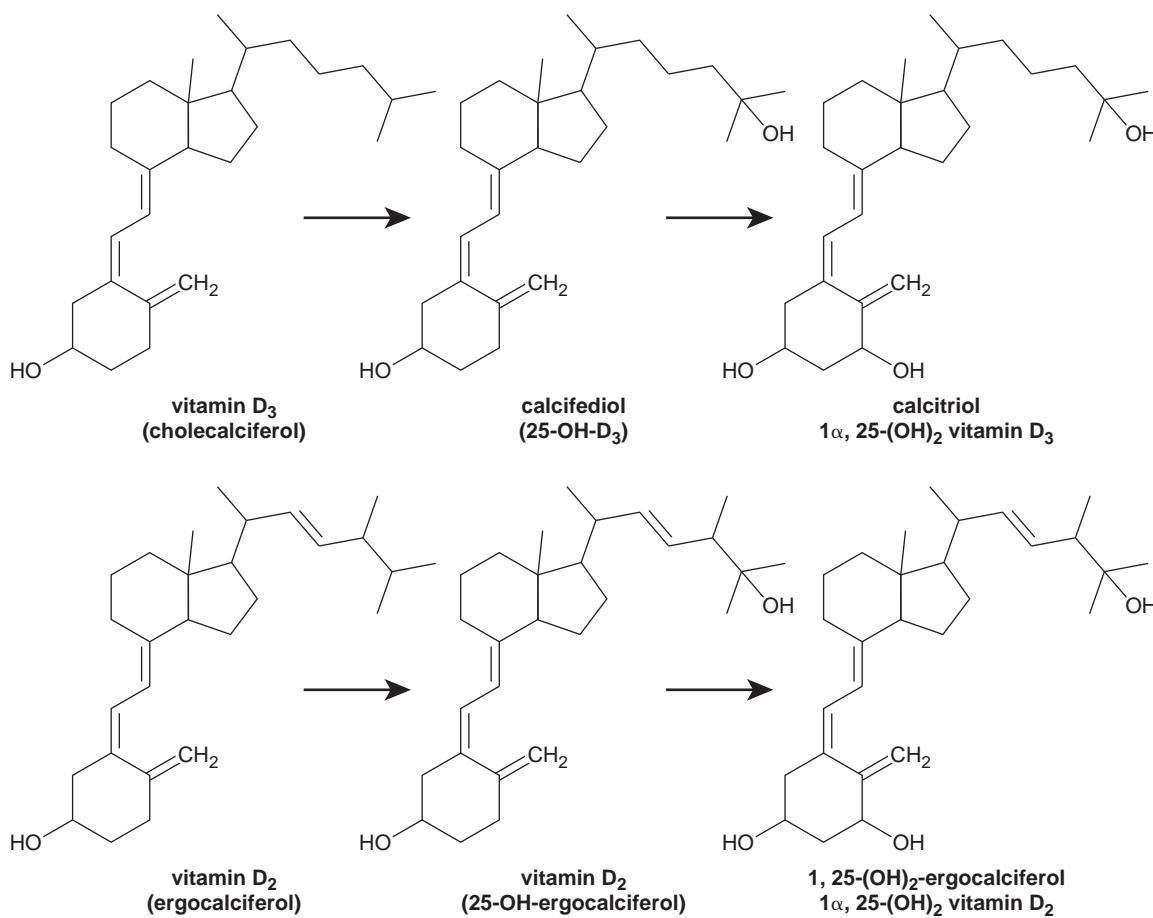
Methimazole


Figure 12-19. Structures of the thiourylene class of antithyroid hormones.

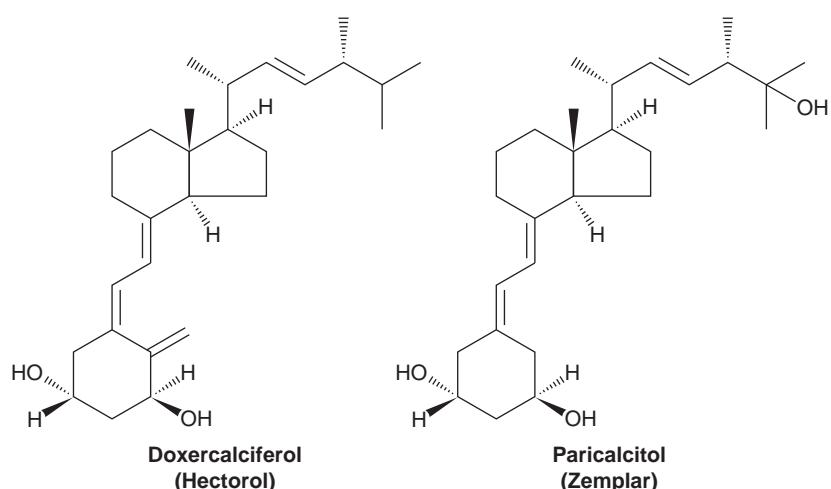
2. **Radioactive iodine** (^{131}I) is administered as a sodium salt, is rapidly trapped by the thyroid gland, and is incorporated into both tyrosine precursors and mature thyroid hormones. **Radioactive β-particle decay produces localized destruction of thyroid cells** and the desired therapeutic effect.

   a. Radioactive iodine is useful, particularly in **treating hyperthyroidism** in older patients and in patients with heart disease.

   b. Because of damage to the thyroid by radioactive iodine, hypothyroidism is a very common adverse effect of radioactive iodine. There is also potential for future offspring of young adults treated with radioactive iodine to have hypothyroid.

3. The **thioamides (i.e., propylthiouracil and methimazole) inhibit the enzyme iodoperoxidase**, thereby inhibiting two crucial steps in thyroid hormone synthesis: the incorporation of iodine into tyrosine precursor molecules and the coupling of iodinated tyrosines to form T_4 and T_3. In addition, **propylthiouracil inhibits the conversion of T_4 to T_3.**

   a. The thioamides are used to control **mild cases of hyperthyroidism**, in conjunction with ^{131}I, and to prepare patients before thyroid surgery. They are less effective in producing permanent remission of Graves disease when used as monotherapy.

   b. Adverse effects of the thioamides include urticarial papular rash, dermatitis, agranulocytosis, thrombocytopenia, granulocytopenia, nausea, vomiting, GI distress, pain stiffness in the joints, headache, and paresthesias. Other rare effects include drug fever, hepatitis, nephritis, and systemic lupus erythematosus–like syndrome.


VI. BONE MINERAL HOMEOSTASIS

A. The management of bone synthesis and remodeling is a complex system that regulates calcium and phosphate absorption from the GI track, secretion from the kidneys, and the storage in the bone. There are **three main hormone regulators of bone and mineral homeostasis: parathyroid hormone (PTH), vitamin D, and fibroblast growth factor 23**. Currently, there are no therapeutic agents that mimic fibroblast growth factor 23 function; however, there are many other targets in bone mineral homeostasis that are pharmacologically modulated by **calcitonin, bisphosphonates, glucocorticoids,** and **estrogen**.

B. PTH is an 84-amino acid protein with the majority of pharmacological activity residing in the N-terminal portion of the protein. PTH **increases serum calcium** (enhances renal retention), **stimulates synthesis of 1,25-dihydroxy vitamin D (1,25[OH]$_2$D)** in the kidney, **decreases serum phosphate**, and **promotes bone formation and resorption**. An excess of PTH results in net bone resorption, whereas low and intermittent doses of PTH stimulate bone formation.

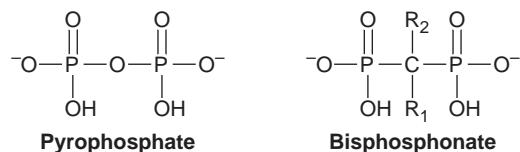
   1. **Teriparatide** (Forteo) is a recombinant protein that is the first 34 N-terminal amino acids of PTH that **retains PTH activity**. Teriparatide is administered by subcutaneous injection and is indicated for the treatment of **osteoporosis**.

   2. Teriparatide is generally well tolerated, but **orthostatic hypotension** can occur within the first several administrations. Teriparatide also carries a black box warning related to observed **osteosarcoma in rats**. Osteosarcoma has not been reported in humans but is still a major concern for which a risk evaluation and mitigation strategy (REMS) has been developed to inform patients of the potential risk.

C. Vitamin D (Vit. D$_3$ or cholecalciferol) is a prodrug produced from 7-dehydrocholesterol in the skin with **exposure to ultraviolet radiation in the form of sunlight**. Vitamin D$_3$ is then hydroxylated in the liver to the 25-hydroxyl vitamin D$_3$ before being converted to the active form, 1,25-dihydroxy vitamin D$_3$ (calcitriol), in the kidney (*Figure 12-20*). The activated form of vitamin D, 1,25(OH)$_2$D, suppresses PTH production, increases calcium and phosphate absorption from the GI track, enhances calcium retention by kidneys, and promotes bone formation and resorption.

   1. Vitamin D has **two very similar forms** that are commercially marketed. The natural form derived from **cholesterol** is **vitamin D$_3$, marketed as cholecalciferol** (various). **Vitamin D$_2$** is an alternative form with equal efficacy to vitamin D$_3$ but **derived from ergosterol** and **marketed as ergocalciferol** (Drisdol; *Figure 12-20*). Other drugs with vitamin D activity include the active vitamin D$_3$ calcitriol (Rocaltrol, injection [Calcijex]), the 1-monohydroxylated form of vitamin D$_2$ doxercalciferol (Hectorol), and a calcitriol analog paricalcitol (Zemplar; *Figure 12-21*).

   2. Vitamin D and its analogs are used to treat or prevent **nutritional rickets**, treat **secondary hypoparathyroidism**, treat or prevent **osteoporosis**, and **treat rickets or osteomalacia in chronic renal failure**.

Figure 12-20. Activation of vitamin D_2 and D_3 to the 25-hydroxylated vitamin D in the liver and the 1,25-dihydroxy ($1\alpha,25$-[OH]$_2$) vitamin D in the kidney.


3. **Hypercalcemia** and **hyperphosphatemia** are the most common adverse effects observed with vitamin D treatment and may be dose limiting.

D. **Calcitonin** is a 32-amino acid peptide with **actions that oppose those of PTH**. Calcitonin **lowers serum calcium and phosphate** by increasing kidney excretion and decreasing osteoclast-mediated bone resorption. The administration of human calcitonin has a very short half-life that makes it impractical for clinical use. **Salmon calcitonin** (nasal [Fortical] or nasal or injection [Miacalcin]) **has a**

Figure 12-21. Vitamin D analogs doxercalciferol and paricalcitol.

> **longer half-life** and therefore is clinically useful in the treatment of **Paget's disease**, **hypercalcemia**, and **osteoporosis**.

E. **Bisphosphonates** are pyrophosphate analogs with a bioisosteric substitution of a carbon in place of an oxygen between the two phosphonate groups (*Figure 12-22*). The net result of this substitution is that bisphosphonates slow the formation and dissolution of hydroxyapatite crystals in the bone and elsewhere in the body by inhibiting the activity of osteoclasts.

1. Alendronate (Fosamax), etidronate (Didronel), ibandronate (Boniva), pamidronate (Aredia), risedronate (Actonel, Atelvia), tiludronate (Skelid), and zoledronic acid (Reclast, Zometa) are marketed bisphosphonates used for the **treatment of hypercalcemia** associated with malignancy, **Paget's disease**, and **osteoporosis**.

2. Bisphosphonates are generally well tolerated but side effects related to their structure and acidic nature include **gastric irritation**, **heartburn**, and **esophageal irritation**. Osteonecrosis of the jaw is rare but has been reported, mostly with the parenteral administration, with bisphosphonates.

F. Other agents that influence bone mineral homeostasis.

1. **Cinacalcet** (Sensipar) is a **calcimimetic drug** that acts as an agonist at the calcium-sensing receptor on the parathyroid gland that regulates PTH secretion. PTH release is inhibited when the calcium-sensing receptor is activated. Cinacalcet is used to treat **hyperparathyroidism secondary to renal failure** and **hypercalcemia caused by parathyroid carcinoma**. Hypocalcemia is the primary adverse effect observed.

Agent name	R_1	R_2
Etidronate	—OH	—CH_3
Tiludronate	—OH	(4-chlorophenyl)—S—
Pamidronate	—$CH_2CH_2NH_2$	—OH
Alendronate	—$CH_2CH_2CH_2NH_2$	—OH
Ibandronate	—CH_2CH_2—N(—CH_3)—$(CH_2)_4$—CH_3	—OH
Risedronate	—CH_2(pyridin-3-yl)	—OH
Zoledronic acid	—CH_2(imidazol-1-yl)	—OH

Figure 12-22. Structures of pyrophosphate and the pyrophosphate analog bisphosphonates.

2. **Denosumab** (Prolia) is a monoclonal antibody that binds the receptor activator of nuclear factor kappa B ligand (RANKL). RANKL binds to osteoclasts to allow proper osteoclast development and activity. With denosumab bound, RANKL cannot stimulate the osteoclasts appropriately, therefore **inhibiting osteoclast activity**.

3. **Glucocorticoids** stimulate the excretion of calcium from the kidney and calcium resorption from bone and decrease calcium absorption from the GI track, and therefore can **precipitate osteoporosis with chronic use**. These effects can be useful in the management of **hypercalcemia** secondary to lymphoma but are more commonly a limitation to long-term use as anti-inflammatory agents.

4. **Estrogens** have use in **slowing postmenopausal bone loss** through a mechanism that is not completely understood. The negative effects of long-term estrogen administration (i.e., breast cancer and cardiovascular events) limit the use of estrogens for the treatment of osteoporosis, but **selective estrogen receptor modulators** (SERMs) such as raloxifene (Evista) have been approved for the treatment of osteoporosis because they are estrogen agonists at the bone but not in breast and uterine tissue. A major side effect of raloxifene is hot flashes that are related to its antiestrogenic activities (see III.B.2.c).

5. **Thiazide diuretics** work at the kidney to **prevent the excretion of calcium** and, as a result, slow bone resorption in the hypercalcemic patient. The thiazides may be more useful in the prevention of the formation of calcium stones in the urine.

VII. ANTIDIABETIC AGENTS.

There are many different treatment options for the management of diabetes, including **insulin replacement** and various other agents that **lower blood glucose** or **increase glucose utilization**.

A. **Parenteral antidiabetic agents**

1. **Insulin** is an endocrine hormone secreted by the β-cells of the pancreas. It is a 51-amino acid protein composed of two polypeptide chains: an A-chain of 21 amino acids and a B-chain of 30 amino acids. Two interchain disulfide bonds connect the A- and B-chains, and a third intrachain disulfide bond is found between Cys6 and Cys11 of the A-chain. Insulin is derived from an 86-amino acid precursor known as proinsulin. At one time, insulin was available as bovine insulin (which differs from human insulin by three amino acids), and porcine insulin (which differs from human insulin only in one terminal amino acid); however, currently, only recombinant human insulin and its analogs are marketed. Exogenous insulin mimics the activity of endogenous insulin, which is required for the **proper use of glucose** in normal metabolism in insulin-sensitive tissues. Insulin monomers interact with a specific cell surface insulin receptor on multiple tissues (i.e., liver, muscle, and adipose tissue) to increase the expression of the GLUT-4 transporter responsible for the transport of glucose into the cells.

    a. **Human insulin** (Novolin, Humulin) is prepared by means of **recombinant DNA technology** using yeast (Novolin) or bacteria (Humulin).

      (1) Various preparations with **differences in their onset, duration, and intensity of action after subcutaneous administration** are manufactured for clinical use. These differences depend on the physical state of the insulin, the zinc content, the nature of the buffer, and the protein content.

      (2) **Regular insulin** (Novolin R, Humulin R) is a soluble insulin prepared at neutral pH. It can be mixed with most other insulins (with the exception of glargine and detemir) and is traditionally the only type of insulin that could be given **intravenously**. Novolog (see VII.A.1.b.[1–2]) is a short-acting, fast onset agent that is also approved for IV administration.

      (3) **Insulin isophane** (Novolin N, Humulin N) is an **intermediate-acting insulin**, which is a combination of recombinant human insulin with protamine (neutral protamine Hagedorn [NPH]) and zinc in stoichiometric amounts. The presence of the protamine enhances the aggregation of the insulin into inactive dimers and hexamers after subcutaneous injection and prolongs its duration of action. In vivo, the dimers and hexamers dissociate to form the active insulin monomers.

    b. Three **analogs of insulin** provide a **shorter onset of activity** (15 to 30 mins) and duration (3 to 4 hrs) than regular insulin due to alteration in the C-terminal of the B-chain responsible for the tendency of insulin to self-associate into hexamers. By hindering the formation

of hexamers, the pharmacologically functional monomer is released more quickly into the circulation. These analogs are used on insulin pumps and can be administered 15 mins before a meal. When compared with regular insulin, these analogs have a lower propensity to cause hypoglycemia, thus reducing the need for snacks between meals.
   (1) **Insulin lispro** (Humalog) differs from normal insulin in that the Lys29 and Pro28 residues of the B-chain are reversed. Insulin lispro is also formulated with protamine (see VII.A.1.a.[3]) and marketed as Humalog Mix 75/25 and Humalog Mix 50/50, which is 75% and 50% insulin lispro protamine, respectively, with the balance being insulin lispro to provide a fast onset and a longer duration of action.

   (2) **Insulin aspart** (NovoLog) differs from normal insulin in that the Pro28 residue of the B-chain is replaced with Asp. Insulin aspart is approved for intravenous administration. Insulin aspart is also formulated with protamine (see VII.A.1.a.[3]) and marketed as Novolog Mix 70/30, which is 70% insulin aspart protamine and 30% insulin aspart to provide a longer duration of action and fast onset, respectively.

   (3) **Insulin glulisine** (Apidra) differs from normal insulin in two ways. First, Asn3 of the B-chain is replaced with Lys, and second, Lys29 of the B-chain is replaced by Glu.

  c. **Long-acting insulin analogs** allow for a once daily administration that produces a constant concentration/time profile that more closely mimics endogenous basal insulin secretion.

   (1) **Insulin glargine** (Lantus) differs from normal insulin in that Gly replaces the Asn21 residue of the A-chain and a basic Arg-Arg dipeptide replaces Thr30 of the B-chain. These structural alterations cause a **decrease in the solubility at physiological pH, precipitation,** and **delayed absorption after subcutaneous injections**, resulting in an increased duration of action for once daily dosing.

   (2) **Insulin detemir** (Levemir) differs from normal insulin in two ways. **A 14-carbon fatty acid (myristic acid)** is covalently bound to Lys29 of the B-chain and Thr30 of the B-chain is removed. In circulation, the myristic acid addition **binds to albumin**, resulting in a longer half-life that mimics endogenous basal insulin secretion.

  d. The various insulin preparations are used to **treat type 1,** or **insulin dependent, diabetes** by replacing insulin not produced by the nonfunctional β-cells of the pancreas. Insulin can also be used to treat type 2, or noninsulin dependent, diabetes that is not adequately controlled by either diet or oral antidiabetic agents. Insulin therapy aims to mimic the natural release of insulin in response to meals. This can be accomplished by administration through continuous infusion pumps with a bolus at meals or multiple daily injections of the different insulin formulations.

  e. The most common adverse effect of insulin is **hypoglycemia**, which is characterized by sweating, tachycardia, and hunger. Severe hypoglycemia can progress to shock with hypoglycemic convulsions or coma. Hypersensitivity reactions and injection site irritation are also reported.

2. **Peptide mimetics** are used as adjunct therapy in combination with either insulin or oral antidiabetic agents to control hyperglycemia.

  a. **Exenatide** (Byetta) is an **incretin mimetic peptide**. **Incretins** are endogenous compounds, such as glucagon-like peptide 1 (GLP-1), that are **released from the stomach** and **improve glycemic control**. Exenatide is isolated from the salivary gland of the lizard *Heloderma suspectum* (Gila monster) and has a **longer duration of action** than endogenous incretins.

   (1) Exenatide binds and **activates the human GLP-1 receptor**. This stimulates glucose-dependent insulin synthesis, **enhances insulin secretion** by the pancreatic β-cells, **suppresses inappropriately elevated glucagon secretion**, and **slows gastric emptying**. These actions improve glycemic control in **type 2 diabetic patients** that are not adequately controlled by other therapies.

   (2) Exenatide is associated with **significant GI side effects** including nausea, vomiting, diarrhea, dyspepsia, and anorexia that are thought to contribute to some of the **weight loss** observed with exenatide treatment. Other adverse effects include hypoglycemia, excessive sweating, asthenia, dizziness, restlessness, and tremors. Additionally, the slowing of gastric emptying by exenatide can decrease the rate and/or extent of oral absorption of other drugs. The coadministration with agents that slow gastric motility (i.e., antimuscarinics) should be avoided.

(3) **Liraglutide** (Victoza) is also a **GLP-1 analog** that has been modified by the **addition of a 16-carbon fatty acid**. The fatty acid addition binds liraglutide to albumin in circulation and slows the metabolism of liraglutide by dipeptidyl peptidase-IV (see VII.B.6). Because the mechanism of action for liraglutide is similar to that of exenatide, the use and side effects are also similar.

b. **Pramlintide** (Symlin) is a synthetic analog of **human amylin**. Amylin is a 37-amino acid neuroendocrine peptide that is secreted by the pancreatic β-cells in response to food intake. Pramlintide contains proline in place of Ala25, Ser28, and Ser29 normally present in amylin. This decreases the viscosity, instability, and aggregation that occur if amylin is placed in solution.

(1) **Amylin** and the amylin analog, pramlintide, **slow gastric emptying** without altering the overall absorption of nutrients. Amylin also **suppresses the postprandial glucagon secretion** and results in a **decreased appetite** and **caloric intake**. Pramlintide is used as an adjunct to mealtime insulin in patients with either type 1 or type 2 diabetes mellitus.

(2) Adverse effects associated with pramlintide include allergic reactions, dizziness, fatigue, headache, abdominal pain, anorexia, nausea, vomiting, arthralgia, cough, and pharyngitis. Because of the slowing of gastric emptying, pramlintide has similar motility concerns as discussed with exenatide.

B. **Oral antidiabetic agents**

1. The **sulfonylureas** are acidic compounds that are divided into first- and second-generation agents based on potency and substitutions on the aromatic ring (*Table 12-1*).

a. Sulfonylureas **block adenosine triphosphate (ATP)-sensitive potassium channels**, which **stimulate the release of insulin from the pancreatic β-cells**. Sulfonylureas are also called **secretagogues** because of their ability to induce insulin secretion. The sulfonylureas may also have a peripheral or extrahepatic activity that results in increased tissue sensitivity to insulin although this is not well established. Because of their activity on the β-cells, the sulfonylureas are used, either alone or in combination with other oral antidiabetic agents, to **treat type 2 diabetes mellitus** that cannot be adequately controlled by diet alone.

b. The sulfonylureas are divided into first- and second-generation agents (see *Table 12-1*).

(1) The first-generation agents are tolbutamide (Orinase), chlorpropamide (Diabinese), tolazamide (Tolinase), and acetohexamide (Dymelor).

(2) The second-generation agents are glyburide (DiaBeta, Micronase), glipizide (Glucotrol), and glimepiride (Amaryl).

c. The sulfonylureas increase the release of insulin regardless of the presence of glucose. As a result of this action, **hypoglycemia**, particularly with longer acting agents (i.e., chlorpropamide) or in patients with renal or hepatic insufficiency, is a significant concern. **Cross-sensitivity (i.e., hypersensitivity) among the sulfonylureas with the benzene sulfonamide functional group found in the sulfonamide antibiotics, thiazide, and loop diuretics is a possibility**. Chlorpropamide can cause hyponatremia due to the potentiation of the effects of antidiuretic hormone. Other potential side effects include blood dyscrasias (i.e., leukopenia, thrombocytopenia, agranulocytosis, and hemolytic anemia), cholestatic jaundice, and GI effects such as nausea, vomiting, diarrhea, and constipation.

d. The sulfonylureas are **highly plasma protein bound** with potential for the drug–drug interactions through plasma protein displacement (e.g., fibrates, sulfonamides). Additionally, drugs that influence cytochrome P450, as either an inhibitor or inducer, can affect the clearance of the sulfonylurea.

2. The **meglitinides** are acidic compounds that act as **secretagogues**.

a. Meglitinides are similar to the sulfonylureas in that they lower blood glucose levels by stimulating the release of insulin by **blocking the ATP-sensitive potassium channels in pancreatic β-cells**. They differ from the sulfonylureas in that they have a **more rapid onset of action and a shorter duration of action**. The meglitinides are indicated for the treatment of **type 2 diabetes** not controlled by diet alone.

b. The meglitinides include repaglinide (Prandin) and nateglinide (Starlix; *Figure 12-23*).

Table 12-1 ORAL HYPOGLYCEMIC AGENTS: THE SULFONYLUREAS

General Sulfonylurea Structure

Drug	R$_1$ Substituent	R$_2$ Substituent
First-generation agents Tolbutamide (Orinase)	CH$_3$	CH$_2$CH$_2$CH$_2$CH$_3$
Chlorpropamide (Diabinese)	Cl	CH$_2$CH$_2$CH$_3$
Tolazamide (Tolinase)	CH$_3$	
Acetohexamide (Dymelor)		
Second-generation agents Glyburide (DiaBeta, Micronase)		
Glipizide (Glucotrol)		
Glimepiride (Amaryl)		

    c. Like the sulfonylureas, the meglitinides are associated with **hypoglycemia**, but because of their short duration of action, the incidence is much lower. Repaglinide is also associated with upper respiratory infection, rhinitis, bronchitis, headache, and back pain.

    d. Like the sulfonylureas, the meglitinides are highly protein bound so the potential for drug displacement exists. Additionally, nateglinide is metabolized by CYP2C9 and CYP3A4, whereas repaglinide is only metabolized by CYP3A4. The potential for drug–drug interactions is possible with agents that affect the activity of CYP2C9 and/or CYP3A4.

3. Biguanides are insulin-sensitizing agents that contain the basic biguanide functional group.

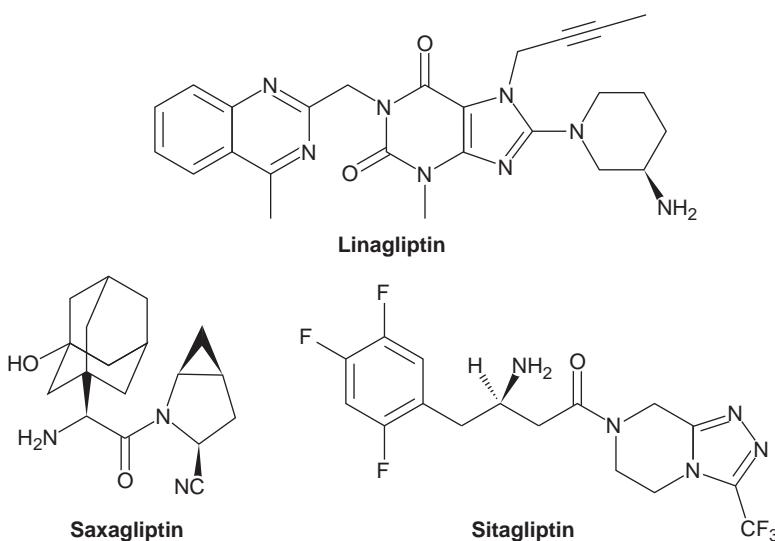
    a. The exact mechanism of action for the biguanides is not known, but they do not stimulate the release of insulin or cause hypoglycemia, and thus are best described as **antihyperglycemic** or **euglycemic agents**. The regulation of blood glucose levels seen with these agents may be due to inhibition of hepatic glucose production by the inhibition of AMP-activated protein kinase.


Figure 12-23. Structures of oral hypoglycemic agents: biguanides (metformin), meglitinides (repaglinide and nateglinide), thiazolidinediones (pioglitazone and rosiglitazone), and α-glucosidase inhibitors (miglitol and acarbose).

The biguanides may also increase tissue insulin sensitivity. Because of these actions, the biguanides are the **first-line therapy for type 2 diabetes**, either alone or in combination with other antidiabetic agents.

b. Phenformin was the originally marketed biguanide, but it was withdrawn from market in 1977 because of a high incidence of **fatal lactic acidosis**. Metformin (Glucophage) is the only biguanide currently marketed (*Figure 12-23*). It is also available in many combination products with sulfonylurea, thiazolidinediones, and DPP4 inhibitors.

c. Adverse effects associated with metformin include epigastric distress, nausea, vomiting, diarrhea, anorexia, and a metallic taste. **Lactic acidosis**, as observed with phenformin, has also been reported with metformin, but occurs with a much lower incidence. Most cases of **metformin-associated lactic acidosis are related to use in patients with contraindications** (i.e., congestive heart failure, hepatic or renal dysfunction) for the use of metformin.

4. The **thiazolidinediones**, or glitazones, are hypoglycemic agents with an acidic 2,4-thiazolidinedione group.
   a. The thiazolidinediones (*Figure 12-23*) act as peroxisome proliferator–activated receptor-gamma (PPAR-γ) agonists. The thiazolidinediones do not stimulate insulin secretion and may be classified as euglycemic agents. The thiazolidinediones act through their binding to the nuclear PPAR-γ because the acidic 2,4-thiazolidinedione group mimics the carboxylate ion of the natural fatty acid PPAR-γ ligands. This PPAR-γ activity stimulates the transcription of insulin-responsive genes and regulates adipocyte differentiation and lipid metabolism. Specifically, they enhance the synthesis and translocation of glucose transporter proteins, enhance insulin sensitivity, and cause a favorable redistribution of fat. These effects decrease insulin resistance and improve target cell response to insulin. These compounds are active only when insulin is present. These actions make the thiazolidinediones useful for the management of **type 2 diabetes** not adequately controlled by diet alone.
   b. Rosiglitazone (Avandia) and pioglitazone (Actos) are currently marketed thiazolidinediones (*Figure 12-23*). Troglitazone (Rezulin) was removed from the market because of rare but severe hepatic toxicity. Rosiglitazone and pioglitazone are also available in various combinations with metformin or glimepiride.
   c. Pioglitazone requires CYP3A4 for oxidative metabolism and, therefore, has possible drug interactions with other compounds that inhibit or induce this isozyme. In addition, pioglitazone can induce CYP3A4 and may decrease the bioavailability of oral contraceptives, and other compounds requiring its activity. In contrast, rosiglitazone is metabolized by CYP2C8 and has no clinically significant drug interactions involving CYP450.
   d. Thiazolidinediones, when used alone, have a **low probability of producing hypoglycemia**. This probability increases when they are used in combination with either insulin or sulfonylureas. Other adverse effects associated with this class of agents include nausea, vomiting, abdominal fullness, epigastric discomfort, diarrhea, weight gain, edema, headache, and upper respiratory infection. There has also been an **increased risk of myocardial ischemic events** (i.e., myocardial infarction, angina), **congestive heart failure**, and increased bone fracture risk in women using thiazolidinediones. As of November 2011, rosiglitazone will only be available for use through a special safety program instituted by the U.S. Food and Drug Administration (FDA) to decrease the risk of myocardial infarction to the patient.

5. **α-Glucosidase inhibitors** are analogs of either monosaccharides or polysaccharides that inhibit the digestion of carbohydrates, especially sucrose, in the small intestine and therefore decrease the postprandial rise in glucose levels.
   a. The α-glucosidase inhibitors **prevent the digestion of complex carbohydrates to absorbable monosaccharides**. This results in lower peaks in blood glucose after a meal. The α-glucosidase inhibitors are indicated for the **treatment of type 2 diabetes mellitus** not controlled by diet alone.
   b. The α-glucosidase inhibitors include miglitol (Glyset) and acarbose (Precose; *Figure 12-23*).
   c. The α-glucosidase inhibitors do not cause hypoglycemia but have been associated with **significant GI distress** as a result of the presence of undigested carbohydrates in the lower GI track. The monosaccharide, miglitol, is better absorbed and produces fewer GI effects than the larger acarbose.

6. **Dipeptidyl peptidase-IV (DPP-4)** inhibitors are basic amine containing peptidomimetic compounds that inhibit the enzyme DPP-4 responsible for inactivating incretin hormones such as GLP-1 (see VII.A.2) and glucose-dependent insulinotropic polypeptide (GIP), as well as other incretins (*Figure 12-24*).
   a. The DPP-4 inhibitors, sitagliptin (Januvia), saxagliptin (Onglyza), and linagliptin (Tradjenta), are indicated as an adjunct to diet and exercise to improve the glycemic control in adults with **type 2 diabetes mellitus**. It should not be used in patients with type 1 diabetes or for the treatment of diabetic ketoacidosis because it is ineffective for these conditions.
   b. Adverse effects of the DDP-4 inhibitors include headache, nasopharyngitis, and upper respiratory tract infections.

Linagliptin

Study Questions

Directions for questions 1–10: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The following structure is a hormone. It would be classified best as

   (A) an estrogen.
   (B) a progestin.
   (C) an androgen.
   (D) a gonadotropin.
   (E) an adrenocorticosteroid.

2. All of the following substances are endogenous tropic hormones secreted by the pituitary gland *except*

   (A) somatotropin.
   (B) human chorionic gonadotropin (hCG).
   (C) follicle-stimulating hormone (FSH).
   (D) thyroid-stimulating hormone (TSH).
   (E) adrenocorticotropic hormone (ACTH).

3. Which of the following substances, when present in urine, is the most likely positive sign of pregnancy?

   (A) thyroid-stimulating hormone (TSH)
   (B) adrenocorticotropic hormone (ACTH)
   (C) human chorionic gonadotropin (hCG)
   (D) interstitial cell-stimulating hormone (ICSH)
   (E) isophane insulin (neutral protamine Hagedorn [NPH])

4. All of the following hormonal drugs possess a steroidal nucleus *except*

   (A) ethinyl estradiol.
   (B) norethindrone.
   (C) liothyronine.
   (D) prednisolone.
   (E) fluoxymesterone.

5. Which of the following glucocorticoids produces the least sodium retention?

   (A) cortisone
   (B) hydrocortisone
   (C) prednisolone
   (D) dexamethasone
   (E) fludrocortisone

6. Which of the following insulins can be administered intravenously?

   (A) regular insulin (Humulin R)
   (B) isophane insulin (neutral protamine Hagedorn; NPH; Humulin N)
   (C) insulin lispromix (Humalog Mix 75/25)
   (D) insulin glargine (Lantus)
   (E) insulin glulisine (Levemir)

7. In comparing levothyroxine to liothyronine, which of the following statements is *not* correct?

    (A) Both levothyroxine and liothyronine are naturally occurring thyroid hormones.
    (B) Liothyronine can be converted in the peripheral circulation to levothyroxine.
    (C) Liothyronine is more potent than levothyroxine.
    (D) The plasma concentration of liothyronine is less than that of levothyroxine.
    (E) Liothyronine has a shorter duration of action than levothyroxine.

8. Which of the following classes of compounds directly stimulates the release of insulin from pancreatic β-cells?

    (A) progestins
    (B) biguanides
    (C) α-glucosidase inhibitors
    (D) DPP-4 inhibitors
    (E) sulfonylureas

9. Which of the following compounds is incorrectly matched with its mechanism of action?

    (A) flutamide: competitively blocks the binding of androgens to their receptor
    (B) finasteride: inhibits 5α-reductase
    (C) miglitol: inhibits α-glucosidase
    (D) pioglitazone: competitively blocks the binding of estrogens to their receptor
    (E) anastrozole: inhibits aromatase

10. Which of the following compounds is incorrectly matched with one of its therapeutic uses?

    (A) raloxifene: ovulation induction
    (B) metformin: type 2 diabetes mellitus
    (C) finasteride: benign prostatic hyperplasia
    (D) propylthiouracil: hyperthyroidism
    (E) tamoxifen: estrogen-dependent breast cancer

11. Which of the following compounds would be most likely to cause hypoglycemia?

    (A) miglitol (Glyset)
    (B) metformin (Glucophage)
    (C) pioglitazone (Actos)
    (D) sitagliptin (Januvia)
    (E) glipizide (Glucotrol)

12. Which of the following compounds has a mechanism of action most similar to exenatide (Byetta)?

    (A) insulin (Humulin R)
    (B) saxagliptin (Onglyza)
    (C) pramlintide (Symlin)
    (D) repaglinide (Prandin)
    (E) metformin (Glucophage)

13. Anastrozole (Arimidex) as to aromatase as _____ is to 5α-reductase.

    (A) flutamide (Eulexin)
    (B) tamoxifen (Nolvadex)
    (C) mifepristone (Mifeprex)
    (D) finasteride (Proscar)
    (E) testosterone

14. All of the following can be used to treat hypothyroid *except*

    (A) thyroid USP (Armour Thyroid).
    (B) liotrix (Thyrolar).
    (C) methimazole (Tapazole).
    (D) levothyroxine (Synthroid).
    (E) liothyronine (Cytomel).

Directions for questions 15–17: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E.**

    A if **I only** is correct
    B if **III only** is correct
    C if **I and II** are correct
    D if **II and III** are correct
    E if **I, II, and III** are correct

15. Hormones that form lipophilic esters without prior structural modifications include

    I. hydrocortisone.
    II. testosterone.
    III. progesterone.

16. Insulin preparations that contain a modifying protein include

    I. insulin glargine.
    II. regular insulin.
    III. isophane insulin (neutral protamine Hagedorn [NPH]).

17. Agents used to treat hypercalcemia include

    I vitamin D.
    II calcitonin.
    III aledronate.

Directions for questions 18–20: Each statement in this section is most closely related to **one** of the following hormones. The hormones may be used more than once or not at all. Choose the **best** answer, **A–E.**

    A Testosterone
    B Insulin
    C Corticotropin
    D Estradiol
    E Vasopressin

18. Secreted by pancreatic β-cells to facilitate glucose and amino acid transport for normal cellular metabolic processes.

19. Initiates and controls male sexual development and maintains the integrity of the male reproductive system.

20. Promotes the reabsorption of water at the renal collecting tubule.

Directions for questions 21–23: Each statement in this section is most closely related to **one** of the following drug classes. The drug classes may be used more than once or not at all. Choose the **best** answer, **A–E.**

    A   Antithyroid agents
    B   Sulfonylureas
    C   Adrenocorticosteroids
    D   Progestins
    E   Androgens

21. Peptic ulceration and gastrointestinal hemorrhage; hyperglycemia, hypertension, and edema; "buffalo hump" and "moon face"; psychological disturbances; and increased susceptibility to infection

22. Agranulocytosis and other blood dyscrasias, cholestatic jaundice, nausea and vomiting, hypoglycemia, and hypersensitivity reactions

23. Rare adverse effects include drug fever, hepatitis, nephritis, and systemic lupus erythematosus–like syndrome.

Answers and Explanations

1. **The answer is A** *[see III.A.1; Figure 12-2].*
Ring A is aromatic. Because the only type of steroidal hormone that has an aromatic A-ring is an estrogen, this structure represents an estrogen. Other structural characteristics of estrogens include the fact that the structure contains 18 carbon atoms; thus it is an estrane and contains a β-alcohol group in position 17.

2. **The answer is B** *[see II.B.1–4].*
hCG is produced by placental tissue and serves to stimulate the secretion of progesterone during pregnancy. Growth hormone (somatotropin), FSH, TSH, and ACTH are all secreted by the anterior pituitary gland.

3. **The answer is C** *[see II.B.4.c].*
hCG is a proteinaceous tropic hormone that is secreted by chorionic (e.g., placental) tissue. Thus, hCG is present in the urine only after conception has occurred.

4. **The answer is C** *[see III.A.1; III.D.1; III.F.2; IV.B.1.b.(2); Figures 12-12, 12-17, and 12-18].*
Liothyronine is a thyroid hormone. Thyroid hormones consist of iodinated aromatic amino acids and are not steroidal in nature. Ethinyl estradiol is a steroidal estrogen, norethindrone is a steroidal 19-norprogestin, prednisolone is an adrenocorticosteroid, and fluoxymesterone is a steroidal androgen.

5. **The answer is D** *[see IV.B.1.b.(4); Figure 12-17].*
Glucocorticoids have varying degrees of mineralocorticoid activity. This mineralocorticoid activity, which can result in sodium and fluid retention, can be blocked by the introduction of a methyl or hydroxyl group in position 16 of the steroidal nucleus. Dexamethasone has a 16α-methyl substituent.

6. **The answer is A** *[see VII.A.1.a.(2)].*
Most insulin preparations are suspensions; thus, they contain particulate matter. Only clear solutions may be administered intravenously. Regular insulin, which consists of water-soluble crystalline zinc insulin, is therefore suitable for intravenous administration. Insulin aspart (Novolog) is also approved for intravenous administration. All other insulin preparations are normally injected subcutaneously.

7. **The answer is B** *[see V.A.1].*
The thyroid gland produces both levothyroxine (T_4) and liothyronine (T_3). The natural ratio of these compounds is 4:1 in favor of levothyroxine; therefore, liothyronine is normally present at a lower concentration than levothyroxine. Liothyronine is more potent than levothyroxine, but has a shorter duration of action. Peripheral conversion involves deiodination; thus, levothyroxine is converted to liothyronine. The reverse process is not possible.

8. **The answer is E** *[see VII.B.1.a; VII.B.3.a; VII.B.5.a; VII.B.6.a].*
Of the five classes of compounds listed, only biguanides, α-glucosidase inhibitors, and sulfonylureas are used in the treatment of type 2 diabetes mellitus. These classes provide their beneficial effects through different mechanisms of action. Biguanides enhance the peripheral use of insulin, suppress gluconeogenesis, and are often referred to as antihyperglycemic agents. α-Glucosidase inhibitors decrease the absorption of glucose. Sulfonylureas and the structurally unrelated compounds, repaglinide and nateglinide, stimulate the secretion of insulin from pancreatic β-cells.

9. **The answer is D** *[see III.C.1; III.G.2; III.H.1; VII.B.4.a; VII.B.5]*.

Pioglitazone does not interact with estrogen receptors. It is an oral antidiabetic agent that produces its effects by binding to nuclear PPARs involved in transcription of insulin-responsive genes and in regulation of adipocyte differentiation and lipid metabolism. The other four agents are correctly matched to their mechanisms.

10. **The answer is A** *[see III.B.2.a–c; III.H.1; V.G.3; VI.F.4; VII.B.3.a–b]*.

Raloxifene is a SERM and is not used to treat ovulation induction. Clomiphene is currently the only antiestrogen that is approved for the induction of ovulation in women who have ovulation failure. Instead, because of its ability to reduce bone resorption and decrease bone turnover, it is used for the prevention of osteoporosis. All of the other four compounds are correctly matched to their therapeutic use. Finasteride is also used to treat androgenic alopecia.

11. **The answer is E** *[see VII.B.1.c, 3.c, 4.c, 5.b, and 6.b]*.

Of all the oral antidiabetics listed, only glipizide, a sulfonylurea, directly stimulates the release of insulin to cause hypoglycemia. The other agents are frequently classified as euglycemic agents (i.e., miglitol, sitagliptin) or insulin sensitizers (i.e., metformin, pioglitazone) that do not frequently cause hypoglycemia.

12. **The answer is B** *[see VII.A.2.a; VII.B.6]*.

Exenatide (Byetta) is an analog of the incretin GLP-1, whereas saxagliptin (Onglyza) is an inhibitor of DDP4 that is responsible for the metabolism of endogenous GLP-1. Each of the other agents has a mechanism of action that does not directly influence the activity or duration of action of the incretins.

13. **The answer is D** *[see III.C.1; III.H.1]*.

Anastrozole inhibits the enzyme aromatase responsible for the synthesis of estrogen. Finasteride inhibits the enzyme 5α-reductase, which is responsible for the conversion of testosterone to DHT. The other agents are receptor antagonists (flutamide, tamoxifen, and mifepristone) or natural agonists (testosterone).

14. **The answer is C** *[see V.B.1–4; V.G.3.a]*.

Methimazole is a thioamide that inhibits the synthesis of thyroid hormones and therefore would not be useful in the treatment of hypothyroid. Thyroid USP, litrix, levothyroxine, and liothyronine are various forms of the two thyroid hormones (T_4 and T_3) that can decrease the symptoms of hypothyroid.

15. **The answer is C (I, II)** *[see Figures 12-7, 12-12, and 12-17]*.

Hydrocortisone has a 21-hydroxyl group, and testosterone has a 17-hydroxyl group; therefore, both of these agents can form esters (e.g., hydrocortisone acetate, testosterone propionate). Progesterone does not have any alcohol groups in its molecule; therefore, it cannot directly form any esters.

16. **The answer is B (III)** *[see VII.A.1.a.(3)]*.

Regular insulin, which is a rapid-acting insulin preparation, contains only zinc insulin crystals. Insulin glargine is a synthetic insulin that has been structurally altered at two sites. The structural alterations cause a decreased solubility and an increased duration of action; however, no protein modifiers are added to this preparation. NPH insulin contains protamine, a strongly basic protein. The protamine reduces the water solubility of zinc insulin and lengthens its duration of action. Isophane insulin is classified as an intermediate-acting insulin preparation, having a duration of action of about 24 hrs.

17. **The answer is D (II, III)** *[see VI.C.3; VI.D; VI.E.1]*.

A common side effect of vitamin D is hypercalcemia due to increased calcium absorption from the GI track and increased calcium retention from the kidney. Calcitonin can be used to treat hypercalcemia because it increases the renal excretion of calcium. Aledronate decreases the resorption of bone calcium, which is useful in the treatment of hypercalcemia.

18. **The answer is B** *[see VI.A.1]*.

19. **The answer is A** *[see III.F]*.

20. **The answer is E** *[see II.A.2]*.

Insulin is required for the proper use of glucose and the transport of glucose and amino acids across cell membranes. Testosterone, which is produced principally from the Leydig cells of the testes, is responsible for male sexual characteristics. Vasopressin is secreted from the posterior pituitary and is sometimes referred to as an antidiuretic hormone.

21. **The answer is C** *[see IV.B.3]*.

22. **The answer is B** *[see VII.B.1.c]*.

23. **The answer is A** *[see V.G.3.b]*.

Exogenously administered adrenocorticosteroids are effective anti-inflammatory agents but give rise to a wide range of metabolic and immunosuppressive effects that result in severe adverse effects. Sulfonylureas are oral antidiabetic agents and can cause blood dyscrasias, impaired liver function, nausea/vomiting, hypoglycemia, and hypersensitivity reactions. The antithyroid agents are associated with rare adverse effects, including drug fever, hepatitis, nephritis, and systemic lupus erythematosus–like syndrome.

Drug–Drug and Drug–Nutrient Interactions

ALICE C. ENGELBRECHT, LEON SHARGEL

I. INTRODUCTION

- **A. Definition of drug interaction**
  1. **Drug interaction** refers to an **altered** drug response produced by the administration of a drug or coexposure of the drug with another substance, which modifies the patient's response to the drug.
     - **a.** Some drug interactions are intentional to improve therapeutic response. For example, probenecid increases the plasma drug concentration of penicillin by decreasing its renal excretion.
     - **b.** Some drug interactions are intentionally used to decrease potential adverse drug reactions. For example, a combination of pentazocine and naloxone (Talwin NX) incorporates an opioid agonist to decrease pain and naloxone, an opioid antagonist to prevent drug abuse.
  2. A **precipitant** drug is the drug, chemical, or food element causing the interaction.
  3. An **object** drug is the drug affected by the interaction.
  4. Drug interactions include the following:
     - **a. Drug–drug** interactions
     - **b. Drug–herbal** interactions
     - **c. Drug–food/alcohol** interactions
     - **d. Drug–chemical** interactions, such as the interaction of a drug with a compounding agent. An example of this is the potential chelation and precipitation of calcium and phosphorous salts in the compounding of total parenteral nutrition (TPN). These types of nonclinical interactions will not be discussed in this chapter.
     - **e. Drug–laboratory test interactions** such as chemical interactions causing false laboratory values. An example of this type of interaction is ibuprofen causing false positive marijuana/cannabis on some enzyme multiplied immunoassay technique (EMIT) assays. Another example is telavancin falsely increasing the values of coagulation tests international normalized ratio (INR), partial thromboplastin time (PTT), activated partial thromboplastin time (aPTT), and coagulation-based factor Xa for patients on warfarin and factor Xa anticoagulants. Although these interactions may have clinical implications if they are not taken into account, they will not be discussed in this chapter, which will focus on clinical implications of drug interactions.
- **B. Classification of drug interactions.** Drug interactions that occur *in vivo* are generally classified as **pharmacokinetic** or **pharmacodynamic** interactions.
  1. **Pharmacokinetic** or **biopharmaceutical** interactions occur when the absorption, distribution (protein and tissue binding), metabolism, or elimination of the drug is affected by another drug, chemical, or food element. **Pharmacogenetic** interactions occur when the pharmacokinetic disposition of the drug is altered by genetic polymorphisms in affecting processes. The changes in the concentration of the object drug changes the therapeutic effect of the drug.

2. **Pharmacodynamic** interactions occur when the pharmacodynamic effect of the drug is altered by another drug, chemical, or food element, producing an antagonistic, synergistic, or additive effect.

3. **Pharmaceutical** interactions are caused by a chemical or physical incompatibility when two or more drugs are mixed together. Pharmaceutical interactions can occur during extemporaneous compounding of drugs, including the preparation of intravenous (IV) solutions. For example, an IV solution of sodium bicarbonate has an alkaline pH and should not be mixed with such drugs as dobutamine, ciprofloxacin, or magnesium sulfate, which decompose or precipitate in alkaline pH. Phenytoin sodium will precipitate from a solution that has an acid pH, such as dextrose 5%. Pharmaceutical interactions are usually considered during the development, manufacturing, and marketing of the drug product. Only drug interactions involving pharmacokinetic, pharmacodynamic, or pharmacogenetic processes will be considered in this chapter.

II. PHARMACOKINETIC INTERACTIONS

A. **Gastrointestinal absorption.** Drug interactions can affect the **rate** and the **extent** of systemic drug absorption (bioavailability) from the absorption site, resulting in increased or decreased drug bioavailability. Most drugs are given orally with drug absorption from the gastrointestinal (GI) tract. Additional sites of absorption drug interactions include skin, lung, nasal, and sublingual areas.

1. **Changes in gastric pH** can increase or decrease GI drug absorption in several different ways depending on the formulation of the drug and whether the drug is a weak electrolyte (e.g., weak base or weak acid).

   a. Agents, which decrease in gastric pH, include certain acidic foods, such as fruit juices, and drugs, such as aspirin and ascorbic acid. Weak acid drugs are less ionized in an acidic environment, becoming more lipid soluble, resulting in an increased absorption from the stomach. Examples include aspirin, the combination of aspirin/dipyridamole, diazepam, and furosemide.

      (1) Drugs, which are weak bases, have enhanced absorption in an alkaline or more neutral stomach environment, such as indomethacin and tetracycline.

      (2) An acid environment, which can develop when eating or when acidic drugs such as ascorbic acid are taken, can cause increased absorption of weak acid drugs such as aspirin or dipyridamole.

   b. Increasing gastric pH produces a more basic stomach environment, which enhances absorption of weak bases and impairs absorption of acidic drugs. Drugs such as antacids and bicarbonate salts increase the gastric pH. In addition, proton pump inhibitors such as omeprazole (Prilosec) will also increase gastric pH. Enteric drug products are formulated with coatings that maintain integrity in an acid environment of the stomach, and then dissolve in the more alkaline environment of the duodenum, releasing the drug. If the gastric pH is increased, the coating dissolves in the stomach rather than the duodenum and the drug is released in the stomach. Some enteric-coated drugs such as aspirin and diclofenac are highly irritating to the stomach linings if the coat is removed in the stomach.

2. **Complexation and chelation** of drugs can cause precipitation of a drug and prevent absorption. Complexation, or binding of a drug, can cause the drug, though not chelated, to be poorly absorbed as it moves through the GI tract.

   a. Chelation of a drug is a form of complexation in which a molecule or atom is trapped in a second molecule. Insoluble chelates such as a calcium-tetracycline complex are not well absorbed. Examples of chelation include calcium, magnesium, aluminum, or iron preparations given with fluoroquinolones or tetracycline. Milk is a source of calcium. Other common divalent anions are in antacids and vitamins/mineral combinations and iron supplementation.

   b. Resins, binders, and certain fiber products can bind various drugs and reduce their absorption. Resins such as cholestyramine, which binds bile, can also bind digoxin and warfarin, reducing the bioavailability of these drugs. Sodium polystyrene sulfonate also binds cations in antacids causing reduced renal clearance of bicarbonate, resulting in systemic acidosis. Fiber products such as Metamucil, which are used to treat constipation, can cause binding of warfarin, digoxin, and salicylates.

    c. Activated charcoal is specifically formulated to adsorb various drugs to prevent absorption of the drug and reduce the risk of toxicity in overdose. Activated charcoal does not adsorb simple chemical compounds such as iron sulfate.

    d. Sevelamer, which binds dietary phosphates, is also known to bind ciprofloxacin and levothyroxine.

3. **Increased GI motility** reduces drug residence time or the amount of time spent in the optimal environment for absorption of particular drugs.

    a. Drugs that increase GI motility include laxatives and cathartics such as bisacodyl, cascara, senna laxatives, and sorbitol.

    b. Psyllium and fiber taken with sufficient fluid can also cause an increase in GI motility and decrease the time available for coadministered drugs to be absorbed.

    c. Drugs that are specifically developed to pharmacologically stimulate the GI tract can also reduce the time available for absorption of coadministered drugs. These include tegaserod (a 5HT-partial antagonist available for compassionate use through the U.S. Food and Drugs Administration [FDA]), methylnaltrexone (opioid antagonist in the GI tract only), alvimopan (peripheral mu-opioid antagonist), metoclopramide, erythromycin, and cisapride (a prokinetic available by a registration system by the FDA).

4. **Decreased GI motility** increases the time a drug spends in its absorptive environment, which can lead to excessive absorption and toxicity, including local irritation to the GI mucosal cells or possible disruption to flora in the large bowel.

    a. Drugs that show anticholinergic activity and slow GI transit include diphenhydramine, hyoscyamine, tricyclic antidepressants, propantheline, and opioid narcotics.

5. **Alteration of intestinal flora** can change the availability of drugs by metabolism that takes place in the GI tract itself. Flora metabolize various drugs that have metabolites that are absorbed and are pharmacologically active. Flora also metabolize drugs into inactive metabolites, reducing the amount of parent drug available, or by metabolizing enterohepatically circulated drugs into inactive compounds. Disruptions in flora change the amounts of drug available.

    a. Decrease in intestinal flora usually occurs as a result of antibiotic treatment. Bacterial flora are the prime metabolizers of several drugs. Colonic cleansing may also reduce intestinal flora, causing GI distress such as diarrhea.

    b. Drugs that are metabolized in the GI by intestinal flora include estrogen contraceptives, which are metabolized to active metabolites. The reduction of GI flora could result in contraceptive failure. Digoxin is metabolized by bacterium into inactive metabolites. Coadministration of antibiotics can cause an increase in digoxin levels.

    c. Antibiotics can also reduce the GI flora, which synthesize vitamin K. Reduction of GI flora by antibiotics can result in too little vitamin K off-setting warfarin therapy, resulting in excessive anticoagulation.

6. **Competition for P-glycoprotein efflux pumps (P-GP)** affects enterohepatic circulation. The pumps, or "transporter proteins," can be activated or inactivated (induced or inhibited) in much the same way CYP450 isoenzymes can be induced or inhibited. If the pumps are inhibited, the systemic circulation of the substrate drug can increase as therapy is continued and elimination is reduced, and toxicity could result. If the pumps are induced, the systemic circulation of the substrate drug is increased and systemic levels of the substrate are decreased, which could lead to subtherapeutic levels. These pumps are located in both the lumen of the GI system and in the renal system.

    a. Known substrates of the P-GP efflux pumps include digoxin and linezolid.

    b. Known inhibitors of the P-GP efflux pumps include erythromycin, itraconazole, cyclosporin, ritonavir, verapamil, ketoconazole, amiodarone, and clarithromycin.

    c. Known inducers of the P-GP efflux pumps include rifampin and St. John's wort.

7. **Ethanol-induced "dose dumping" syndrome** affects the bioavailability of drugs in delayed-distribution or extended-release formulation. Studies involving coadministered ethanol in strengths of 40% and 20% lead to an increase in C_{max} of fivefold and twofold, respectively. The primary mechanism leading to the increase in therapeutic drug relates to the drug dissolution characteristics in ethanol.

    a. An FDA study reported a 16-fold increase in average peak hydromorphone concentration from a modified-release preparation when ingested with 40% ethanol as compared to water. A similar effect has been described with the coadministration of ethanol and controlled-released diazepam.

    b. The effect is similar to food-induced "dose dumping" caused by the effect of food on pH or on the drug itself. Enteric-coated products are sensitive to pH, and a high gastric pH due to food or due to a drug such as omeprazole can disrupt the enteric coating, causing rapid release of the drug. Similarly, the sustained-release mechanism may be compromised, causing the immediate release of the entire drug amount in the dosage form. This has been observed in sustained-release theophylline, and has resulted in guidance by the FDA on drug delivery design.

    c. In the absence of consistent FDA guidance, concomitant ethanol ingestion should be discouraged because it may result in "dose dumping" syndrome and toxicity.

  8. **Alteration of intestinal blood flow** caused by the precipitant drug. In congestive heart disease, the blood flow to the GI tract is poor and an orally administered drug can have a slower rate of absorption. After digoxin therapy, the perfusion of the GI tract is improved along with bioavailability of the object drug.

B. **Transdermal absorption**

  1. Transdermal medications are formulated for absorption through the hydrophobic and hydrophilic layers of the skin. The vehicle chosen determines the best placement of the drug on the skin—considering the pharmacokinetic properties of the vehicle.

  2. Alterations in blood flow to the area of application can change the amount and extent of drug absorption.

    a. Vasoconstrictors such as epinephrine can decrease blood flow to the area. In combination with lidocaine, this allows local anesthesia with minimal bleeding and without systemic absorption of the lidocaine while repairing a skin wound.

    b. Vasodilators such as irritants like menthol creams, or local application of heat can increase blood flow to the area and increase drug absorption. This can result in toxicity if the dosage form is a controlled-release fentanyl or morphine patch.

C. **Pulmonary absorption**

  1. Drug delivery by inhalation or by nebulizer is becoming more common. Drugs that inhibit lung absorption can theoretically reduce the amount of drug absorbed. Drugs that are bronchodilators may enhance absorption. Drugs that affect viscosity of pulmonary fluids can inhibit or block pulmonary absorption of the therapeutic drug. Vehicles for the nebulized drugs can influence the depth of penetration of the therapeutic drug into the pulmonary tree. The order in which several nebulized drugs are given can affect the absorption extent of the therapeutic drugs. For example, a nebulized bronchodilator dose theoretically may enhance penetration and absorption of a nebulized dose of morphine.

D. **Distribution.** Distribution can be affected by various protein cells in the body that are used for transportation, efflux and influx, and storage. Some of these glycoproteins are also thought to be involved in limited drug metabolism. Drugs that are highly bound (> 70%) to a carrier protein can be displaced if the second drug introduced has a higher binding affinity to the carrier protein.

  1. The following conditions must apply if a drug is to be displaced from its carrier protein by another drug.

    a. The displaced drug must be highly protein bound, greater than 90%.

    b. The drug has very potent pharmacodynamic activity (e.g., warfarin).

    c. Both drugs must bind to a common binding site.

    d. The displacing drug must have a higher affinity for the binding site than the drug being displaced—or the free concentration of the displacing drug must be higher than that of the drug being displaced.

      (1) **Albumin** is quantitatively the primary protein in the serum. It is the major binder and transporter for many drugs. It is synthesized by the liver and the concentration in blood is affected by various diseases, including hepatic and renal disease. If the concentration of serum albumin is substantially decreased, the concentration of "free" drug may increase multiple-fold, resulting in an adverse response.

        (a) Albumin is basic and binds primarily acidic and neutral drugs. Drugs that are highly bound to albumin include warfarin, salicylates, digoxin, fluoxetine, ibuprofen, citalopram, ketoconazole, phenytoin, prednisolone, and nafcillin.

      (2) **Alpha-1 acid glycoprotein (AAG)** is a carrier protein that circulates in the plasma. AAG is a carrier of basic and neutrally charged lipophilic molecules such as carbamazepine, lidocaine, lopinavir, methadone, prazosin, quinine, cocaine, and erythromycin.

(3) Organic anion transporting polypeptides (OATPs) are a family of proteins that provide membrane influx transport for anionic drugs across various tissues. Some of these influx transporters provide uptake through hepatocyte membranes, providing access for liver metabolism of substrate drugs. The extent to which drugs interact with particular OATP transporters depends on the physiochemical properties of the substrate and the size, lipophilicity, and degree of ionization of the drugs. Pharmacogenetic polymorphisms (genetic variabilities) can affect the extent of activity of these transporters in much the same way they affect the activity of CYP450 isoenzymes.

   (a) OATPs are a family of 11 membrane influx transporters that regulate uptake for substrates into cells.

   (b) OATP transporters can be in limited distribution, such as OATP4C1 being limited to the kidney, or may be found in tissues throughout the body. These tissues include hepatic, brain, kidney, intestinal, and skin tissues, among other sites. The most significant of these in terms of drug interactions are

   OATP1A2 distributes to brain, kidney, liver, intestines;

   OATP1B1 distributes to the liver;

   OATP1B3 distributes to the liver;

   OATP2B1 distributes to the liver, placenta, intestines, heart, and skin.

   (c) Drugs that are substrates for the OATP transport proteins can also be substrates for other metabolic processes, so determining the exact drug–drug interaction site among involved proteins and enzymes can be difficult (*Table 13-1*).

E. Drug elimination and clearance

   1. Drug metabolism and hepatic clearance

   a. Drug metabolism (hepatic clearance) can be affected by enzyme induction, enzyme inhibition, substrate competition for the same enzyme, and changes in hepatic blood flow (*Table 13-2*).

   b. Many drugs that share the same drug-metabolizing enzymes have a potential for a drug interaction. For example, fluconazole inhibits the hepatic metabolism of warfarin, causing increased risk of bleeding. Carbamazepine is both a substrate and an inducer of the CYP3A4 isoenzyme, thereby inducing its own metabolism and taking 3 to 5 weeks to reach stable blood levels. (*Table 13-3*). Phenytoin is also a substrate of the CYP3A4 and induces its own metabolism.

   c. Over-the-counter (OTC) drugs and herbal preparations can also be involved in CYP450 isoenzyme metabolism and can cause serious drug–herbal interactions. For example, St. John's wort may induce CYP3A4 isoenzymes and decrease cyclosporine to subtherapeutic levels. Tobacco use (smoking) can induce the CYP1A2 isoenzyme and decrease clozapine levels, increasing the risk of therapeutic failure in treating obsessive–compulsive disorder (OCD).

   d. Foods may also interfere with hepatic drug metabolism. For example, grapefruit juice is a powerful inhibitor of the CYP3A4 isoenzyme and will increase blood levels of CYP3A4 substrates such as ritonavir, methadone, amlodipine, alprazolam, cyclosporine, and diltiazem if taken together. Apple juice and orange juice are also implicated in inhibiting function of OATP transporter proteins.

| **Table 13-1** | OATP TRANSPORTER DRUG–DRUG INTERACTIONS |

OATP	Inhibitors	Substrates
OATP1B1	Carbamazepine, caspofungin clarithromycin, digoxin erythromycin, ketoconazole statins, tacrolimus, methotrexate, rifampicin sildenafil, valsartan cyclosporine, gemfibrozil	Bile acids, conjugated steroids, statins, ACE inhibitors, angiotensin II receptor blockers, caspofungin, repaglinide
OATP1A2	Apple, grapefruit, and orange juices; rifampicin; verapamil	Erythromycin, levofloxacin, imatinib levofloxacin, rocuronium, saquinavir
OATP1B3	Clarithromycin, cyclosporine erythromycin, rifampicin	Digoxin, docetaxel, statins, thyroxine valsartan, erythromycin, enalapril
OATP2B1	Cyclosporine, gemfibrozil	Statins, benzylpenicillin, bosentan fexofenadine

ACE, angiotensin-converting enzyme.

Table 13-2   DRUG INTERACTIONS THAT AFFECT THE DRUG METABOLISM

Drug Interaction	Examples (Precipitant Drugs)	Effect (Objective Drugs)
Enzyme induction		
	Smoking (polycyclic aromatic hydrocarbons)	Smoking increases duloxetine metabolism and decreases duloxetine levels
	Phenytoin	Tacrolimus levels are decreased because of increased metabolism
Enzyme inhibition		
Mixed function oxidase	Cimetidine	Decreased atorvastatin clearance and increased drug levels
Induction of UDP-G metabolism	Phenytoin, cimetidine, midazolam, rifabutin	Decreased posaconazole levels due to induction of metabolism
Nonhepatic enzymes	Monoamine oxidase inhibitors (MAOIs) (e.g., pargyline, tranylcypromine)	Serious hypertensive crisis can occur following ingestion of foods with a high content of tyramine or other pressor substances (e.g., cheddar cheese, red wines, avocados) and catecholamines
Inhibition of drug metabolism by intestinal cells	MAOIs such as phenelzine and tranylcypromine	MAOIs inhibit metabolism of albuterol and levalbuterol, leading to hypertension
Alteration of intestinal flora	Antibiotics	Digoxin has better bioavailability when taken after erythromycin. Erythromycin administration reduces bacterial inactivation of digoxin. Estrogen/progestin birth control requires intestinal flora to facilitate enterohepatic circulation. Antibiotics reduce intestinal flora and reduce estrogen/progestin levels, resulting in failure of ovulation suppression and menstrual changes.

MAOIs, monoamine oxidase inhibitors; *UDP-G*, Uridine 5'-diphosphate glucose.

    e. Nonhepatic enzymes can be involved in drug interactions. For example, *serotonin syndrome* has been reported in patients receiving antidepressants such as amitriptyline or citalopram (a selective serotonin reuptake inhibitor [SSRI]) in combination with a monoamine oxidase inhibitor (MAOI), such as linezolid. A considerable portion of the CYP3A4 enzymes are found not only in the liver but also in the GI tract, where some of these substrates are metabolized.

    f. A decrease in the hepatic blood flow can decrease the hepatic clearance for high extraction drugs, such as propranolol and morphine.

  2. Renal drug clearance can be affected by changes in glomerular filtration, tubular reabsorption, active drug secretion, and renal blood flow and nephrotoxicity (*Table 13-4*).

III. PHARMACODYNAMIC INTERACTIONS

  A. Drugs that have similar pharmacodynamic actions may produce an excessive pharmacodynamic response or a **toxic response**.

    1. For example, central nervous system depressants, such as the combination of opioids, alcohol, and antihistamines (e.g., diphenhydramine, chlorpheniramine), can produce increased drowsiness in the patient.

    2. Drugs with anticholinergic effects, such as promethazine and OTC antihistamines, can cause excessive dryness of the mouth, blurred vision, and urinary retention.

    3. Drugs that prolong the QTc interval, such as paliperidone, amiodarone, sotalol, moxifloxacin, and atypical antipsychotics such as ziprasidone, have a much greater risk of causing QTc interval arrhythmias when given together.

| Table 13-3 | DRUG/HERB/FOOD ACTIONS WITH CYTOCHROME P450 ENZYMES |

Enzyme	Inhibitor	Inducer	Substrate
CYP1A2	Ciprofloxacin	Phenytoin	Naproxen
	Levofloxacin	Carbamazepine	Amitriptyline
	Cimetidine	Charbroiled foods	Verapamil
	Citalopram	Tobacco	Clopidogrel
	Ketoconazole	Ritonavir	Duloxetine
	Paroxetine	St. John's wort	Ramelteon
CYP2C9	Cimetidine	Rifampin	Tamoxifen
	Fluoxetine	Carbamazepine	Losartan
	Voriconazole	Phenytoin	S-Warfarin
	Fluconazole		Celecoxib
	Amiodarone		Phenytoin
	Efavirenz		Carvedilol
	Metronidazole		Voriconazole
			Glyburide
			Sildenafil
CYP2C8	Gemfibrozil	Phenobarbital	Paclitaxel
	Nicardipine	Rifampin	Carbamazepine
	Atazanavir	Carbamazepine	Amiodarone
	Trimethoprim		Pioglitazone
CYP2C19	Ketoconazole	Rifampin	Diazepam
	Omeprazole	Carbamazepine	Phenytoin
	Topiramate	Phenytoin	Citalopram
	Fluoxetine		Omeprazole
	Fluvoxamine		Diphenhydramine
			Duloxetine
			R-Warfarin
CYP2D6	Methadone	Carbamazepine	Amitriptyline
	Cimetidine	Phenytoin	Metoprolol
	Fluoxetine	Ethanol	Paroxetine
	Ritonavir	St. John's wort	Duloxetine
	Haloperidol	Ritonavir	Haloperidol
	Amiodarone		Venlafaxine
	Paroxetine		Tramadol
	Quinidine		Trazodone
	Sertraline		Narcotic analgesics
CYP2E1	Cimetidine	Ritonavir	Acetaminophen
	Disulfiram	Isoniazid	Caffeine
		Ethanol	Venlafaxine
CYP3A family	Erythromycin	Carbamazepine	Atorvastatin
	Ketoconazole	Phenobarbital	Warfarin
	Saquinavir	St. John's wort	Lidocaine
	Verapamil	Nevirapine	Ethyl estradiol
		Efavirenz	
	Metronidazole	Carbamazepine	Cyclosporine
	Amiodarone	Rifampin	Alprazolam
	Cimetidine	Garlic supplements	Ziprasidone
	Diltiazem	Grapefruit	Doxorubicin
	Posaconazole	Seville orange	Amitriptyline
	Metronidazole	Bitter orange	Methadone

Table 13-3   Continued.

Enzyme	Inhibitor	Inducer	Substrate
	Nifedipine		Cyclosporine
	Voriconazole		Amlodipine
	Atazanavir		Indinavir
			Cyclosporine
			Paclitaxel
			Ritonavir
			Lidocaine
			Lovastatin
			Midazolam
			Tamoxifen
			Zaleplon
			Atazanavir

B. The pharmacodynamic effect of one drug can be antagonized by a second drug that has an opposing pharmacodynamic effect. For example, the antihypertensive effect of β-blockers can be overcome by the use of vasopressors. This drug combination can have a deleterious effect such as a therapeutic failure. In some cases, the combination (e.g., Talwin NX) may be part of a therapeutic strategy in clinical treatment, depending on the situation.

C. Drug therapy can produce an adverse effect that results in an **increased receptor sensitivity** or **toxicity** when another drug is given. For example, the alteration of electrolyte concentrations produced by a diuretic, such as a thiazide derivative, will deplete potassium, resulting in sensitization of the heart to digoxin therapy. Depletion of sodium by a diuretic can also result in lithium toxicity.

D. **Pharmacodynamic** drug interactions also occur with drug–herbal interactions and drug–food interactions. For example, large amounts of vitamin K in the diet antagonize the anticoagulant effect of anticoagulation of warfarin.

E. Starting and stopping therapies that influence metabolism of other drugs can result in therapeutic failure if the induced metabolism reduces the blood levels of the target drug. For example, starting a patient on nicotine patches replaces smoking for a patient. Because the patient is no longer smoking tobacco, the CYP1A2 isoenzymes are no longer induced, and the substrates of the CYP1A2 system (e.g., clozapine or haloperidol) may be increased to toxic levels. This effect can occur in several enzyme systems when stopping phenytoin, an inducer for several CYP enzyme systems.

Table 13-4   DRUG INTERACTIONS THAT AFFECT THE RENAL CLEARANCE

Drug Interaction	Examples	Effect
Glomerular filtration rate (GFR) and renal blood flow	Methylxanthines (e.g., caffeine, theobromine)	Increased renal blood flow and GFR will decrease time for reabsorption of various drugs, leading to more rapid urinary drug excretion.
Active tubular secretion	Probenecid	Probenecid blocks the active tubular secretion of penicillin and some cephalosporin antibiotics.
Tubular reabsorption and urine pH	Antacids, sodium bicarbonate	Alkalinization of the urine increases the reabsorption of amphetamine and decreases its clearance. Alkalinization of urine pH increases the ionization of salicylates, decreases reabsorption, and increases its clearance.

IV. HERBAL–DRUG INTERACTIONS

A. Herbal preparations are various combinations of herbs, sometimes being one herb, or a combination of herbs.

   1. Herbal preparations generally contain several different pharmacologically active alkaloids or other active constituents. For example, St. John's wort has at least six different constituents: hyperforin, biapigenin, hypericin, quercetin, chlorogenic acid, and pseudohypericin. Each constituent has its own metabolism, binding, and pharmacologic action. The predominant effect or interaction depends on the relative potency of each constituent in the herb. For example, the constituents of St. John's wort have inhibitory activity of the CYP450 isoenzymes 3A4, 2C9, 1A2, 2D6, and 2D9, but none of these effects are considered clinically significant. St. John's wort appears overall to be an inducer of CYP3A4, and its constituents have many additional effects on metabolism and binding sites (*Table 13-5*).

   2. Herbal preparations with the same name, for example, St John's wort, marketed by different manufacturers do not have equivalent amounts of each constituent. The USP-NF is attempting to create quality standards for these preparations.

   3. Many herbal drugs interact at the same transport, metabolism, and receptor sites as traditional prescription drugs (*Table 13-6*).

   4. Traditional Chinese medicine (TCM) may contain a combination of herbs. Some imported TCM products have been found to contain unlisted legend drugs. An example is a TCM medication advertised to treat diabetes that was found to contain the pharmaceuticals glyburide and phenformin.

   5. Some herbal preparations may contain unrecognized contaminants such as heavy metals or a similar-appearing herb that is mistakenly harvested. These quality control issues are to a large extent unregulated by government agencies.

B. Drug–herbal interactions can occur as pharmacokinetic or pharmacodynamic interactions (*Table 13-7*).

C. Drugs with narrow therapeutic windows are at greater risk for drug–herbal interactions. For example, important drug–herb interactions occur with patients taking warfarin.

   1. Coenzyme Q10 has a chemical structure related to vitamin K. The combination of warfarin and coenzyme Q10 results in antagonized warfarin activity and inadequate anticoagulation.

   2. Ginger, garlic, and feverfew also increase bleeding in patients taking warfarin by directly inhibiting platelets and causing increased risk of bleeding.

   3. Wheat grass actually contains high levels of vitamin K, which directly antagonizes warfarin, causing inadequate anticoagulation and therapeutic failure.

D. Potency of herbal preparations is influenced by various factors:

   1. The stage of growth during which the herb was harvested

   2. The drying time

   3. The solvents used in extraction of the herb

   4. The shelf life and storage conditions of the herbal extract

---

Table 13-5   PHARMACOKINETIC ACTIVITY OF THE CONSTITUENTS OF ST. JOHN'S WORT

Activity	Site
Metabolized	CYP450, most notably by the 3A4 isoenzyme
Transported	Intestinal P-glycoprotein
Active at receptor sites	GABA, norepinephrine, dopamine, L-glutamate receptor sites
Active at reuptake sites	Serotonin reuptake and norepinephrine reuptake sites
Inhibits	MAO and possibly the cellular phosphodiesterase sites
Inhibits	Beta-adrenergic and muscarinic receptor sites
Binding site competition	DNA sites in human leukemia cells

GABA, gamma-aminobutyric acid; *MAO*, monoamine oxidase.

Table 13-6   ST. JOHN'S WORT DRUG INTERACTIONS

Pharmacokinetic Process	Site	Action	Results in	Drug
Metabolism	CYP3A4	Induces	Lower levels of	NNRTI Protease inhibitors Benzodiazepines Calcium-channel blockers Carbamazepine Cyclosporine Irinotecan Digoxin
	CYP2C9	Induces	Lower levels of	Warfarin
	CYP1A2	Induces	Lower levels of	Warfarin
Transporter proteins	Intestinal P-glycoprotein transporter proteins	Increased catalyzed efflux of substrate drug	Lower levels of	Digoxin calcium-channel blockers Simvastatin
Pharmacodynamic toxicity	Serotonin reuptake receptor sites	Inhibits serotonin reuptake	Additive SSRI activity	SSRIs
	Serotonin reuptake receptor sites	Serotonin agonist activity	Additive serotonin toxicity	Serotonin agonists (e.g., fenfluramine) and "triptans"
	MAO receptor sites	Increased MAOI and serotonin activity	Additive serotonin toxicity	MAOIs
Pharmacokinetic	Serotonin and norepinephrine reuptake sites	Inhibits reuptake of norepinephrine and serotonin	Norepinephrine and serotonin toxicity	Nefazodone
	DNA-binding sites in human leukemia cells	Distorts DNA-binding sites	Reverses etoposide-stabilized cleavage complexes	Antagonizes chemotherapy effect of etoposide (in vitro)

MAOI, monoamine oxidase inhibitor; *NNRTI*, nonnucleoside reverse transcriptase inhibitor; *SSRI*, selective serotonin reuptake inhibitor.

V. FOOD–DRUG INTERACTIONS

A. Food can increase, decrease, or not affect the absorption of drugs (*Table 13-8*).

B. Food can influence the bioavailability of a drug from both modified-release dosage and immediate-release dosage forms, depending on the physical and chemical characteristics of the drug.

   1. Generally, oral systemic absorption of lipid-soluble drugs is increased in the presence of fatty foods, whereas water-soluble drugs are decreased and possibly delayed due to delayed gastric emptying time.

   2. Oral modified-release dosage forms such as controlled-release, delayed-release (enteric coated), or extended-release dosage forms may be adversely affected by food because these products may stay within an area of the GI tract to release drug over a period (e.g., 12-hour release product).

C. Complexation and adsorption of the drug in the GI tract with another food element is a common drug interaction that reduces the extent of drug absorption; for example, quinolone antibiotics complex with calcium (found in milk products) and magnesium.

   1. Quinolone antibiotics will complex with calcium from the diet and the result will be reduced quinolone antibiotic.

| Table 13-7 | TABLE OF COMMON HERBS AND POTENTIAL DRUG INTERACTIONS |

Herb	Drug/Drug Class	Interaction	Effect
Black cohosh	Antihypertensives	Pharmacodynamic potentiation	Increased effect of antihypertensives (hypotension)
Coenzyme Q10	Warfarin	Pharmacodynamic antagonism	Vitamin K antagonism (increased INR and risk of bleed)
Dong quai	β-blockers	Inhibition of CYP450 enzymes	Increased level of β-blockers (increased hypotension)
	Benzodiazepines	Inhibition of CYP450 enzymes	Increased benzodiazepine levels (increased drowsiness and CNS depression)
Echinacea	Immunosuppressants Monoclonal antibodies	Pharmacodynamic antagonism	Decreased immunosuppression (flair of autoimmune disease, transplant graft rejection)
Ephedrine Ma Huang	β-blockers	Pharmacodynamic antagonism	Sympathomimetic effect (hypertension)
	MAOIs	Blocked metabolism	Increased and prolonged sympathomimetic effect (hypertensive crisis)
	Corticosteroids	Increased metabolism Induced hepatic metabolism	Decreased corticosteroid levels (decreased steroid effectiveness)
Evening primrose oil	Antiplatelets	Pharmacodynamic potentiation	Decreased platelet aggregation (increased risk of bleed)
	Phenothiazines	Additive toxicity	Reduced seizure threshold (seizures)
Ginkgo biloba	Warfarin, LMWH	Pharmacodynamic potentiation	Increased inhibition of platelet aggregation (increased risk of bleed)
Ginseng	MAOI	Pharmacodynamic effect	Increased GABA metabolism and increased dopamine levels (mania symptoms)
Kava kava	Acetaminophen Azole antifungals Statins	Additive toxicity	Increased potential for hepatic toxicity (elevated LFT, hepatic failure)
	Barbiturates Benzodiazepines	Synergy	Increased GABA receptor binding affinity (increased drowsiness, CNS depression)
	Levodopa	Antagonism	Dopamine blockade (decreased effectiveness of levodopa)
Soy	Levothyroxine	Impaired absorption	Decreased levels of levothyroxine (hypothyroid symptoms)
St. John's wort	Irinotecan	Induced CYP3A4 Metabolism	Reduced levels of active irinotecan metabolite for chemotherapy (decreased myelosuppression)
Valerian	Sedatives	Pharmacodynamic	Increased CNS depression (drowsiness and sedation)
	Benzodiazepines	Displacement from binding sites	Displaced benzodiazepine but additive CNS depression (possible increased drowsiness)

CNS, central nervous system; *GABA*, gamma-aminobutyric acid; *INR*, international normalized ratio; *LFT*, liver function test; *LMWH*, low-molecular-weight-heparin; *MAOI*, monoamine oxidase inhibitor.

Table 13-8	AFFECT OF FOOD ON DRUG BIOAVAILABILITY	

Reduced or Delayed	Increased	Not Affected by Food
NSAIDs (nonsteroidal anti-inflammatory drugs) naproxen, naproxen sodium	Griseofulvin	Theophylline[a]
Aspirin	Metoprolol	Metronidazole
Acetaminophen	Phenytoin	
Antibiotics (tetracycline and penicillin)	Propoxyphene	
Ethanol	Dicumarol	
	Morphine	

[a]Food does not significantly affect drug absorption of theophylline in an immediate-release dosage form. However, food may affect theophylline absorption from a controlled-release formulation.

2. Ibandronate for osteoporosis has significantly reduced absorption when given with food. Oral ibandronate absorption is very poor, with less than 0.6% bioavailability in the fasted state and a significant reduction in absorption in the fed state, which may reduce the systemic drug concentrations to subtherapeutic levels.

3. Several drugs, such as phenytoin and quinolone antibiotics, are adsorbed to calcium and iron in tube feedings.

D. Food is processed by the same liver enzymes that metabolize drugs, causing enzyme inhibition or induction, and resulting in toxic or subtherapeutic drug levels. For example, grapefruit and valencia oranges inhibit the CYP3A4 isoenzyme system, causing increased levels of substrate drugs such as saquinavir, indinavir, midazolam, nimodipine, nifedipine, lovastatin, cyclosporine, carbamazepine, and verapamil.

E. Constituents in some foods can pharmacodynamically antagonize the effect of some drugs. For example, spinach and broccoli provide dietary sources of vitamin K, which antagonizes the effect of warfarin. Garlic can cause additive antiplatelet effect in combination with warfarin, heparin, and low molecular weight heparin (LMWH), and cause increased risk of bleeding.

F. Foods may contain pharmacologically active compounds that competitively interact with drugs that target endogenous substrates. MAOIs are antidepressant drugs that prevent normal metabolism of catecholamines as well as inhibit the metabolism of tyramine. Patients on MAOIs who consume tyramine-containing foods such as red wine and cheese will have increased levels of tyramine resulting in a hypertensive crisis.

VI. CHEMICAL–DRUG INTERACTIONS

A. Tobacco smoke contains aromatic polycyclic hydrocarbons that induce the CYP1A2 isoenzyme metabolism and decrease levels of substrate drugs such as theophylline, diazepam, tricyclic antidepressants, duloxetine, and ramelteon.

B. **Ethanol** can increase or decrease the activity of hepatic drug-metabolizing enzymes.

1. Chronic alcoholism increases the rate of metabolism of tolbutamide, warfarin, and phenytoin.

2. Acute alcohol intoxication can inhibit hepatic enzymes in nonalcoholic individuals.

3. Ethanol induces metabolism in the CYP1A2 and 2E1 isoenzymes. Levels of 1A2 substrates clozapine, cyclobenzaprine, imipramine, and naproxen are decreased. Levels of the 2E1 substrates acetaminophen are reduced.

4. Disulfiram inhibits alcohol dehydrogenase, resulting in limited metabolism of ethanol and causing severe ethanol intolerance.

VII. PHARMACOGENETICS AND DRUG INTERACTIONS

A. Genetic differences in drug metabolism are the result of genetically based variations in **alleles** for genes that code for enzymes responsible for the metabolism of drugs. A review of pharmacogenetics and the genetic basis for variation in drug response is discussed in Chapter 8.

1. The gene encoding for the enzyme is generally composed of two alleles. **Polymorphism** leads to genetic variation in enzyme systems. Of particular interest is the occurrence of polymorphism in

Table 13-9 ETHNIC DIFFERENCES IN THE CYP2D6 ENZYME ACTIVITY[a]

Ethnicity	As a Percentage of the Population
Caucasians	7–10% PM/1% UM
African Americans	8% PM
Asians	> 50% PM/1% UM

[a]Adapted from Zagaria MAE. The promise of pharmacogenomics. Available online at http://www.uspharmacist.com/index.asp?show=article&page=8_1190.htm. Retrieved January 18, 2006; and Johansson I et al. Genetic analysis of the Chinese cytochrome P4502D locus: characterization of variant CYP2D6 genes present in subjects with diminished capacity for debrisoquine hydroxylation. *Mol Pharmacol.*1994;46:452–459.
PM, poor metabolizer; *UM*, ultra-rapid metabolizer.

drug metabolism, including the CYP450 hepatic enzymes, the mixed oxidase and the *N*-acetyl transferase systems, and the UGT metabolic enzyme systems. In the CYP450 system, the CYP2D6, CYP2C9, and CYP2C19 polymorphisms are the most extensively studied.

2. **Polymorphisms** (differences in the alleles) can also vary within an ethnic group by geographic distribution. For example, in Western Europeans, polymorphism for the CYP2D6 alleles can vary with 10 times as many ultra metabolizers (UMs) in Greece as in Austria (*Table 13-9*).

3. The extent of the drug interaction is predicted based on the intrinsic enzyme activity in an individual. This intrinsic enzyme activity depends on the type and extent of polymorphic changes to the enzyme.

4. Drug metabolism activity is often classified according to the quantitative rate of intrinsic enzyme activity. Classifications include poor metabolizers (PMs), intermediate metabolizers (IMs), normal metabolizers, extensive metabolizers (EMs), and ultra-rapid metabolizers (UMs).

5. Genetic changes may inactivate or reduce enzymatic activity (e.g., PMs), leading to increases in the parent drug concentrations.

6. Genetic duplication may increase enzymatic activity (e.g., EMs), resulting in lower levels of the parent drug.

7. In the CYP2D6 enzyme, genetic variation can cause a 10- to 30-fold difference in the levels of drugs metabolized by that enzyme. Some CYP2D6 variants and their effects on drug metabolism activity are listed in *Table 13-10*.

B. Polymorphisms affect drug interactions by altering the effect of inhibitors and inducers on the enzymes. The result is an exaggerated effect or minimal effect on the substrate.

1. In an **EM**, the level of substrate drug is normally low because of the rapid metabolism by the enzyme. An **inhibitor** to the enzyme will substantially inhibit the extensive metabolism and cause

Table 13-10 ALLELE ACTIVITY PATTERNS IN THE CYP2D6 ISOENZYME[a]

Gene	Polymorphism	Enzyme Activity	Phenotype
CYP2D6*1	Wild-type	Normal	EM or normal
CYP2D6*2	Same as CYP2D6*1 but possible duplication or amplification	Increased enzyme activity	EM/UM
CYP2D6*4	Defective splicing	Inactive enzyme	PM
CYP2D6*5	Gene depletion	No enzyme	PM
CYP2D6*10	Single AA substitution predominant variant in people of Asian descent	Reduction in enzyme activity	PM
CYP2D6*17	Single AA substitution predominant variant in people of African descent	Reduction in enzyme activity	PM

Evaluation of inhibitory drug interactions during drug development: genetic polymorphisms must be considered. *Clin Pharmacol Ther.* 2005;78:1–6.
EM, extensive metabolizer; *PM*, poor metabolizer; *UM*, ultra-rapid metabolizer.

Table 13-11   THE EFFECT OF INHIBITION OF EM/UM AND PM ON CYP2D6 SUBSTRATES[a]

Enzyme	Inhibitor	Substrate	Effect of EM/UM on the Substrate	Effect of PM on the Substrate
CYP2D6	Diphenhydramine	Metoprolol	Increased 61%	Little change
CYP2D6	Quinidine	S-venlafaxine	Increased 4x	Little change
CYP2D6		R-venlafaxine	Increased 12x	No change
CYP2D6	Diphenhydramine	Venlafaxine	Increased 2x	Little change
CYP2D6	Fluoxetine	Risperidone	Increased 4x	Increase 1.3x

[a]Adapted from Lee LS et al. Evaluation of inhibitory drug interactions during drug development: Genetic polymorphisms must be considered. *Clin Pharmacol Ther*. 2005;78:1–6.
EM, extensive metabolizer; *PM*, poor metabolizer; *UM*, ultra-rapid metabolizer.

significant elevations in the active (substrate) drug. The substrate levels rise dramatically because the effect of the inhibitor is much greater in an EM. The drug interaction may occur to a greater extent than it would in normal metabolizers (*Table 13-11*).

2. In a **PM**, the level of substrate drug remains high because the metabolism of the substrate is much less than normal. When an **inhibitor** is added to the regimen, the additional inhibition of metabolism is not much greater than is already occuring in a PM. Therefore, the effect of an inhibitor on a PM is less than it would be in normal metabolizers. The drug interaction may not occur.

3. In an **EM**, the level of substrate drug is again lower than expected in a normal metabolizer because of the rapid metabolism. The addition of an **inducer** does not cause a great difference in the level of substrate because the metabolism is already increased greatly. The drug interaction may not occur.

4. In a **PM**, the level of substrate drug is again higher than expected in a normal metabolizer because of the lower metabolism of the substrate. The addition of an **inducer** will cause a significant increase in the metabolism of the substrate and cause a much lower level of substrate than expected in a normal metabolizer. The drug interaction may occur to a greater extent than in normal metabolizers, or the drug interaction may result in substrate levels similar to those of normal metabolizers.

5. As a general rule, the effect of inhibitors is greater in EMs than in PMs. The effect of inducers is greater in PMs than in EMs.

6. The addition of an inhibitor to a UM is expected to show an even greater drug reaction than would be seen with an EM.

7. Complex drug interactions can be seen when a substrate is metabolized through more than one enzyme system where one or more enzymes are affected by polymorphism. In these cases, the substrate is metabolized through a polymorphic enzyme and becomes an active metabolite and an inhibitor or inducer in a second system. Polymorphism in the first enzyme can cause the level of the inhibitor or inducer to be greater or less than expected, thus causing the extent of the expected inhibition or induction of the second enzyme to be significantly changed.

C. Some examples of specific pharmacogenomic drug interactions include the following:

1. **Omeprazole.** Omeprazole affects the pharmacokinetics of moclobemide according to the genetic polymorphism of CYP2C19. The effect of omeprazole inhibition of moclobemide metabolism varied according to the degree of genetic polymorphism, for example, extensive metabolizers (EM) and poor metabolizers (PM). In EM patients, the AUC level of the substrate moclobemide almost doubled, reflecting the greater effect of omeprazole inhibition on moclobemide, which is normally extensively metabolized. In comparison, PM subjects have poor metabolism of the moclobemide. Thus, inhibition of the 2C19 enzyme by omeprazole in PM did not show an extensive change in the AUC levels of moclobemide, because normal metabolism in these patients was already impaired.

2. **Fluvoxamine.** Fluvoxamine inhibits the metabolism of diphenhydramine by inhibiting the CYP2C19 isoenzyme. When EM patients on diphenhydramine were given fluvoxamine, the AUC and C_{max} levels of diphenhydramine were increased significantly. When PM patients on diphenhydramine were given fluvoxamine, the AUC and C_{max} of diphenhydramine did not change significantly. The effect of inhibition of CYP2C19 in an EM patient was greater than the effect of inhibition of CYP2C19 in PM patients. This demonstrates that the degree of inhibition varies by genotype. Homozygous EMs showed greater reduction in enzyme activity than

heterozygous EMs. EMs show greater inhibition than PMs because PMs already have reduced enzyme activity and will not show a great change in C_{max} or AUC, even with concurrent administration of an inhibitor such as fluvoxamine.

3. Diphenhydramine. Diphenhydramine inhibits the metabolism of metoprolol. In EM in the CYP2D6, the C_{max} and AUC of diphenhydramine increased by 16% and 61%, respectively, as compared to nonpolymorphisms. The inhibitor diphenhydramine decreased conversion of metoprolol to its metabolite by a factor of 3. In the PM, the change in metoprolol conversion was insignificant. Again, the effect of inhibition on the substrate in the EM was greater than in PM. There is significant interaction between the nonprescription antihistamine diphenhydramine and the CYP2D6 substrate metoprolol in healthy men with high or low CYP2D6 activity.

4. Diphenhydramine. Diphenhydramine inhibits the metabolism of venlafaxine by the CYP2D6 isoenzyme. When diphenhydramine is given to an EM who is taking venlafaxine, the levels of venlafaxine rise twofold. Diphenhydramine given to a PM who is taking venlafaxine causes insignificant change in the levels of venlafaxine. As with the previous example with metoprolol, the extent of inhibition in EM is much greater than in PM.

D. The effect of polymorphism on drug development and drug safety

1. Pharmacogenomic testing during drug development can identify the dosing variables in certain polymorphic populations and could lead to a greater safety in the use of these drugs. Clinical trials in warfarin therapy with genetic testing for polymorphisms in CYP2C9, such as the CYP2C9*2 and CYP2C9*3.

2. In small studies, or in studies of genetically homogeneous subjects, the pharmacokinetics described for the drug may be skewed toward the polymorphisms prevalent in the subject population. This can occur when, for example, Asians are the primary subject population for pharmacokinetic studies for a drug metabolized by CYP2C19. CYP2C19 polymorphisms occur in 20% to 25% of the Asian population.

3. When polymorphisms and pharmacogenomics are not considered during drug development, the result can be the development of some drugs that have shown toxicity in certain populations after FDA approval. Drugs that had to be withdrawn after market approval due to polymorphism include troglitazone (Rezulin) and mibefradil.

4. The identification of polymorphic factors in a specific drug under development may limit the clinical use of that drug to certain pharmacogenomic populations. Therefore, the FDA may make recommendations or require labeling for genetic testing of patients to determine polymorphisms that affect drug metabolism or transport. Some tests include the following:

   a. The Invader UGT1A1 molecular assay for UGT1A1 detects polymorphisms that can reduce the metabolism of irinotecan, a chemotherapy for colorectal cancer.

   b. The FDA has cleared the AmplicChip cytochrome P450 genotyping test for polymorphisms in the CYP450 isoenzyme system, which is extensively involved in drug metabolism.

   c. The FDA has added labeling to various drugs to test for genetic polymorphisms that affect metabolism, such as antiepileptic drugs.

   d. The FDA has also mandated the testing of HIV strains for guidance in using maraviroc.

VIII. CLINICAL SIGNIFICANCE AND MANAGEMENT OF DRUG INTERACTIONS

A. Potential drug interactions

1. **Multiple-drug therapy**, including both **prescription** and **nonprescription** (OTC) medication, can potentially lead to drug interactions. The more drugs used by a patient, the greater the potential for a drug interaction.

2. **Multiple prescribers.** Patients can be seen by different prescribers who prescribe interacting medication.

3. **Patient compliance.** Patients need to follow proper instructions for taking medications. For example, a patient might take tetracycline with food rather than before meals.

4. **Patient risk factors**

   a. Older patients are at more risk for drug interactions than younger patients. Older patients might have changes in their physiological and pathophysiological condition that lead to altered body composition, altered GI transit time and drug absorption, decreased protein

binding, altered distribution, and decreased drug clearance. These changes can exacerbate or increase the risk of a drug interaction.

 b. Patients with predisposing illness (diabetes, asthma, AIDS, and alcoholism) and patients who are clinically hypersensitive (atopic) are more at risk for drug interactions than nonatopic patients.

 c. Pharmacogenetic polymorphisms in enzyme function can occur at different rates in different racial populations and, to a lesser extent, in different nations. These pharmacogenetic differences can lead to a wide variation in the potential for a drug interaction.

B. Clinical significance

 1. Not all drug interactions are clinically significant or cause an adverse effect. In some cases, interacting drugs can be prescribed for patients as long as the patient is given proper instructions and is compliant. For example, cimetidine and an antacid might be prescribed to the patient, but the patient should be instructed to not take both medications at the same time.

 2. Combination drug therapy can have beneficial effects. Drug combinations are used to improve the therapeutic objective or to decrease adverse events. Some examples include the following:

  a. Trimethoprim and sulfamethoxazole—combination antibiotic for increased efficacy in urinary tract infections.

  b. Amoxicillin and clavulanate potassium—combination containing a beta-lactamase inhibitor (clavulanate) to inhibit the breakdown of amoxicillin.

  c. Hydrochlorothiazide and triamterene—combination diuretic and antihypertensive to minimize potassium excretion.

  d. Ritonavir is given as a "booster" with tipranavir. Coadministration increased tipranavir levels 30-fold by inhibition of the CYP3A4 enzyme responsible for metabolism of tipranavir.

  e. Probenecid inhibits renal tubular secretion of penicillin, thereby prolonging the plasma half-life of the antibiotic.

 3. Some drug–food interactions are utilized for their beneficial effects. Phenytoin is given with dietary fats to increase its bioavailability through enhanced absorption.

 4. Another type of drug–drug interaction occurs when the conversion of a prodrug to the active metabolite is inhibited or induced at the metabolizing enzyme.

  a. The conversion of inactive codeine to its active metabolite morphine can be reduced by CYP2D6 isoenzyme inhibition caused by cimetidine or citalopram. The reduced metabolism can result in subtherapeutic levels of morphine and therapeutic failure in pain treatment.

  b. The induction of the metabolism of CYP2D6 by phenytoin or St. John's wort can increase metabolism of codeine to morphine, raise morphine levels, and may result in excessive sedation and narcotic toxicity.

  c. Other prodrugs depend on metabolic conversion to active metabolites that include enalapril, valacyclovir, levodopa, and carisoprodol.

 5. The determination of the clinical significance of a potential drug interaction should be documented in the literature. The likelihood of a drug interaction can be classified as follows:

  a. Established—a drug interaction supported by well-proven clinical studies

  b. Probable—a drug interaction that is very likely but might not be proven clinically

  c. Suspected—a drug interaction that might occur; some data might be available

  d. Possible—a drug interaction that could occur; limited data are available

  e. Unlikely—a drug interaction that is doubtful; no good evidence of an altered clinical effect is available

 6. The clinical relevance of a potential drug interaction should also consider the following:

  a. Size of the dose and the duration of therapy

  b. Onset (rapid, delayed) and **severity** (major, moderate, minor) of the potential interaction

  c. Extrapolation to related drugs

 7. Polymorphism in pharmacogenetics may affect the toxicity and the clinical efficacy of certain drugs in certain populations. Known inhibitors may pose significant risks to EMs of enzyme systems.

C. Management of drug interactions

 1. Review the patient profile, including drug history and patient risk factors. The patient's past medical history can reveal a tendency for noncompliance, past therapeutic failures, and evidence for pharmacogenetic considerations.

Table 13-12	FDA ENCOURAGES GENETIC TESTING FOR PATIENTS WHO WILL TAKE SPECIFIC DRUGS		

Imatinib	Atomoxetine	Venlafaxine
Voriconazole	Tamoxifen	Omeprazole
Fluoxetine	Celecoxib	Tramadol
Capecitabine	β-blockers	5FU
Rifampin	Dapsone	Irinotecan
Rasburicase	Valproic acid	Primaquine

Adapted from http://www.fda.gov/cder/genomics/genomics_biomarkers_table.htm.

2. Avoid complex therapeutic drug regimens.
3. Determine the probability of a clinically significant drug interaction. Genetic testing may be useful. (*Table 13-12*).
4. Suggest a different drug if there is a high probability for a clinically significant drug interaction. For example, acetaminophen can be used for headache instead of aspirin for a patient on anticoagulant therapy.
5. Carefully instruct the patient about the timing of the medication. For example, an antacid and H-2 blocker should not be taken at the same time. The patient should use maximum spacing between drugs. Instruct the patient about the timing of medications to be taken "on an empty stomach" when an acid stomach environment is best for aspirin, itraconazole capsules, and dipyridamole.
6. Monitor the patient for adverse events. Sulfonamides, such as sulfisoxazole and sulfamethoxazole, can prolong prothrombin time in patients given warfarin therapy. The prothrombin times should be monitored in these patients.
7. Reevaluate the patient profile and drug history when changing drug therapy. For example, when discontinuing the diuretic of a congestive heart failure patient on digoxin, a review of the profile may reveal a potassium supplement that should be discontinued as well.
8. Evaluate the risks of drug therapy with respect to pharmacogenetic polymorphic status of metabolism. Consider risks identified with racial groups and geographic distribution. Test for enzyme phenotype when feasible. Select drug and adjust doses as indicated and according to clinical response. Consider genotype testing when for polymorphisms when unexpected variations in clinical response.

IX. REFERENCES. A vast number of drug interactions are reported in the literature. Some general references that are updated periodically include the following:

Study Questions

Directions for questions 1–2: Each question contains three suggested answers, of which **one** or more is correct. Choose the answer, **A–E**.

   A   **I only** is correct
   B   **III only** is correct
   C   **I and II** are correct
   D   **II and III** are correct
   E   **I, II, and III** are correct

1. Drug interactions may be classed as

   I.   pharmacokinetic interactions
   II. pharmacodynamic interactions
   III. pharmaceutical interactions

2. Situations that can potentially lead to drug interactions include

   I.   multiple-drug therapy
   II. multiple prescribers
   III. patient compliance

Directions for questions 3–10: Each question is followed by four suggested answers. Select the **one** lettered answer that is the **best** response to the question.

3. Which of the following statements regarding drug interactions is true?

   (A) All drug interactions can potentially cause an adverse response in the patient.
   (B) The clinical significance for each potential drug interaction must be considered individually.
   (C) A precipitant drug that inhibits the metabolism of the object drug causes a more serious drug interaction compared to a precipitant drug causing an increase in the bioavailability of the object drug.
   (D) If the patient is prescribed drugs that can potentially interact, the prescriber should be called, and a different precipitant drug should be suggested.

4. A patient on indinavir antiretroviral therapy (ART) begins taking St. John's wort for depression and suffers unexpected reduction in CD4 count. This is most likely due to

   (A) pharmacodynamic interaction producing additive toxicity.
   (B) pharmacodynamic interaction producing antagonistic therapeutic effect.
   (C) enzyme induction by St. John's wort causing increased metabolism of ART.
   (D) enzyme inhibition by St. John's wort causing toxic levels of ART.

5. Which of the following is a valid therapeutic use of a drug interaction?

   (A) The use of probenecid with penicillin G to prolong high penicillin levels to treat a sexually transmitted disease
   (B) Giving aspirin with warfarin to enhance anticoagulation
   (C) Instructing the patient to take levofloxacin with milk or antacid to decrease GI intolerance to oral therapy
   (D) The treatment of depression with a combination of citalopram and a MAOI

6. Which of the following is not a harmful food–drug interaction?

   (A) Raw green salads for patients on warfarin deep vein thrombosis (DVT) prophylaxis
   (B) Grapefruit juice and cyclosporine to prevent graft-versus-host rejection of a transplanted kidney
   (C) Omeprazole beads in applesauce for a patient with problems swallowing capsules secondary to gastroesophageal reflux disease (GERD)
   (D) Milk with doxycycline to treat *Helicobacter pylori*

7. Which of the following statements regarding pharmacogenetic polymorphisms is not true?

   (A) An EM taking metoprolol for hypertension begins to take OTC Tagamet® regularly for heartburn. He or she is at increased risk for bradycardia and cardiac arrhythmias.
   (B) An EM taking methadone begins taking Tegretol® for neuropathic pain. He or she is at risk for treatment failure and pain crisis.
   (C) A PM taking atorvastatin for hyperlipidemia is placed on ketoconazole for a fungal infection. He or she is at increased risk for myalgia and rhabdomyolysis.
   (D) A PM taking metoprolol for tachycardia begins taking Benadryl® for sleep. He or she is not at risk for significant bradycardia and cardiac block.

8. Asians are at greatest risk of all racial groups for genetic polymorphism in which one of the following CYP450 isoenzymes?

   (A) CYP2D6
   (B) CYP3A4
   (C) CYP2C19
   (D) CYP1A2

9. Which of the following statements regarding pharmacogenetics is false?

    (A) Polymorphisms occur only in the CYP450 hepatic enzymes.
    (B) Polymorphisms result in many variations of an isoenzyme.
    (C) The overall expression of the combined alleles is the phenotype of the enzyme.
    (D) Single-nucleotide polymorphisms (SNPs) can occur as errors of transcription, defective splicing, start and stop codones, and amino acid changes.

10. Which of the following statements regarding allele polymorphisms is false?

    (A) Wild-type alleles encode for "normal" metabolism.
    (B) Ultra-rapid metabolizers (UMs) have two or more amplified alleles.
    (C) Poor metabolizers (PMs) carry one defective allele and one amplified allele.
    (D) Extensive metabolizers (EMs) with heterozygous alleles have slower metabolism than metabolizers with homozygous alleles.

Answers and Explanations

1. **The answer is E** *[see I.B]*.
   Most drug interactions in vivo are caused by pharmacokinetic and pharmacodynamic interactions. Pharmaceutical interactions can occur during extemporaneous compounding, preparation of IV admixtures, and improper dosing, as in the case of giving aspirin with acidic juices (e.g., orange, cranberry).

2. **The answer is E** *[see IV.A.1–3]*.
   Patient profiles might not contain all the drug history information of the patient. Patients who take nonprescription (OTC) medications and who go to several different physicians or purchase drugs at various pharmacies may neglect to inform the pharmacist of all the medications being taken.

3. **The answer is B** *[see IV.B]*.
   Not all drug interactions are clinically significant. Some potential clinically significant drug interactions can be prevented by proper patient instruction and compliance. The potential for a clinically significant drug interaction should be documented before calling a physician concerning the prescribed medication.

4. **The answer is C** *[see II.E.1.c; Table 13-3]*.
   St. John's wort induces CYP3A4 isoenzymes, increasing the metabolism of the indinavir and resulting in low indinavir levels and therapeutic failure of ART. St. John's wort itself has no direct effect on CD4.

5. **The answer is A** *[see II.E.2; Table 13-4]*.
   Probenecid is given with penicillin and some cephalosporins in the treatment of some sexually transmitted diseases. Probenecid competes with penicillins for renal elimination, prolonging the half-life of the penicillin. Aspirin and warfarin cause additive anticoagulation, leading to bleeding. Levofloxacin taken with milk to decrease GI irritation causes complexation of the levofloxacin with the calcium in the milk and results in decreased levofloxacin to be available. Concomitant treatment of depression of citalopram and MAOI results in serotonin syndrome, an additive toxicity.

6. **The answer is C** *[see V.B]*.
   Omeprazole beads are enteric coated. Giving an enteric-coated bead with an acidic food such as applesauce preserves the enteric coating and allows the drug to pass intact through the acidic stomach environment and into the basic duodenum environment where it is absorbed. The result is improved drug absorption and decreased drug destruction in the acidic stomach than if the beads were not in an acidic food.

7. **The answer is C** *[see VII.C.2]*.
   The PM already has inhibited metabolism of atorvastatin. Additional inhibition will not significantly increase the blood levels of atorvastatin. Therefore, dose-related toxicity is unlikely. The EM taking metoprolol and Tagamet® (cimetidine) will show a greater increase in the metoprolol levels due to the exaggerated effect of the inhibitor in EM. The EM taking methadone and Tegretol® (carbamazepine) will have increased enzyme induction and metabolism of the methadone, lowering methadone levels and putting the patient at risk for treatment failure of his pain. The PM taking metoprolol and Benadryl® (diphenhydramine) will show inhibition of the metabolism of the metoprolol and increased levels of metoprolol, leading to a higher risk of bradycardia and cardiac block.

8. **The answer is A** *[see VII.A.3]*.
   Polymorphism is highest in the CYP2D6 isoenzyme in Asians, reaching incidence of greater than 50%.

9. **The answer is A** *[see VII.A.2]*.
   Polymorphisms can occur in any enzyme system including mixed oxidase and *N*-acetyl transferase systems as well as the CYP450 hepatic enzyme system.

10. **The answer is C** *[see VII.B.3.a]*.
    PMs carry a normal allele combined with a defective or deleted allele.

Drug Information Resources

PAUL F. SOUNEY, CONNIE LEE BARNES, VALERIE B. CLINARD

I. DEFINITION. Drug information is current, critically examined, relevant data about drugs and drug use in a given patient or situation.

- A. **Current information** uses the most recent, up-to-date sources possible.
- B. **Critically examined information** should meet the following criteria:
  1. More than one source should be used when appropriate.
  2. The extent of agreement of sources should be determined; if sources do not agree, good judgment should be used.
  3. The plausibility of information, based on clinical circumstances, should be determined.
- C. **Relevant information** must be presented in a manner that applies directly to the circumstances under consideration (e.g., patient parameters, therapeutic objectives, alternative approaches).

II. DRUG INFORMATION RESOURCES. There are three sources of drug information: journals/clinical trials (primary sources), indexing and abstracting services (secondary sources), and textbook and databases (tertiary sources).

- A. **Primary sources**
  1. **Benefits.** Clinical trials provide the most current information about drugs and, ideally, should be the source for answering therapeutic questions. Journals enable pharmacists to:
     a. Keep abreast of professional news
     b. Learn how another clinician handled a particular problem
     c. Keep up with new developments in pathophysiology, diagnostic agents, and therapeutic regimens
     d. Distinguish useful from useless or even harmful therapy
     e. Enhance communication with other health care professionals and consumers
     f. Obtain continuing education credits
     g. Share opinions with other health care professionals through letters to the editor
     h. Prepare for the board certification examination in pharmacotherapy, nutrition support, oncology, and so forth.
  2. **Limitations.** Although publication of an article in a well-known, respected journal enhances the credibility of information contained in an article, this does not guarantee that the data are accurate. Many articles possess inadequacies that become apparent as the ability to evaluate drug information improves.
  3. **Review articles (narrative reviews and systematic reviews), articles of opinion, correspondence, and special reports.** All material included in a journal is not considered a primary resource. Original clinical trials are considered primary literature; however, review articles, articles of opinion, correspondence, and special reports are not.
- B. **Secondary sources**
  1. **Benefits.** Indexing and abstracting services are valuable tools for quick and selective screening of the primary literature for specific information, data, citation, and articles (*Table 14-1*). In some cases, the sources provide sufficient information to serve as references for answering drug information requests.

| Table 14-1 | EXAMPLES OF ABSTRACTING AND INDEXING SERVICES |

Secondary References	Journals Indexed
CINAHL*	2999
ClinAlert	150
Current Contents/Clinical Medicine	1120
Embase	7500
Medline/PubMed	5516
International Pharmaceutical Abstracts	800
Iowa Drug Information System	353
Pharmaceutical News Index	—
Reactions Weekly	—
Science Citation Index	3700

*Cumulative Index to Nursing and Allied Health Literature.

2. **Limitations.** Each indexing or abstracting service reviews a finite number of journals. Therefore, relying on only one service can greatly hinder the thoroughness of a literature search. Another important fact to remember is the substantial difference in lag time (i.e., the interval between the publication of an article and the citation of that article in an index) among the available services. For example, the approximate lag time for PubMed may be less than 1 week, whereas the approximate lag time for the Iowa Drug Information Service may be 30 to 60 days.

    a. Secondary sources usually **describe** only articles and clinical studies from journals. Frequently, readers respond to, criticize, and add new information to published articles and studies through letters. Services such as Medline/PubMed or the Iowa Drug Information Service generally do include pertinent letters to the editor within the scope of coverage.

    b. Indexing and abstracting services are primarily used to **locate** journal articles. In general, abstracts should not be used as primary sources of information because they are typically interpretations of a study and may be a misinterpretation of important information. Additionally, abstracts may not include enough information to critically evaluate the study. Thus, pharmacists should obtain and evaluate the original clinical trial instead of relying on the abstract alone.

C. **Tertiary sources**

  1. **Benefits**

    a. **Textbooks.** General reference textbooks can provide easy and convenient access to a broad spectrum of related topics. Background information on drugs and diseases is often available. Although a textbook might answer many drug-related questions, the limitations of these sources should not be overlooked.

      (1) It could take several years to publish a text, so information available in textbooks might not include the most recent developments in the field. Other resources should be used to update or supplement information obtained from textbooks.

      (2) The author of a textbook might not have conducted a thorough search of the primary literature, so pertinent data could have been omitted. An author also might have misinterpreted the literature. Reference citations should be available to verify the validity and accuracy of the data.

    b. **Databases.** Computer databases are convenient, easy to use, and often referenced. These resources are similar to textbooks, but are typically updated more frequently. Computer databases are easy to search and are often useful resources for drug monographs, pill identifications, drug interactions, drug compatibility, and various therapeutic calculations. Additionally, computer databases may address clinical questions. In some instances, a mobile version of the database is available. Examples include Clinical Pharmacology Mobile, Clinical Xpert, Lexicomp On-Hand, and Epocrates Rx or Epocrates Essentials.

2. **General considerations** when examining and using textbooks and/or databases as sources of drug information consider the following:
   a. The author, publisher, or both: What are the author's and publisher's areas of expertise?
   b. The year of publication (copyright date) or last revision date?
   c. The edition of the text: Is it the most current edition?
   d. The presence of a bibliography: If a bibliography is included, are important statements accurately referenced? When were the references published?
   e. The scope of the textbook or database: How accessible is the information?
   f. Alternative resources that are available (e.g., primary and secondary sources, other relevant texts)

III. INTERNET

A. **Benefits.** The Internet expands the ability to search therapies that have been recently published or discussed in the media. An Internet search may be used for the following: company-specific information, issues currently in the news, alternative medicine, or U.S. government information. One of the many available search engines can be used to find available data.

B. **Limitations**
   1. Unlike information published in journals and textbooks, information obtained from the Internet may not be peer reviewed or edited before release.
   2. Information received from the Internet may be only as reliable as the person who posted it and the users who read and comment on its content. A Web site should be evaluated by its source (author) of information. The name, location, and sponsorship should be disclosed. Also, a reputable site will provide easy access to information and references to support the information provided. Pharmacists should use traditional literature evaluation skills to determine whether information on the Web site is clear, concise, unbiased, relevant, and referenced. A selection of several reliable Web sites is provided in *Table 14-2*.
   3. Web sites are always changing and may not exist after several years. It is important to document when and where information from the Internet was found.

IV. STRATEGIES FOR EVALUATING INFORMATION REQUESTS.
It is important to obtain as much information as possible about drug information requests before beginning a literature search. Both time and money can be lost doing a vast search. The following are important questions to ask the inquirer or to evaluate before a manual or computerized search.

A. **Converse with the inquirer.** Before spending time searching for information, talk to the person who is requesting the information and acquire any necessary additional information.
   1. **Determine the reason for the inquiry.** Find out where the inquirer heard or read about the drug. Is he or she taking the medication? If so, why? Because the search can be done by the drug or disease name, determine whether the inquirer has a medical condition. Ascertaining the reason for the inquiry helps determine what additional information should be provided. For example, if the inquiry concerns a foreign drug, the inquirer might ask for a domestic equivalent.
   2. **Clarify the drug's identification and availability.** Make sure that the drug in question is available and double-check information about the drug, such as the following:
      a. The **correct spelling** of the drug's name
      b. Whether it is a **generic** or **brand name drug**
      c. What **pharmaceutical company** manufactures the drug and in what **country** the drug is manufactured
      d. Whether the drug is **prescription** or **nonprescription**
      e. Whether the drug is still **under investigation** and, if it is on the market, **the length of time on the market**
      f. The **dosage form** of the drug
      g. The **purpose** of the drug (i.e., what medical condition or symptom the drug is intended to alleviate; this information helps narrow the search if products with similar names are found)

B. To **identify** or **assess product availability**, consider using the following resources (see also Appendix E). Some of these resources are available in an electronic format or in an Internet/intranet version.
   1. For drugs manufactured in the **United States**, the following resources are available:
      a. *The American Drug Index*
      b. *Drug Facts and Comparisons/Facts and Comparison E Answers*

   b. *Natural Medicines Comprehensive Database*
   c. *Natural Standards*
   d. *Natural Products Database (Lexicomp Online)*
   e. *Clinical Pharmacology*

V. SEARCH STRATEGIES.

To develop an effective search strategy for locating drug information literature, the following tactics should be followed after determining whether primary or secondary sources are desired.

  A. Determine whether the question at hand is **clinical** or **research related**. **Define the question** as specifically as possible. Also, identify appropriate index terms (also called keywords or descriptors) with which to search for the information.

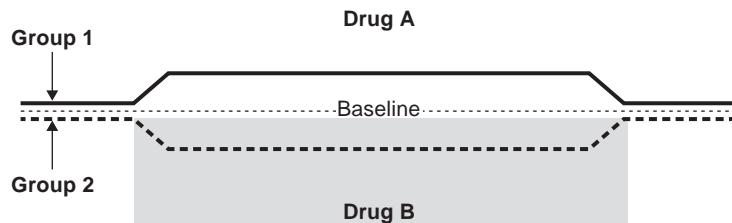
  B. Determine the **type of information** and **how much** is needed (i.e., only one fact, the most recent clinical trials, review articles, or a comprehensive database search).

  C. **Ascertain as much information as possible** about the drug being questioned and the **inquirer's association** with it. Remember that data on adverse drug effects or drug interactions are often fragmented and inadequately documented. See IV.A.2 for the specific drug information that should be acquired. Determine the answers to the following questions:

   1. What is the indication for the prescribed drug?

   2. Is the drug's use approved or unapproved? This information can be found in the following resources (remember to check how often these resources are updated to ensure having the latest information).

    a. **Approved uses** of drugs can be checked in the following:
     (1) *AHFS Drug Information*
     (2) *Drug Facts and Comparisons/Facts and Comparison E Answers*
     (3) *PDR*
     (4) *USP Drug Information*
     (5) *Drugdex (Micromedex)*
     (6) *Clinical Pharmacology*
     (7) *Drug Information Handbook/Lexi-Drugs Online (Lexicomp Online)*

    b. **Unapproved uses** of drugs can be found in the following:
     (1) *AHFS Drug Information*
     (2) *Drug Facts and Comparisons/Facts and Comparison E Answers*
     (3) *Martindale: The Complete Drug Reference*
     (4) Medline
     (5) *Drugdex* (Micromedex)


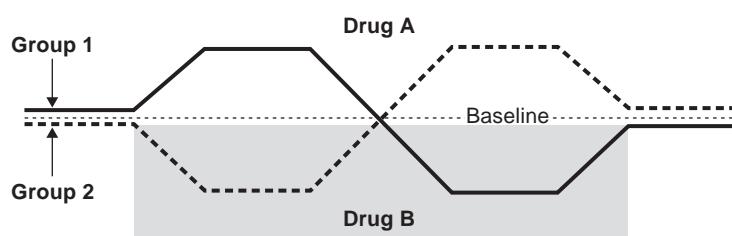
> **(6)** *USP Drug Information*
> **(7)** *Clinical Pharmacology*
> **(8)** *Drug Information Handbook/Lexi-Drugs Online (Lexicomp Online)*

3. What is the age, sex, and weight of the patient in question?
4. Does the patient have any other medical conditions or renal or hepatic disease?
5. Is the patient taking any other medications?
6. What drugs has the patient taken during the past 6 months, and what were the dosages?
7. Did the patient experience any signs or symptoms of a possible adverse drug reaction? If so,
>**a.** How severe was the reaction?
>**b.** When did the reaction appear?
>**c.** Has the patient (or any member of the patient's family) experienced any allergic or adverse reactions to medications in the past?
>**d.** Consult the following resources for more information:
>>**(1)** *Meyler's Side Effects of Drugs*
>>**(2)** A general drug reference (e.g., *PDR, Clinical Pharmacology*)
>>**(3)** Medline
>
>**e.** The manufacturer of the drug may be a useful source for missing information. Most companies request further information regarding a suspected adverse drug reaction.

8. Did the patient experience any signs or symptoms of a drug interaction? If so,
>**a.** What were the specific drugs in question?
>**b.** What were the respective dosages of the drugs?
>**c.** What was the duration of therapy?
>**d.** What was the length of the course of administration?
>**e.** What are the details of the events secondary to the suspected reaction?
>**f.** Consult the following resources for more information:
>>**(1)** A drug interactions reference—for example, *Drug Interaction Facts/Facts and Comparisons E Answers, Hansten's Drug Interaction Analysis and Management, Evaluations of Drug Interactions (EDI)*
>>**(2)** A general drug reference (e.g., *PDR*)
>>**(3)** *Reactions Weekly*
>>**(4)** Medline
>>**(5)** *Lexi-International (Lexicomp Online)*
>>**(6)** *Clinical Pharmacology*
>>**(7)** *Micromedex*

9. What is the patient's current medication status?
10. Does the patient have any underlying diseases?
11. How has the patient been managed so far?
12. What is the stability of the drug? How is compatibility of the drug with other drugs? What are the administration techniques? What are appropriate containers for the product? Resources available with this information include the following:
>**a.** *Trissel's Handbook on Injectable Drugs*
>**b.** *King's Guide to Parenteral Admixtures*
>**c.** *Trissel's Stability of Compounded Formulations*
>**d.** *Handbook of Drug Administration via Enteral Feeding Tubes*
>**e.** *Extended Stability for Parenteral Drugs*

D. Explore other possible information resources if necessary. For example, it may be useful to find background material in textbooks or databases (tertiary references) or via the Internet, and then search the journal literature (primary references) for more current information.

VI. EVALUATING A CLINICAL STUDY. Resource identification is followed by a critical assessment of the available information. This step is critical in developing an appropriate response for the inquirer.


A. Evaluate the objective of the study. Determine the aim of the research that was performed.
1. What did the researchers intend to examine?
2. Is this goal stated clearly (i.e., is the objective specific)?
3. Was the research limited to a single objective, or were there multiple drugs or effects being tested?

B. Evaluate the subjects of the study. Determine the profile of the study population by assessing the following information:

1. Were healthy subjects or affected patients used in the study?
2. Were the subjects volunteers?
3. What were the criteria for selecting the subjects?
4. How many subjects were included, and what are the demographics of the subjects (age, sex, and race)?
5. If a disease was being treated, did any of the subjects have diseases other than that initially being treated? Were any additional treatments given? Were there any contraindications to the therapy?
6. What was the patient selection method and who was excluded from the study?
7. A patient selection review should be done. You will find that most groups of subjects are homogeneous (i.e., they all have comparable characteristics). If a disease state is studied, patients should exhibit similar severity of symptoms. Researchers aim to eliminate interpatient variability. By selecting patients with similar characteristics, researchers can avoid results that are caused by individual differences among patients. Strong individual differences can obscure the results of the experiment. If studying a group of patients who exhibit significant interpatient variability is necessary, researchers may divide the patients into groups according to the variables likely to be associated with responsiveness to therapy. This is known as stratification.

C. Evaluate the administration of the drug treatment. For each drug being investigated, determine the following information:

1. **Details of treatment** with the agent being studied:
   a. Daily dose
   b. Frequency of administration
   c. Hours of day when administered
   d. Route of administration
   e. Source of drug (i.e., the supplier)
   f. Dosage form
   g. Timing of drug administration in relation to factors affecting drug absorption
   h. Methods of ensuring compliance
   i. Total duration of treatment
2. **Other therapeutic measures** in addition to the agent being studied

D. Evaluate the setting of the study. Try to determine the environment of the study and the dates on which the trial began and ended. Assess the following information:

1. People who made the observations; various professionals who offer different and unique perspectives based on their backgrounds and interests (Were the same people making observations throughout the study?)
2. Whether the study was done on an inpatient or outpatient basis
3. Description of physical setting (e.g., hospital, clinic, ward)
4. Length of the study (i.e., dates on which the trial began and ended)

E. Evaluate the methods and design of the study. The method section of the research paper explains how the research was conducted. The study design (i.e., retrospective, prospective, blind, crossover) and the methods used to complete the study are important in judging whether the study and the results are reliable and valid. From the study, try to determine answers to the following questions:

1. Are the methods of assessing the therapeutic effects clearly described?
2. Were the methods standardized?
   a. **Retrospective versus prospective**
      (1) **Retrospective** studies evaluate events that have already occurred to find some common link among them, require reliance on patient memories and accurate medical records, and are unable to show cause and effect. Retrospective studies are useful for studying rare diseases (or effects) and can help a health care professional decide whether enough information exists to warrant prospective examination of a problem.
      (2) **Prospective** studies follow identified patients forward in time to answer a specific question. They can be observational or experimental (i.e., clinical trials).
   b. **Treatment allocation**
      (1) **Parallel** study design is a protocol in which two or more patient groups are studied concurrently. The groups are treated identically except for one variable, such as a drug therapy (*Figure 14-1*).

Figure 14-1. Parallel study design.

> **(2) Crossover** design may be used as an additional control for interpatient and intrapatient variability (*Figure 14-2*). In this type of design, each patient group undergoes each type of treatment. However, the sequence in which the subjects undergo treatment is reversed for one group. Crossover design reduces the possibility that the results were strongly influenced by the order in which therapy was given. And because both groups of patients receive both types of treatment, any differences in responsiveness between the groups as a result of patient selection will be uncovered.

3. Were **control measures** used to reduce variation that might influence the results? Examples of such control methods include the following:
   a. Concurrent controls
   b. Stratification or matched subgroups
   c. A run-in phase
   d. The patient as his or her own control (i.e., crossover design)
   e. Identical ancillary treatment
4. Were controls used to reduce bias? Examples of such controls include the following:
   a. **Blind assessment**, which means that the people observing the patients do not know who is a subject and who is a control
   b. **Blind patients**, which means that the patients do not know whether they received the substance being studied or a placebo (**double-blind** combines this point with a point previously [VI.E.4.a]) (*Table 14-3*)
   c. **Random allocation**, which means that the patients involved in the study have an equal chance of being assigned to either the group of subjects receiving the active drug or the group receiving a placebo
   d. **Matching dummies**, which are placebos that are physically identical to the active agent being studied
   e. **Comparison** of a placebo or a therapy to a recognized standard practice (placebo-controlled)
F. **Evaluate the analysis of the study.** After assessing specific areas of the study separately, compile the information together to determine whether the trial is acceptable and the conclusions are justified by determining answers to the following questions (*Figure 14-3*):
   1. Were the subjects suitably selected in relation to the aim(s) of the study?
   2. Were the methods of measurement valid in relation to the aim(s) of the study?
   3. Were the methods adequately standardized?
   4. Were the methods sufficiently sensitive?
   5. Was the design appropriate?
   6. Were enough subjects enrolled?
   7. Was the dosage appropriate?

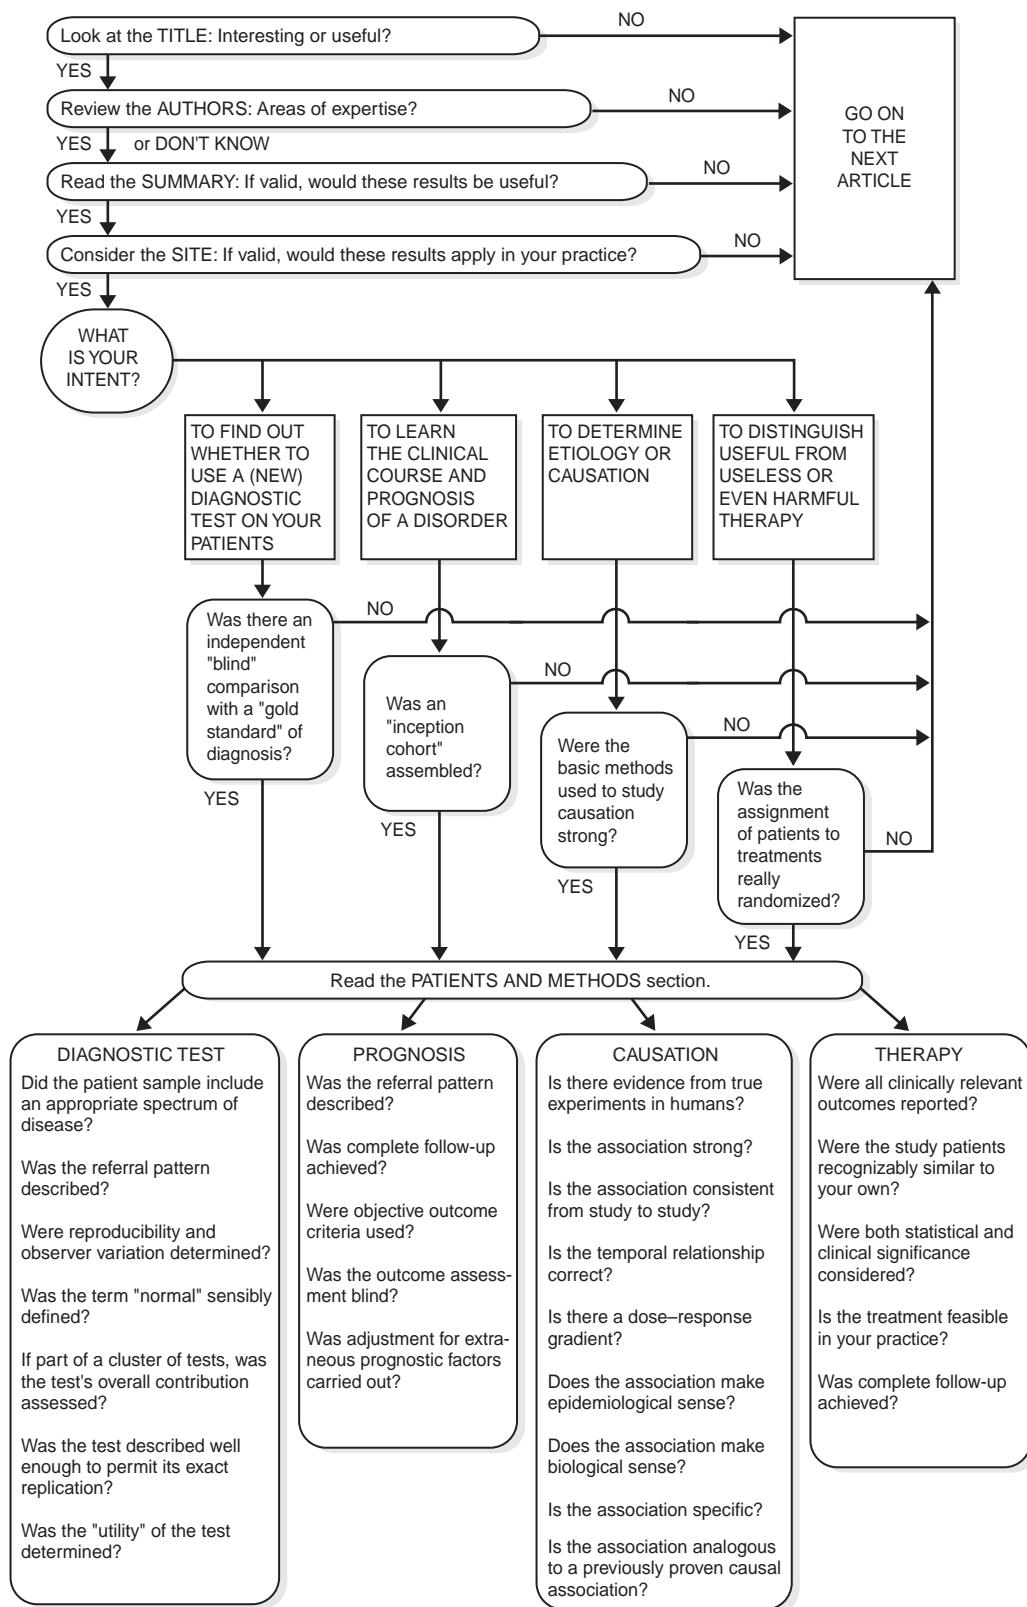
Figure 14-2. Crossover study design.


Table 14-3 TYPES OF BLIND STUDIES

Types of Blinds	Patient Aware of Treatment	Physician Aware of Treatment
Open label (nonblind)	✓	✓
Single-blind	—	✓
Double-blind	—	—

8. Was the duration of treatment adequate?
9. Were carryover effects avoided, or were compensations made for them? Did a wash-out period exist?
10. If no controls were used, were they unnecessary or overlooked?
11. If controls were used, were they adequate?
12. Was the comparability of treatment groups examined?
13. Are the data adequate for assessment?
14. If statistical tests were not done, were they unnecessary or overlooked?
15. If statistical tests are reported, assess the following:
    a. Is it clear how the statistical tests were done?
    b. Were the tests appropriately used?
    c. If results show no significant difference between test groups, were enough patients studied (i.e., statistical power)?

VII. GENERAL GUIDELINES FOR RESPONSES TO DRUG INFORMATION REQUESTS

A. **Do not guess!**
B. Responses to a member of the public must take several ethical issues into account.
   1. Patient privacy must be protected.
   2. Professional ethics must be maintained.
   3. The patient–physician relationship cannot be breached.
   4. A response is not necessary if the inquirer intends to misuse or abuse information that is provided. The inquirer often admits intent or offers clues to potential abuse, such as in the following examples:
      a. A patient asks how a certain drug is dosed (i.e., how much the drug can be increased, when it can be increased, what the maximum daily dose is). This kind of inquiry signals that the patient might be adjusting his or her own therapy.
      b. A patient asks a pharmacist to identify a tablet that is a prescription product known for a high rate of abuse.
C. Organize information before attempting to communicate the response to the inquirer. Responses should be concise and succinct. Anticipate additional questions.
D. Tailor the response to the inquirer's background. Also, consider the environment of the practice, institutional policy and procedure, and formulary.
E. Tell the inquirer where the information was found. Exercise caution when making statements such as, "There are no reports in the literature."
F. Use *extreme* caution when making statements such as, "I recommend . . ." Do not hesitate to refer consumers to their physicians.
G. Use more than abstracts to answer drug information questions. The information included in abstracts may be taken out of context and does not include all of the data available in the original article.
H. Alert the inquirer of a possible delay when it takes longer than anticipated to answer the question.
I. Ask if the information that is provided answers the inquirer's questions.
J. Ask if the inquirer would like to have reprints of articles or a written response.

Figure 14-3. Evaluation of study analysis.

Study Questions

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or completions of the statement. Select the **one** lettered answer or completion that is **best** in each case.

1. Primary literature includes which of the following?

   (A) Original clinical trials
   (B) Letters to the editor
   (C) Systematic reviews
   (D) Special reports

2. Which of the following statements is TRUE regarding tertiary resources?

   (A) Tertiary resources include textbooks and computer databases.
   (B) Textbooks typically include the most recent literature and/or information.
   (C) Tertiary resources do not typically include a bibliography.
   (D) The credentials of the editor of a tertiary resource are not considered important.

3. Which of the following should NOT be done when developing an effective search strategy?

   (A) Determine if the question is clinical or research-related
   (B) Identify appropriate search terms
   (C) Disregard other medications the patient may be taking
   (D) Ascertain if the inquirer is a health care professional

4. Which of the following resources would be appropriate for identifying a drug manufactured in a foreign country?

   (A) *Martindale: The Complete Drug Reference*
   (B) *Clinical Pharmacology*
   (C) *Trissel's Stability of Compounded Formulations*
   (D) *AHFS*

5. Which of the following resources would be appropriate for identifying the capsule with the imprint code of Watson 405?

   I. *Facts and Comparison E Answers*
   II. *Lexi-Drugs ID (Lexicomp Online)*
   III. *Myler's Side Effects of Drugs*

   (A) **I** and **II** only
   (B) **I** and **III** only
   (C) **II** and **III** only

6. Which of the following resources would be appropriate for determining the adverse effects of ginkgo biloba?

   I. *Natural Medicines Comprehensive Database*
   II. *Facts and Comparisons E Answers*
   III. *Natural Standards*
   IV. *Handbook on Injectable Drugs*

   (A) **I** and **II** only
   (B) **II** and **III** only
   (C) **I, II**, and **III** only
   (D) **II** and **IV** only

7. Which of the following resources would be appropriate for determining if Levaquin is compatible or stable in D_5W?

   (A) *Evaluations of Drug Interactions (EDI)*
   (B) *Trissel's Handbook on Injectable Drugs*
   (C) *Red Book*
   (D) *Nonprescription Products Therapeutics*

8. Which of the following resources can be used to determine unapproved uses of drugs?

   (A) *Clinical Pharmacology*
   (B) *PDR*
   (C) *Index Nominum*
   (D) *King's Guide to Parenteral Admixtures*

9. Which of the following is *not* important when evaluating a clinical study?

   (A) Study objective
   (B) Patient demographics
   (C) Drug administration
   (D) Number of authors

10. Which of the following statements is TRUE?

    (A) Prospective studies evaluate events that have already occurred.
    (B) Retrospective studies are useful for evaluating rare diseases.
    (C) A run-in phase typically increases variation.
    (D) Crossover design allows patients to undergo only one type of treatment.

11. Which of the following resources would be appropriate in evaluating the drug interaction between tramadol and citalopram?

   I. *Evaluations of Drug Interactions (EDI)*
   II. *Lexi-Interact (Lexicomp Online)*
   III. *Trissel's Stability of Compounded Formulations*

   A. **I** and **II** only
   B. **I** and **III** only
   C. **II** and **III** only
   D. **I, II,** and **III**

12. Which of the following resources would be appropriate for determining whether ranitidine causes edema?

   I. *Red Book*
   II. *PDR*
   III. *Myler's Side Effects of Drugs*

   A. **I** and **II**
   B. **I** and **III** only
   C. **II** and **III** only
   D. **I, II,** and **III**

13. What resource should be used when searching for the most current clinical trials on the use of atenolol for hypertension?

   A. *King's Guide to Parenteral Admixture*
   B. Medline
   C. *American Hospital Formulary Service (AHFS)*
   D. *The American Drug Index*

14. Which of the following resources would be appropriate for evaluating information on orphan drugs?

   I. *Drug Facts and Comparisons/Facts and Comparison E Answers*
   II. The FDA Office of Orphan Products Development (OOPD)
   III. The National Institutes of Health (NIH) Office of Rare Diseases

   A. **I** and **II** only
   B. **I** and **III** only
   C. **II** and **III** only
   D. **I, II,** and **III**

15. Which of the following control methods are used in clinical trials to reduce bias?

   I. Random allocation
   II. Double-blind trial design
   III. Matching dummies

   A. **I** and **II** only
   B. **I** and **III** only
   C. **II** and **III** only
   D. **I, II,** and **III**

Answers and Explanations

1. **The answer is A** *[see II.A.3].*
   All material included in a journal is not considered a primary resource. Original clinical trials are considered primary literature; however, review articles, articles of opinion, correspondence, and special reports are not.

2. **The answer is A** *[see II, II.C].*
   Tertiary resources include both textbooks and databases. Information available in textbooks may not include the most recent data because it could take several years to publish. A bibliography and reference citations should be present in both textbooks and databases so that the reader may refer to a specific reference if desired. Additionally, the areas of expertise for the author and/or publisher should be evaluated when using a tertiary resource.

3. **The answer is C** *[see V.A; V.C; VII.B; VII.D].*
   One should determine whether the question is related to a clinical scenario or is research related to develop an effective search strategy. Appropriate index terms should be identified to assist in the literature search.

Other medications, including herbal products, and disease states should be taken into consideration. The background of the inquirer should be determined so that the response can be tailored to the specific inquirer.

4. **The answer is A** *[see IV.B.2.a].*
   Martindale: The Complete Drug Reference is one resource that may be used to identify a drug manufactured in a foreign country. Other resources for identifying drugs manufactured in a foreign country include *Index Nominum, Lexi-Drugs International Online (Lexicomp Online)*, and the *USP Dictionary of United States Adopted Names (USAN) and International Drug Names. Clinical Pharmacology, Trissel's Stability of Compounded Formulations,* and *AHFS* do not contain this type of information.

5. **The answer is A** *[see IV.B.5].*
   For an unknown drug, the physical characteristics, including an imprint code, may be used to identify the drug. Several resources, including *Facts and Comparison E Answers* and *Lexi-Drugs Online (Lexicomp Online)* may be used.

6. The answer is C *[see IV.B.6]*.

For a natural product, the following resources are available: *Facts and Comparison E Answers*, *Natural Medicines Comprehensive Database*, *Natural Standards*, and *Natural Products Database (Lexicomp Online)*.

7. The answer is B *[see V.C.12]*.

The stability of a drug, the compatibility of a drug with other drugs and/or appropriate containers, and proper administration techniques are included in *Trissel's Handbook on Injectable Drugs*, *King's Guide to Parenteral Admixtures*, and *Trissel's Stability of Compounded Formulations*. Databases such as *Clinical Pharmacology*, *Micromedex*, *Lexicomp Online*, and *Facts and Comparison E Answers* may also be used for these types of questions.

8. The answer is A *[see V.C.2.b]*.

Unapproved uses of drugs can be found in *Clinical Pharmacology*. This information is not available in the *PDR*, *Index Nominum*, or *King's Guide to Parenteral Admixtures*.

9. The answer is D *[see VI.A; VI.B; VI.C]*.

A critical assessment of available information is important in developing an appropriate response. The study objective, the study subjects (via demographics and inclusion and exclusion criteria), and drug administration should be evaluated.

10. The answer is B *[see VI.E]*.

Retrospective studies evaluate events that have already occurred and are useful for studying rare diseases. Prospective studies follow identified patients forward in time to answer a specific question. Crossover design allows for each patient group to undergo each type of treatment. A run-in phase is a control measure used to reduce variation.

11. The answer is A *[see V.C.8.f]*.

The following resources may be helpful when evaluating drug–drug interactions: *Drug Interaction Facts*, *Hansten's Drug Interaction Analysis and Management*, *Evaluations of Drug Interactions (EDI)*, and a general drug reference such as the *PDR*. Medline may also be useful in identifying reports of drug interactions documented in the primary literature.

12. The answer is C *[see V.C.7.d]*.

Adverse drug reactions are documented in the *PDR*/package insert, *Myler's Side Effects of Drugs*, and in databases such as *Clinical Pharmacology*, *Micromedex*, *Facts and Comparison E Answers*, and *Lexicomp Online*. Additionally, Medline may be used to search the primary literature for case reports of adverse drug reactions.

13. The answer is B *[see II.B; Table 14-1]*.

Indexing and abstracting services, such as Medline, are helpful tools for searching the primary literature for specific information, data, citations, and articles. It is important to remember, however, that each indexing or abstracting service reviews a finite number of journals. Thus, multiple services must be used to conduct a thorough search of the available literature.

14. The answer is D *[see IV.B.4]*.

Orphan drugs are used to prevent or treat rare diseases. The following resources can be used for information on these drugs: *Drug Facts and Comparisons/Facts and Comparison E Answers*, The FDA Office of Orphan Products Development (OOPD), and The National Institutes of Health Office of Rare Disorders.

15. The answer is D *[see VI.E]*.

The methods used when completing a study are important when determining whether the results of the study are reliable and valid. Controls that are often used to reduce bias include blind assessment, patient blinding, random allocation, matching placebos, and controlled comparisons.

Biostatistics[1]

CHARLES HERRING

I. TYPES OF DATA[1]

A. Nonparametric (aka discrete) variables[1]

    1. Nominal: Numbers are purely arbitrary or without regard to any order of ranking of severity.[2-6] This includes dichotomous (binary) data (lived/died, yes/no, hospitalized/not hospitalized) and categorical data without order or inherent value (race, eye color, hair color, religion, blood type, acute renal failure [ARF]/congestive heart failure [CHF]/diabetes mellitus [DM]).[5,6]

    2. Ordinal: Categorical, but scored on a continuum, without a consistent level of magnitude of difference between ranks (pain scale, New York Heart Association [NYHA] class, trauma score, coma score).[2-8]

B. Parametric (aka continuous or measuring): Order and consistent level of magnitude of difference between data units (drug concentrations, glucose, forced expiratory volume in 1 second [FEV_1], heart rate, blood pressure [BP]).[2-6]

II. MEASURES OF CENTRAL TENDENCY[9]

A. Mean (aka average): "Sum of all values divided by the total number of values."[4] Mean is affected by outliers (extreme values) and is used for parametric data.[4,5,7,9] Mu (μ) is the population mean.[4,7] X-bar ($\overline{X}$) is the sample mean.[4,7,9]

B. Median (aka 50th percentile): The "mid-most" point. Median is not affected by outliers and may be used for ordinal or parametric data.[4,7,9]

C. Mode: The most common value.[4,7,9] Mode is not affected by outliers and may be used for nominal, ordinal, or parametric data.[4,7,9]

D. A weakness of measures of central tendency is that they do not describe variability or spread of data.[1]

III. MEASURES OF VARIABILITY: DESCRIBE DATA SPREAD AND CAN HELP INFER STATISTICAL SIGNIFICANCE[9]

A. Range: The interval between lowest and highest values. Range is simply descriptive and only considers extreme values, so it is affected by outliers.[3,4,7,9]

B. Interquartile range: The interval between the 25th and 75th percentiles, so it is not affected by outliers. Because it is directly related to median, it is typically used for ordinal data.[5,7,9]

C. Variance: Deviation from the mean, expressed as the square of the units used.[3,9]

    1. Variance = sum of (mean − data point) squared, divided by $n-1$

    2. Variance $= \Sigma \dfrac{(\overline{X} - X_1)^2}{n-1}$

D. Standard deviation (SD): Square root of variance. SD estimates data scatter around a sample mean. SD is only used for parametric data.[3-5,7,9] Sigma (σ) is the population SD.[3] S is the sample SD.[3]

    1. SD $= \sqrt{\text{variance}}$

E. Standard error of the mean (SEM) (aka standard error [SE]): SD divided by the square root of n. As a measure of variability, SEM is misleading. If one is provided SEM, SD and/or confidence intervals (CIs) should be calculated to see true sample variability.[3,4,7,9]

    1. SEM $= \dfrac{\text{SD}}{\sqrt{n}}$

F. CI: In medical literature, a 95% CI is most frequently used, and it is a range of values that "if the entire population could be studied, 95% of the time the true population value would fall within the CI estimated from the sample."[9] CIs are descriptive and inferential. All values contained in the CI are statistically possible.[4]

1. 95% CI $= \overline{X} \pm 1.96$ (SEM)

2. Interpretation of statistical significance for CI in superiority trials:

   a. For **differences** such as BP reduction, cholesterol reduction, fingerstick blood sugar (FSBS) or A1c reductions, relative risk reductions or increases, and absolute risk reductions or increases, if the 95% CI includes 0, then the results are not statistically significant (NSS).[4,7]

   b. For **ratios** such as relative risk (aka risk ratio), odds ratio, and hazards ratio, if the 95% CI includes 1, then the results are NSS.[5–7]

IV. HYPOTHESIS TESTING[10]

A. H_0 (null hypothesis) = For superiority trials, H_0 is that no difference exists between the populations studied.[4,5,10] H_1 (alternative hypothesis) = For superiority trials, H_1 is that a difference does exist between the populations studied.[5,10] Statistical significance is tested (hypothesis testing) to indicate whether H_0 should be accepted or rejected.[4,6,10]

1. For superiority trials, H_0 is "rejected" if a statistically significant difference between groups is detected (results unlikely due to chance). H_0 is "accepted" if no statistically significant difference is detected.[4,6,10]

B. A type 1 error occurs if one rejects H_0 when, in fact, H_0 is true.[5,10] For superiority trials, this occurs when one finds a difference between treatment groups when, in fact, no difference exists.[4–6,10] Alpha (α) is the probability of making a type 1 error.[5,6,10] H_0 is rejected when $P \le \alpha$.[4,10] By convention, α is usually 0.05, which means that 1 time out of 20, a type 1 error will be committed. This is a consequence that investigators are generally willing to accept and is denoted in trials as a $P \le 0.05$.[4–6,10]

C. A type 2 error occurs when one accepts H_0 when, in fact, H_0 is false.[4–6,10] For superiority trials, this is when one finds no difference between treatment groups when, in fact, a difference does exist.[5,6] Beta (β) is the probability of making a type 2 error.[5,6,10] By convention, β is $\le 20\%$ (0.2).[4,5,10]

D. Power is the ability of an experiment to detect a statistically significant difference between samples when a significant difference truly exists.[4–6,10] (Power = $1 - \beta$) Inadequate power may cause one to conclude that no difference exists when, in fact, a difference does exist (type 2 error).[10] Note that in most cases, power is an issue only if one accepts H_0. If one rejects H_0, there is no way that one could have made a type 2 error[1] (*Table 15-1*).

E. Clinical versus statistical significance

1. Just because one finds a statistically significant difference does not mean that the difference is clinically meaningful.[4,10] With enough patients, one can find all kinds of statistically significant differences that are *not* clinically meaningful. For example, with a large enough sample size, one could detect a statistically significant difference between one BP medication that decreases systolic BP by 10 mm Hg and another that decreases BP by 11 mm Hg. This would be statistically but not clinically significant. Also, lack of statistical significance does not mean the results are unimportant.[4,11] A nonstatistically significant difference is more likely to be accepted as being clinically significant in the instance of safety issues such as adverse effects.[1]

2. To help judge the clinical significance of a statistically significant data set, determine what others think is clinically significant by considering the effect used in the sample size calculation

---

Table 15-1 TYPE 1 AND 2 ERROR FOR SUPERIORITY TRIALS

Decision from statistical test	Reality	
	Difference exists (H_0 false)	No difference exists (H_0 true)
Difference found (Reject H_0)	Correct	Incorrect
	No error	Type 1 error (aka false positive)
No difference found (Accept H_0)	Incorrect	Correct
	Type 2 error (false negative)	No error

(if reported), the existing evidence-based or expert consensus statements, and any cost-effectiveness or decision analyses that have been performed.[8,12] Absent such guidance, require that the minimum worthwhile effect be large when the intervention is costly (e.g., in terms of time, money, or other resources), the intervention is high risk, a patient is risk averse, or the outcome is unimportant or has intermediate importance but with uncertain benefit to patients.[8,12] Accept the minimum worthwhile effect as small when the intervention is low cost, the intervention is low risk, the patient is risk taking, or the intervention is important and has an unambiguous outcome (e.g., death).[8,12]

V. STATISTICAL INFERENCE TECHNIQUES IN HYPOTHESIS TESTING FOR PARAMETRIC DATA[13]

A. *T* test
1. Nonpaired *t* test. Observations between groups are independent as in a parallel trial.[4,13]
2. Paired *t* test (aka matched or repeated measures data). Patients are their own control (i.e., observations between groups are dependent as in a pretest/posttest or crossover trial).[4,13]

B. The *t* test is the statistical test of choice when making a single comparison of parametric data between two groups. When making either multiple comparisons between two groups or a single comparison between multiple groups, type 1 error risk increases, and one should make an effort to keep the type 1 error risk $\leq 5\%$ (i.e., ≤ 0.05). One of the best ways to help control for type 1 error risk when analyzing parametric data for multiple groups or comparisons is analysis of variance (ANOVA) testing.[1]

C. ANOVA tests for a statistically significant difference among a group's collective values.[13] ANOVA involves calculation of an F-ratio, which answers the question, "Is 'the variability between the groups large enough in comparison to the variability of data within each group to justify the conclusion that two or more of the groups differ?'"[5,13]

D. ANOVAs for independent (aka nonpaired) samples
1. One-way ANOVA. Used if no confounders, the experimental groups differ in one factor (e.g., type of drug evaluated), and greater than or equal to three independent (i.e., nonpaired) groups are being evaluated.[3]

E. Multifactorial ANOVA for independent (aka nonpaired) samples. Any type of ANOVA controlling for one or more confounders (i.e., samples differ in greater than or equal to two factors). These include the following:
1. Two-way ANOVA. Used if there is one confounder (i.e., samples differ in two factors at a time—drug and confounder) for two or more independent groups (nonpaired).[1]
   a. Example 1: Weight loss studies with at least two groups would use this because heavier patients lose weight faster than less heavy patients. This type of ANOVA will show if variability in results is attributable to either factor independently and/or the two factors are combined.[1]

F. Analysis of covariance (ANACOVA, ANCOVA) for independent (aka nonpaired) samples. Used if there are two or more confounders and two or more independent groups (nonpaired).[1]
1. Three-way ANOVA. Used if there are two confounders (i.e., samples differ in three factors at a time—drug and two confounders) for two or more independent groups (nonpaired).[1]
2. Four-way ANOVA. Used if there are three confounders (i.e., samples differ in four factors at a time—drug and three confounders) for two or more independent groups (nonpaired).
3. . . . and so on . . .

G. ANOVAs for related (aka paired, matched, repeated) samples
1. Repeated measures ANOVA. Used if there are no confounders and three or more related samples (paired). Subjects participate in more than one treatment group as in a crossover trial.[1]
2. Two-way repeated measures ANOVA. Used if there is one confounder and two or more related samples (paired).[1]
3. Repeated measures regression. Used if there are two or more confounders and two or more related samples (paired).[1]

H. ANOVA will indicate whether a difference exists between groups but will not indicate where this difference exists.[5] For this, one must use multiple comparison methods (MCMs). These are types of post hoc tests. MCMs are performed only after a statistically significant *F* test.[13]

VI. STATISTICAL INFERENCE TECHNIQUES IN HYPOTHESIS TESTING FOR NONPARAMETRIC DATA[14]

A. If data are not parametric, nonparametric statistical methods must be used.[14] We will start with nominal data. Chi-square and Fisher exact tests can be used for proportions and frequencies of nominal data matrices (e.g., prevalence).[14]

B. Chi-square tests are "used to answer questions about rates, proportions, or frequencies."[5,14] Used to determine whether a difference between populations or groups exists but will not indicate where the difference lies.[5,14]

    1. Chi-square test of independence (aka test of association). Used to compare two or more groups ($\geq 2 \times 2$ table, i.e., 2×2, 2×3, 4, 5, 3×3, etc).[4,5,14] (Sample size must be > 20).[14] Chi-square test of independence "cannot be used for paired data."[14]

        a. Example of a chi-square test: Might compare the Board of Pharmacy exam pass rates of candidates from three different pharmacy schools. This kind of table is a contingency table. It expresses the idea that one variable (such as passing or failing the examination) may be contingent on the other variable (such as which pharmacy school one attended).[1]

	Passing Scores	Failing Scores
School A	90	5
School B	120	9
School C	130	11

        b. There are two possible results (passing vs. failing) for three schools of pharmacy. Therefore, this is called a 2×3 table or matrix.[1]

C. Once chi-square calculations (for greater than 2×2 contingency table) indicate a statistically significant difference, one must perform post hoc tests to determine which groups or treatments differ from one another.[5] These post hoc tests should only be performed if the chi-square test was significant.[1]

D. Fisher exact test may be used when the sample size for a nominal data set is between 20 and 40.[14] It may also be used for a 2×2 matrix when a nominal data set is 20 or less.[4,14] In addition, Fisher exact test may be used for matched or paired data (i.e., crossover or prepost test design).[1]

VII. STATISTICAL INFERENCE TECHNIQUES IN HYPOTHESIS TESTING FOR ORDINAL DATA[14]

A. Mann-Whitney U test and Wilcoxon rank sum test. These may be used when one comparison is being made with two nonpaired groups (which need not be of equal size).[5,14] These are not appropriate for grouping into a "cumulative frequency distribution."[14]

B. Kolmogorov-Smirnov test. This can also be used when one comparison is being made with two nonpaired groups.[14] However, this test is used when data are grouped into a "cumulative frequency distribution" (i.e., individual scores or data values are lumped together into groups for further analysis).[14] An example of a cumulative distribution grouping is the manner in which the Glasgow Coma Score is used to help determine trauma score.[14]

C. Wilcoxon signed rank test (not to be confused with Wilcoxon rank sum test). This may be used when one comparison is being made with two paired groups.[4,14]

D. Kruskal-Wallis test (for nonpaired data). This may be used when two or more comparisons are being made with three or more nonpaired groups.[4,14]

E. Friedman test (for paired data). This may be used when two or more comparisons are being made with three or more paired groups.[4,14]

    1. As with chi-square and ANOVA tests for more than two groups, once Kruskal-Wallis or Friedman tests indicate a statistically significant difference, one must perform post hoc tests to determine which groups or treatments differ from one another.[5] These post hoc tests should only be performed if the Kruskal-Wallis or Friedman test was statistically significant.[1]

F. ANOVA rank tests are generally used to account for confounders in ordinal data with the exception of using repeated measures regression to account for two or more confounders in crossover design.[1]

VIII. CORRELATION[11] SIMPLY EXPLAINS THE STRENGTH OF A RELATIONSHIP BETWEEN TWO VARIABLES[4,11,15]

A. The sample correlation coefficient for parametric data is the Pearson correlation coefficient or Pearson product moment r.[5,11]
1. r ranges from -1 to $+1$[5,11]
2. -1 = perfect negative linear relationship[5,11]
3. $+1$ = perfect positive linear relationship[5,11]
4. zero = no relationship[5,11]
5. H_0 is that $r = 0$ (i.e., no relationship between variables)[11]
6. There is not a consistent level of magnitude of difference between r values.[15] Therefore, r of 0.25 is not half the relationship of an r of 0.5 and "an r of $\pm$ 0.5 does not imply that the strength of the relationship is 'half-way' between no correlation/relationship and a perfect correlation."[11,15]
7. The strength of a relationship depends on the data being evaluated. In one field of study, an $r = 0.6$ may be a strong correlation, whereas in another field of study, an $r = 0.8$ may be required to indicate a strong correlation.[1]
8. Some general guidelines are the following:
    a. $r < 0.25$: "doubtful" correlation[15,16]
    b. $r = 0.26$–0.5: "fair" correlation[15,16]
    c. $r = 0.51$–0.75: "good" correlation[15,16]
    d. $r > 0.75$: "superior" correlation[15,16]
9. There is a P value associated with r and CIs can be calculated[5] [e.g., $r = 0.74$ (95% CI: $0.53 - 0.98$)].

B. The sample correlation coefficient for ordinal data is Spearman rho or Spearman rank order r.[5,11]

C. Most of the time, relationships are "confounded by extraneous variables."[11] This "adversely affects a 'perfect' correlation."[11]
1. Example: There is an association with overuse of albuterol (ProAir HFA) and mortality. However, there are multiple confounders that prevent an absolute understanding of the relationship. Possible confounders include the type of controller medication being used, inhalation technique/medication compliance, concomitant disease states (chronic obstructive pulmonary disease [COPD], heart failure [HF]), concomitant medications (β-blockers), and one of many triggers.[1]

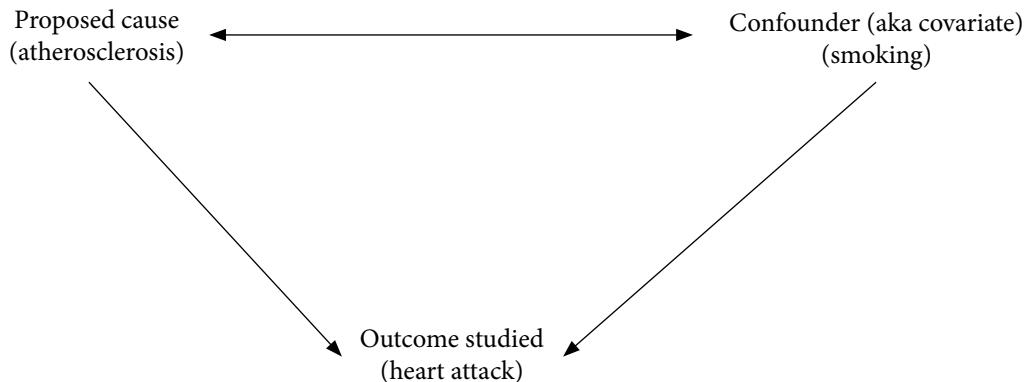
D. Correlation has many limitations. Although it does a good job of recognizing and measuring the strength of relationship(s) between variables, it does not establish causality.[11,15] Remember the ageless question of which came first, the chicken or the egg? A more relevant example is, does overuse of albuterol (ProAir HFA) lead to poorly responsive, severe asthma attacks? Or does poorly responsive, severe asthma lead to albuterol (ProAir HFA) overuse?[1]

E. Correlations do not have the ability to "predict" one variable based on another.[1]

IX. REGRESSION TAKES CORRELATION ONE STEP FURTHER

Regression not only recognizes and measures the strength of relationship(s) between variables, it also describes a relationship such that an equation for predicting one variable from another variable can be developed.[4,11]

A. With simple linear regression, where m = slope of the line, "y is the dependent variable, x is the independent variable," and "b is the y-intercept of the line."[11]

$$y = mx + b$$


B. r-squared (r^2) is known as the coefficient of determination. It "represents the percentage of variation in y that is accounted for by x."[8] For example, if a study produces a correlation/regression analysis

between stroke and hypertension reporting an $r = 0.70$, then $r^2 = 0.49$, and one could say that 49% of stroke risk may be explained by BP.[1]

1. Conversely, $1 - r^2$ represents the proportion of the variation that is not related to the independent variables (i.e., the residual variation).[11] This is sometimes referred to as the *coefficient of nondetermination*.[15]
2. As with correlation, CIs can be calculated for regression analyses. Also, as with correlation, the existence of this kind of statistical association is not in itself evidence of causality. One must take into account what type of analysis is being performed (i.e., case control vs. cohort vs. randomized controlled trial [RCT]).[1]

C. Multiple regression. When more than one independent variable is used to predict a dependent variable, multiple (or multivariate) regression analysis (MRA) is used.[4,15] For example, the national cholesterol guidelines use multiple regression to help establish 10-year coronary heart disease (CHD) risk for patients based on population data. A patient's 10-year CHD risk is the dependent variable because its estimate "depends on" several independent variables. The independent variables include age, total cholesterol, high-density lipoprotein (HDL) cholesterol, smoking status, and systolic BP. All of these independent variables are used to help predict a patient's 10-year CHD risk.[1]

1. Multiple linear regression is "used with parametric (aka continuous) outcomes like BP" and lipid values.[17]
2. Logistic regression is used with nominal outcomes such as death and hospitalization.[8,17]
3. Cox proportional hazards regression is "used when an outcome is the length of time to an event."[17] For example, time until death or hospitalization or time until discharge.[5,17]

X. ERROR VERSUS BIAS.
Errors are "mistakes that do not systematically under- or overestimate effect size."[18] Biases are systematic errors/flaws in study design that lead to incorrect results.[5,6,18] More common types of biases include publication bias, investigator bias, compliance bias, selection bias, diagnostic or detection bias, recall bias, and channeling bias (aka confounding by indication).[5–7,18–20] The best way to minimize bias is through proper study design (e.g., randomization, inclusion/exclusion criteria, blinding, using controls and objective outcome measures).[5,6,8,18,19]

XI. CONFOUNDING.
Confounders are "causes, other than the one studied, which may be linked to the studied outcomes and/or the hypothesized cause."[5,7,19] Although these are sometimes difficult to detect, investigators should account for known confounders.[5,19] For example, atherosclerosis causes myocardial infarction (MI). There is an association between atherosclerosis and smoking, smoking and risk for an MI, and atherosclerosis and risk for an MI. The proposed cause is atherosclerosis. The potential confounder is smoking, so investigators need to account for any significant smoking differences among studied groups.[19]

A. Ways of controlling for confounders include proper study design (e.g., randomization, inclusion/exclusion criteria, blinding, using controls and objective outcome measures) and proper statistical analysis (stratification, MRA, and use of ANOVA [for parametric data]).[5–8,18,19]

XII. CONTROLLED VERSUS NONCONTROLLED TRIALS

A. Controlled trials attempt to "keep the study groups as similar as possible and to minimize bias. Ideally the groups will differ only in the factor (treatment) being studied."[7]

B. Uncontrolled trials generally only evaluate one group[7] (i.e., no control group).[1]

C. Various types of controls

1. "Placebo control: One or more groups are given active treatment while the control group receives a placebo."[7]

2. "Historical Control: The data from a group of subjects receiving the intervention are compared to data from a group of subjects previously treated during a different time period, perhaps in a different place"[7] (experimental group vs. past group).

3. "Crossover control: Each subject serves as his/her own control. During a defined period of time, group A receives the experimental drug while group B receives the control. Then for the next defined period of time, group A receives the control and group B receives the experimental drug."[7]

4. "Standard Treatment (aka Active Treatment) Control: Control group subjects receive 'gold standard' treatment while the other group receives the experimental treatment."[7] These are mainly used when a placebo control would be unethical.[7]

5. "Within Patient Comparison Control: One part of the body is treated with the experimental treatment while another part of the body is treated with either the 'gold standard' or placebo." This is mainly used for dermatology trials.[7]

XIII. BLINDING DOES SEVERAL THINGS.

It helps minimize clinicians' treating/assessing one group differently from another, helps control for a placebo effect, and helps maximize equal patient compliance. Blinding is especially important if there is any degree of subjectivity associated with outcome assessment. Common types of blinding are listed in the following[1]:

A. Nonblinded trial: The investigator and subject know what treatment or intervention the subject is receiving. This is commonly referred to as an *open* or *open-label trial.*[7]

B. Single-blind trial: Someone (usually the patient) is unaware of what treatment or intervention the subject is receiving.[7]

C. "Double-blind trial: Neither the investigator nor the subject is aware of what treatment or intervention the subject is receiving."[7]

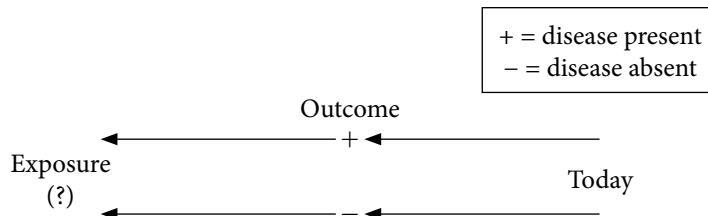
D. "Double-dummy trials are used if one is comparing two different dosage forms and doesn't want the patient or investigator to know in which arm the patient is participating. For example, if one is comparing intranasal sumatriptan (Imitrex) to injectable sumatriptan (Imitrex STATdose), one group would receive intranasal sumatriptan and a placebo injection, while the other group would receive intranasal placebo and a sumatriptan injection."[7]

XIV. VALIDITY

A. Internal validity. To what degree does a study appropriately test and answer the question(s) being asked and measure what is claimed to be measured? It "addresses issues of bias, confounding, and measurement of endpoints." [19] It directly affects external validity.[7,18,19]

B. External validity. Presuming internal validity, this assesses whether the results can be extrapolated to the general population, to other groups, patients, or systems.[7,18,19]

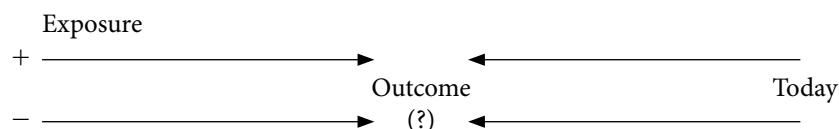
XV. ASSESSING RISK[1]

A. Absolute risk (AR) (aka incidence)


$$AR = \frac{\text{number who develop outcome during a specified period}}{\text{number available to develop outcome at the beginning of the study}}$$

1. Absolute risk reduction (ARR) = $AR_{Control} - AR_{Experimental}$
2. Numbers-needed-to-treat (NNT) = $1/ARR$

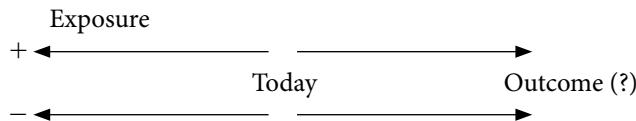
B. Relative risk (RR) (aka risk ratio, rate ratio, or incidence rate ratio) = $AR_{Experimental}/AR_{Control}$

1. Relative risk reduction (RRR) = $1 - RR$ and RRR = $ARR/AR_{Control}$


C. Odds ratio (OR) is an estimate of RR and is generally used for case-control trials.[5,15]

D. Hazard ratio (HR) estimates RR and is generally used with Cox proportional hazards regression analysis.

E. OR and HR are fairly accurate estimates of RR if the incidence of an outcome is < 15%.[17]

XVI. TRIAL DESIGN[1]


A. Prospective versus retrospective
1. Prospective study: Subjects are followed forward in time from a specified time point. Data are collected and outcomes or variables are measured and analyzed.[1]
2. Retrospective study: Always begins and sometimes ends in the past (case report, case series, case control, retrospective cohort) but may end in the present or future (prospective cohort). The investigator(s) look(s) back in time to collect and analyze data.[1]

B. Relative strength of causal relationships based on "trial designs."[19] The following study designs are listed in a "weakest to strongest order for establishing causality and confidence in conclusions/results."[18,19]
1. Case report[18,19] (weakest) (not analytical or interventional)
2. Case series[18,19] (simply more patients than case reports) (not analytical or interventional)
3. Cross-sectional studies "survey characteristics of a population at a given time and are particularly useful for measuring the prevalence of a disease or event."[20]
4. Case-control study[18,19] (aka epidemiological or observational trial designs)[5] (analytical)
5. Cohort study[18,19] (aka epidemiological or observational trial designs, outcomes or follow-up studies)[5] (analytical)
   a. Retrospective cohort (exposure and end point occurred in the past)[1]
   b. Prospective cohort (exposure occurred in the past, end point in the future)[1]
   c. True prospective cohort (exposure in the present or future, end point in the future)[1]
6. Meta-analysis. This is controversial, but most are of the opinion that, as long as the meta-analysis included only RCTs and was conducted appropriately, its strength to determine causality is between that of a cohort and RCT.[19]
7. RCT. Strongest for establishing causality (interventional)[5,18,19]

C. Retrospective trials (arrow charts for trial designs shown hereafter)[19]
1. Case-control study (aka "risk factor studies")[19]:
   a. These are retrospective, identify patients based on outcome or disease, and are therefore good for rare outcomes or diseases.[6,19] These are good for identifying possible "causal influences on relatively uncommon outcomes" or slow-developing diseases, can be used in diseases with long latencies such as Alzheimer, and are inexpensive and quick.[5,18,19] Problems include their being only hypothesis generating, subject to bias and confounding, not good for rare exposures, and that selection of controls can be challenging.[5,18,19]
2. Retrospective cohort study (aka "outcomes studies")[19]:

3. Prospective cohort study (aka "outcomes studies")[19]:

+ ←——————————— Exposure
              Today   Outcome (?)
− ←———————————   ————————————→
    a. This is called a prospective cohort, but it is really a retrospective design because exposure took place in the past.[19]

4. Very rarely, one may see the following type of prospective cohort study, which is truly prospective[18]:

    Exposure
+ ———————————————————————→
Today   Outcome (?)
− ———————————————————————→
    a. Cohorts are good for studying frequent outcomes or diseases such as atherosclerosis.[5,18] Subjects are identified based on exposures, which allows investigators to study multiple diseases and/or uncommon exposures.[6,19] These are subject to less bias than case control, can help determine incidence of disease, and can help define temporal trends between exposure and disease. [5,6,18,19] Problems include loss of follow-up, inability to control exposures, bias (although less than with case control), time, and expense.[1]

D. Randomized trials. Randomization (aka allocation) means that all within a population have an equal and independent opportunity of being selected as part of a sample.[1]

1. Parallel design (arrow charts for trial designs shown hereafter) [19]

2. Crossover design. Used when there is wide, interpatient variability. "Since each patient serves as his or her own control, variation between treatment groups is minimized."[20]

    a. Crossovers may be used for certain "chronic, stable diseases, such as osteoarthritis, or for pharmacokinetic studies."[20] Crossovers are not appropriate for chronic, unstable diseases (e.g., allergic rhinitis or asthma).[20] Also, crossovers are not suitable for "acute conditions, such as postoperative pain or infections."[20] They are not appropriate for certain types of treatment questions (e.g., treatment of nausea/vomiting in chemotherapy trials). Also, there may be cases where crossovers are unethical or impractical (e.g., a smoking cessation trial). To prevent carryover effect, "a typical washout period should last at least 5 half-lives of the study drug or its active metabolite."[20]

3. Randomized trials are the "best design for determining causality" by minimizing bias and dividing confounders equally.[5,19] However, these are expensive and time and labor intensive, and generalization of results depends highly on appropriate inclusion/exclusion criteria.[5,19]

Study Questions*

1. Which measure(s) of central tendency is/are sensitive to outliers?

   (A) Mean
   (B) Median
   (C) Mode

2. For what type of data can standard deviation (SD) be used?

   (A) Parametric data
   (B) Ordinal data
   (C) Nominal data

3. Which of the following is correct regarding measures of variability?

   (A) Range can be both descriptive and inferential.
   (B) Standard error of the mean (SEM) is always larger than SD.
   (C) All values contained in a confidence interval (CI) are statistically possible.
   (D) CI is a descriptive measure only.

4. A study was performed to determine the effect of a new antipsychotic agent (Drug A) on psychosis in patients with underlying schizophrenia as compared to placebo. A sample size of 300 patients was calculated to be needed based on an α of 0.05 and a β of 0.2. The double-blind, parallel, superiority trial was performed in 350 patients for 8 weeks. At the end of the 8-week period, the new antipsychotic agent was found to induce remission in 20% of patients as compared to 19% in the placebo group ($P = 0.04$). Which of the following statements is true based on the results of the study?

   (A) Drug A was found to have a statistically significant and clinically significant difference on remission of psychosis as compared to placebo.
   (B) Drug A was found to have a statistically significant difference but not a clinically significant difference on remission of psychosis as compared to placebo.
   (C) Drug A was found to have a clinically significant difference but not a statistically significant difference on remission of psychosis as compared to placebo.
   (D) Drug A was not found to have a clinically or statistically significant difference on remission of psychosis as compared to placebo.

(For the next two questions) A study of the effects of bupropion (Zyban) versus nicotine gum (Nicorette) on the primary end point of change in the number of cigarettes smoked per day in a parallel, randomized trial. The investigators plan to include 450 subjects (150 in each arm) to reach statistical significance based on a β of 0.2 and α of 0.05.

5. Which of the following statistical tests would be the most appropriate? (Hint: assume no confounders)

   (A) One-way ANOVA
   (B) Chi-square (χ^2)
   (C) Fisher exact test
   (D) Friedman test
   (E) *t* test

6. Which of the following statistical tests would be the most appropriate if the study had evaluated three groups instead of only two? (i.e., bupropion [Zyban] vs. nicotine patches [Nicoderm CQ] vs. nicotine gum [Nicorette])

   (A) One-way ANOVA
   (B) Chi-square (χ^2)
   (C) Fisher exact test
   (D) Friedman test
   (E) Student's *t* test

7. A study is designed to evaluate the change in blood pressure lowering between metoprolol tartrate (Lopressor®) and metoprolol succinate (Toprol XL®). The investigators decide to perform a parallel trial in 200 patients. There were significant baseline differences between the groups in diet and exercise. Which of the following statistical tests would be most appropriate?

   (A) One-way ANOVA
   (B) Chi-square (χ^2)
   (C) Fisher exact test
   (D) ANCOVA
   (E) Student's *t* test

---

* These study questions were composed by Melanie Pound, PharmD, BCPS and Rebekah Grube, PharmD, BCPS.

8. The makers of eplerenone (Inspra) want to design a study to compare their medication to the current standard of spironolactone (Aldactone) in the treatment of heart failure. They decide to perform a parallel trial of the two agents in 2000 patients with NYHA classes II to IV heart failure over 2 years. The primary end point is mortality. Which of the following statistical tests would be most appropriate to use?

   (A) ANOVA
   (B) Fisher exact test
   (C) Chi-square (χ^2)
   (D) Mann-Whitney U test
   (E) Student's *t* test

9. A retrospective study produces correlation/regression analysis between a high sodium intake (> 2.4 g/day) and hypertension (HTN) reporting an $r = 0.45$. Which of the following is correct?

   (A) 20% of HTN may be explained by high sodium intake.
   (B) 20% of HTN is not explained by high sodium intake.
   (C) 80% of HTN is explained by high sodium intake.
   (D) 55% of HTN is not explained by high sodium intake.
   (E) 45% of HTN may be explained by high sodium intake.

10. A study was performed to evaluate a possible correlation between the use of the herbal product Goldenseal and changes in pain relief (based on pain scale scores). Which type of correlation analysis should be used in this trial?

    (A) Pearson
    (B) Spearman
    (C) Linear
    (D) Cox

(For the next two questions) In the RE-LY trial, dabigatran (Pradaxa) was compared with warfarin (Coumadin) for the prevention of cerebrovascular accident (CVA) in atrial fibrillation (AF) patients. The primary outcome in this trial was CVA or systemic thromboembolism (TE). The results are presented as follows:

End point	Dabigatran ($n = 6076$)	Warfarin ($n = 6022$)	RR, 95% CI
CVA or TE	134 (2.2%)	159 (2.6%)	0.66 (0.53–0.82)
MI	89 (1.5%)	63 (1.0%)	1.38 (1.00–1.91)

11. What can be concluded about the outcome "CVA or TE"?

    (A) Dabigatran (Pradaxa) has a clinically significant lower risk than warfarin (Coumadin), although it is not statistically significant because the CI does not include 1.
    (B) Dabigatran (Pradaxa) has a clinically significant lower risk than warfarin (Coumadin), although it is not statistically significant because the CI does not include 0.
    (C) Dabigatran (Pradaxa) has a clinically significant higher risk than warfarin (Coumadin), and it is statistically significant because the CI does not include 0.
    (D) Dabigatran (Pradaxa) has a clinically significant lower risk than warfarin (Coumadin), and it is statistically significant because the CI does not include 1.

12. What can be concluded about the outcome "MI"?

    (A) Dabigatran (Pradaxa) has a higher MI risk than warfarin (Coumadin), although it is not statistically significant because the CI includes 1.
    (B) Dabigatran (Pradaxa) has a higher MI risk than warfarin (Coumadin), although it is not statistically significant because the CI does not include 0.
    (C) Dabigatran (Pradaxa) has a higher MI risk than warfarin (Coumadin), and it is statistically significant because the CI includes 1.
    (D) Dabigatran (Pradaxa) has a higher MI risk than warfarin (Coumadin), and it is statistically significant because the CI does not include 0.

13. A researcher was interested in examining the association between postmenopausal hormone replacement therapy (HRT) and development of heart disease. All women who were characterized as postmenopausal were approached regarding their interest in participating in the study by answering a questionnaire annually regarding their medication use and medical conditions. Of the 16,168 women who provided consent, the average length of follow-up was 12.5 years (range, 6 to 16 years). Which of the following best describes the study design?

    (A) Case-control study
    (B) Prospective cohort study
    (C) Randomized controlled trial
    (D) Meta-analysis

14. An investigator wishes to study a new drug for the treatment of hypertension in patients with diabetes. What is the best type of trial design the investigator should use for determining causality in this particular study?

(A) A case-control study
(B) A prospective cohort study
(C) A prospective, randomized, placebo-controlled trial
(D) A prospective, randomized, standard-of-care comparison trial
(E) A meta-analysis

15. Which of the following would be appropriate for a crossover design study?

(A) Effects of Drug A versus Drug B on hypertension in 100 patients
(B) Effects of varenicline (Chantix) compared to placebo on smoking cessation
(C) Effects of fluticasone/salmeterol (Advair) and budesonide/formoterol (Symbicort) on asthma exacerbations
(D) Effects of hydralazine and hydrochlorothiazide (Microzide) on all-cause mortality

Answers and Explanations

1. The answer is A *[see II.A]*.
Mean is the correct answer because it is affected by outliers. Median and mode are incorrect because they are not affected by outliers.

2. The answer is A *[see III.D]*.
Parametric (aka continuous) data is correct. Standard deviation is only meaningful for parametric data. It is not meaningful for nominal data. Measures of variability are not meaningful for nominal data. Standard deviation is usually not meaningful for ordinal data. Interquartile range is the preferred measure of variability for ordinal data.

3. The answer is C *[see III.F]*.
Answer C is correct because all values within a CI are statistically possible. Answer A is incorrect because range is descriptive only. Range is not inferential because one is unable to "infer" statistical significance for a data set based on range. Answer B is incorrect because SEM is always smaller than SD. Answer D is incorrect because CI is not only descriptive but also inferential since one is able to "infer" statistical significance for a data set based on CI.

4. The answer is B *[see IV.E]*.
Answer B is correct. The difference was statistically significant because the *P* value was .04. Based on this *P* value, there is a 4% chance that a type 1 error occurred, which is less than the prespecified acceptable risk of 5% (preset α was 0.05 or 5%). However, the difference was not clinically meaningful because there was only a 1% difference in the primary end point (induction of remission) between the treatment groups. For these reasons, answers A, C, and D are incorrect.

5. The answer is E *[see V.A–B]*.
Answer E is correct because a *t* test is the test of choice for evaluating statistical differences in parametric data (change in the number of cigarettes smoked daily) when only two groups are being evaluated and there are no detected confounders. Answer A is incorrect because one-way ANOVA is used for testing three or more groups. Answers B and C are incorrect because chi-square and Fisher exact test are used to test nominal data. Answer D is incorrect because Friedman test is used to test ordinal data.

6. The answer is A *[see V.C–D]*.
Answer A is correct because one-way ANOVA is used to test parametric data (change in the number of cigarettes smoked daily) when there are three independent groups and no detected confounders are present. Answers B and C are incorrect because chi-square and Fisher exact test are used to test nominal data. Answer D is incorrect because Friedman test is used to test ordinal data. Answer E is incorrect because *t* test is used for evaluating statistical differences in parametric data when only two groups are being evaluated.

7. The answer is D *[see V.F]*.
Answer D is correct because ANCOVA is used to test parametric data (change in BP) when two or more groups are being evaluated and two or more confounders (diet and exercise differences) are detected. Answer A is incorrect because one-way ANOVA is used when no detected confounders are present. Answers B and C are incorrect because chi-square and Fisher exact test are used to test nominal data. Answer E is incorrect because *t* test is used when no detected confounders are present.

8. **The answer is C** *[see VI.A–B]*.

    Answer C is correct because chi-square is used to detect statistical differences for nominal data (mortality) when there are large numbers of patients in each treatment group. Answers A and E are incorrect because ANOVA and *t* test are used to test parametric data. Answer B is incorrect because Fisher exact test is used when there are small numbers of patients in each treatment group ($<$ 40 patients). Answer D is incorrect because Mann-Whitney *U* test is used to test ordinal data.

9. **The answer is A** *[see IX.B]*.

    Answer A is correct because $r = 0.45$, r-squared (r^2) $= 0.2$ or 20%. Therefore, 20% of one variable (hypertension) may be explained by the other variable (high-sodium diet). This would mean that $1 - 0.2 = 0.8$ or 80% of hypertension would not be explained by a high-sodium diet. Therefore, answers B, C, D, and E are incorrect.

10. **The answer is B** *[see VIII.B]*.

    Answer B is correct because pain scale scores are ordinal data, and Spearman is the sample correlation coefficient for ordinal data. Answer A is incorrect because Pearson is the sample correlation coefficient for linear (parametric) data. Answer C is incorrect because pain scale is ordinal data, not linear (parametric). Answer D is incorrect because Cox is a type of regression analysis, not a form of correlation analysis.

11. **The answer is D** *[see III.F.1.b, IV.E, and XV.B]*.

    Answer D is correct because the outcome measure is relative risk (RR). For ratios like relative risk, it is the difference from 1 that determines statistical significance. Answer A is incorrect because there is a statistically significant difference in CVA or TE because the 95% CI does not include 1. Answers B and C are incorrect because, for ratios like relative risk, it is the difference from 1 that determines statistical significance, not difference from 0.

12. **The answer is A** *[see III.F.1.b, IV.E, and XV.B]*.

    Answer A is correct because for ratios like relative risk, it is the difference from 1 that determines statistical significance. The 95% CI included 1, so although this may be clinically meaningful, it is not statistically significant. Answers B and D are incorrect because for ratios like relative risk, it is the difference from 1 that determines statistical significance, not difference from 0. Answer C is incorrect because all values within the 95% CI are statistically possible and the 95% CI for MI contains 1. Therefore, it is statistically possible that there is no difference between dabigatran (Pradaxa) and warfarin (Coumadin) for the outcome of MI.

13. **The answer is B** *[see XVI.C.4]*.

    Answer B is correct because postmenopausal women were identified based on exposure (medications they were taking, i.e., whether or not they were taking HRT) as is done in cohort studies. Answer A is incorrect because, for case-control studies, subjects are identified based on disease (heart disease in this case) rather than exposure (HRT), which was not the setup for this study. Answer C is incorrect because patients were not randomized to an intervention. Answer D is incorrect because meta-analyses include multiple studies, which is not the case in this example.

14. **The answer is D** *[see XII.C.4 and XVI.D.3]*.

    Answer D is correct because the most robust and ethical way of determining differences between hypertension treatments and determining causality is through a randomized trial with a standard of care control. Answer A is incorrect because a case-control study is very weak at determining causality. Answers B and E are incorrect because cohort studies and meta-analyses are weaker than randomized trials for establishing causality. Answer C is incorrect because it would be unethical to treat hypertensive, diabetic patients with a placebo rather than an established therapy that has been shown to improve cardiovascular outcomes.

15. **The answer is A** *[see XVI.D.2.a]*.

    Answer A is correct. Answer B is incorrect because it would be unethical to ask those who had stopped smoking in the first part of the trial to restart smoking in order to obtain data for the second part of the study. Answer C is incorrect because crossovers are not good for treatment evaluation in unstable diseases. Asthma severity may vary depending on seasons. Answer D is incorrect because those who died in the first part of the crossover trial could not be evaluated during the second part of the trial.

Clinical Toxicology

16

JOHN J. PONZILLO

I. OVERVIEW

A. This chapter is intended to provide the reader with an overview of the management of various toxic exposures. Emergency medical services (EMS) should be immediately contacted to provide advanced life support for patients with unstable vital signs resulting from a poisoning exposure. In addition, these patients should be referred to a hospital for follow-up. A nationwide toll-free poison center number became available. This number, 800-222-1222, is available 24 hr/day and should be used by health care professionals and the general public when dealing with exposures to potentially toxic substances.

B. **Definitions**
   1. **Clinical toxicology.** Focuses on the effects of substances in patients caused by accidental poisonings or intentional overdoses of medications, drugs of abuse, household products, or various other chemicals
   2. **Intoxication.** Toxicity associated with any chemical substance
   3. **Poisoning.** A clinical toxicity secondary to accidental exposure
   4. **Overdose.** An intentional exposure with the intent of causing self-injury or death
   5. **Toxidromes.** A group of signs, symptoms, and laboratory findings that suggest a specific ingestion

C. **Epidemiology.** In 2007, a total of 27,658 unintentional drug overdose deaths occurred in the United States (more information can be found at the Centers for Disease Control and Prevention's [CDC] Web site, http://www.cdc.gov). Over the past several years, the number of poisoning exposures, emergency room visits, and subsequent costs has risen. Pharmacists are playing an increasing role in poison prevention and overdose management.

D. **Information resources**
   1. **Computerized databases**
      a. POISINDEX is a database that is updated quarterly and is a primary resource for poison control centers.
   2. **Printed publications.** Textbooks and manuals provide useful information regarding the assessment and treatment of patients exposed to various substances, although their usefulness is limited by the lag time of information published in the primary literature reaching updated editions.
      a. Ellenhorn MJ, ed. *Medical Toxicology: Diagnosis and Treatment of Human Poisonings*. 2nd ed. New York, NY: Elsevier Science; 1997.
      b. Fraunfelder FT, Fraunfelder FW. *Drug-Induced Ocular Side Effects*. 5th ed. Little Rock, AR: Butterworth-Heinemann; 2001.

3. **Internet**[1]
   a. Centers for Disease Control and Prevention (CDC) at http://www.cdc.gov
   b. U.S. Food and Drug Administration (FDA) at http://www.fda.gov
   c. National Library of Medicine at http://www.nlm.nih.gov
   d. National Institute for Occupational Safety and Health (NIOSH) at http://www.cdc.gov/niosh
   e. American Society of Health–System Pharmacists at http://www.ashp.org
   f. Material Safety Data Sheets at http://www.msdssearch.com
   g. U.S. Environmental Protection Agency (EPA) at http://www.epa.gov
4. **Poison control centers** accredited by the American Association of Poison Control Centers (AAPCC) provide information to the general public and health care providers. These centers are the most reliable and up-to-date sources of information; thus, the AAPCC's phone number (800-222-1222) should be readily available. In Canada, call 1-800-268-0917.

II. GENERAL MANAGEMENT

A. **Supportive care and ABCs.** Evaluating and supporting the vital functions (airway, breathing, and circulation [ABCs]) are the mandatory first steps in the initial management of drug ingestions. After the patient is stabilized, the specific issue(s) of poison management should be addressed.[1]
B. **Treatment** for patients with depressed mental status includes the following:
   1. To rule out or treat hypoglycemia, 50 mL of 50% dextrose in adults and 1 mL/kg in children intravenously (IV)
   2. Thiamine 100 mg IV push (glucose can precipitate the Wernicke-Korsakoff syndrome in thiamine-deficient patients)
   3. Naloxone (Narcan) 0.4 to 2 mg IV push, if opiate ingestion is suspected. Naloxone may also be administered by the following routes: inhalation, intramuscular, and intranasal.
C. **Obtaining a history of exposure**
   1. **Identify** the substance(s) ingested, the route of exposure, the quantity ingested, the amount of time since ingestion, signs and symptoms of overdose, and any associated illness or injury. **Corroborate** history and other physical evidence (e.g., pill containers) from prehospital providers.
   2. **Neurological examination** evaluates any seizures, alterations in consciousness, confusion, ataxia, slurred speech, tremor, headache, or syncope.
   3. **Cardiopulmonary examination** evaluates any syncope, palpitations, cough, chest pain, shortness of breath, or burning or irritation of the upper airway.
   4. **Gastrointestinal (GI) examination** evaluates any abdominal pain, nausea, vomiting, diarrhea, or difficulty in swallowing.
   5. **Past medical history** should include
      a. Medications, including nonprescription (over-the-counter [OTC]) substances
      b. Use of herbal medications
      c. Alcohol or drug abuse
      d. Psychiatric history
      e. Allergies
      f. Occupational or hobby exposures
      g. Travel
      h. Prior ingestions
      i. Social history with potential for domestic violence or neglect
      j. Last normal menstrual period or pregnancy
D. **Routine laboratory assessment**
   1. Complete blood cell (CBC) count
   2. Serum electrolytes
   3. Blood urea nitrogen (BUN); serum creatinine (SCr)
   4. Blood glucose
   5. Urinalysis

6. Electrocardiogram (ECG)
7. Chest roentgenogram and/or kidneys, ureters, and bladder (**KUB**) x-ray

E. Toxicology laboratory tests

1. Advantages
  a. Confirm or **determine** the presence of a particular agent
  b. Predict the anticipated toxic effects or severity of exposure to some poisons
  c. Confirm or **distinguish** differential or contributing diagnosis
  d. Occasionally help **guide therapy**

2. Disadvantages
  a. These tests cannot provide a specific diagnosis for all patients.
  b. All possible intoxicating agents cannot be screened.
  c. In critically ill patients, supportive treatment is needed before laboratory results of the toxicology screen are available.
  d. Laboratory drug-detection abilities differ.
  e. In general, only a **qualitative determination** of a substance or substances is necessary; however, **quantitative levels** of the therapeutically monitored drugs may be necessary to guide therapy. Consult with your local laboratory for the availability of specific drug assays.

F. Skin decontamination should be performed when percutaneous absorption of a substance may result in systemic toxicity, or when the contaminating substance may produce local toxic effects (e.g., acid burns). The patient's clothing is removed, and the areas are irrigated with copious quantities of water. **Neutralization should not be attempted.** For example, neutralizing acid burns with sodium bicarbonate will produce an exothermic chemical reaction, thereby exacerbating the patient's condition.

G. Gastric decontamination may be attempted when supportive care is begun. GI decontamination involves removal of the ingestant with emesis or lavage, the use of activated charcoal potentially to bind any ingestants, and the use of cathartics to hasten excretion and thereby limit absorption.

1. Emesis
  a. Contraindications
    (1) Children younger than 6 months of age
    (2) Patients with central nervous system (CNS) depression or seizures
    (3) Patients who have ingested a strong acid, alkali, or a sharp object
    (4) Patients with compromised airway protective reflexes (including coma and convulsions)
    (5) Patients who have ingested some types of hydrocarbons or petroleum distillates
    (6) Patients who have ingested substances with an extremely rapid onset of action
    (7) Patients with emesis after the ingestion
  b. Syrup of ipecac. Owing to concerns of safety, efficacy, and the delay of antidote administration, syrup of ipecac is no longer recommended for general use. Ipecac may be administered within 30 mins of ingestion and **only on the advice of a poison control center.**[2]

2. Gastric lavage
  a. Use. Gastric lavage is infrequently used in patients who are not alert or have a diminished gag reflex. This procedure should also be considered in patients who are seen early after massive ingestions. This procedure is **contraindicated in patients who have ingested acids, alkalis, or hydrocarbons**. In addition, **patients should not receive gastric lavage if they are at risk for GI perforation or if they are combative**.

3. Activated charcoal adsorbs almost all commonly ingested drugs and chemicals and is usually administered to most overdose patients as quickly as possible (ideally, within 1 hr of ingestion). Commonly ingested substances not adsorbed include **ethanol, iron, lithium, cyanide, ethylene glycol, lead, mercury, methanol, organic solvents, potassium, strong acids**, and **strong alkalis**.
  a. Dosage. Activated charcoal (Actidose with sorbitol) is available as a colloidal dispersion with water or sorbitol. In **adults**, the dose of activated charcoal is 25 to 100 g; the dose in **children** 1 to 12 years of age is 25 to 50 g; the dose in children up to 1 year of age is 1 g/kg. Constipation has not been observed after the administration of a single dose of activated charcoal. **Multiple doses** of any cathartics should be avoided because they can cause electrolyte

---

[2]Manoguerra AS, Cobaugh DJ; Guidelines for the Management of Poisonings Consensus Panel. Guideline on the use of ipecac syrup in the out-of-hospital management of ingested poisons. *Clin Toxicol*. 2005;43:1–10.

imbalances and/or dehydration. Toxic ingestions with drugs having an enterohepatic circulation (e.g., carbamazepine, theophylline, phenobarbital, tricyclic antidepressants, phenothiazines, digitalis) generally require that the charcoal be readministered every 6 hrs to prevent reabsorption during recirculation.

    b. Adverse effects. Charcoal aspiration and empyema have been reported in the literature. As such, charcoal should be withheld if patients are vomiting. Bowel obstruction may occur with multiple doses of activated charcoal and/or patients who are receiving concomitant therapy with neuromuscular-blocking drugs.[3]

H. Whole bowel irrigation has been shown to be effective under certain conditions, particularly when activated charcoal lacks efficacy. An isosmotic cathartic solution such as polyethylene glycol (GoLYTELY, Colyte) is used. The dosage is 1 to 2 L/hr given orally or by nasogastric tube until the rectal effluent is clear.

I. Forced diuresis and **urinary pH manipulation** may be used to enhance the elimination of substances, whose elimination is primarily renal, if the substance has a relatively small volume of distribution with little protein binding. However, the use of these methods is associated with fluid and electrolyte disturbances.

    1. Alkaline diuresis promotes the ionization of weak acids, thereby preventing their reabsorption by the kidney, which facilitates the excretion of such weak acids. This procedure has been used in the management of patients who have ingested long-acting barbiturates such as phenobarbital or salicylic acid. Patients are given 50 to 100 mEq of sodium bicarbonate IV push, followed by a continuous infusion of 50 to 100 mEq of sodium bicarbonate in 1 L of 0.25% to 0.45% normal saline, maintaining a urine pH of 7.3 to 8.5. Urine output should be 5 to 7 mL/kg/hr. **Complications** include metabolic alkalosis, hypernatremia, hyperosmolarity, and fluid overload.

J. Dialysis. In patients who fail to respond to the measures of decontamination already outlined, hemodialysis, and to a lesser extent peritoneal dialysis, may enhance drug elimination. Substances that are removed by hemodialysis generally are water soluble, have a small volume of distribution (< 0.5 L/kg), have a low molecular weight (< 500 Da), and are not significantly bound to plasma proteins. Hemodialysis usually is indicated for life-threatening ingestions of ethylene glycol, methanol, or paraquat. This technique also has been used to enhance the elimination of ethanol, theophylline, lithium, salicylates, and long-acting barbiturates.

K. Hemoperfusion is a technique in which anticoagulated blood is passed through (perfused) a column containing activated charcoal or resin particles. This method of elimination clears substances from the blood more rapidly than hemodialysis, but it does not correct fluid and electrolyte abnormalities as does hemodialysis. Hemoperfusion, although more effective in removing phenobarbital, phenytoin, carbamazepine, methotrexate, and theophylline than hemodialysis, is less effective in removing ethanol or methanol. **Complications** of hemoperfusion include thrombocytopenia, leukopenia, hypocalcemia, hypoglycemia, and hypotension.

III. MANAGEMENT OF SPECIFIC INGESTIONS

A. Acetaminophen (Tylenol) is an antipyretic-analgesic that can produce fatal hepatotoxicity in untreated patients through the generation of a toxic metabolite.

    1. Available dosage forms. Acetaminophen is available in a variety of OTC and prescription drug products.

    2. Toxicokinetics. Acetaminophen is well absorbed from the GI tract and has a half-life between 2 and 3 hrs. Less than 5% is excreted unchanged in the urine; the remainder is metabolized in the liver by the cytochrome P450 system.

    3. Clinical presentation

        a. Phase I (12 to 24 hrs postingestion). Nausea, vomiting, anorexia, and diaphoresis

        b. Phase II (1 to 4 days postingestion). Asymptomatic

        c. Phase III (2 to 3 days in untreated patients). Nausea, abdominal pain, progressive evidence of hepatic failure, coma, and death

[3]Chyka PA, Seger D. Position statement: Single-dose activated charcoal. American Academy of Clinical Toxicology; European Association of Poisons Centres and Clinical Toxicologists. *J Toxicol Clin Toxicol.* 1997;35:721–741.

4. **Laboratory data**
   a. **Serum acetaminophen levels.** Patients with levels greater than 150, 70, or 40 mg/mL at 4, 8, or 12 hrs after ingestion require antidotal therapy with *N*-acetylcysteine (NAC) according to the Rumack-Matthews nomogram.
   b. Baseline liver function tests should be done in all patients.
   c. Renal function tests, including a BUN and SCr, should be done.
   d. Coagulation studies include prothrombin time (PT), partial thromboplastin time (PTT), and bleeding time.
5. **Treatment**
   a. Adult patients who have ingested > 10 g or children who have ingested > 200 mg/kg require treatment. Elderly and alcoholic patients have an increased susceptibility to acetaminophen hepatotoxicity.
   b. The recommended treatment is GI decontamination with activated charcoal.
   c. Antidotal therapy with NAC is indicated for patients with toxic blood levels of acetaminophen.
      (1) **NAC dosage** is 140 mg/kg as a loading dose followed by 70 mg/kg every 4 hrs for a total of 17 doses. NAC is administered either orally or via a nasogastric tube. NAC (Mucomyst) 20% contains 200 mg/mL. Each dose must be diluted 1:3 in either cola or fruit juice to mask the unpleasant taste and smell. The dose of NAC should be repeated if the patient vomits within 30 mins of administration. Patients with severe nausea secondary to NAC may be pretreated with IV metoclopramide (Reglan) 10 mg every 6 hrs. Metoclopramide acts as an antiemetic while increasing the rate of NAC absorption.
      (2) **IV NAC** (Acetadote)
         (a) Loading dose: 150 mg/kg over 60 mins
         (b) Maintenance dose: 50 mg/kg over 4 hrs followed by 100 mg/kg over 16 hrs
         (c) Anaphylactoid reactions are observed in approximately 20% of patients. **Caution** should be exercised in patients with a history of **asthma**.

B. **Alcohols**[4]
1. **Ethylene glycol**
   a. **Available forms.** Ethylene glycol commonly is used in antifreeze and windshield de-icing solutions. This form is sometimes colorless and has a sweet taste.
   b. **Toxicokinetics.** Ethylene glycol is hepatically metabolized by alcohol dehydrogenase to glycolaldehyde, which is metabolized by aldehyde dehydrogenase to glycolic acid. Glycolic acid is converted to glyoxylic acid, whose most toxic metabolite is oxalic acid.
   c. **Clinical presentation**
      (1) **Stage I** (0.5 to 12 hrs postingestion). Ataxia, nystagmus, nausea and vomiting, decreased deep tendon reflexes, and severe acidosis (more severe overdoses: hypocalcemic tetany and seizures, cerebral edema, coma, and death)
      (2) **Stage II** (12 to 24 hrs postingestion). Tachypnea, cyanosis, tachycardia, pulmonary edema, and pneumonitis
      (3) **Stage III** (24 to 72 hrs postingestion). Flank pain and costovertebral angle tenderness; oliguric renal failure
   d. **Laboratory data** may reveal severe metabolic acidosis, hypocalcemia, and calcium oxalate crystals in the urinalysis.
   e. **Treatment**
      (1) **Gastric lavage** is performed within 30 mins of ingestion.
      (2) **IV ethanol (EtOH) is used in situations in which fomepizole is not available.**
         (a) **Indications** include an ethylene glycol level > 20 mg/dL, suspicion of ingestion pending level, or an anion gap metabolic acidosis with a history of ingestion, regardless of the level.
         (b) **EtOH dosage**
            (i) An EtOH level of at least 100 mg/dL should be maintained.
            (ii) Loading dose is 7.5 to 10 mL/kg of a 10% ethanol in dextrose 5% in water (D_5W) over 1 hr, followed by a maintenance infusion of 1.4 mL/kg/hr.
            (iii) Infusion rates may need to be increased in patients receiving hemodialysis.

[4]Megarbane B, Borron SW, Baud FJ. Current recommendations for the treatment of severe toxic alcohol poisonings. *Intensive Care Med.* 2005;31:189–195.

      (3) Fomepizole (Antizol) is a potent inhibitor of alcohol dehydrogenase that can prevent the formation of the toxic metabolites of either methanol or ethylene glycol.

        (a) Administer a **loading dose** of 15 mg/kg (up to 1 g) in 100 mL of D_5W or 0.9% sodium chloride (NaCl) infused over 30 mins.

        (b) Maintenance doses: 10 mg/kg every 14 hrs for four doses, then increase to 15 mg/kg (to offset autoinduction phenomenon) until methanol or ethylene glycol levels are < 20 mg/dL.

      (4) Pyridoxine (100 mg IV every day) and **thiamine** (100 mg IV every day) are cofactors that may convert glyoxylic acid to nonoxalate metabolites.

      (5) Sodium bicarbonate is used as needed to correct the acidosis.

      (6) Hemodialysis. Fomepizole must be continued, and the rate of administration may need to be increased. **Indications** include ethylene glycol level > 50 mg/dL, congestive heart failure, renal failure, and severe acidosis.

  2. Methanol

    a. Available forms include gas-line antifreeze, windshield washer, and some sterno.

    b. Toxicokinetics. Alcohol dehydrogenase converts methanol to formaldehyde, which is then converted to formic acid.

    c. Clinical presentation

      (1) Stage I. Euphoria, gregariousness, and muscle weakness for 6 to 36 hrs, depending on the rate of formation of formic acid

      (2) Stage II. Vomiting, upper abdominal pain, diarrhea, dizziness, headache, restlessness, dyspnea, blurred vision, photophobia, blindness, coma, cerebral edema, cardiac and respiratory depression, seizures, and death

    d. Laboratory data include severe metabolic acidosis, hyperglycemia, and hyperamylasemia.

    e. Treatment

      (1) Gastric lavage. Charcoal has not been shown to absorb alcohols.

      (2) IV EtOH (used in situations in which fomepizole is not available)

        (a) Indications include any peak methanol level > 20 mg/dL, a suspicious ingestion with a positive history, or any symptomatic patient with an anion gap acidosis.

        (b) Administration is the same as per ethylene glycol (see III.B.1).

      (3) Folic acid administered at 1 mg/kg (maximum 50 mg) IV every 4 hrs for six doses increases the metabolism of formate.

      (4) Fomepizole (Antizol) (see III.B.1.e.[3])

      (5) Sodium bicarbonate is used for severe acidosis.

      (6) Hemodialysis is used for methanol levels > 50 mg/dL, severe and resistant acidosis, renal failure, or visual symptoms.

C. Anticoagulants[5]

  1. Heparin/Low-Molecular-Weight Heparin (LMWH)

    a. Available dosage forms include parenteral dosage forms for IV and subcutaneous administration.

    b. Toxicokinetics. Heparin has a half-life of 1 to 1.5 hrs and is primarily metabolized in the liver. The newer LMWHs—enoxaparin (Lovenox), dalteparin (Fragmin), tinzaparin (Innohep)—have a longer half-life, especially in patients with renal failure.

    c. Clinical presentation. Look for any signs or symptoms of bleeding or bruising.

Van Ryn J, Stangier J, Haertter S, et al. Dabigatran etexilate—a novel, reversible, oral direct thrombin inhibitor: interpretation of coagulation assays and reversal of anticoagulant activity. *Thromb Haemost*. 2010;103:1–12.

    d. Laboratory data. Obtain PTT, bleeding time, and platelet counts.

    e. Treatment

       (1) Stopping heparin administration for 1 to 2 hrs and restarting therapy at a reduced dose can reverse mild over-anticoagulation.

       (2) Severe overdoses may require the administration of **protamine**.

         (a) Protamine combines with heparin and neutralizes it: **1 mg protamine neutralizes 100 U heparin**.

         (b) Protamine should be administered slowly, intravenously over 10 mins. The maximum dose of protamine is 50 mg in any 10-min period.

         (c) Considerable controversy exists about the method of reversing the over-anticoagulation with LMWHs. Some sources recommend the administration of protamine to neutralize part of the effects of these anticoagulants, whereas case reports reported successes with recombinant factor VII (NovoSeven).

         (d) These overdoses should be referred to a hematologist and/or the poison control center.

  2. Warfarin (Coumadin)

    a. Available dosage forms include oral tablets and a solution for parenteral administration.

    b. Toxicokinetics. Warfarin is well absorbed after oral administration. Its mean half-life is 35 hrs; protein binding is 99%, with 5-day duration of activity. Vitamin K-dependent clotting factors begin to decline 6 hrs after administration, but therapeutic anticoagulation may require several days.

    c. Clinical presentation includes minor bleeding, bruising, hematuria, epistaxis, and conjunctival hemorrhage. More serious bleeding includes GI, intracranial, retroperitoneal, and wound site.

    d. Laboratory data include PT, international normalized ratio (INR), and bleeding time.

    e. Treatment

       (1) If **PT** or **INR** is **slightly elevated**, withhold warfarin for 24 to 48 hrs, then reinstitute therapy with a reduced dosage.

       (2) If **PT** or **INR** is **elevated** and **bleeding**, administer 10 mg of phytonadione (vitamin K) over 30 mins. Patients who are bleeding may require the administration of blood products that contain clotting factors.

       (3) For mild over-anticoagulation, follow American College of Chest Physicians (ACCP) guidelines.

       (4) For patients with life-threatening bleeding or intracranial hemorrhage, the ACCP recommends the use of prothrombin complex concentrates or recombinant factor VIIa to immediately reverse the INR.

  3. Pradaxa (dabigatran)

    a. Available dosage forms include oral capsules.

    b. Toxicokinetics. Dabigatran is poorly absorbed following oral administration, but it has a half-life of 12 to 17 hrs in healthy subjects with normal renal function.

    c. Clinical presentation includes minor bleeding, bruising, hematuria, and epistaxis. More serious bleeding includes GI, intracranial, retroperitoneal, and wound site.

    d. Laboratory data specialized hematologic monitoring may be required such as thrombin clotting time and ecarin clotting time.

    e. Treatment

       (1) Mild bleeding. Local treatment and withholding one dose

       (2) Moderate bleeding. Consider blood product transfusion and/or hemodialysis

       (3) Severe bleeding. As noted earlier with the additional consideration of charcoal filtration along with either recombinant factor VII or prothrombin complex concentrates. Dabigatran is the first FDA-approved oral direct-acting thrombin inhibitor. Many more compounds are in clinical trials and due to the paucity of overdose data with these drugs, consultation with a hematologist and/or a poison information specialist is highly recommended.

D. Antidepressants

  1. Tricyclic antidepressants (TCAs)

    a. Available forms include amitriptyline (Elavil), nortriptyline (Aventyl), imipramine (Tofranil), desipramine (Norpramin), doxepin (Sinequan), protriptyline (Vivactil), and clomipramine (Anafranil).

    b. Toxicokinetics. The compounds are hepatically metabolized, undergo enterohepatic recirculation, are highly bound to plasma proteins, and have an elimination half-life of approximately 24 hrs.

     c. **Clinical presentation.** Anticholinergic effects include mydriasis, ileus, urinary retention, and hyperpyrexia. **Cardiopulmonary toxicity** exhibits tachycardias, conduction blocks, hypotension, and pulmonary edema. **CNS manifestations** range from agitation and confusion to hallucinations, seizures, and coma.

     d. **Laboratory data.** Blood level monitoring does not correlate well with clinical signs and symptoms of toxicity. Some authors suggest that electrocardiographic monitoring is a better guide to assessing the severity of ingestion.

     e. **Treatment**

        (1) **GI decontamination.** Syrup of ipecac is not recommended because patients may quickly become comatose, increasing the risk of aspiration. **Activated charcoal** is given every 6 hrs.

        (2) **Alkalinization** with sodium bicarbonate 1 to 2 mEq/kg to maintain an arterial pH of 7.45 to 7.55 decreases the free fraction of the absorbed toxins, while reversing some of the cardiac abnormalities.

        (3) **Phenytoin (Dilantin)** and/or **benzodiazepines** may be required to control seizures. Phenytoin must be administered at a rate not exceeding 25 mg/min because of hypotensive side effects. (**Fosphenytoin [Cerebyx]** may be used because it has a lower incidence of hypotension than phenytoin.)

        (4) **Physostigmine** 2 mg IV over 1 min may be used to reverse **severe** anticholinergic toxicity owing to these drugs. **Because this antidote may cause asystole, the use of this antidote for TCA overdoses is declining.**

  2. **Selective serotonin reuptake inhibitors (SSRIs)**

     a. **Available forms** (nontricyclic agents) include fluoxetine (Prozac), sertraline (Zoloft), and paroxetine (Paxil).

     b. **Toxicokinetics.** SSRIs are well absorbed after oral administration. Peak levels occur within 2 to 6 hrs. SSRIs are hepatically metabolized with a half-life between 8 and 30 hrs.

     c. **Clinical presentation** includes mild symptomatology. Patients may become agitated, drowsy, or confused. Seizures and cardiovascular toxicity are rare.

     d. **Laboratory data.** ECG monitoring is recommended. Blood level monitoring is not recommended.

     e. **Treatment** includes gastric lavage and supportive treatment. Some toxicologists may recommend the use of cyproheptadine (Periactin) to manage the serotonin syndrome, which may manifest as a result of these ingestions.

E. **Benzodiazepines**

  1. **Available forms** include chlordiazepoxide (Librium), diazepam (Valium), flurazepam (Dalmane), midazolam (Versed), lorazepam (Ativan), alprazolam (Xanax), and triazolam (Halcion).

  2. **Toxicokinetics.** These drugs are hepatically metabolized.

  3. **Clinical presentation** includes drowsiness, ataxia, and confusion. Fatalities are rare.

  4. **Laboratory data.** Drug level monitoring is not indicated.

  5. **Treatment**

     a. **Supportive** treatment includes gastric emptying, activated charcoal, and a cathartic.

     b. **Flumazenil (**Romazicon) is given 0.2 mg IV over 30 secs; repeat doses of 0.5 mg over 30 secs at 1-min intervals for a maximum cumulative dose of 5 mg.

        (1) Flumazenil has a short elimination half-life.

        (2) **Careful observation** for **resedation** is necessary, especially for ingestions of long-acting benzodiazepines.

        (3) **Flumazenil is contraindicated in mixed overdose patients (particularly involving tricyclic antidepressants) in whom seizures are likely.**

F. **β-adrenergic antagonists**

  1. **Available dosage forms.** Class examples include propranolol (Inderal), metoprolol (Lopressor), and atenolol (Tenormin). Oral and parenteral dosage forms are available.

  2. **Toxicokinetics.** All of the members within this class differ in regard to renal versus hepatic elimination, lipid solubility, and protein binding. Patients may become toxic owing to changes in organ function.

  3. **Clinical presentation** includes hypotension, bradycardia, and atrioventricular block. Bronchospasm may occur, particularly with noncardioselective agents.

  4. **Laboratory data** include serum electrolytes and blood glucose (patients may become hypoglycemic).

5. **Treatment**
   a. **GI decontamination** includes gastric lavage and activated charcoal.
   b. **Glucagon** is given 50 to 150 mcg/kg as a loading dose over 1 min, followed by a continuous infusion of 1 to 5 mg/hr.
   c. **Epinephrine** should be used cautiously in β-blocker overdoses. Unopposed α-receptor stimulation in the face of complete β-receptor block may lead to profound hypertension.
   d. Calcium salts (see "Calcium Channel Antagonists")
   e. High-dose insulin dextrose (see "Calcium Channel Antagonists")

G. **Calcium channel antagonists**
   1. **Available forms** include verapamil (Calan), diltiazem (Cardizem), and the dihydropyridine class (nifedipine derivatives [Procardia]).
   2. **Toxicokinetics.** Onset of action is approximately 30 mins, whereas the duration is 6 to 8 hrs. Several compounds are available as sustained-release dosage forms, which may contribute to prolonged toxicity.
   3. **Clinical presentation.** Hypotension is common to all classes. Bradycardia and atrioventricular block are more commonly seen with ingestions of verapamil or diltiazem. Pulmonary edema and seizures (verapamil) have been reported.
   4. **Laboratory data** include ECG and serum electrolytes.
   5. **Treatment**
      a. **GI decontamination** includes gastric lavage, activated charcoal, and whole-bowel irrigation (especially for ingestions with sustained-release products).
      b. **Calcium.** Calcium chloride 10% (10 to 20 mL) IV push is given for the management of hypotension, bradycardia, or heart block.
      c. **Glucagon** dosage is the same as for β-blocker overdose.
      d. **Combined insulin and dextrose administration** has been used in selected cases. The insulin dosages used are as follows: regular insulin 1 U/kg and a loading dose along with IV dextrose 0.5 g/kg. This should be followed with a continuous infusion of insulin at a rate of 0.5 to 2 U/kg/hr along with continuous dextrose infusions of 0.5 g/kg/hr to maintain serum glucose levels within a 100 to 250 mg/dL range. Insulin dosages are titrated to appropriate hemodynamic indices in an intensive care environment. This should be **used only in consultation with a poison control center**.
      e. Phosphodiesterase inhibitors. Inamrinone or milrinone.

H. **Cocaine**
   1. **Available forms** include alkaloid obtained from *Erythroxylon coca*.
   2. **Toxicokinetics.** Cocaine is well absorbed after oral, inhalational, intranasal, and IV administration. Cocaine is metabolized in the liver and excreted in the urine.
   3. **Clinical presentation** includes CNS and sympathetic stimulation (e.g., hypertension, tachypnea, tachycardia, nausea, vomiting, seizures). Death may result from respiratory failure, myocardial infarction, or cardiac arrest.
   4. **Laboratory data** include cocaine and cocaine metabolite urine screens.
   5. **Treatment** is **supportive**: benzodiazepines for sedation seizure treatment, labetalol (Normodyne) for hypertension.

I. **Corrosives**
   1. **Available forms** include strong acids or alkalis.
   2. **Toxicokinetics.** Corrosives are well absorbed after oral and inhalational administration.
   3. **Clinical presentation.** These compounds produce burns on contact.
   4. **Laboratory data.** Arterial blood gases (ABGs), chest radiographs, and at least 6 hrs of observation are required for inhalation exposure.
   5. **Treatment** is **decontamination.** Exposed skin must be irrigated with water. **Neutralization** should be **avoided** because these reactions are exothermic and will produce further tissue damage.

J. **Cyanide**
   1. **Available forms** include industrial chemicals and some nail polish removers.
   2. **Toxicokinetics.** The drug is rapidly absorbed after oral or inhalation exposure.
   3. **Clinical presentation** includes headache, dyspnea, nausea, vomiting, ataxia, coma, seizures, and death.
   4. **Laboratory data** include cyanide levels, ABGs, electrolytes, and an ECG.

5. **Treatment**
   a. Cyanide antidote kit
      (1) **Amyl nitrite.** Pearls are crushed and held under the patient's nostrils.
      (2) **Sodium nitrite** 10 mL IV push. Converts hemoglobin to methemoglobin, which binds the cyanide ion.
      (3) **Sodium thiosulfate** 50 mL of a 25% solution IV push. May be repeated if there is no response.
   b. **Oxygen**
   c. **Sodium bicarbonate.** As needed for severe acidosis
   d. Hydroxocobalamin (Cyanokit) adult dose is 5 g IV over 15 mins. Dose may be repeated for a total dose of 10 g. No data are available for pediatric dosing.[6]

K. **Digoxin (Lanoxin)**
   1. **Available dosage forms** include oral and parenteral.
   2. **Toxicokinetics.** Digoxin is well absorbed, is primarily renally eliminated, and has a half-life of 36 to 48 hrs. Its volume of distribution is 7 to 10 L/kg. Equilibration between serum level and myocardial binding requires 6 to 8 hrs.
   3. **Clinical presentation** includes confusion, anorexia, nausea, and vomiting in mild cases. In more severe cases, cardiac dysrhythmias are seen.
   4. **Laboratory data** include serum digoxin levels, electrolytes, particularly serum potassium levels, and an ECG.
   5. **Treatment**
      a. **Decontamination** with activated charcoal is recommended.
      b. **Supportive therapy** includes managing hyperkalemia or hypokalemia and inotropic support as needed.
      c. **Digoxin-specific Fab antibodies (Digibind).** To determine the dosage, use the following formula:

      $$\text{Dose (mg)} = [(\text{serum digoxin concentration [ng/mL]} \times \text{weight (kg)}/100]) \times (\text{mg/vial})$$

      Digibind 38 mg/vial or Digifab 40 mg/vial

L. **Electrolytes**
   1. **Magnesium**
      a. **Available dosage forms** include oral, rectal, and parenteral. Magnesium-containing cathartics (e.g., magnesium citrate) have been reported to produce hypermagnesemia in patients receiving repetitive doses with activated charcoal.
      b. **Toxicokinetics.** Magnesium is found intracellularly and is renally eliminated.
      c. **Clinical presentation**
         (1) **Mild.** Deep tendon reflexes may be depressed; lethargy and weakness
         (2) **Severe.** Respiratory paralysis and heart block; prolonged PR, QRS, and QT intervals
      d. **Laboratory data**
         (1) **Mild:** > 4 mEq/L
         (2) **Severe:** > 10 mEq/L
      e. **Treatment** is **10% calcium chloride** 10 to 20 mL to temporarily antagonize the cardiac effects of magnesium. In severe cases, **hemodialysis** may be required.
   2. **Potassium**
      a. **Available dosage forms** are oral and parenteral.
      b. **Toxicokinetics.** Potassium is primarily an intracellular cation. Changes in acid–base balance produce shifts in serum potassium values (e.g., a 0.1 U increase in serum pH produces a 0.1 to 0.7 mEq/L decrease in serum potassium values).
      c. **Clinical presentation** includes cardiac irritability and peripheral weakness with minor increases. Cardiac dysrhythmias, including bradycardia, may progress to asystole.
      d. **Laboratory data.** ECG data include **peaked T waves** and prolongation of the QRS complex.

---

[6]Hall AH, Dart R, Bogdan G. Sodium thiosulfate or hydroxocobalamin for the empiric treatment of cyanide poisoning? *Ann Emerg Med.* 2007;49:806–813.

e. **Treatment**
   (1) **Calcium.** Administer calcium chloride 10% 10 to 20 mL to antagonize the cardiac effects of hyperkalemia.
   (2) **Sodium bicarbonate.** 1 to 2 mEq/kg IV increases serum pH and causes an intracellular shift of potassium.
   (3) **Glucose and insulin.** 50 mL of 50% dextrose and 5 to 10 U of regular insulin are administered via IV push to shift potassium from the extracellular fluid into the cells.
   (4) **Cation exchange resins** bind potassium in exchange for another cation (sodium). **Sodium polystyrene sulfonate** (Kayexalate) is given 15 g/60 mL with 23.5% sorbitol in doses 15 to 30 g by mouth every 3 to 4 hrs as needed until the hyperkalemia resolves. Alternatively, 50 g of sodium polystyrene sulfonate can be given rectally in 200 mL of sodium chloride as a retention enema. There have been reports of colonic necrosis and other GI events. Some authors recommend other treatments before utilizing exchange resin therapy.[7]
   (5) **Hemodialysis** is reserved for life-threatening hyperkalemia that does not respond to the aforementioned measures.

M. **Iron (Fe)**
   1. **Available dosage forms.** Numerous OTC products are available. Toxicity is based on the amount of elemental iron ingested: sulfate salt 20% elemental Fe; fumarate salt 33% elemental Fe; and gluconate salt 12% elemental Fe.
   2. **Toxicokinetics.** Iron is absorbed in the duodenum and jejunum.
   3. **Clinical presentation**
      a. **Phase I.** Nausea, vomiting, diarrhea, GI bleeding, hypotension
      b. **Phase II.** Clinical improvement seen 6 to 24 hrs postingestion
      c. **Phase III.** Metabolic acidosis, renal and hepatic failure, sepsis, pulmonary edema, and death
   4. **Laboratory data** include serum Fe levels, total iron-binding capacity (TIBC; **is controversial**), ABGs, liver function tests (LFTs), hemoglobin, and hematocrit. Radiological evaluation of the abdomen notes the presence of radiopaque pills.
   5. **Treatment**
      a. **Decontamination.** For ingestions > 40 mg/kg. Gastric lavage using sodium bicarbonate is of questionable efficacy. Whole-bowel irrigation is used for large ingestions.
      b. **Supportive treatment**
      c. **Deferoxamine** (Desferal) is used to chelate iron. Administer at a rate of 15 mg/kg/hr up to a maximum dose of 6 to 8 g/day. Continue until patient is clinically stable.

N. **Isoniazid (INH)**
   1. **Available dosage forms** include oral and parenteral.
   2. **Toxicokinetics.** INH is well absorbed orally. Peak levels are within 1 to 2 hrs postingestion. Isoniazid is hepatically metabolized.
   3. **Clinical presentation** includes nausea, vomiting, slurred speech, ataxia, generalized tonic–clonic seizures, and coma.
   4. **Laboratory data** include severe lactic acidosis, hypoglycemia, mild hyperkalemia, and leukocytosis.
   5. **Treatment**
      a. **Decontamination.** Avoid emesis because patients are at high risk for developing seizures; for severe ingestions, use activated charcoal gastric lavage.
      b. **Pyridoxine**, which reverses INH-induced seizures, is given in gram doses equivalent to the amount of isoniazid ingested. Pyridoxine is mixed as a 10% solution in D_5W and infused at 0.5 g/min until seizures stop, with the remainder infused over 4 to 6 hrs (maximum adult dose: 5 g).
      c. **Sodium bicarbonate** corrects the acidosis.

---

[7]Sterns RH, Rohas M, Bernstein P, Chennupati S. Ion-exhchange resins for the treatment of hyperkalemia: Are they safe and effective? *J Am Soc Nephrol.* 2010;21:733–735.

O. Lead
1. **Available forms** include lead-containing paint or gasoline fume inhalation.
2. **Toxicokinetics.** Lead has slow distribution, with a half-life of approximately 2 months.
3. **Clinical presentation** includes nausea, vomiting, abdominal pain, peripheral neuropathies, convulsions, and coma.
4. **Laboratory data** include anemia and an elevated blood-lead level.
5. **Treatment**
   a. **Edetate calcium disodium (Calcium Disodium Versenate)** is given 50 to 75 mg/kg/day intramuscularly (IM) or via slow IV in four divided doses.
   b. **Dimercaprol (BAL)** is given 4 mg/kg IM every 4 hrs for 3 to 5 days.
      Dimercaprol therapy is administered first. Following the second dose, concomitant edetate calcium disodium is initiated and both therapies are continued for up to 5 days. Oral chelation therapy is used for less severe cases.

P. Lithium (Eskalith)
1. **Available dosage forms** include liquid, capsules, and tablets (immediate and sustained release).
2. **Toxicokinetics.** Lithium is well absorbed after oral administration. It is not appreciably bound to plasma proteins and has a small volume of distribution (V_d) of 0.5 L/kg. Elimination is renal, with a half-life of 14 to 24 hrs.
3. **Clinical presentation**
   a. **Mild.** Polyuria, blurred vision, weakness, slurred speech, ataxia, tremor, and myoclonic jerks
   b. **Severe.** Delirium, coma, seizures, and hyperthermia
4. **Laboratory data**
   a. Therapeutic range: 0.6 to 1.2 mEq/L
   b. Mild toxicity: 1.5 to 2.5 mEq/L
   c. Moderate toxicity: 2.5 to 3.0 mEq/L
   d. Severe toxicity: > 3.0 mEq/L
5. **Treatment**
   a. **Supportive** care, including basic life support and fluid and electrolyte replacement
   b. **Decontamination**
      (1) **Syrup of ipecac not recommended**
      (2) **Activated charcoal** ineffective
      (3) **Sodium polystyrene sulfonate** has been effective in experimental models. Need to monitor potassium levels.
      (4) **Whole-bowel irrigation** for large ingestions, especially those involving sustained-release products
      (5) **Hemodialysis** for severely symptomatic patients with acute exposure levels > 2.5 mEq/L or chronic levels > 1.5 mEq/L. **Note**: Lithium levels may rise after dialysis owing to a rebound effect.

Q. Opiates
1. **Available dosage forms** include oral immediate-release and sustained-release preparations as well as parenteral agents.
2. **Toxicokinetics.** Some agents have prolonged elimination half-lives (e.g., heroin, methadone).
3. **Clinical presentation** includes respiratory depression and a decreased level of consciousness. Rare effects include hypotension, bradycardia, and pulmonary edema. Seizures have been reported in patients with renal dysfunction in individuals who are receiving meperidine owing to the accumulation of the metabolite or meperidine.
4. **Laboratory data** include baseline ABGs and toxicology screens.
5. **Treatment**
   a. **Naloxone** is given 0.4 to 2.0 mg every 5 mins up to 10 mg and 0.03 to 0.1 mg/kg in pediatric patients. Naloxone has a very short half-life, and resedation is a concern in patients overdosing on long-acting opioids or sustained-release dosage forms.
   b. **Nalmefene (Revex)** has a half-life of 4 to 8 hrs. Initial dosages are 0.5 mg/70 kg. A follow-up dose 2 to 5 mins later is 1 mg/70 kg.

R. Organophosphates
1. **There are several available forms**; they are usually pesticides or chemical warfare agents.
2. **Toxicokinetics.** Organophosphates are absorbed through the lungs, skin, GI tract, and conjunctiva.

3. **Clinical presentation** includes excessive cholinergic stimulation.
4. **Laboratory data** include red blood cell acetylcholinesterase activity.
5. **Treatment**
   a. **Decontamination**
   b. **Atropine** is given 0.5 to 2.0 mg IV to reverse the peripheral muscarinic effects.
   c. **Pralidoxime (2-PAM**; **Protopam)** is given 1 g IV over 2 mins and repeated in 20 mins as needed.

S. **Salicylates**
1. **Available dosage forms** include several OTC products: oral, rectal, and topical.
2. **Toxicokinetics.** Salicylates are well absorbed after oral administration. The half-life is 6 to 12 hrs at lower doses. In overdose situations, the half-life may be prolonged to more than 20 hrs.
3. **Clinical presentation** includes nausea, vomiting, tinnitus, and malaise (mild toxicity). Lethargy, convulsions, coma, and metabolic acidosis appear in more severe overdoses. Potential **complications** from therapeutic and toxic doses include GI bleeding, increased PT, hepatic toxicity, pancreatitis, and proteinuria.
4. **Laboratory data** for the following 6-hr postingestion levels are:
   a. 40 to 60 mg/dL: tinnitus
   b. 60 to 95 mg/dL: moderate toxicity
   c. More than 95 mg/dL: severe toxicity
   d. With the presence of acidemia and aciduria, evaluate ABGs.
   e. In addition, laboratory evaluation may show leukocytosis, thrombocytopenia, increased or decreased serum glucose and sodium, hypokalemia, and increased serum BUN, creatinine, and ketones.
5. **Treatment**
   a. **Decontamination.** Repetitive doses of activated charcoal every 6 hrs, with one dose of cathartic for patients who ingested > 150 mg/kg. Whole-bowel irrigation for large ingestions.
   b. **Alkaline diuresis** is given as noted in decontamination section to enhance salicylate excretion. This is indicated for levels > 40 mg/dL.
   c. **Hemodialysis** is used for severe intoxications when serum levels are > 100 mg/dL. This method of decontamination is much better than repetitive doses of activated charcoal.
   d. **Fluid** and **electrolyte** replacement is administered as needed.
   e. **Vitamin K (Aquamephyton)** and **fresh frozen plasma** are used to correct any coagulopathy.

T. **Snake bites**
1. **Types.** There are numerous species of snakes found worldwide. The venomous snakes found in North America include the following: rattlesnake, cottonmouth, copperhead, and coral. Because patients may be exposed to more exotic snakes, a herpetologist should be consulted for a more definitive identification.
2. **Toxicokinetics.** Onset of symptomatology depends on the species of snake and the patient's underlying medical condition.
3. **Clinical presentation** includes nausea; vomiting; diarrhea; syncope; tachycardia; and cold, clammy skin. Local findings include pain, edema, and erythema. More severe envenomations can lead to severe tissue injury, compartment syndrome, and shock.
4. **Laboratory data**
   a. CBC and platelet count
   b. Coagulation profile
   c. Fibrin degradation products
   d. Electrolytes
   e. BUN, SCr, and urinalysis
5. **Treatment**
   a. **Supportive.** Move the patient away from striking distance of the snake. Ideally, the patient should be transported to a medical facility as soon as possible. Constrictive clothing, rings, watches, etc. should be removed. Tetanus immunization should be assessed, and surgical intervention may be necessary for severe cases.
   b. **Antivenoms**
      (1) Antivenin (Crotalidae) polyvalent is a horse-derived product that has been reported to produce allergic reactions. For mild bites, the recommended dose is 5 to 10 vials; moderate, 10–20; and severe envenomations may require 20 or more vials.

(2) Crotalidae polyvalent immune Fab is a polyvalent antivenin made from sheep sources. The initial dose is four to six vials diluted in 250 mL of 0.9% normal saline (NS) administered over 1 hr. Additional doses may be required for severe envenomations.

U. Theophylline

1. **Available dosage forms** include liquid, sustained-release tablets, and capsules as well as parenteral forms.
2. **Toxicokinetics.** Well absorbed orally with a V_d of approximately 0.5 L/kg. Theophylline is hepatically metabolized and has a half-life of 4 to 8 hrs. Theophylline clearance depends highly on age, concomitant disease states, and interacting drugs.
3. **Clinical presentation** includes nausea, vomiting, seizures, and cardiac dysrhythmias. Chronic toxicity carries a poorer prognosis than acute toxicity.
4. **Laboratory data.** Therapeutic theophylline levels are 5 to 20 μg/mL. Hyperglycemia and hypokalemia are seen with acute ingestions. Other useful laboratory tests include serum electrolytes, BUN, creatinine, hepatic function, and ECG monitoring.
5. **Treatment**
   a. **Supportive** therapy includes maintaining an airway and treating seizures and dysrhythmias as they occur.
   b. **Decontamination. Syrup of ipecac not recommended.**
   c. **Activated charcoal** (repetitive doses) to enhance elimination. **Whole-bowel irrigation** for massive ingestions (especially with sustained-release products). **Charcoal hemoperfusion** is used in unstable patients who are in status epilepticus. **Hemodialysis** is used when hemoperfusion is unavailable.
   d. **β-adrenergic antagonists** (e.g., esmolol, Brevibloc) are used to treat the hypotension, tachycardia, and dysrhythmias caused by elevated cyclic adenosine monophosphate levels.

Study Questions

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A physician receives a call from the parent of a 2-year-old child who has ingested an unknown quantity of morphine controlled-release tablets and is now unconscious. The physician's initial recommendation is to
   (A) Call emergency medical services (EMS) and have the child taken to the hospital emergency department.
   (B) Administer 1 g/kg of activated charcoal with sorbitol.
   (C) Administer syrup of ipecac 15 mL by mouth to induce vomiting.
   (D) Suggest that the child receive emergency hemodialysis.
   (E) Suggest that the child receive acid diuresis with ammonium chloride.

2. A grandfather arrives at your pharmacy asking to purchase a bottle of syrup of ipecac to keep in his home in the event of a poisoning when grandchildren are visiting. What should you tell him?
   (A) Administer 15 mL of syrup of ipecac at the first sign of ingestion.
   (B) Syrup of ipecac is no longer recommended by the American Association of Poison Control Centers and the American Academy of Pediatrics.
   (C) Provide him with the toll-free number for the poison control center.
   (D) Both B and C.

3. An unconscious patient is brought into the emergency department. The patient is given 50 mL of 50% dextrose in water, thiamine 100 mg IV, followed by naloxone 1 mg, at which point he awakens. This patient most likely has overdosed on which of the following substances?
   (A) Methanol
   (B) Amitriptyline
   (C) Cocaine
   (D) Haloperidol
   (E) Heroin

4. Contraindications to the administration of syrup of ipecac include which of the following?

   (A) An unconscious patient
   (B) A patient who is experiencing a generalized tonic–clonic seizure
   (C) A patient who has ingested a caustic substance
   (D) All of the above
   (E) None of the above

5. An unconscious patient is brought to the emergency department with a history of an unknown drug overdose. Which of the following actions should the physician perform?

   (A) Administer 50 mL of 50% dextrose, thiamine 100 mg IV push, and naloxone 0.4 mg IV push.
   (B) Protect the patient's airway and ensure that vital signs are stable.
   (C) Order the following laboratory tests: complete blood count (CBC), electrolytes, and a toxicology screen.
   (D) All of the above.

6. A patient who overdoses on acetaminophen is admitted to the hospital for antidotal therapy with *N*-acetylcysteine (NAC). The patient has the following medication orders: NAC 140 mg/kg loading dose followed by 70 mg/kg for a total of 17 doses, ranitidine 50 mg IV every 8 hrs, prochlorperazine 10 mg IM every 6 hrs as needed for nausea, thiamine 100 mg IV every day for three doses, and Darvocet-N 100 one to two tablets every 4 hrs as needed for headache. What is the best course of action?

   (A) Call the physician to increase the dosage of ranitidine to 50 mg IV every 6 hrs.
   (B) Call the physician to have the Darvocet-N 100 discontinued.
   (C) Call the physician to initiate hemodialysis therapy.
   (D) Have the patient prophylactically intubated to protect the airway.
   (E) Administer ethanol 10% at a loading dose of 7.5 mL/kg over 1 hr, followed by a continuous infusion of 1.4 mL/kg/hr for 48 hrs.

7. Ethyl alcohol (EtOH) is administered to patients who have ingested either ethylene glycol or methanol because EtOH

   (A) helps sedate patients.
   (B) increases the metabolism of ethylene glycol and methanol.
   (C) blocks the formation of the toxic metabolites of ethylene glycol and methanol.
   (D) increases the renal clearance of ethylene glycol and methanol.
   (E) is not an antidote for ethylene glycol or methanol overdoses.

8. A patient with renal failure is inadvertently given three doses of potassium chloride 40 mEq IV in 100 mL of 0.9% sodium chloride over a 3-hr period. This error is immediately discovered, and a STAT serum potassium level is 8.0 mEq/L. The patient is bradycardic with a markedly prolonged QRS complex. The patient should receive which of the following?

   (A) Calcium chloride 10% 10 mL IV push
   (B) Sodium bicarbonate 50 mEq IV push
   (C) Insulin 10 U and 50% dextrose 50 mL IV push
   (D) Sodium polystyrene sulfonate 30 g by mouth every 3 hr for four doses
   (E) None of the above

9. Parenteral calcium is used as an antidote for which of the following situations?

   (A) Verapamil overdoses
   (B) Hyperkalemia
   (C) Cocaine intoxication
   (D) Verapamil overdoses and hyperkalemia

10. A 65-year-old woman with normal renal function is administered a 0.25 mg dose of digoxin IV push. A serum level obtained 1 hr after drug administration is 5 ng/mL. Your recommendation to the physician is which of the following?

    (A) Administer two vials of digoxin immune antibodies STAT.
    (B) Administer repetitive doses of activated charcoal.
    (C) Call a nephrologist, and put the patient on hemodialysis.
    (D) Repeat the serum digoxin level 6 to 8 hrs after the dose, and reassess the patient.

11. A 16-year-old woman is reported to have overdosed on 40 sustained-release theophylline tablets. She is transported to the emergency department, where gastric lavage was performed and she was given one dose of activated charcoal. An initial theophylline level is 42 μg/mL, but a follow-up level in the intensive care unit (ICU) is 95 μg/mL. What is the most appropriate course of therapy?

    (A) Charcoal hemoperfusion and multiple-dose activated charcoal
    (B) Syrup of ipecac administration
    (C) Forced alkaline diuresis
    (D) Nasogastric administration of sodium-polystyrene sulfonate

12. A 23-year-old man is admitted to the intensive care unit (ICU) after ingesting 20 acetaminophen tablets 500 mg with a six-pack of beer. He was initially awake and alert in the emergency department and was given one dose of activated charcoal. His initial acetaminophen level taken approximately 2 hrs after ingestion is 90 µg/mL. What would be the most appropriate course of action?

  (A) Administer repeated doses of activated charcoal and sorbitol.
  (B) Administer syrup of ipecac.
  (C) Administer a loading dose of *N*-acetyl-L-cysteine (NAC), and repeat the acetaminophen level in 4 hrs.
  (D) Discharge the patient to home.

13. An overdose victim presents to the emergency department with an elevated heart rate, decreased blood pressure, dilated pupils, and lethargy. Upon arrival to the intensive care unit (ICU), she has a generalized tonic–clonic seizure that is treated with IV diazepam and fosphenytoin. Which of the following is the most likely intoxicant?

  (A) Ethyl alcohol
  (B) Methanol
  (C) Acetaminophen
  (D) Oxycodone
  (E) Amitriptyline

14. A 37-year-old man is admitted to the ICU with an overdose of approximately 50 tablets of Depakote 500 mg sustained-release tablets. He never lost consciousness. He denies fevers, syncope, headache, vision changes, weakness, shortness of breath, chest pain, nausea, vomiting, or diarrhea. His initial valproic acid level was 41 mg/dL (therapeutic range 50 to 100 µg/mL). His ammonia level was elevated and therapy with intravenous levocarnitine was begun. At this point, you should recommend the following:

  (A) Discontinue levocarnitine.
  (B) Transfer the patient to in-patient psychiatry because the patient is asymptomatic.
  (C) Restart his home dose of valproic acid sustained-release tablets so that his level does not fall below the therapeutic range.
  (D) Recheck a follow-up valproic acid level and continue to observe in the ICU.

Answers and Explanations

1. **The correct answer is A** *[see I].*
Patients with unstable vital signs should be taken to an emergency department for immediate treatment.

2. **The correct answer is D** *[see II.G.b].*
Induced vomiting is no longer an acceptable option of managing poisonings at home because it is a relatively ineffective method of removing toxins and results in a delay in administering antidotal therapy. It is important to counsel patients on poison prevention and to give parents and other friends and relatives the toll-free number for the poison control center. Parents should also know basic first aid and cardiopulmonary resuscitation (CPR).

3. **The correct answer is E** *[see III.Q].*
Naloxone reverses the effects of opioid receptor agonists, such as heroin, morphine, and propoxyphene.

4. **The correct answer is D** *[see II.G.a].*
Contraindications to ipecac include the three Cs: caustics, conscious, and convulsions; see also the answer to question 2. The use of syrup of ipecac is reserved for rare circumstances and only under the direction of the poison control center and/or a physician. These are new recommendations, and many parents, relatives, and friends may have this product in their medicine cabinets.

5. **The correct answer is D** *[see II].*
The management of unconscious overdose patients involves aggressive support of vital signs and the administration of empiric antidotal therapy, while obtaining various laboratory tests to determine the nature of the overdose.

6. **The correct answer is B** *[see III.a].*
Darvocet-N 100 is an acetaminophen-containing product that should not be given to a patient with documented acetaminophen toxicity. Be aware particularly of OTC products containing acetaminophen.

7. **The correct answer is C** *[see III.b]*.
Ethanol saturates alcohol dehydrogenase and prevents the formation of the toxic metabolites of either ethylene glycol or methanol; however, this antidote is falling out of favor owing to its adverse metabolic and central nervous system effects. Fomepizole (Antizol), a specific inhibitor of alcohol dehydrogenase, is becoming the preferred antidote for methanol or ethylene glycol overdoses. Ethanol may be used in situations in which fomepizole is not available.

8. **The correct answer is A** *[see III.L.2]*.
All of the selections are used to manage hyperkalemia, although, in an unstable patient, the cardiac effects of hyperkalemia must first be reversed with intravenous calcium.

9. **The correct answer is D** *[see III.F & G]*.
Parenteral calcium is used to reverse the cardiac effects of calcium-channel blocker overuse and hyperkalemia.

10. **The correct answer is D** *[see III.K]*.
The plasma–tissue distribution phase for digoxin is 6 to 8 hrs postadministration. Sampling digoxin levels sooner may give a falsely elevated level. Only symptomatic patients should receive digoxin immune antibodies. Hemodialysis is of no value in managing digoxin overdoses.

11. **The correct answer is A** *[see III.U]*.
Large ingestions of sustained-release products may act as drug reservoirs, necessitating aggressive measures to remove the toxin.

12. **The correct answer is C** *[see III.A]*.
Large acetaminophen ingestions (> 140 mg/kg) may be fatal if unrecognized. The Rumack–Matthew nomogram requires a 4-hr level to accurately assess the potential for toxicity. If the 4-hr level is in the toxic range, the full course of NAC therapy should be administered.

13. **The correct answer is E** *[see III.D]*.
Tricyclic antidepressant overdoses will produce seizures, hypotension, mydriasis, hypotension, and ventricular dysrhythmias. The cardiac and CNS effects of tricyclic antidepressant toxicity will respond to bicarbonate therapy. Opiates such as oxycodone will produce miosis.

14. **The correct answer is D** *[see II]*.
The patient in this case ingested a sustained-release dosage form. Also from the history, it was estimated that the patient took 50 tablets that may produce a delayed release effect in and of itself. While the patient was asymptomatic, he may develop symptoms after a period as more drug are absorbed. In this case, a follow-up valproic acid level was 155 mg/dL, the patient was observed in the ICU, and carnitine therapy was continued. Carnitine has been shown to reverse the hyperaminemia induced by valproic acid and was continued while the patient was in the ICU. The next day, the valoproic acid level fell to 50 µg/dL, the patient remained asymptomatic, and he was transferred out of the ICU.

Sterile Products

CHRISTOPHER VITALE, CARYN DOMENICI BELISLE, JOHN FANIKOS

I. INTRODUCTION.

The *United States Pharmacopeia* (*USP*) and the National Formulary published practice standards for compounding sterile preparations after case reports of patient harm and fatality. The procedures and requirements outlined in *USP* Chapter 797 are intended to prevent patient harm resulting from ingredient errors and microbial contamination. This chapter includes compounding personnel responsibilities, training and evaluation requirements, medication preparation sterility and accuracy verification, classification of microbial contamination risk, and equipment and environmental quality and control. Although these standards apply to all facilities (hospitals, nursing homes, pharmacies) and all practitioners (physicians, nurses, technicians), they are especially important for pharmacists who are most often involved with sterile medication preparation. Because the standards require substantial investment in labor, equipment, and supplies, regulatory agencies (U.S. Food and Drug Administration, The Joint Commission on Accreditation of Health Care Organizations, U.S. state boards of pharmacy) are expecting implementation by January 2006, with evidence of long-term compliance and routine monitoring thereafter.

II. DEFINITIONS

A. **Sterility**, an absolute term, means the absence of living microorganisms.
   1. **Microbe** is a microscopic organism such as a bacterium, fungus, protozoon, or virus.
   2. **Pyrogens** are metabolic by-products of live or dead microorganisms that cause a pyretic response (i.e., a fever) upon injection.
   3. **Sterile products** are pharmaceutical dosage forms that are sterile. This includes products like parenteral preparations, irrigating solutions, and ophthalmic preparations (see Chapter 19). Sterile product compounding requires cleaner facilities, personnel training and testing, and a sound knowledge of sterilization and stability principals and practices.
   4. **Aseptic technique** refers to the sum total of methods and manipulations required to minimize the contamination of compounded sterile products and is of paramount importance when preparing such preparations.
   5. **Compounded sterile preparations** (CSPs) include
      a. Preparations that, when prepared according to manufacturer instructions, expose a sterile agent to potential microbial contamination.
      b. Preparations made from nonsterile ingredients that must be sterile before patient administration.
      c. Sterile or nonsterile biologicals (vaccines, immune globulins), diagnostics, medications, nutritionals, and radiopharmaceuticals that must be sterile prior to administration or use as an irrigation, bath, implant, inhalation, injection, or for use in the eye or ear.
   6. Beyond-use dating (BUD) is outlined by *USP* <797> subsection <71>, which defines the usability of CSPs postpreparation or after expiration of a punctured medication vial, based on product storage and microbial contamination risk levels (*Tables 17-1* and *17-2*).
      a. **Microbial contamination risk levels** are assigned according to the probability of contaminating a preparation with microbial organisms, endotoxins, or with foreign chemical or physical particulate matter.
         (1) **Low-risk level CSPs** are compounded by aseptically transferring a single sterile dosage form from a sterile ampoule, vial, bottle, or bag using sterile needles and syringes to a final sterile container or device for patient administration.

Table 17-1	MICROBIAL CONTAMINATION RISK LEVELS AND BEYOND USE DATING OF COMPOUNDED STERILE PREPARATIONS

Type of CSP	Beyond Use Date in the Absence of Sterility Testing (*USP* <71>)		
	Room Temperature	Refrigeration	Frozen (≤ 10°C)
Low risk	48 hrs	14 days	45 days
Medium risk	30 hrs	9 days	45 days
High risk	24 hrs	3 days	45 days
Immediate use	1 hr		

CSP, compounded sterile preparation; *USP*, United States Pharmacopeia.

    (2) Medium-risk level CSPs are compounded by aseptically transferring multiple sterile dosage forms from sterile ampoules, vials, bottles, or bags using sterile needles and syringes to a single final sterile container or device for administration to multiple patients or to one patient on multiple occasions.

    (3) High-risk level CSPs are compounded from nonsterile ingredients and are terminally sterilized prior to patient administration or sterile ingredients that are compounded under inferior air quality conditions.

    (4) Immediate-use CSPs are compounded in emergency situations or where immediate patient administration is mandated to avoid harm that may result from delays in treatment.

  7. Compounded parenteral preparations are pharmaceutical dosage forms that are injected through one or more layers of skin. Because the parenteral route bypasses the protective barriers of the body, parenteral preparations must be sterile. The pH of a solution may markedly influence the stability and compatibility of parenteral preparations.

III. DESIGN AND FUNCTION OF STERILE COMPOUNDING AREAS

  A. Clean rooms are areas specially constructed and maintained to reduce the probability of environmental contamination of sterile products during the manufacturing process. Engineering controls to reduce the potential for airborne contamination include airflow through high-efficiency particulate-air (HEPA) filters, use of horizontal flow clean benches, vertical flow clean benches, biological safety cabinets, and barrier isolators. Clean rooms are traditionally designed in multicompartments or partitioned work areas for aseptic processing (*Figure 17-1*).

    1. Ante-area provides a clean area for personal cleaning and for donning personal protective equipment such as hair covers, gloves, gowns, or full clean room attire. Supplies are removed from shipping cartons and decontaminated with a disinfecting agent. The area should provide at least an International Organization for Standardization (ISO) class 8 or better work environment.

    2. Buffer area contains the work surfaces for the staging of supplies and equipment used in CSP preparation. It should provide at least an ISO class 7 work environment. The buffer area should

Table 17-2	BEYOND USE DATING OF PUNCTURED MEDICATION VIALS

Type of Vial	Beyond Use Date of Punctured Vials Under Refrigeration (*USP* <71>)
Single-dose vial	6 hrs after initial puncture within an ISO class 5 area or cleaner
Multi-dose vials containing an antimicrobial preservative	28 days
Ampoules	Requires immediate use

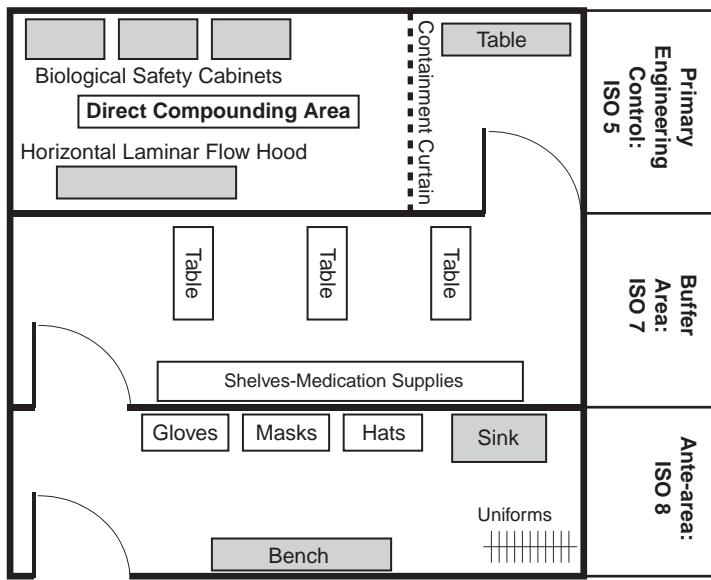
ISO, International Organization for Standardization; *USP*, United States Pharmacopeia.


Figure 17-1. Clean room layout.

contain no sinks or drains and be free of objects that shed particles (cardboard, paper, cotton, etc.). Traffic flow in and out is minimized and restricted to qualified compounding personnel.

3. **Primary engineering control** is the room that provides the ISO class 5 environment for CSP preparation.

4. **Direct compounding area** is the critical area with the primary engineering control where compounding is performed and critical sites are exposed to HEPA-filtered air.

5. **HEPA filters** are used to cleanse the air entering the room. These filters remove all airborne particles 0.3 mm or larger, with an efficiency of 99.97%. The reference standards for HEPA-filtered rooms have changed to a metric-based system (*Table 17-3*). HEPA-filtered rooms are classified as ISO class 3 through 8. An ISO class 8 room contains no more than 3,520,000 particles of 0.5 μm or larger per cubic meter of air.

6. **Positive-pressure airflow** is used to prevent contaminated air from flowing into the clean room. In order to achieve this, the air pressure inside the clean room must be greater than the pressure outside the room, so that when a door or window to the clean room is opened, the airflow is outward.

7. **Counters** in the clean room are made of stainless steel or other nonporous, easily cleaned material.

8. **Walls**, **floors**, and **ceilings** do not have cracks or crevices and have rounded corners. All surfaces should also be nonporous and washable to enable regular disinfection. If walls or floors are painted, epoxy paint is used.

| Table 17-3 | INTERNATIONAL ORGANIZATION OF STANDARDIZATION (ISO) CLASSIFICATION OF PARTICULATE MATTER IN ROOM AIR |

Class Name		Particle Size	
ISO Class	U.S. Federal Standard[a]	ISO (Particles per cubic meter)	U.S. Federal Standard[a] (Particles per cubic foot)
3	Class 1	35.2	1
4	Class 10	352	10
5	Class 100	3,520	100
6	Class 1000	35,200	1,000
7	Class 10,000	352,000	10,000
8	Class 100,000	3,520,000	100,000

[a]Federal Standard No. 209E, General Services Administration, Washington DC, 20407.

     9. Airflow. As with the HEPA filters used in clean rooms, the airflow moves with a uniform velocity along parallel lines. The velocity of the airflow is 27 m/min (90 f).

    10. Critical site is any opening providing a direct path between a sterile product and the environment or any surface coming in direct contact with the sterile product and the environment. Laminar flow work benches are used to provide an adequate critical site environment. *USP* Chapter 797 requires sterile preparation compounding be performed in at least an ISO class 5 quality air environment.

B. Laminar flow work benches (LFWB) are generally used in conjunction with clean rooms and are specially designed to create an aseptic environment for the preparation of sterile products. An ISO class 5 environment exists inside a certified horizontal or vertical LFWB.

  1. HEPA filter requirement. Like clean rooms, laminar flow work benches use HEPA filters, but the benches use a higher efficiency air filter than do clean rooms.

  2. Types of laminar flow work benches

    a. Horizontal laminar flow hoods (*Figure 17-2*) were the first hoods used in pharmacies for the preparation of sterile products. Airflow in horizontal hoods moves across the surface of the work area, flowing first through a prefilter and then through the HEPA filter. The major disadvantage of the horizontal hood is that it offers no protection to the operator, which is especially significant when antineoplastic agents are being prepared (see IX.D.2).

    b. Vertical laminar flow hoods (*Figure 17-3*) provide two major **advantages** over horizontal flow hoods.

      (1) The airflow is vertical, flowing down on the work space. This airflow pattern protects the operator against potential hazards from the products being prepared.

      (2) A portion of the HEPA-filtered air is recirculated a second time through the HEPA filter. The remainder of the filtered air is removed through an exhaust filter, which may be vented to the outside to protect the operator from chronic, concentrated exposure to hazardous materials.

C. Biological safety cabinets (BSCs) are vertical flow hoods with four major types available. They are differentiated by the amount of air recirculated in the cabinet, whether this air is vented to the room or outside, and whether contaminated ducts are under positive or negative pressure.

  1. Type A cabinets recirculate 70% of cabinet air through HEPA filters back into the cabinet, the remainder is discharged through a HEPA into the clean room, and contaminated ducts are under positive pressure.

  2. Type B1 cabinets recirculate 30% of cabinet air through HEPA filters back into the cabinet, the remainder is discharged through HEPA filters to the outside environment, and contaminated ducts are under negative pressure.

Figure 17-2. Horizontal laminar flow hood. (Courtesy of William Salkin.)

Figure 17-3. Vertical laminar flow hood. (Courtesy of William Salkin.)

     3. Type B2 cabinets discharge all cabinet air through HEPA filters to the outside environment with contaminated ducts under negative pressure.

     4. Type B3 cabinets recirculate 70% of cabinet air through HEPA filters back into the cabinet, 30% is discharged through HEPA filters to the outside, and contaminated ducts are under negative pressure.

  D. Compounding aseptic isolators (CAI) provide an ISO class 5 environment for product preparation, with aseptic manipulations occurring inside a closed, pressurized environment accessible only via sealed gloves that reach into the work area (*Figure 17-4*).

Figure 17-4. Compounding aseptic isolator. (Courtesy of William Salkin.)

Figure 17-5. Advanced robotic automated compounding device. (Courtesy of William Salkin.)

E. **Compounding aseptic containment isolators** protect workers from exposure to undesirable or hazardous drugs during the compounding and material transfer processes. An isolator uses unidirectional or turbulent airflow to remove contaminants from the unit. It uses positive air pressure to keep external airborne particles out of the isolator. This technology represents an acceptable alternative to LFWBs in clean rooms for aseptic processing.

F. **Automated compounding devices (ACDs)** are important pieces of equipment used for the preparation of sterile products. ACDs provide accuracy, safety, and efficiency through technology. Portable ACDs are required to be in an ISO class 5 environment. **Advanced robotic ACDs** are available for compounding sterile syringes, chemotherapy and small-volume sterile products. Robotic devices are typically stand-alone machines housed within a fully enclosed ISO class 5 or better environment (*Figure 17-5*).

G. **Inspection and certification.** Clean rooms, LFWBs, BSCs, and barrier isolators are inspected and certified when they are first installed; at least every 6 months thereafter; and, in the case of LFWB, BSCs, and isolators, when moved to a new location.

 1. **Inspections** should be conducted by National Sanitation Foundation (NSF)-accredited and certified technicians with expertise and training in contamination control technologies. Equipment used for testing has appropriate tolerance for the specified testing and is calibrated to National Institute of Standards and Technology (NIST) traceable standards.

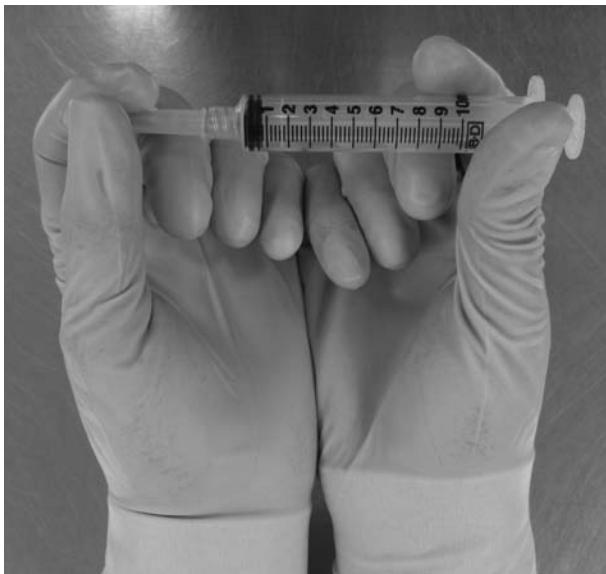
 2. **Testing** is performed per relevant industry standards and at minimum includes
    a. HEPA filter integrity testing
    b. Airflow testing: downflow and inflow where appropriate
    c. Particulate monitoring
    d. Pressurization monitoring (clean rooms and barrier isolators) ensures that no particle larger than 0.3 mm passes through the HEPA filter. In addition, an anemometer is used to determine airflow velocity, and a particle counter is used to determine the particle count.

IV. ASEPTIC MANIPULATIONS

A. **Aseptic technique** refers to the sum total of methods and manipulations required to minimize the contamination of compounded sterile products and is of paramount importance when preparing such preparations. Aseptic technique starts with proper gowning procedures, hand washing, and proper use of sterile gloves. A working knowledge and ability to perform appropriate manipulations of sterile compounding instrumentation such as syringes, needles, sterile vials, and infusion bags is also necessary to ensure sterility of the end product and thus patient safety.

B. **Full-body garb** has been shown to reduce the number of particles emitted from those working in a sterile environment. Proper gowning is required prior to entering the clean room and should take place in the ISO 8 Ante-Area. Gowning from "head-to-toe" should take place, including the use of hairnets or bonnets, surgical mask, shoe covers, sterile gloves, and sterile gown or full clean room attire (*Figure 17-6*).

C. **Hand antisepsis** has been shown to reduce the incidence of health care–associated infections by decreasing microbial transmission from patient to patient via the health care worker. This same

Figure 17-6. Full-body garb including hairnet, surgical mask, shoe covers, sterile gloves, and gown. (Courtesy of William Salkin.)


concept is applied to the preparation of CSPs, and thorough hand washing is required every time prior to entering the sterile environment. The following CDC guidelines for proper hand hygiene of the health care professional should be followed:

1. Removal of all artificial nails, nail polish, and jewelry.
2. Hands should be scrubbed with antimicrobial soap for 15 secs and rinsed with warm water. Dry thoroughly with a disposable towel. Alcohol-based hand sanitizers are alternatives to soap and water to disinfect **unsoiled** hands.
3. Washed hands that have been coughed or sneezed into, or that have come in contact with nonsterile surfaces, should be washed or sanitized again.

D. **Sterile gloves** should be donned after gowning and hand washing but prior to entering the ISO 5 direct compounding area and must be changed upon leaving the clean room. During CSP preparation, gloves should be rinsed frequently with an alcohol-based hand sanitizer and changed when their integrity is compromised by coming in contact with nonsterile surfaces or are coughed or sneezed into. The following steps should be taken when putting on a pair of sterile gloves:

1. Open sterile glove packaging then paper wrapper around gloves, ensuring not to touch any outer portion of either glove.
2. Place the first glove on one hand by only touching the folded, inner portion of the glove. Pull the glove up over the outer cuff of the sterile gown. Repeat.
3. Pickup and discard the sterile glove packaging by touching only the sterile paper wrapper.

E. **Proper preparation of the laminar flow hood** (LAFW or BSC) and all supplies must be performed prior to the manufacturing of CSPs to ensure a biological and particulate-free work environment. When working in a laminar flow hood, all manipulations must take place at a minimum of 6 inches within the work surface (*Figure 17-7*). When preparing the work surface and supplies, the following steps should be followed:

1. Remove all supplies from the work surface.
2. Wash all surfaces of the laminar flow hood, excluding the HEPA filter grate, using 70% isopropyl alcohol. All surfaces should be wiped down with lint-free cleaning cloths by using side-to-side motions that extend entirely from one wall of the work surface to the other. Cleaning should always start in the back of the laminar flow hood and move toward the front in order to pull any debris out of the work area.

Figure 17-7. Working within a laminar flow hood. (Courtesy of Chistopher J. Belisle.)

3. All nonsterile supplies, such as vials and infusion bags, should be removed from their outer packaging and wiped down with 70% isopropyl alcohol and lint-free cleaning cloths prior to being placed within the laminar flow hood.

4. Instrumentation that is in sterile packaging such as needles and syringes should be opened within the laminar flow hood just prior to use. This packaging should always be "peeled" opened as intended as opposed to being torn open, to reduce the creation of particulate matter within the sterile environment. Place packaging to the side.

5. Place all sterilized supplies on the workbench in a manner that airflow is unobstructed from all vials and infusion bags.

6. Remove vial covers from all vials. Place to the side.

7. Use an alcohol swab to sterilize the rubber stoppers of the vials and the injection ports of the infusion bags by wiping thoroughly.

F. **Proper aseptic technique** must be used when preparing compounded sterile preparations, along with creating a slight negative pressure within the diluent and medication vials in order to prevent spray back from vial stoppers upon withdrawal of the needle. This can be accomplished by performing the following steps:

1. Proper technique for **removing a needle cap** from a Luer-Lok needle that is attached to a syringe is necessary to reduce the risk of a finger stick, and includes the following steps (*Figure 17-8*):

   a. Hold the syringe with attached/capped needle in one hand like a pen.

   b. Place the heels of your hands together.

Figure 17-8. Proper technique for removing a needle cap from a Luer-Lok needle. (Courtesy of William Salkin.)

    c. Grasp the needle cap with the finger and thumb of the opposite hand.

    d. While keeping the heels of your hands firmly together, roll your thumbs away from each other until the needle cap is fully removed from the needle.

    e. Place the needle and syringe in an appropriate sharps container after use. In order to minimize the risk of needle sticks, NEVER recap a needle.

G. Anticoring technique: While inserting a needle through a medication vial stopper, a small piece of the stopper can become sheared off or cored and left floating in the medication infusion bag. This core can easily go unnoticed due to its small size or if visualization is blocked by a medication label and can result in a foreign body being injected into the patient. Although coring is generally considered a low-frequency event, case reports have established it as a potential medical risk. In order to prevent coring when preparing compounded sterile preparations, the following technique should be used:

    1. Position the needle on the vial stopper at about a 45 to 60 degree angle to the closure surface so that the bevel is facing upward (*Figure 17-9*).

    2. Apply downward pressure on the needle as if writing with a pen, while gradually moving the needle to an upright position, reaching 90 degrees just before penetration is complete.

H. Reconstituting powdered medication (this step will be necessary only when working with lyophilized medication vials):

    1. By pulling back on the syringe plunger, draw into the syringe a volume of air equal to about 1 mL less than the volume of diluent that will be used for reconstitution. This information can be found in the product package insert.

    2. After penetrating the diluent vial, invert the vial by using the thumb and forefinger to hold the vial, and the little finger and the palm of the hand to hold the barrel of the syringe.

    3. Using the other hand to manipulate the syringe plunger, use multiple small injections and withdrawals to transfer the air in the syringe and a slight excess of the diluent solution from the vial.

    4. Prior to withdrawing the needle from the vial, remove all air bubbles by tapping the syringe and then adjust the syringe to the proper diluent volume.

    5. Keeping the drug vial upright upon the work surface, insert the needle and use multiple small injections and withdrawals to transfer the diluent in the syringe and remove a volume of air from the vial equal to about 1 mL greater than the amount of diluent that was just added.

    6. Swirl the vial according to the manufactures recommendations until the drug is fully dissolved.

I. Reconstituted medications or medications that are already in solution:

    1. Using a new needle and syringe, draw into the syringe a volume of air equal to about 1 mL less than the volume of solution that will be used.

    2. Withdraw the calculated amount of medication solution from the vial as previously described.

    3. Transfer the drug solution in the syringe into a final container via the injection port. Cover the injection port with a protective cover.

    4. Inspect the final container for integrity, evidence of particulates, and verification of product accuracy.

Figure 17-9. Anticoring technique. (Courtesy of William Salkin.)

Figure 17-10. Glass medication ampoule. (Courtesy of Chistopher J. Belisle.)

J. **Ampoules** are small, sealed glass vials used to contain and preserve a medication (*Figure 17-10*). The following steps should be followed when using an ampoule:
   1. To open the ampoule:
      a. Hold upright and gently tap the top to remove any solution from the head space.
      b. Swab the neck of the ampoule with an alcohol swab.
      c. Grasp the top of the ampoule with the thumb and forefinger of one hand, while firmly holding the bottom of the ampoule with the other.
      d. By moving your hands away and out from you, quickly snap open the ampoule.
   2. To withdraw medication from the ampoule:
      a. Insert a 5 micron filter needle or straw into the ampoule while holding at a slight angle.
      b. Withdraw the appropriate amount of solution by positioning the needle or straw in the corner area of the ampoule, beveled edge down.
      c. Replace with new needle prior to transferring the solution to the final container.

V. QUALITY CONTROL AND QUALITY ASSURANCE

A. **Definitions**
   1. **Quality control** is the day-to-day assessment of all sterile compounding operations. This includes receipt of raw materials, preparation, storage, distribution, patient administration, and includes analytic testing of the finished product.
   2. **Quality assurance**, an oversight function, involves the auditing of quality control procedures and systems, with suggestions for changes as needed.
B. **Testing procedures.** Various types of tests are used to ensure that all sterile products are free of microbial contamination, pyrogens, and particulate matter.
   1. **Clarity testing** is used to check sterile products for particulate matter and leaks. Before dispensing a parenteral solution, pharmacy personnel should check it for particulates by swirling the solution and looking at it against both light and dark backgrounds, using a clarity testing lamp or other standard light source.
   2. **Compound accuracy checking** is a double check of the used drug products and supplies by a person other than the compounder. This includes an inspection of the label and syringes used to measure the additives.
   3. **Beyond use dating** represents the date and time beyond which a product should not be administered because of potency, sterility, or storage concerns. Beyond use dating should be assigned in accordance with the manufacturers' product labeling and should comply with *USP <797>* guidelines (*Table 17-1*, *Table 17-2*).
   4. **End product testing** is sterility and pyrogen testing that should be performed on all high-risk CSPs that are prepared in batches of 25 units or more, multidose vials, or preparations that are exposed longer than 6 to 12 hrs prior to sterilization.
      a. **Sterility testing** ensures that the process used to sterilize the product was successful. The **membrane sterilization method** is often used to conduct sterility testing. Test samples are

passed through membrane filters, and a nutrient medium is then added to promote microbial growth. After an incubation period, microbial growth is determined.

   b. **Pyrogen testing** can be accomplished by means of qualitative fever response testing in rabbits or by in vitro limulus lysate testing. Commercial laboratories are available to perform these tests. People handling sterile products can attempt to avoid problems with pyrogens by purchasing pyrogen-free water and sodium chloride for injection from reputable manufacturers and by using proper handling and storage procedures.

C. **Environmental testing** includes air and surface sampling to measure microbiology conditions of the clean room and assesses the effectiveness of cleaning and sanitizing procedures.

   1. **Viable air sampling** includes volumetric air collection in the controlled environment and evaluation of airborne microorganisms or collection of airborne organisms by exposing sterile nutrient plates containing tryptic soy broth (TSB) or tryptic soy agar (TSA) for a suitable time frame.

   2. **Nonviable air sampling** is intended to evaluate the equipment that is used to create clean air. **Total particle counts** (*Table 17-3*) should be within established ISO classifications for a given compounding area.

   3. **Surface sampling** uses TSA plates called replicate organism detection and counting (RODAC) plates to capture microorganism.

   4. Both air and surface sampling plates are collected and incubated. The number of discrete colonies of organisms, colony forming units (CFUs), are counted and reported.

D. **Practical quality assurance programs** for noncommercial sterile products include training, monitoring the manufacturing process, personnel competency assessment, quality control check, and documentation.

   1. **Training of pharmacists and technicians** in proper aseptic techniques and practices is the single most important aspect of an effective quality assurance program. Training should impart a thorough understanding of departmental policies and procedures.

   2. By **monitoring the manufacturing process**, a supervisor can check adherence to established policies and procedures and take corrective action as necessary.

   3. After training is completed, **competency assessment** through performance evaluation and reevaluation is required for routine tasks like hand washing, gowning, gloving, and aseptic manipulations. Evaluations should occur annually for personnel compounding and low- and medium-risk CSPs, and semi-annually for high-risk CSPs.

E. **Process validation** provides a mechanism for ensuring processes consistently result in sterile products of acceptable quality. This should include a written procedure to follow as well as evaluation of aseptic technique through process simulation.

F. **Process simulation testing or personnel evaluation** duplicates sterile compounding of low-, medium-, and high-risk level CSPs under most stressful conditions except that an appropriate growth media (Soybean-Casein Digest Medium) is used in place of the drug products. After preparation and incubation of the final product, no growth indicates proper aseptic techniques were followed.

G. **Quality control checking** includes monitoring the sterility of a sample of manufactured products. The membrane sterilization method is practically employed using a commercially available filter and trypticase soy broth media.

H. **Documentation** of training procedures, quality control results, laminar flow hood certification, and production records are required by various agencies and organizations.

VI. STERILIZATION METHODS AND EQUIPMENT.
Sterilization is performed to destroy or remove all microorganisms in or on a product. Sterilization can be achieved through thermal, chemical, radioactive, or mechanical methods.

A. **Thermal sterilization** involves the use of either moist or dry heat.

   1. **Moist-heat sterilization** is the **most widely used** and reliable sterilization method.

     a. Microorganisms are destroyed by **cellular protein coagulation**.

     b. The objects to be sterilized are exposed to saturated steam under 1 atmosphere pressure at a minimum temperature of **121°C** for at least 20 to 60 mins.

     c. An **autoclave** is commonly used for moist-heat sterilization.

     d. Because it does not require as high a temperature, moist-heat sterilization causes **less product and equipment damage** compared to dry-heat sterilization.

2. **Dry-heat sterilization** is appropriate for materials that cannot withstand moist-heat sterilization. Objects are subjected to a temperature of at least **160°C** for **120 mins** (if higher temperatures can be used, less exposure time is required).

B. **Chemical (gas) sterilization** is used to sterilize surfaces and porous materials (e.g., surgical dressings) that other sterilization methods may damage.
   1. In this method, **ethylene oxide** is used generally in combination with heat and moisture.
   2. **Residual gas** must be allowed to dissipate after sterilization and before use of the sterile product.

C. **Radioactive sterilization** is suitable for the industrial sterilization of contents in sealed packages that cannot be exposed to heat (e.g., prepackaged surgical components, some ophthalmic ointments).
   1. This technique involves either **electromagnetic** or **particulate radiation**.
   2. Accelerated drug decomposition sometimes results.

D. **Mechanical sterilization (filtration)** removes but does not destroy microorganisms and clarifies solutions by eliminating particulate matter. For solutions rendered unstable by thermal, chemical, or radiation sterilization, filtration is the preferred method. A depth filter or screen filter may be used. Personnel should ensure the filter used either during compounding or administration is chemically and physically compatible with the CSP at the temperature and pressure conditions used.
   1. **Depth filters** usually consist of fritted glass or unglazed porcelain (i.e., substances that trap particles in channels).
   2. **Screen (membrane) filters** are films measuring 1 to 200 μm thick made of cellulose esters, microfilaments, polycarbonate, synthetic polymers, silver, or stainless steel.
      a. A **mesh** of millions of microcapillary pores of identical size filters the solution by a process of physical sieving.
      b. **Flow rate.** Because pores make up 70% to 85% of the surface, screen filters have a higher flow rate than depth filters.
      c. **Types of screen filters**
         (1) **Particulate filters** remove particles of glass, plastic, rubber, and other contaminants.
            (a) **Other uses.** These filters also are used to reduce the risk of phlebitis associated with administration of reconstituted powders. Filtration removes any undissolved powder particles that may cause venous inflammation.
            (b) The **pore size** of standard particulate filters ranges from 0.45 to 5 μm. Special particulate filters are required to filter blood, emulsions (e.g., fat emulsions), or colloidal dispersions or suspensions because these preparations have a larger particle size.
         (2) **Microbial filters** with a pore size of 0.22 μm or smaller ensure complete microbial removal and sterilization. This is referred to as cold sterilization.
         (3) **Final filters**, which may be either particulate or microbial, are often included as part of the tubing used in drug administration. They are referred to as in-line filters and are used to remove particulates or microorganisms from an intravenous (IV) solution during infusion.

VII. PACKAGING OF PARENTERAL PRODUCTS.
Parenteral preparations and other sterile products must be packaged in a way that maintains product sterility until the time of use and prevents contamination of contents during opening.

A. **Types of containers**
   1. **Ampoules**, the oldest type of parenteral product containers, are made entirely of **glass** (*Figure 17-10*).
      a. Intended for **single use only**, ampoules are opened by breaking the glass at a scored line on the neck.
      b. **Disadvantages.** Because glass particles may become dislodged during ampoule opening, the product must be filtered before it is administered. Their unsuitability for multiple-dose use, the need to filter solutions before use, and other safety considerations have markedly reduced the ampoule as a package form.

Figure 17-11. Medication vials. (Courtesy of Chistopher J. Belisle.)

2. **Vials** are glass or plastic containers closed with a rubber stopper and sealed with an aluminum crimp (*Figure 17-11*).
   a. Vials have several **advantages** over ampoules.
      (1) Vials can be designed to hold multiple doses (if prepared with a bacteriostatic agent).
      (2) The drug product is easier to remove from vials than from ampoules.
      (3) Vials eliminate the risk of glass particle contamination during opening.
   b. However, vials also have certain **disadvantages**.
      (1) The rubber stopper can become **cored**, causing a small bit of rubber to enter the solution (see IV.H).
      (2) Multiple withdrawals (as with multiple-dose vials) can result in microbial contamination.
   c. Some drugs that are unstable in solution are packaged in vials unreconstituted and must be **reconstituted** with a diluent before use. Sterile water or sterile sodium chloride for injection are the most commonly used drug diluents.
      (1) To accelerate the dissolution rate and permit rapid reconstitution, many powders are lyophilized (freeze dried).
      (2) Some of these drugs come in vials that contain a double chamber.
         (a) The top chamber, containing sterile water for injection, is separated from the unreconstituted drug by a rubber closure.
         (b) To dislodge the inner closure and mix the contents of the compartments, external pressure is applied to the outer rubber closure. This system eliminates the need to enter the vial twice, thereby reducing the risk of microbial contamination.
3. Some drugs come in vials that may be attached to a diluent-containing bag for reconstitution and administration, such as the **ADD-Vantage System** by Abbott or the **Mini-Bag Plus System** by Baxter (*Figure 17-12*). Premeasured drug and diluent may also be stored in separate compartments within a delivery system and then combined at the point of use, such as the **Duplex System** by B. Braun.
   a. The ADD-Vantage vial is screwed into the top of an ADD-Vantage diluent bag, and the rubber diaphragm is dislodged from the vial, allowing the diluent solution to dissolve the drug prior to administration.
   b. The Mini-Bag Plus System contains an adaptor that links standard 20 mm powdered drug vials with Baxter's Mini-Bag containers, allowing vial and bag to be attached without activation until time of administration.
   c. The Duplex systems has two compartments where a seal is broken and drug and diluent are mixed to form a solution prior to administration.
   d. The premixed piggyback contains drug solution that is prediluted and ready to be administered with no further preparation needed.

Figure 17-12. A. Prefilled intravenous medication piggyback dose. **B.** MiniBag Plus System by Baxter. **C.** ADD-Vantage System by Abbott. (Courtesy of Chistopher J. Belisle.)

4. **Prefilled syringes** and **cartridges** are designed for maximum convenience (*Figure 17-13*).
   a. **Prefilled syringes.** Drugs administered in an emergency (e.g., atropine, epinephrine) are available for immediate injection when packaged in prefilled syringes.
   b. **Prefilled cartridges** are ready-to-use parenteral packages that offer improved sterility and accuracy. They consist of a plastic cartridge holder and a prefilled medication cartridge with a needle attached. The medication is premixed and premeasured. Narcotics such as meperidine (Demerol) and hydromorphone (Dilaudid) are commonly available in prefilled cartridges.
5. **Infusion solutions** are divided into two categories: **small-volume parenterals** (SVPs), those having a volume less than 100 mL; and **large-volume parenterals** (LVPs), those having a volume of 100 mL or greater. Infusion solutions are used for the intermittent or continuous infusion of fluids or drugs.
B. **Packaging materials.** Materials used to package parenteral products include glass and plastic polymers.
   1. **Glass**, the original parenteral packaging material, has superior clarity, facilitating inspection for particulate matter. Compared to plastic, glass less frequently interacts with the preparation it contains.
   2. **Plastic polymers** used for parenteral packaging include polyvinylchloride (PVC) and polyolefin.
      a. **PVC** is flexible and nonrigid.
      b. **Polyolefin** is semirigid; unlike PVC, it can be stored upright.
      c. Both types of plastic offer several **advantages** over glass, including durability, easier storage and disposal, reduced weight, and improved safety.

Figure 17-13. A. Prefilled syringe and medication cartridge. **B.** Prefilled medication Capuject by Hospira. (Courtesy of William Salkin.)

VIII. PARENTERAL ADMINISTRATION ROUTES. Parenteral preparations may be given by a variety of administration routes.

A. **Subcutaneous (SC or SQ)** administration refers to injection into the subcutaneous tissue beneath the skin layers, usually of the abdomen, arm, or thigh. Insulin is an example of a subcutaneously administered drug.

B. **Intramuscular (IM)** administration means injection into a muscle mass. The mid-deltoid area and gluteus medius are common injection sites.

   1. No more than 5 mL of a solution should be injected by this route.

   2. Drugs intended for prolonged or delayed absorption such as medroxyprogesterone (Depo Provera) and methylprednisolone (Depo Medrol) commonly are administered intramuscularly.

C. **Intravenous (IV)** administration is the most important and most common parenteral administration route. It allows an immediate therapeutic effect by delivering the drug directly into the circulation. However, this route precludes recall of an inadvertent drug overdose. Antibiotics, cardiac medications, and many other drugs are given intravenously.

D. **Intradermal (ID)** administration involves injection into the most superficial skin layer. Because this route can deliver only a limited drug volume, its use generally is restricted to skin tests and certain vaccines.

E. **Intra-arterial (IA)** administration is injection directly into an artery. It delivers a high drug concentration to the target site with little dilution by the circulation. Generally, this route is used only for radiopaque materials, thrombolytic agents, and some antineoplastic agents.

F. **Intracardiac (IC)** administration is injection of a drug directly into the heart.

G. **Hypodermoclysis** refers to injection of large volumes of a solution into subcutaneous tissue to provide a continuous, abundant drug supply. This route occasionally is used for antibiotic administration in children.

H. **Intraspinal** administration refers to injection into the spinal column. Local anesthetics (e.g., lidocaine, bupivacaine) are frequently administered via this route during surgical procedures.

I. **Intra-articular** administration means injection into a joint space. Corticosteroids (e.g., methylprednisolone, hydrocortisone) use this route for the treatment of arthritis.

J. **Intrasynovial** administration refers to injection into the joint fluid.

K. **Intrathecal (IT)** administration is injection into the spinal fluid; it sometimes is used for antibiotics and cancer chemotherapy.

L. **Epidural (ED)** administration refers to the injection of medications, usually local anesthetics and/or narcotics near or outside the dura mater of the central nervous system. This route is frequently used during childbirth.

IX. PARENTERAL PREPARATIONS

A. **IV admixtures.** These preparations consist of one or more sterile drug products added to an IV fluid, generally dextrose or sodium chloride solution alone or in combination. IV admixtures are used for drugs intended for continuous infusion. Drugs that may cause irritation or toxicity when given as a rapid direct IV injection are also prepared as IV admixtures.

B. **IV fluids and electrolytes**

   1. **Fluids** used in the preparation and administration of parenteral products include sterile water and sodium chloride, dextrose, and Ringer's solutions, all of which have multiple uses. These fluids serve as vehicles in IV admixtures, providing a means for reconstituting sterile powders. They serve as the basis for correcting body fluid and electrolyte disturbances and provide a caloric source in parenteral nutrition.

   a. **Dextrose (D-glucose) solutions** are the most frequently used glucose solutions in parenteral preparations.

   (1) **Uses.** Generally, a solution of dextrose 5% in water (D_5W) is used as a vehicle in IV admixtures. D_5W may also serve as a hydrating solution. In higher concentrations (e.g., a 10% solution in water), dextrose provides a source of carbohydrates in parenteral nutrition solutions.

   (2) **Considerations.** Because the pH of D_5W ranges from 3.5 to 6.5, instability may result if it is combined with an acid-sensitive drug.

   (a) Dextrose concentrations greater than 15% must be administered through a central vein.

   (b) Dextrose solutions should be used cautiously in patients with diabetes mellitus.

b. Sodium chloride usually is given as a 0.9% solution. Because it is isotonic with blood, this solution is called normal saline solution (NSS). A hypotonic solution of 0.45% sodium chloride is termed half-normal saline. A hypotonic solution of 0.225% sodium chloride is termed quarter-normal saline. Sodium chloride solutions greater than 0.9% concentration are hypertonic.

  (1) Sodium chloride for injection, which is a solution of 0.9% sodium chloride, is used as a vehicle in IV admixtures and for fluid and electrolyte replacement. In smaller volumes, it is suitable for the reconstitution of various medications.

  (2) Bacteriostatic sodium chloride for injection, which is also a 0.9% solution, is intended solely for multiple reconstitutions. It contains an agent that inhibits bacterial growth (e.g., benzyl alcohol, propylparaben, methylparaben), which allows for its use in multiple-dose preparations.

c. Waters are used for reconstitution and for dilution of such IV solutions as dextrose and sodium chloride. Waters suitable for parenteral preparations include sterile water for injection and bacteriostatic water for injection.

d. Ringer's solutions, which are appropriate for fluid and electrolyte replacement, commonly are administered to postsurgical patients.

  (1) Lactated Ringer's injection (i.e., Hartmann's solution, Ringer's lactate solution) contains sodium lactate, sodium chloride, potassium chloride, and calcium chloride. Frequently, it is combined with dextrose (e.g., as 5% dextrose in lactated Ringer's injection).

  (2) Ringer's injection differs from lactated Ringer's injection in that it does not contain sodium lactate and has slightly different concentrations of sodium chloride and calcium chloride. Like lactated Ringer's injection, it may be combined in solution with dextrose.

2. Electrolyte preparations. With ions present in both intracellular and extracellular fluid, electrolytes are crucial for various biological processes. Surgical and medical patients who cannot take food by mouth or who need nutritional supplementation require the addition of electrolytes in hydrating solutions or parenteral nutrition solutions.

a. Cations are positively charged electrolytes.

  (1) Sodium is the chief extracellular cation.

   (a) Importance. Sodium plays a key role in interstitial osmotic pressure, tissue hydration, acid–base balance, nerve-impulse transmission, and muscle contraction.

   (b) Parenteral sodium preparations include sodium chloride, sodium acetate, and sodium phosphate.

  (2) Potassium is the chief intracellular cation.

   (a) Importance. Potassium participates in carbohydrate metabolism, protein synthesis, muscle contraction (especially of cardiac muscle), and neuromuscular excitability.

   (b) Parenteral potassium preparations include potassium acetate, potassium chloride, and potassium phosphate.

  (3) Calcium

   (a) Importance. Calcium is essential to nerve-impulse transmission, muscle contraction, cardiac function, bone formation, and capillary and cell membrane permeability.

   (b) Parenteral calcium preparations include calcium chloride, calcium gluconate, and calcium gluceptate.

  (4) Magnesium

   (a) Importance. Magnesium plays a vital part in enzyme activities, neuromuscular transmission, and muscle excitability.

   (b) Parenteral preparation. Magnesium is given parenterally as magnesium sulfate.

b. Anions are negatively charged electrolytes.

  (1) Chloride is the major extracellular anion.

   (a) Importance. Along with sodium, it regulates interstitial osmotic pressure and helps to control blood pH.

   (b) Parenteral chloride preparations include calcium chloride, potassium chloride, and sodium chloride.

  (2) Phosphate is the major intracellular anion.

   (a) Importance. Phosphate is critical to various enzyme activities. It also influences calcium levels and acts as a buffer to prevent marked changes in acid–base balance.

   (b) Parenteral phosphate preparations include potassium phosphate and sodium phosphate.

(3) **Acetate**
(a) **Importance.** Acetate is a bicarbonate precursor that may be used to provide alkali to assist in the preservation of plasma pH.
(b) **Parenteral acetate preparations** include potassium acetate and sodium acetate.

C. **Parenteral antibiotic preparations** are available as sterile unreconstituted powders, which must be reconstituted with sterile water, normal saline, or D_5W, or as a sterile, ready-to-use liquid parenteral.

1. **Administration methods.** Parenteral antibiotics may be given intermittently by direct IV injection, short-term infusion, intramuscular injection, or intrathecal injection.
2. **Uses.** Parenteral antibiotics are used to treat infections that are serious and require high antibiotic blood levels or when the gastrointestinal tract is contraindicated, such as in ileus.
3. **Dosing frequencies** of parenteral antibiotics vary from once daily to as often as every 2 hrs, depending on the kinetics of the drug, seriousness of the infection, the site of infection, and the patient's disease or organ status (e.g., renal disease).

D. **Parenteral antineoplastic agents.** Studies suggest that these medications may be toxic to the personnel who prepare and administer them. The evidence is not conclusive, which necessitates special precautions to ensure safety and minimize risks. In response to concerns, the Occupational Safety and Health Administration (OSHA) has published a technical manual, "Controlling Occupational Exposure to Hazardous Drugs." Every facility must have a written plan that includes drug preparation precautions, storage, transport, personal protective equipment (gloves, gowns, masks), work equipment, waste disposal, spill management, and personnel medical surveillance.

1. **Administration methods.** Parenteral antineoplastics may be given by direct IV injection, short-term infusion, or long-term infusion. Some are administered by a non-IV route, such as the subcutaneous, intramuscular, intra-arterial, or intrathecal route.
2. **Safe antineoplastic handling guidelines.** All pharmacy and nursing personnel who prepare or administer antineoplastics should receive special training in the following guidelines to reduce the risk of exposure to these drugs.
   a. A **vertical laminar flow hood** should be used during drug preparation, with exhaust directed to the outside (*Figure 17-3*).
   b. All syringes and IV tubing should have **Luer-Lok fittings** (see XI.B).
   c. **Clothing.** Personnel should wear personal protective equipment, including closed-front cuffed gowns resistant to liquid permeation and latex or nitrile gloves approved for use when handling chemotherapy (*Figure 17-6*). Double gloving is recommended.
   d. **Final dosage adjustment** should be made into the vial, ampoule, or directly into an absorbent gauze pad.
   e. **Priming equipment.** Special care should be taken when IV administration sets are primed. The IV tubing should be primed before adding the drug, or the tubing can be primed with drug-free fluid before connecting it to the chemotherapy drug container. If these are not available, prime the tubing into sterile gauze in a sealable plastic bag.
   f. Proper procedures should be followed for **disposal** of materials used in the preparation and administration of antineoplastics.
      (1) **Needles** should not be clipped or recapped.
      (2) **Preparations** should be discarded in containers that are puncture-proof, leak-proof, and properly labeled.
      (3) **Hazardous waste.** A color-coded system was created by the Environmental Protection Agency (EPA), of which use is required by facilities to ensure safe and proper disposal of hazardous waste (*Table 17-4*). Trace chemotherapy refers to any product that was exposed to a chemotherapy agent, such as a syringe, needle, or empty vial that once contained chemotherapy. All items with trace chemotherapy must be placed in a yellow container. All other hazardous waste that is not considered trace must be placed in a black container.
   g. After removal of gloves, personnel should **wash hands** thoroughly.
   h. Personnel and equipment involved in the preparation and administration of antineoplastic agents should be **monitored** routinely.

Table 17-4	ENVIRONMENTAL PROTECTION AGENCIES REQUIRED SYSTEM FOR PROPER DISPOSAL OF HAZARDOUS WASTE

Type of Waste	Container Color
Hazardous toxic	
Hazardous ignitable	Black
Hazardous infectious	
Trace chemotherapy	Yellow
Drain disposal	Sink/sewer
Nonregulated drugs	White with blue top or cream with purple top

    3. Patient problems. Infusion phlebitis and extravasation are the most serious problems that may occur during the administration of parenteral antineoplastics.

        a. Infusion phlebitis (inflammation of a vein) is characterized by pain, swelling, heat sensation, and redness at the infusion site. Drug dilution and filtration can eliminate or minimize the risk of phlebitis.

        b. Extravasation (infiltration of a drug into subcutaneous tissues surrounding the vein) is especially harmful when antineoplastics with vesicant properties are administered. Proper measures must be taken immediately if extravasation occurs.

E. Total parenteral nutrition (TPN) are large-volume admixtures that are used when enteral nutrition cannot be tolerated.

    1. Two in one admixture contains both amino acids and dextrose.

    2. Three in one admixture contains amino acids, dextrose, and intralipid or "fat."

    3. Formulas. Most TPN admixtures contain various amounts of electrolytes and other additives such as insulin, H2 antagonists, and vitamins.

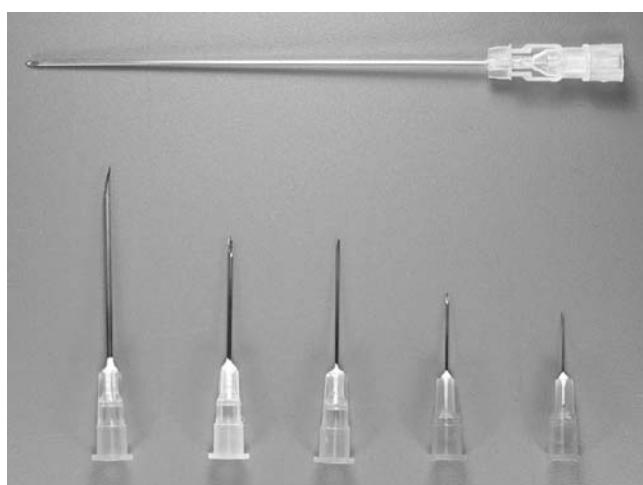
    4. Calcium and phosphorus-containing solutions form a precipitate when mixed together and are therefore deemed incompatible. This reaction is avoided when these ingredients are added non-consecutively to a TPN solution containing amino acid.

    5. Administration. TPN is most commonly administered through a central line. TPN can also be administered through a peripheral or femoral line. Osmolality must be taken into consideration when choosing the route of administration of TPN.

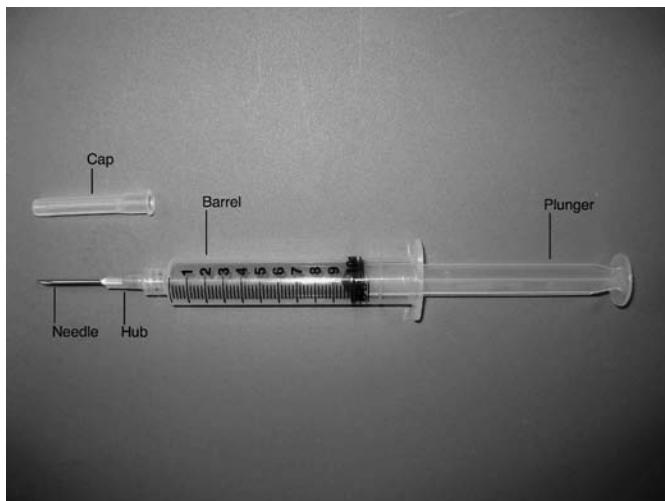
F. Parenteral biotechnology products are created by the application of recombinant technology to the generation of therapeutic agents, such as monoclonal antibodies, various vaccines, and colony-stimulating factors.

    1. Uses of these agents include cancer therapy, infections, transplant rejection, rheumatoid arthritis, inflammatory bowel disease, respiratory diseases, and malaria as well as vaccines against cancer, HIV infection, and hepatitis B.

    2. Characteristics. Protein and peptide biotechnology drugs that have a shorter half-life often require special storage such as refrigeration or freezing and must not be shaken vigorously to avoid destroying the protein molecules.

    3. Administration. Many biotechnology products require reconstitution with sterile water or normal saline and may be parenterally administered by direct IV injection or infusion, or by intramuscular or subcutaneous injection.


X. IRRIGATING SOLUTIONS.
Although these sterile products are manufactured by the same standards used to process IV preparations, they are **not intended for infusion into the venous system**. Labeling differences between irrigation solutions and injections are specified in the *United States Pharmacopeia* (*USP*) and reflect differences in acceptable particulate matter levels, volume of solution available for use, and the container design.

A. Topical administration. Irrigating solutions for topical use are packaged in pour bottles so that they can be poured directly onto the desired area. These solutions are intended for such purposes as irrigating wounds, moistening dressings, and cleaning surgical instruments.


B. Infusion of irrigating solutions. This procedure, using an administration set attached to a Foley catheter, is commonly used for many surgical patients. Surgeons performing urological procedures often use irrigating solutions to perfuse tissues in order to maintain the integrity of the surgical field, remove blood, and provide a clear field of view. To decrease the risk of infection, 1 mL of Neosporin G.U. Irrigant, an antibiotic preparation, often is added to these solutions.

C. Dialysis. Dialysates are irrigating solutions used in the dialysis of patients with such disorders as renal failure, poisoning, and electrolyte disturbances. These products remove waste materials, serum electrolytes, and toxic products from the body.

   1. In **peritoneal dialysis**, a hypertonic dialysate is infused directly into the peritoneal cavity via a surgically implanted catheter. The dialysate, which contains dextrose and electrolytes, removes harmful substances by osmosis and diffusion. After a specified period, the solution is drained. Antibiotics and heparin may be added to the dialysate.

   2. In **hemodialysis**, the patient's blood is transfused through a dialyzing membrane unit that removes the harmful substances from the patient's vascular system. After passing through the dialyzer, the blood reenters the body through a vein.

XI. NEEDLES AND SYRINGES

A. Hypodermic needles are stainless steel or aluminum devices that penetrate the skin for the purpose of administering or transferring a parenteral product (*Figure 17-14*).

   1. **Needle gauge** is the outside diameter of the needle shaft; the larger the number, the smaller the diameter. Gauges in common use range from 13 (largest diameter) to 27. Subcutaneous injections usually require a 24-gauge or 25-gauge needle. Intramuscular injections require a needle with a gauge between 19 and 22. Needles between 18 gauge and 20 gauge are commonly used for compounding parenterals.

   2. **Bevels** are slanting edges cut into needle tips to facilitate injection through tissue or rubber vial closures.
      a. **Regular-bevel needles** are the most commonly used type, and they are suitable for subcutaneous and intramuscular injections and hypodermoclysis.
      b. **Short-bevel needles** are used when only shallow penetration is required (as in IV injections).
      c. **Intradermal-bevel needles** are designed for intradermal injections and have the most beveled edges.

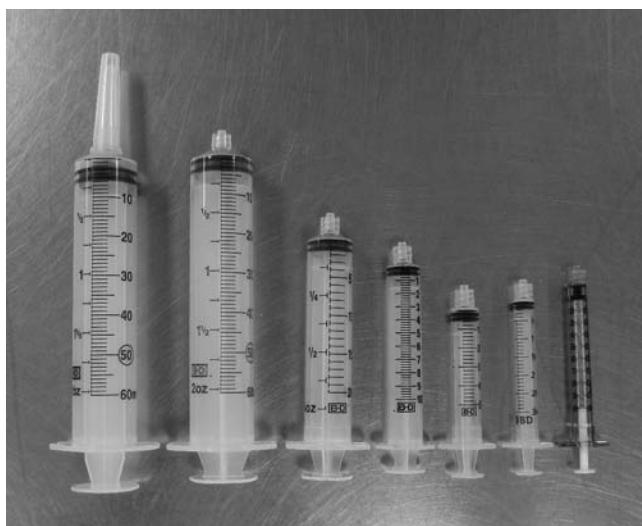
   3. **Needle lengths** range from ¼ inch to 6 inches. Choice of needle length depends on the desired penetration.
      a. For **compounding parenteral preparations**, 1 ½-inch-long needles are commonly used.
      b. **Intradermal and subcutaneous injections** necessitate a short needle length, usually ¼ inch to ⅝ inch.
      c. **Intraspinal injection** requires a needle length of 3 ½ inches.
      d. **IV infusion** requires needles that range in length from 1 ¼ inches to 2 ½ inches.


Figure 17-14. Hypodermic needles. *Top*: 20 gauge-3 ½ inch. *Left to right*: 18 gauge-1 ½ inch, 20 gauge-1 inch, 23 gauge-1 inch, 25 gauge- ⅝ inch, 27 gauge-½ inch. (Courtesy of Chistopher J. Belisle.)

Figure 17-15. Luer-Lok syringe and needle. (Courtesy of Chistopher J. Belisle.)

B. **Syringes** are devices for injecting, withdrawing, or instilling fluids. Syringes consist of a glass or plastic barrel with a tight-fitting plunger at one end; a small opening at the other end accommodates the head of a needle (*Figure 17-15*, *Figure 17-16*).
1. The **Luer syringe**, the first syringe developed, has a universal needle attachment accommodating all needle sizes.
2. **Syringe volumes** range from 0.3 to 60 mL. Insulin syringes have unit gradations (100 units/mL) rather than volume gradations.
3. **Calibrations** are in the metric system, and vary in specificity depending on syringe size. The smaller the syringe, the smaller the measurement scale.
4. **Syringe tips** come in several types.
   a. **Luer-Lok tips** are threaded to ensure that the needle fits tightly in the syringe. Antineoplastic agents should be administered with syringes of this type.
   b. **Luer-Slip tips** are unthreaded so that the syringe and needle do not lock into place. Because of this, the needle may become dislodged.
   c. **Eccentric tips**, which are set off center, allow the needle to remain parallel to the injection site and minimize venous irritation.
   d. **Catheter tips** are used for wound irrigation and administration of enteral feedings. They are not intended for injections.

Figure 17-16. Syringes. *Left to right*: 60 mL catheter tip, 60 mL, 30 mL, 10 mL, 5 mL, 3 mL, 1 mL. (Courtesy of Chistopher J. Belisle.)

XII. INTRAVENOUS DRUG DELIVERY

A. **Injection sites**

1. **Peripheral vein injection** is preferred for drugs that do not irritate the veins, administration of isotonic solutions, and patients who require only short-term IV therapy. Generally, the dorsal forearm surface is chosen for venipuncture.

2. **Central vein injection** is preferred for administration of irritating drugs or hypertonic solutions, patients requiring long-term IV therapy, and situations in which a peripheral line cannot be maintained. Large veins in the thoracic cavity, such as the subclavian vein, are used.

B. **Infusion methods**

1. **Continuous-drip infusion** is the slow, primary-line infusion of an IV preparation to maintain a therapeutic drug level or provide fluid and electrolyte replacement.

   a. **Flow rates** must be carefully monitored. Generally, these rates are expressed as volume per unit of time (e.g., mL/hr, drops/min) and sometimes as mg/min for certain drugs.

   b. **Administration.** Drugs with a narrow therapeutic index such as oxytocin (Pitocin), heparin, and pressor agents such as norepinephrine (Levophed) and phenylephrine (Neo-Synephrine) typically are administered by this method.

2. **Intermittent infusion** allows drug administration at specific intervals (e.g., every 4 hrs) and is most often used for antibiotics.

   a. **Three different techniques** may be used.

      (1) **Direct (bolus) injection** rapidly delivers small volumes of an undiluted drug. This method is used to

         (a) Achieve an immediate effect (as in an emergency)

         (b) Administer drugs that cannot be diluted

         (c) Achieve a therapeutic serum drug level quickly

      (2) **Additive set infusion**, using a volume-control device, is appropriate for the intermittent delivery of small amounts of IV solutions or diluted medications. The fluid chamber is attached to an independent fluid supply or placed directly under the established primary IV line.

      (3) The **piggyback method** is used when a drug cannot be mixed with the primary solution. A special coupling for the primary IV tubing permits infusion of a supplementary secondary solution through the primary system. This method eliminates the need for a second venipuncture or further dilution of the supplementary preparation.

   b. In some cases, **intermittent infusion injection devices** are used. Also called scalp-vein, heparin-lock, or butterfly infusion sets, these devices permit intermittent delivery while eliminating the need for multiple venipunctures or prolonged venous access with a continuous infusion. To prevent clotting in the cannula, dilute heparin solution or NSS may be added. Benefits of intermittent infusion injection devices include the following:

      (1) This method is especially suitable for patients who do not require, or would be jeopardized by, administration of large amounts of IV fluids (e.g., those with congestive heart failure).

      (2) Because intermittent infusion injection devices do not require continuous attachment to an IV bottle or bag and pole, they permit greater patient ambulation.

C. **Pumps** and **controllers** are the electronic devices used to administer parenteral infusions when the use of gravity flow alone might lead to inaccurate dosing or risk patient safety. Pumps and controllers are used to administer parenteral nutrition, chemotherapy, cardiac medications, and blood products.

1. **Pumps** are used to deliver IV infusions with accuracy and safety.

   a. Two **types of mechanisms** are used in infusion pumps.

      (1) **Piston-cylinder mechanisms** use a piston in a cylinder or a syringe-like apparatus to pump the desired volume of fluid.

      (2) **Linear peristaltic mechanisms** use external pressure to expel the fluid out of the pumping chamber.

   b. **Types of pumps**

      (1) **Volumetric pumps** are used for intermittent infusion of medications such as antibiotics. They are also used for continuous infusion of IV fluid, parenteral nutrition, anticoagulants, and antiasthma medications.

> **(2) Syringe pumps** are used to administer intermittent or continuous infusions of medications (e.g., antibiotics, opiates) in concentrated form.
>
> **(3) Mobile infusion pumps** are small infusion devices designed for ambulatory and home patients and used for administering chemotherapy and opiate medications.
>
> **(4) Implantable pumps** are infusion devices surgically placed under the skin to provide a continuous release of medication, typically an opiate. The reservoir in the pump is refilled by injecting the medication through a latex diaphragm in the pump.
>
> **(5) Patient-controlled analgesic pumps** are used to administer narcotics intermittently or on demand by the patient within the patient-specific parameters, which are ordered by the physician and programmed into the pump.
>
> **(6) Smart pumps** contain programmable "drug libraries" that reflect an institution's specific medication administration guidelines (*Figure 17-17*). These libraries can prevent an incorrect dose or administration rate entry into the pump.

    c. Benefits. Despite their extra costs and the training required by personnel, smart pumps provide a number of important benefits. They maintain a constant, accurate flow rate and can detect infiltrations, occlusions, and air. Pumps also may decrease the amount of time a nurse spends dispensing medication. As a result, smart pumps are associated with decreased medication errors.

2. Controllers, unlike pumps, exert no pumping pressure on the IV fluid. Rather, they rely on gravity and control the infusion by counting drops electronically, or they infuse the fluid mechanically and electronically (e.g., volumetric controllers). In **comparison to pumps**, the following are characteristics of controllers:

    a. They are less complex and generally less expensive.

    b. They achieve reasonable accuracy.

    c. They are very useful for uncomplicated infusion therapy but cannot be used for arterial drug infusion or for infusion into small veins.

D. IV incompatibilities. When two or more drugs must be administered through a single IV line or given in a single solution, an undesirable reaction can occur. Although such incompatibilities are relatively rare, their consequences can be deadly. A patient who receives a preparation in which an incompatibility has occurred could experience toxicity or an incomplete therapeutic effect.

Figure 17-17. *Alaris* Smart Pump for controlled intravenous medication administration. (Courtesy of William Salkin.)

1. **Types of incompatibilities**
   a. A **physical incompatibility** occurs when a drug combination produces a visible change in the appearance of a solution. The solution should never be administered to a patient.
      (1) An **example** of physical incompatibility is the evolution of carbon dioxide when sodium bicarbonate and hydrochloric acid are admixed.
      (2) Various **types** of physical incompatibilities may occur
         (a) Visible color change or darkening
         (b) Formation of precipitate, which may result from the combination of phosphate and calcium.
   b. A **chemical incompatibility** reflects the chemical degradation of one or more of the admixed drugs, resulting in toxicity or therapeutic inactivity.
      (1) The degradation is not always visible. **Nonvisible chemical incompatibility** may be detected only by analytical methods.
      (2) Chemical incompatibility occurs in several **varieties**.
         (a) **Complexation** is a reaction between products that inactivates them. For example, the combination of calcium and tetracycline leads to formation of a complex that inactivates tetracycline.
         (b) **Oxidation** occurs when one drug loses electrons to the other, resulting in a color change and therapeutic inactivity.
         (c) **Reduction** takes place when one drug gains electrons from the other.
         (d) **Photolysis** (chemical decomposition caused by light) can lead to hydrolysis or oxidation, with resulting discoloration.
   c. A **therapeutic incompatibility** occurs when two or more drugs, IV fluids, or both are combined, and the result is a response other than that intended. An example of a therapeutic incompatibility is the reduced bactericidal activity of penicillin G when given after tetracycline. Because tetracycline is a bacteriostatic agent, it slows bacterial growth; penicillin, on the other hand, is most effective against rapidly proliferating bacteria.

2. **Factors affecting IV compatibility**
   a. **pH.** Incompatibility is more likely to occur when the components of an IV solution differ significantly in pH. This increased risk is explained by the chemical reaction between an acid and a base, which yields a salt and water; the salt may be an insoluble precipitate.
   b. **Temperature.** Generally, increased storage temperature speeds drug degradation. To preserve drug stability, drugs should be stored in a refrigerator or freezer, as appropriate.
   c. **Degree of dilution.** Generally, the more diluted the drugs are in a solution, the less chance there is for an ion interaction leading to incompatibility.
   d. **Length of time in solution.** The chance for a reaction resulting in incompatibility increases with the length of time that drugs are in contact with each other.
   e. **Order of mixing.** Drugs that are incompatible in combination, such as calcium and phosphate, should not be added consecutively when preparing an admixture of total parental nutrition (TPN). This keeps these substances from pooling, or forming a layer on the top of the IV fluid, and, therefore, decreases the chance of an incompatibility. Thorough mixing after each addition is also essential.

3. **Preventing or minimizing incompatibilities.** To reduce the chance for an incompatibility, the following steps should be taken:
   a. Each drug should be mixed thoroughly after it is added to the preparation.
   b. Solutions should be administered promptly after they are mixed to minimize the time available for a potential reaction to occur.
   c. The number of drugs mixed together in an IV solution should be kept to a minimum.
   d. If a prescription calls for unfamiliar drugs or IV fluids, compatibility references should be consulted.

E. **Hazards of parenteral drug therapy.** A wide range of problems can occur with parenteral drug administration.
   1. **Physical hazards**
      a. **Phlebitis**, which is generally a minor complication, may result from vein injury or irritation. Phlebitis can be minimized or prevented through proper IV insertion technique, dilution of irritating drugs, and a decreased infusion rate.

  b. **Thrombosis** is the formation of a blood clot in a vein or artery.

  c. **Extravasation** may occur with administration of drugs with vesicant properties.

  d. **Irritation** at the injection site can be reduced by varying the injection site and applying a moisturizing lotion to the area.

  e. **Pain** from infusion is most common with peripheral IV administration of a highly concentrated preparation. Switching to central vein infusion and/or diluting the drug might alleviate the problem.

  f. **Air embolism**, potentially fatal, can result from entry of air into the IV tubing.

  g. **Infection**, a particular danger with central IV lines, may stem from contamination during IV line insertion or tubing changes. Infection may be local or generalized (septicemia). The infection risk can be minimized by following established protocols for the care of central lines.

  h. **Allergic reactions** can result from hypersensitivity to an IV solution or additive.

  i. **Central catheter misplacement** may lead to air embolism or pneumothorax. To ensure that the catheter has passed into the subclavian vein and advanced to the level of the vena cava, the placement should always be verified radiologically.

  j. **Hypothermia**, possibly resulting in shock and cardiac arrest, might stem from administration of a cold IV solution. This problem can be prevented by allowing parenteral products to reach room temperature.

  k. **Neurotoxicity** may be a serious complication of intrathecal or intraspinal administration of drugs containing preservatives. Preservative-free drugs should be used in these circumstances.

 2. Mechanical hazards

  a. **Infusion pump** or **controller failure** can lead to runaway infusion, fluid overload, or incorrect dosages.

  b. **IV tubing** can become kinked, split, or cracked. It also may produce particulates, allow contamination, or interfere with the infusion.

  c. **Particulate matter** may be present in a parenteral product and can cause embolism.

  d. **Glass containers** may break, causing injury.

  e. **Rubber vial closures** may interact with the enclosed product.

 3. Therapeutic hazards

  a. **Drug instability** may lead to therapeutic ineffectiveness.

  b. **Incompatibility** may result in toxicity or reduced therapeutic effectiveness.

  c. **Labeling errors** can cause administration of an incorrect drug or improper dosage.

  d. **Drug overdose** can be caused by runaway IV infusion, failure of an infusion pump or controller, or nursing or pharmacy errors.

  e. **Preservative and solubilizing agent toxicity** can be a serious complication, especially in children. For example, premature infants receiving parenteral products containing benzyl alcohol can develop a fatal acidotic toxic syndrome, which is referred to as the *gasping syndrome*. Rapid administration of phenytoin (Dilantin) and diazepam (Valium) both use propylene glycol as a solubilizing agent, which has been associated with cardiovascular collapse.

Study Questions

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the **one** lettered answer or completion that is **best** in each case.

1. Parenteral products with an osmotic pressure less than that of blood or 0.9% sodium chloride are referred to as

 (A) isotonic solutions.
 (B) hypertonic solutions.
 (C) hypotonic solutions.
 (D) iso-osmotic solutions.
 (E) neutral solutions.

2. Aseptic technique should be used in the preparation of all of the following medications with the exception of

 (A) neomycin irrigation solution.
 (B) ganciclovir (Cytovene) intraocular injection.
 (C) phytonadione (Aquamephyton) subcutaneous injection.
 (D) ampicillin (Principen) IV admixture piggyback.
 (E) bacitracin ointment.

3. Which needle has the smallest diameter?

   (A) 25 gauge, 3 ¾ inches
   (B) 24 gauge, 3 ½ inches
   (C) 22 gauge, 3 ½ inches
   (D) 20 gauge, 3 ⅜ inches
   (E) 26 gauge, 3 ⅝ inches

4. Intra-articular injection refers to injection into the

   (A) muscle mass.
   (B) subcutaneous tissue.
   (C) spinal fluid.
   (D) superficial skin layer.
   (E) joint space.

5. Advantages of the intravenous route include

   (A) ease of removal of the dose.
   (B) a depot effect.
   (C) low incidence of phlebitis.
   (D) rapid onset of action.
   (E) a localized effect.

6. A central vein, either subclavian or internal jugular, may be considered a suitable route for IV administration in which of the following situations?

   (A) When an irritating drug is given
   (B) When hypertonic drugs are given
   (C) For long-term therapy
   (D) For administering dextrose 35% as parenteral nutrition
   (E) All of the above

7. To prepare a total parenteral nutrition (TPN) that requires 10 mEq of calcium gluconate and 15 mM of potassium phosphate, the appropriate action to take would be which of the following?

   (A) Add the calcium first, add the other additives, then add the phosphate last, thoroughly mixing the solution after addition.
   (B) Add the calcium gluconate and potassium phosphate consecutively.
   (C) Do not combine the agents together but give them as a separate infusion.
   (D) None of the above.

8. Which needle gauge would be most likely used as a subcutaneous injection of epoetin?

   (A) 25 gauge, ⅝ inch
   (B) 16 gauge, 1 inch
   (C) 18 gauge, 1 ½ inches
   (D) 22 gauge, 1 ½ inches
   (E) None of the above

9. Which of the following compounded sterile products should NOT be prepared in a horizontal laminar flow hood?

   (A) Total parenteral nutrition (TPN)
   (B) Dopamine
   (C) Cisplatin (Platinol)
   (D) Nitroglycerin
   (E) Bretylium tosylate (Bretylol)

10. All of the following statements about D_5W are true EXCEPT

    (A) its pH range is 3.5 to 6.5.
    (B) it is hypertonic.
    (C) it is a 5% solution of D-glucose.
    (D) it should be used with caution in diabetic patients.
    (E) it is often used in IV admixtures.

11. All of the following are potential hazards of parenteral therapy EXCEPT

    (A) hypothermia.
    (B) phlebitis.
    (C) extravasation.
    (D) allergic reactions.
    (E) ileus.

12. Procedures for the safe handling of antineoplastic agents include all of the following EXCEPT

    (A) use of Luer-Lok syringe fittings.
    (B) wearing double-layered latex gloves.
    (C) use of negative-pressure technique when medication is being withdrawn from vials.
    (D) wearing closed-front, surgical-type gowns with cuffs.
    (E) use of horizontal laminar flow hood.

13. In preparing an intraspinal dose of bupivacaine, the best pore size filter for cold sterilization would be

    (A) 8-μm filter.
    (B) 5-μm filter.
    (C) 0.45-μm filter.
    (D) 0.22-μm filter.
    (E) None of the above.

14. Process simulation is a method of quality assurance that

    (A) evaluates the adequacy of a practitioner's aseptic technique.
    (B) requires the use of a microbial growth medium.
    (C) is carried out in a manner identical to normal sterile admixture production under routine operating conditions.
    (D) All of the above.

15. *USP* <797> was developed to

    (A) decrease microbial contamination of compounded sterile preparations.

    (B) ensure the proper use of aseptic technique during the manufacturing of sterile preparations.

    (C) prevent harm to patients, including death.

    (D) decrease unintended physical and chemical contaminates found in compounded sterile preparations.

16. When withdrawing drug solution from an ampoule, the one-way use of what kind of needle is required?

    (A) 5 micron filter needle

    (B) 25-gauge needle

    (C) 27-gauge needle

    (D) tuberculin needle

17. Proper use of sterile gloves includes which of the following:

    (A) Glove packaging should be discarded by touching only the sterile glove outerwrapper.

    (B) Sterile gloves should be donned after gowning, hand washing, and entering the ISO 5 direct compounding area.

    (C) Gloves can be placed on the hands by touching any sterile portion of the glove.

    (D) Gloves should be rinsed frequently with ethyl alcohol-based product, and changed when their integrity is compromised.

18. According to EPA regulations, the following form of pharmaceutical waste can be disposed of in a yellow container:

    (A) Nonregulated drugs

    (B) Hazardous toxic

    (C) Hazardous infectious

    (D) Trace chemotherapy

19. Low-risk compounded sterile products are prepared using the following:

    (A) Complex aseptic manipulations

    (B) Multiple pooled sterile commercial products

    (C) Sterile commercial drugs using commercial sterile devices

    (D) Nonsterile ingredients or with nonsterile devices

20. Proper preparation of the laminar airflow work bench

    (A) requires that all nonsterile supplies be removed from their outer packaging and wiped down with 70% isopropyl alcohol.

    (B) includes wiping down all surfaces by using side-to-side motions while working from the front of the work bench to the back.

    (C) does not include sterilizing the rubber stoppers of medication vials because they are sealed with a sterile safety cap.

    (D) allows the placement of larger supplies to be placed in the back of a horizontal airflow work bench.

Case Presentation

The pharmacist receives a prescription for hydromorphone (Dilaudid) injection to be compounded to a solution of 15 mg/mL. Dilaudid is commercially available in an ampoule, but the concentration is 10 mg per mL. The physician would like a more concentrated solution prepared so that 50 mL can be instilled into the titanium reservoir of a Medtronic infusion pump. The hydromorphone solution will be continuously infused, intrathecally, over approximately 30 days, for a patient with chronic back pain, uncontrolled with oral narcotics. The pharmacist checks his inventory and finds a bottle of hydromorphone powder, *USP*. He proceeds to weigh out enough powder for a 60 mL preparation. The weighing step is checked by a colleague pharmacist.

21. According to *USP* Chapter 797, this sterile preparation would be considered a

    (A) high-risk level CSP.

    (B) medium-risk level CSP.

    (C) low-risk level CSP.

    (D) None of these.

22. What would be an appropriate environment for the aseptic manipulations required for this preparation?

    (A) Pharmacy workbench or counter in ambient room air

    (B) Inside an anteroom, with ISO class 8 quality air

    (C) Inside a Barrier Isolator with ISO class 5 quality air

    (D) A horizontal laminar flow workbench, newly installed, with no certification, but manufacturer guaranteed to be ISO 5 class air quality.

23. The pharmacist begins to gather his supplies for this preparation. These should include:

(A) Millipore 0.45 μm HV Filter with sterile water for injection.

(B) Millipore 0.22 μm GS Filter with sodium chloride 0.9%.

(C) Bectin-Dickinson 16-gauge, 5 micron filter needle with sodium chloride 0.9%.

(D) Millipore AA 0.8 μm Filter with dextrose 5% in water.

24. After the solution was prepared, what would the appropriate quality assurance or double check by another pharmacist include?

(A) Inspection of the powder and the label to ensure hydromorphone was the prepared ingredient and that the label contained a beyond use date and the 15 mg per mL concentration.

(B) Sending a solution sample or aliquot to a microbiology lab to test for the presence of bacteria and pyrogens prior to dispensing.

(C) Check to ensure a correct sterilizing filter was used.

(D) Visual inspection to ensure the final aqueous solution had no visible participates.

(E) All of the above.

Answers and Explanations

1. The answer is C *[see IX.B.1.b]*.
Hypotonic solutions have an osmotic pressure less than that of blood (or 0.9% saline), whereas hypertonic solutions have an osmotic pressure greater than that of blood, and isotonic or iso-osmotic solutions have an osmotic pressure equal to that of blood.

2. The answer is E *[see II.A.4]*.
Irrigation solutions, ophthalmic preparations and parenteral products, and subcutaneous and IV medications should be prepared using aseptic technique. Because bacitracin ointment is applied to the skin and does not bypass the body's protective barriers, its preparation would not be held to the same requirements.

3. The answer is E *[see XI.A.1]*.
The gauge size refers to the outer diameter of the needle. The lower the gauge size number, the larger the needle.

4. The answer is E *[see VIII.I]*.
Intra-articular injection refers to an injection into the joint space. This administration route generally is used for certain types of corticosteroids to reduce inflammation associated with injury or rheumatoid arthritis.

5. The answer is D *[see VIII.C]*.
The IV route of drug administration allows for rapid onset of action and, therefore, immediate therapeutic effect. There can be no recall of the administered dose, and phlebitis or inflammation of a vein can occur. In addition, a depot effect (i.e., accumulation and storage of the drug for distribution) cannot be achieved by administering a drug intravenously. Delivering a drug intravenously results in a systemic rather than a localized effect.

6. The answer is E *[see XII.A.2]*.
Irritating drugs, hypertonic drugs, long-term therapy, and dextrose 35% are best given by central IV administration. Peripheral vein injection is used for postoperative hydration, administration of nonirritating drugs, or isotonic solutions and for short-term IV therapy.

7. The answer is A *[see IX.E.4]*.
Physical incompatibilities occur when two or more products are combined and produce a change in the appearance of the solution, such as the formation of a precipitate. Calcium and phosphate solutions when directly combined or added consecutively to a solution will form a white precipitate. By altering the order of mixing, they can be safely added to TPN solutions.

8. The answer is A *[see XI.A.1]*.
Because subcutaneous injection does not require penetration through several skin layers or muscle tissue, a short needle with a narrow diameter is used. A 16- or 18-gauge needle is most commonly used in the pharmacy for preparing parenteral solutions. A 22-gauge needle would be used for intramuscular injection.

9. The answer is C *[III B 2 a]*.
Cisplatin is an antineoplastic agent and, consequently, should be prepared only in a vertical laminar flow hood because of the potential hazard of these toxic agents to the operator.

10. The answer is B *[see IX.B.1.a]*.
D_5W (dextrose [D-glucose] 5% in water) is acidic, its pH ranges from 3.5 to 6.5, and it is isotonic. It is often used in IV admixtures and should be used with caution in diabetic patients.

11. **The answer is E** *[see XII.E.1]*.
Parenteral therapy is often a treatment for ileus. Hypothermia, phlebitis, extravasation, and allergic reactions can be hazards of parenteral therapy.

12. **The answer is E** *[see IX.D.2]*.
In order to prevent drug exposure, a vertical flow laminar hood (not horizontal) should be used when an antineoplastic agent is prepared. The other precautions mentioned in the question are important safety measures for handling parenteral antineoplastics. All pharmacy and nursing personnel who handle these toxic substances should receive special training.

13. **The answer is D** *[see VI.D.2.c.ii]*.
Because intraspinal and epidural doses of bupivacaine are frequently prepared from nonsterile powders, cold sterilization, accomplished by filtration, is a simple method of ensuring complete microbial removal. The filters listed 8 μm to 0.45 μm will remove only particulate matter. A 0.22-μm filter ensures the removal of microorganisms.

14. **The answer is E** *[see.V.F]*.
Process simulation is one part of an overall quality assurance program. It requires duplicating sterile product preparation using a growth medium in place of actual products. It serves to evaluate the aseptic technique of the individual performing all the necessary steps of sterile product preparation.

15. **The answer is C** *[see I]*.
Chapter <797> of the *USP* was developed to prevent harm to patients, including death. This is accomplished by following a rigorous set of guidelines, including the proper use of aseptic technique during the manufacturing of sterile preparations, and decreasing microbial and unintended physical and chemical contaminates found in compounded sterile preparations.

16. **The answer is A** *[see IV.J.2.a]*.
Although when done properly, ampoule with opening resulting in a clean break with no glass shards, a single pass through a 5 micron filter needle or straw is still required to remove any unseen particulate matter that may be created.

17. **The answer is D** *[see IV.D]*.
Proper use of sterile gloves includes rinsing frequently with a 62% w/w ethyl alcohol product and changing when integrity is compromised by coming in contact with nonsterile surfaces, or the glove is coughed or sneezed into.

18. **The answer is D** *[see IX.D.2.f.(3)]*.
A color-coded system was created by the EPA to help facilities ensure safe and proper disposal of waste. Hazardous toxic, hazardous ignitable, and hazardous infectious waste should be disposed in a black container. Trace chemotherapy waste should be disposed of in a yellow container. Drain disposal waste can be flushed down the sink or sewer. Nonregulated pharmaceutical waste should be placed in a white with blue top or cream with purple top.

19. **The answer is C** *[see II.A.6.a.(1)]*.
Low-risk CSPs are compounded from sterile commercial drugs using commercial sterile devices in an ISO class 5 located within an ISO 7 buffer area. Compounding procedures involve only transferring, measuring, and mixing manipulations using not more than three sterile products and not more than two entries into each sterile container.

20. **The answer is A** *[see IV.E]*.
All nonsterile supplies, such as vials and infusions bags, should be removed from their outer packaging and wiped down with 70% isopropyl alcohol and lint-free cleaning cloths prior to being placed on the sterile workbench.

21. **The answer is A.**
The hydromorphone preparation is a high-risk level CSP because it is made from nonsterile powder.

22. **The answer is C.**
USP Chapter 797 requires an ISO class 5 air quality environment for this preparation. A Barrier Isolator within a clean room creates an ISO class 5 environment. Ambient room air is unacceptable for any preparation. An anteroom is generally an area of relatively high personnel and supply traffic. Although air quality may be acceptable, it does not provide an acceptable critical site of aseptic manipulations. All new laminar flow work benches should be tested for air velocity and filter integrity prior to use.

23. **The answer is B.**
The hydromorphone requires sterilization prior to intrathecal administration. This is best achieved with a 0.22 μm filter. Sodium chloride 0.9% is the solution most similar to the CNS fluid and would be a better choice over sterile water of dextrose 5% injection.

24. **The answer is E.**
Each step in sterile compounding should have an associated quality assurance double check. Inspection of the initial ingredients, review of supplies, monitoring of aseptic technique, and examination of the final product creates multiple opportunities to intercept an error and make necessary corrections. High-risk level CSPs should be used within 24 hrs in the absence of sterility testing. Given that this product will be administered over 30 days, a sterility and pyrogen test would be appropriate.

Parapharmaceuticals, Diagnostic Aids, and Medical Devices

JENNY A. VAN AMBURGH, TODD A. BROWN

I. AMBULATORY AIDS

A. Canes. These simple ambulatory aids provide balance and allow for the transfer of weight off a weakened leg.

   1. Height. A cane that is correctly fitted allows for maximum weight transfer without allowing the patient to lock the elbow. The correct height should provide a 25-degree angle at the elbow, or the top of the cane should come to the crease of the wrist while patient is standing erect.

   2. Types of canes. Canes may be made of wood or metal.

   a. Wooden canes come in various sizes and shapes and may be cut to the correct height for the patient.

   b. Metal canes are adjustable in height to fit the individual patient.

   c. Folding canes will fold to allow for easy transport or storage when not in use.

   d. A **quad cane** is a metal cane that has a quadrangular base with four legs. The base of the quad cane comes in two sizes. The larger base provides greater stability but is more difficult to manipulate because of the size and weight.

   e. Seat canes contain an area that can be folded down and used to sit on. They are useful for individuals who cannot walk long distances without resting.

B. Crutches may be used by patients with temporary disabilities (e.g., sprains, fractures) or by those with chronic conditions.

   1. Use. Crutches are used to take all the weight off an injured or weakened leg. The crutches are used in place of the leg. Crutches come in various sizes. Accessories that are used with a crutch include a tip to prevent slipping, handgrip cushion, and arm pad (for axillary crutch).

   2. Types of crutches

   a. An **axillary crutch**, the **most commonly used** crutch, is typically used for temporary disabilities. The top of the crutch should be 2 inches below the axilla to prevent nerve damage. The height of the handgrip should be set so that the elbow forms a 25-degree angle.

   b. A **forearm crutch** (also called a **Canadian** or **Lofstrand** crutch) remains in position by attaching to the forearm by a collar or cuff. It is commonly used by patients who need crutches on a long-term basis.

   c. A **quad crutch** is a forearm crutch with a quadrangular base that has four legs. The base is attached to the crutch with a flexible rubber mount. This allows for more stability and constant contact with the ground.

   d. A **platform crutch** contains a rectangular area in which to place the forearm. The crutch may be held by a handgrip or secured by a belt that wraps around the forearm. It is commonly used by patients who do not have enough hand strength and control for a forearm crutch.

C. Seat lift chairs are electric-powered chairs that raise the patient from a sitting to a standing position.

D. **Walkers** are lightweight rectangular-shaped devices that are made of metal tubing and have four widely placed legs.
   1. **Use.** Walkers are used by patients who need more **support** than a cane or crutch or who have trouble with balance during ambulation. The user requires reasonably good arm, hand, and wrist function. The patient holds on to the walker and takes a step, then moves the walker and takes another step.
   2. **Types of walkers.** Walkers are adjustable in height. Some walkers fold to make storage or transporting easier. Walkers can have wheels on the front legs to allow the user to move the walker by raising the back legs and rolling it instead of having to pick it up. Patients with loss of arm, wrist, or hand function on one side might use a **hemiwalker** or a **side walker**.
      a. A **hemiwalker** is similar to a standard walker except that it has one handle in the center of the walker for manipulation.
      b. A **side walker** is placed to the side of the patient instead of in front of the patient.
      c. A **reciprocal walker** contains two hinges, one on each side of the walker. This allows the user to swing each side alternately during ambulation.
      d. A **rollator** is a walker with wheels on all four legs. The movement is controlled by hand brakes.
E. **Wheelchairs.** Many different types of wheelchairs are available. The patient's disabilities, size, weight, and activities are the main considerations in wheelchair selection. The following options should be considered when selecting a wheelchair.
   1. **Seat size.** The standard chair is 18 inches wide and 16 inches deep. A narrow wheelchair is 16 inches wide. Wheelchairs are available in widths up to 48 inches. The chair should be 2 inches wider than the widest part of the patient's body (usually around the buttocks or thighs). **Seat upholstery** holds the patient in the chair. Seats come in various materials to accommodate patients' needs. **Back upholstery** supports the patient's back while he or she is sitting in the chair.
   2. **Weight.** Standard wheelchairs weigh 35 to 50 lb. Lightweight wheelchairs (25 to 35 lb) are available for those who are unable to manipulate a standard chair and for ease of transport.
   3. **Arms** can be fixed or detachable to allow transfer on and off the chair. Half-length arms (as opposed to full length) allow the user to get closer to a table or work surface. Various types of padding and adjustments in the arm position can assist the patient in obtaining a position that is comfortable and keeping the arms on the arm rests.
   4. **Tires** can be hard rubber or pneumatic (i.e., air filled) which allows the chair to transverse rougher surfaces. **Wheels** can be reinforced with spokes or can be composite based.
   5. **Leg rests** can be of different sizes and are available with padding. Some have adjustable elevation to aid in healing an acute injury. **Calf rests** can be of different sizes and are available with padding. **Foot rests** can be of different sizes and are available with or without heel loops to keep the foot on the foot rest.
F. **Sports chairs** are wheelchairs that are lightweight and durable. They are designed for people who are very active.
G. **Powered wheelchairs** are designed for people who cannot wheel themselves. This type of wheelchair is powered by an electric motor and battery.

II. BATHROOM EQUIPMENT. This equipment is used for patients who cannot get to the bathroom or for patients who need assistance using the toilet or bathtub.

A. **Elevated toilet seats** are used to increase the height at which the patient sits over the toilet. This assists patients in getting on and off the toilet. Additional support can be provided with **toilet safety rails**. These rails allow the patient to transfer weight from the feet to the hands, and they help prevent the patient from falling.
B. **Commodes** are portable toilets that are used by patients who cannot get to the bathroom. Commodes contain a frame (with or without a back rest), a seat, and a bucket. Some are adjustable in height and have arms that drop to facilitate transfer to and from the commode.
C. **Three-in-one commodes** function as a commode, elevated toilet seat, and toilet safety rails. These are beneficial for patients requiring varying assistance during recuperation.

D. **Bath benches** are seats with or without a back that fit in the bathtub and allow the patient to sit while taking a shower.

E. **Transfer benches** are placed over the outside of the bathtub. They are available with or without a back. A transfer bench assists the patient in getting into the bathtub and serves as a bath bench while the patient takes a shower.

F. **Grab bars** are bars that either attach to the wall around the bathtub or to the bathtub itself to assist patients in getting in and out of the bathtub.

III. BLOOD PRESSURE MONITORS.
Patients with hypertension use this equipment to monitor blood pressure so that appropriate therapeutic decisions can be made. A patient's blood pressure measured at home is typically 5 mm Hg lower than when measured at the office.[1] The type of monitor that is recommended should be determined by the patient's ability to use the product correctly. Items to consider when assisting a patient in the selection of a blood pressure monitor include ease of use (e.g., automatic inflation), use of the monitor with one hand (has D-ring cuff), the size of the display monitor (visually impaired patients), blood pressure cuff size, and the capability to store readings. Types of monitors include the following:

A. **Aneroid sphygmomanometer.** This type of monitor is the **accurate** and requires regular calibration. These types of monitors are portable, lightweight, and most require manual inflation of the cuff, but a separate stethoscope is not required.

B. **Electronic or digital monitor.** This type of monitor detects blood pressure by using a microphone or by oscillometric technology, which converts movement of vessels into blood pressure. This type is easier to use than an aneroid or mercury sphygmomanometer as most offer automatic inflation and deflation and there is not a need for a separate stethoscope. These models are more **expensive**, can provide inaccurate readings if the patient moves while the blood pressure is being performed, and requires frequent calibration against a provider's in-office sphygmomanometer; but they represent an alternative for patients who cannot use a sphygmomanometer. Some of these monitors come with a wrist cuff, which may be useful in overweight or obese patients for whom the regular size arm blood pressure cuff is too small. Patients with very large or very small upper arms may need to purchase a special cuff in order to obtain an accurate reading.

C. **Finger monitors.** These detect blood pressure by compressing the finger and converting blood vessel movement into blood pressure by oscillometric technology. Many environmental conditions and medications can interfere with the results of these monitors. Finger blood pressure monitors are **least accurate** and not recommended for home monitoring.

IV. HEAT AND COLD THERAPY.
For musculoskeletal disorders (e.g., sprains, strains, arthritis), treatment may include the application of heat or cold to specific areas of the body.

A. **Heat** can be applied in a dry or moist form. **Dry** heat is less effective than moist heat but is tolerated better; thus its clinical effectiveness is similar. **Moist** heat has an advantage of not causing as much perspiration and is often recommended. The application of heat produces vasodilation and muscle relaxation. Products that can deliver heat include the following:

1. A **hot water bottle**, a rubber container that is half filled with hot water. The remaining air is squeezed out of the container resulting in a flexible container that can be shaped to the area of the body for which it is being used to provide dry heat.

2. A **heating pad** is an electrically powered pad that can produce moist or dry heat. Moist heat is supplied by inserting a wet sponge in a pocket that is next to the pad. Patients should place the pad on top of the body instead of lying on the pad to prevent burning.

3. A **moist-heat pack** (also called a hydrocollator) contains silica beads, which absorb heat when placed in boiling water. The heated pack is wrapped in a towel and applied to the body to provide moist heat. A moist-heat pack must be kept moist to retain its absorbent properties. The pack should be wrapped in plastic and stored in the refrigerator or freezer.

4. A **gel pack** provides dry heat after it is heated in boiling water or in the microwave. It is reusable by repeating the heating process.

---

[1]National Heart, Lung, and Blood Institute. The seventh report of the Joint National Committee on prevention, detection, evaluation, and treatment of high blood pressure. August 2004. Available at http://www.nhlbi.nih.gov/guidelines/hypertension/jnc7full.htm.

5. **Chemical hot packs** provide dry heat by mixing chemicals from two compartments. The chemicals undergo an exothermic reaction. Some packs are reusable by reheating in boiling water or in the microwave.

6. **Paraffin baths** provide moist heat by covering the body with heated paraffin. Once the wax cools and hardens, it is removed. This method is commonly used for patients with arthritis in the hands and fingers.

B. **Cold** application is indicated mainly as acute therapy to decrease circulation to a local area and to provide pain relief. Cold is contraindicated in patients with circulatory stasis or lacerated tissue. Products that can deliver cold include the following:

1. An **ice bag** is a flexible plastic container designed to hold ice. The bag is then applied to the body.

2. A **gel pack** can be used to apply cold by freezing and then applying to the body.

3. **Chemical packs** can be used to apply cold. Chemicals from two compartments are mixed together, resulting in a chemical reaction that produces cold. These packs are used once and then disposed of.

V. DIAGNOSTIC AIDS

A. **Self-care tests** or **kits** are used as screening tests or for monitoring. Many factors can affect the accuracy of the tests. The most common factors are patients not following directions and patients having poor technique. Pharmacists should be prepared to counsel patients on the selection of a test, on the proper use, and on interpretation of results. Pharmacists should refer patients to the appropriate health care provider if necessary.

B. **Types of tests**

1. **Urine tests**

a. The **urine glucose test** detects sugar in the urine. Patients with diabetes can use this to evaluate glucose control. Blood glucose monitoring is preferred, however, because it is more accurate and gives a better description of current glycemia.

b. The **ketone test** detects the presence of ketones in the urine. This is used by patients with diabetes as an indicator of severely uncontrolled diabetes.

c. The **microalbuminuria test** detects the presence of protein in the urine (microalbuminuria). This test can be used annually by patients with diabetes to detect an early sign of kidney damage. The simple test is performed at home and mailed to the company for a professional evaluation. If the test is positive, the patient is recommended to follow up with his or her health care provider.

d. **Ovulation prediction tests** predict when ovulation occurs to increase the chance of conception. These tests detect the presence of **luteinizing hormone (LH)** in the urine. Its presence means that ovulation should occur within 20 to 48 hrs. The test is performed daily until a positive result is obtained. It is recommended to test at the same time each day between 10 A.M. and 8 P.M. and not to use the first morning urine as the LH surge typically starts in the morning. The day on which the patient begins testing depends on the length and regularity of her menstrual cycle. Patients with menstrual cycles of consistent length may need to test only for 4 days, whereas those with menstrual cycles that change in length may need to test for 8 or 9 days. False-positive results can occur if the patient is taking fertility medications (e.g., clomiphene), oral contraceptives, or hormone-replacement therapy or if the patient has polycystic ovary syndrome or impaired liver or kidney function.

e. **Pregnancy tests** detect pregnancy by the presence in the urine of **human chorionic gonadotropin (hCG)**, which is secreted after fertilization. Many pregnancy test kits can detect hCG 1 day after missed menses. False-positive results can occur if the patient takes the test too early, is taking fertility medications (e.g., hCG), or has ovarian cysts. If a patient uses a household container or a waxed cup to collect urine, it may affect the test results. Patients should be referred to the appropriate health care provider if they receive a positive result or two negative results 7 days apart and have not had menses.

f. The **urinary bacteria test** detects the presence of leukocytes and/or nitrite in the urine. The presence of nitrite is used as an indicator of a **urinary tract infection (UTI)** because the most common bacteria associated with UTIs are gram-negative bacteria, which convert nitrate to nitrite. This test is used by patients who have recurrent or chronic UTIs or many risk factors. Risk factors include previous UTIs, diabetes, urinary tract abnormalities, enlarged

prostate, and behavioral risk factors (e.g., frequent sexual activity, delayed urination, the use of spermicides or diaphragms). Because this test is not specific for bacteria, false results can occur. False positives can result from medications (e.g., phenazopyridine) the patient may be taking or from menstrual blood in the urine, depending on the test used. In addition, a false negative may be detected if the patient is taking high doses of vitamin C, adheres to a strict vegetarian diet, or has frequent urination.

g. There are various FDA-approved **urine drug tests** available for use at home. Substances that may be detected in the urine include amphetamine, methamphetamine, ecstasy, marijuana, cocaine, phencyclidine, opiates, benzodiazepine, barbiturates, methadone, tricyclic anti-depressants, and oxycodone. Most urine drug tests require two steps: screening (at home—collection of urine and reviewing the results as color bands on the device) and confirmation (sending the urine sample that was collected for the home test to the drug test manufacturer's contracted laboratory; results are available in 7 to 10 business days).

2. **Blood tests**

a. The **cholesterol test** determines a patient's total cholesterol (TC), low-density lipoprotein (LDL), high-density lipoprotein (HDL), and/or triglycerides (TGs). Some tests provide only a TC level, whereas others provide a full lipid profile (TC, LDL, HDL, and/or TGs). Some kits are a single-use test requiring the patient to apply a blood sample on a collecting card, which is mailed to a laboratory for evaluation; others can be performed and evaluated by the patient at home. Regardless of the test used, the patient places a large drop of blood on the test card or cassette. Some of the tests require the patient to fast—meaning nothing to eat or drink except water for 12 to 14 hrs before collecting the blood. These tests can be useful as screening test as well as for patients who want to monitor their therapy. Patients who tested borderline or higher for high cholesterol should be referred to the appropriate health care provider.

b. The **blood glucose test** measures the concentration of glucose in the blood. Patients with diabetes use this information, along with diet, exercise, and medication, to keep glucose levels within a target range. Other tests are designed to be used with **blood glucose meters**, which read the test and display the actual blood glucose value. Whole blood is approximately 15% lower than plasma glucose, which is what is measured in the standard laboratory tests. Most glucometers available provide results as the "plasma equivalent," meaning they test whole blood but use an internal algorithm to calculate the plasma glucose. Patients using blood glucose tests must perform the tests properly and understand the appropriate actions to take when the resulting values are outside the desired range.

c. Other **home blood test kits** are available that provide results at the time of testing in the home or the collected specimen is sent to a laboratory for results. These home testing kits include HIV, hepatitis C virus (HCV), glycosylated hemoglobin A1c (A1c), anemia, prostate specific antigen (PSA), and thyroid. If the specimen is mailed away for processing, the results can be obtained by calling a toll-free number.

d. There are various **point-of-care testing (POCT)** devices that are available for use in pharmacies. Because most of them meet the Clinical Laboratory Improvements Amendments (CLIA)-waived requirements, pharmacies are able to offer these services to their patients. When selecting a POCT device for use, make sure to research the device specifications, portability, testing procedure, and cost. Examples of point-of-care tests available in selected pharmacies include electronic peak flow meters, portable spirometry, HIV rapid test, rapid *Strep* testing, coagulation analyzers, osteoporosis screening with quantitative ultrasound or peripheral dual-energy absorptiometry, and blood tests that measure A1c, fructosamine, ketones, microalbuminuria, alanine aminotransferases, and lipid profiles.

3. **Fecal occult blood tests** detect the presence of blood in the stool as a screening test for colorectal cancer. Patients drop a pad into the toilet after defecation. The pad will change color if blood is present. Patients should eat high-fiber foods during the testing period and are instructed to test three consecutive stool samples. Patients with a positive result should be referred to the appropriate health care provider. Certain conditions (gastrointestinal bleed, nosebleed, menstruation), foods (red meat), medications (nonsteroidal anti-inflammatory drugs [NSAIDs]), and toilet-bowl cleaners can produce false-positive results.

4. **Fertility microscopes** allow women to determine their most fertile time of the month. A woman places saliva on a viewing slide or plate, allows the saliva to dry for 7 to 10 mins, and then views it under a microscope. The appearance of a ferning pattern means ovulation has occurred. Estrogen levels rise and peak with ovulation, causing an increase in salt levels in the saliva, resulting in a fernlike pattern in dried saliva. Simple dots or a bubble-like appearance is found during a nonfertile period. A woman should be advised to avoid smoking, eating, or drinking for 2 hrs before testing. Polycystic ovary syndrome and perimenopause can cause false-positive results.

5. **Vaginal pH** kits allow women to distinguish vaginal symptoms from vulvovaginal candidiasis (VVC), bacterial vaginosis, or trichomoniasis by assessing the vaginal pH. A vaginal pH greater than 4.5 is associated with bacterial infections requiring an appointment with a health care provider. A vaginal pH less than 4.5 is likely VVC and can be treated with over-the-counter medications as long as the woman has been previously diagnosed with VVC.

VI. HOSPITAL BEDS AND ACCESSORIES. Hospital beds are used by patients who are confined to bed for long periods or who require elevation of the head or feet as part of their treatment. Hospital beds may be manually or electrically operated. Electric hospital beds can be adjusted manually in case of the loss of electricity.

A. **Accessories**
  1. **Bed rails** keep the patient in the bed and allow the patient to change positions.
  2. A **trapeze** is a triangular-shaped object that hangs above the patient and is used to change the patient's position.
  3. **Alternating pressure pads** are used by patients to prevent decubitus ulcers (i.e., bed sores). As a preventive measure, these pads inflate, thus changing the areas of the body that receive pressure.

VII. INCONTINENCE AND INCONTINENCE PRODUCTS

A. **Urinary incontinence** is a condition in which involuntary urine loss is a social or hygienic problem and is objectively demonstrable. Types of incontinence include:
  1. **Urge** incontinence, which is uncontrolled contractions of the bladder.
  2. **Stress** incontinence, a weakness of the sphincter that causes leakage when intra-abdominal pressure increases (e.g., while laughing, coughing, sneezing) and is common in pregnancy.
  3. **Overflow** incontinence, which is caused by obstruction of urine flow from the bladder and is common in elderly men as a result of prostate enlargement.
  4. **Functional incontinence**, which is related to physical or psychological problems that impair the patient's ability to get to the bathroom.
  5. **Transient incontinence**, which is caused by medications, UTIs, or mental impairment.
  6. **Mixed incontinence**, which is a combination of more than one type of incontinence.
B. **Incontinence products**
  1. **Shields** are disposable, absorbent pads that are placed in the underwear and held with an adhesive strip on the back of the pad. These pads are used for light incontinence problems.
  2. **Undergarments** are disposable absorbent garments that are worn under the underwear and held in place with elastic straps that go around the hips. They are designed for moderate incontinence problems.
  3. **Briefs** look like adult-size diapers that are kept in place with adhesive strips. They are designed for heavy incontinence problems.
  4. **Pull-up pants** are absorbant disposable garments that look like underwear and are used for heavy incontinence problems.
  5. **Underpads** are absorbent pads to be placed on the bed underneath a patient with incontinence. These pads contain a barrier to protect the bedding.
  6. **Waterproof sheets** are plastic or vinyl sheets that protect the mattress. They may be lined with a soft material to prevent friction against the skin.
  7. **Incontinence systems** are garments that look like underwear but have a pouch or pocket designed for a disposable or reusable pad.

VIII. ORTHOPEDIC BRACES AND SURGICAL FITTINGS.
These products promote proper body alignment and support injured areas. Pharmacists should have additional training before attempting to fit an orthopedic device.

A. **Abdominal supports** are elastic and are used to support and hold surgical dressings in place. Abdominal supports come in different widths.

B. **Arm slings** are used to provide comfort and support during recuperation from fractures, sprains, and surgery. The elbow should form a 90-degree angle in an arm sling to allow for proper circulation.

C. **Back supports** are worn by patients to provide support or promote proper alignment. Such supports are named after the area of the spine on which it is worn.
   1. A **sacral belt** (also called **sacral cinch** or **sacroiliac belt**) supports the lower back.
   2. A **lumbosacral support** supports the lower and middle back.
   3. A **thoracolumbar support** supports the middle and higher areas of the back.

D. **Cervical collars** support or limit the range of motion of the neck. The width of the cervical collar should equal the measurement from the chin to the sternum when the patient is standing straight, looking ahead.
   1. **Soft** or **foam** cervical collars provide mild support and remind the wearer to keep the neck straight.
   2. **Hard** or **rigid** cervical collars provide more support and limit movement to a greater degree.
   3. A **Philadelphia** or **extrication** collar is used to immobilize the neck and is commonly used in emergency situations.

E. **Clavicle supports** are used as aids for the reduction and stabilization of the clavicle (i.e., collarbone). These supports are sometimes called **figure-eight straps** because of their appearance.

F. **Knee braces** (also called **knee cages**) are used to support the knee. Some braces have metal stays on the side to prevent the lateral movement of the knee. Those with metal stays may also have hinges to allow for movement of the knee. Some knee braces have a cut-out hole and padding around the patella (i.e., knee cap) to prevent its movement.

G. **Knee immobilizers** prevent any motion of the knee and are used for severe injuries and fractures. They are available in different lengths and are adjustable in size.

H. **Nighttime ankle brace** keeps the ankle at a 90-degree angle while sleeping. It can be used in the treatment of Achilles tendon injuries or plantar fasciitis.

I. **Shoulder immobilizers** prevent movement of the shoulder and arm. The elbow should be at a 90-degree angle to allow for healing without affecting circulation.

J. **Tennis elbow supports** apply pressure to the forearm to provide pain relief and decrease inflammation from tennis elbow (i.e., epicondylitis).

K. **Wrist braces** prevent movement of the wrist to allow healing. The brace may be shaped to have the wrist flexed so that the tendons in the hand remain stretched during the period of inactivity.

IX. OSTOMY APPLIANCES AND ACCESSORIES

A. **Definitions.** An **ostomy** is a surgical procedure in which an artificial opening is created in the abdominal wall for the purpose of eliminating urine or fecal waste. The opening is called a **stoma**. Ostomies can be temporary to allow for repair or healing of the digestive tract or can be permanent. Each procedure is named to describe the anatomical location involved.
   1. In a **colostomy**, part of the colon is cut and attached to the abdominal wall. A colostomy may be temporary or permanent, the discharge may be liquid or semisolid (as with an **ascending** colostomy), or it may be solid (as with a **descending** or **sigmoid** colostomy). Patients with an ascending colostomy and some patients with a transverse colostomy have gastric enzymes present in the discharge. These patients must take extra care to ensure that the discharge does not come into contact with the skin.
   2. In an **ileostomy**, the ileum is attached to the abdominal wall. This procedure is performed in patients with ulcerative colitis or Crohn disease.
   3. A **urostomy** is performed in patients with bladder cancer. In this procedure, an **ileal conduit** is created by attaching the ureters to the ileum and the distal end of the ileum to the abdominal wall.

B. **Ostomy appliances.** The ostomy appliance contains a **skin barrier** that attaches to the skin around the stoma. The skin barrier protects the skin and allows for the attachment of the **collection device** or **pouch**. The selection of an ostomy appliance depends on the type of discharge produced. In addition

to size, color, and flexibility, appliances may have detachable pouches and be able to be drained by releasing a clip at the bottom of the appliance.

C. **Ostomy accessories**
   1. **Washers**, **powder paste**, and **ointments** are designed to be used with a skin barrier and provide additional protection of the skin around a stoma.
   2. **Cement**, **elastic belts**, and **tape** are used to hold the appliance in place.
   3. **Deodorizers** help control fecal odor. **External** deodorizers can be placed into the appliance; systemic deodorizers (e.g., bismuth subgallate, chlorophyll, charcoal) can be ingested as **internal** deodorizers.
   4. **Moisturizers** and **disinfectants** can be used to treat the skin and prevent complications.
   5. **Irrigation devices** are used by patients who have control over the elimination of waste to facilitate removal of the accumulated waste. The devices are used to instill water into the intestine, which produces peristalsis.

X. RESPIRATORY EQUIPMENT

A. **Continuous positive airway pressure** (CPAP) is used in patients with sleep apnea. The pressure supplied from this machine keeps the airway open. It is typically worn while sleeping to allow the patient to sleep without disturbance.

B. A **humidifier** puts moisture into the air by breaking water into small particles and blowing them into the air to be evaporated. Humidifiers are sometimes referred to as called "cool-mist vaporizers." **Vaporizers** are similar to humidifiers in that they are used to deliver moisture to the air. However, a vaporizer produces a steam to increase humidity, whereas a humidifier produces a nonheated mist. An **ultrasonic humidifier** contains a transducer, which produces a finer mist. It is commonly used to promote expectoration in patients with upper respiratory infections. Both types of humidifiers and vaporizers need to be cleaned regularly to prevent the growth of mold or bacteria.

C. A **nebulizer** is used to deliver medication to the mouth or throat. Patients with a sore throat may use a nebulizer to deliver a topical anesthetic to the throat. An **ultrasonic nebulizer** is used to deliver medication into the lungs. The medication is diluted with normal saline and then inhaled. An ultrasonic nebulizer is used by patients with respiratory infections, asthma, or chronic obstructive pulmonary disease (COPD).

D. **Oxygen** is administered for various conditions. Oxygen can be stored as a gas or a liquid or can be extracted from the air via a **concentrator**. The amount of oxygen required by the patient is measured in liters per minute (L/min). A **registered respiratory therapist** can be consulted for information on the correct procedures, cautions, and laws regarding oxygen use.

E. A **peak flow meter** is used by patients with asthma to detect constriction of the airways before symptoms appear. Early detection of an upcoming attack allows for therapy designed to stop or minimize the severity of the disease. Patients exhale as much as possible into a peak flow meter to obtain the expiratory flow rate. If this rate is below a predetermined baseline, patients might be instructed to change therapy.

F. **Home spirometry** is a noninvasive pulmonary function test. It allows for measurement of (a) the forced expiratory volume in one second (FEV_1), and (b) the forced vital capacity (FVC) in the person's home. This device may be used for post lung transplant patients or patients with a history of asthma and/or COPD.

XI. THERMOMETERS. These instruments measure body temperature and are **most commonly used** to detect or evaluate the treatment of infections.

A. **The basal thermometer** is used to measure basal body temperature. Basal thermometers are available as a glass or digital thermometer. A digital thermometer may lower the potential for user error as it offers more accuracy. The basal body temperature is used to predict ovulation to increase or decrease the chance of conception. Basal body temperature can be taken orally, rectally, or vaginally, but the route should be consistent.

B. **Digital thermometers** register temperature quickly. Heat alters the current running through a resistor, and the temperature is displayed via a digital readout. The current is supplied by a battery, some of which are rechargeable. Digital thermometers can be used orally, rectally, or

axillary, and generally require placing a plastic sheath over the tip of the thermometer before using. Digital thermometers have been integrated into pacifiers to assist in taking an infant's temperature.

1. **Oral** temperature is taken by placing the thermometer under the tongue, and the lips are sealed around the thermometer for 3 to 4 mins. Invalid results may occur if the patient eats, drinks, or chews gum before the temperature is taken; incorrectly places the thermometer in the mouth; talks or breathes rapidly through mouth or nose while the temperature is being taken; or has oral abscess or dentures.

2. **Rectal** temperature is taken by inserting the thermometer to 1 inch into the rectum and left for at least 2 mins. A lubricant should be used to aid insertion. Rectal temperature is 1°F higher than oral temperature. Rectal temperatures have been found to lag behind the core temperature. So if a patient has a rapid change in core temperature, the rectal temperature will not immediately reflect it.

3. **Axillary** temperature can be used if an oral or rectal temperature cannot be taken. An axillary temperature is taken by holding the thermometer snugly under the arm for 3 to 4 mins. Axillary temperature is 1°F lower than oral temperature. However, there is controversy about the accuracy of axillary temperature. Using this temperature location can be clinically useful as long as the site is recorded and used consistently.[2]

C. **Tympanic thermometers** use infrared technology to detect the temperature of the tympanic membrane. The temperature is determined within seconds and is less invasive than other thermometers. These thermometers use disposable tips that are inserted into the ear. The American Academy of Pediatrics recommends that this type of thermometer be used in older babies and children because the probe needs to accurately fit into the ear. Inappropriate placement and too much earwax can cause inaccurate readings.[3]

D. **Skin thermometers** are placed directly on the skin (usually the forehead) to calculate body temperature. This type of thermometer is a liquid-crystal strip that changes colors based on temperature. Environment factors such as sweating and ambient temperature will affect the skin temperature. This method is not as accurate as the others and should be reserved for situations in which other methods are not possible.

XII. URINARY CATHETERS. These devices allow for the **collection** and **removal of urine** from the bladder.

A. **External** catheters are used for **heavy incontinence** problems or complete loss of urine control. They are attached to a stationary collection device or a leg bag to allow for ambulation. Types of external catheters include the following:

1. The **male** external catheter is placed around the penis. Some have adhesive to assist in keeping the catheter secure.

2. The **female** external catheter, which is a contoured device that fits snugly in the vagina.

B. **Internal** catheters are used during **surgery** or when external catheters are inappropriate. Internal catheters can be used at home, but the patient must be taught proper insertion techniques to prevent infection. The catheter is inserted through the urethra into the bladder and is attached to a stationary collection device or leg bag. Catheters are sized by the **French scale**: the larger the number, the larger the diameter of the catheter. Types of catheters include the following:

1. The **straight** catheter is used for **intermittent catheterization** to drain the bladder. It consists of a rubber tube; urine drains from one end and the other end connects to the collection device.

2. The **Foley** catheter, an indwelling catheter, can be used for **up to 30 days**. The end inserted into the bladder contains a balloon, which is inflated with sterile water or saline to hold the catheter in place. The balloon is deflated before removal.

---

Study Questions

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the **one** lettered answer or completion that is **best** in each case.

1. When a patient is fitted with an axillary crutch, how far below the underarm should the top of the crutch rest?

   (A) 0.5 inch
   (B) 1 inch
   (C) 2 inches
   (D) 3 inches
   (E) 4 inches

2. What angle should the elbow form when a cane is the correct height?

   (A) 10 degree
   (B) 25 degree
   (C) 45 degree
   (D) 60 degree
   (E) 90 degree

3. A product that delivers moisture to the air by heating water to produce steam is called a

   (A) nebulizer.
   (B) humidifier.
   (C) ventilator.
   (D) peak flow meter.
   (E) vaporizer.

4. An absorbent product designed for patients with light incontinence problems is a

   (A) brief.
   (B) shield.
   (C) undergarment.
   (D) underpad.
   (E) catheter.

5. When an oral temperature is taken, the thermometer should be placed into the mouth for

   (A) 1 to 2 mins.
   (B) 3 to 4 mins.
   (C) 5 to 6 mins.
   (D) 7 to 8 mins.
   (E) > 9 mins.

6. The diameter of urinary catheters is measured by which of the following scales?

   (A) Leur
   (B) English
   (C) French
   (D) gauge
   (E) metric

7. A cervical collar that immobilizes the neck is called a

   (A) soft cervical collar.
   (B) hard cervical collar.
   (C) foam cervical collar.
   (D) extrication collar.
   (E) rigid cervical collar.

8. Incontinence that is caused by an obstruction of the bladder is called

   (A) overflow incontinence.
   (B) urge incontinence.
   (C) stress incontinence.
   (D) functional incontinence.
   (E) transient incontinence.

9. A colostomy or ileostomy could be performed for all of the following conditions *except*

   (A) lower bowel obstruction.
   (B) malignancy of the colon or rectum.
   (C) ulcerative colitis.
   (D) duodenal ulcer.
   (E) Crohn disease.

10. Pregnancy test kits are designed to detect which substance?

    (A) luteinizing hormone (LH)
    (B) progesterone
    (C) human chorionic gonadotropin (hCG)
    (D) estrogen
    (E) follicle-stimulating hormone

Answers and Explanations

1. **The answer is C** *[see I.B.2.a]*.
   When a patient is fitted for an axillary crutch, the top of the crutch should be 2 inches below the axilla (underarm).

2. **The answer is B** *[see I.A.1]*.
   When a patient is properly fitted for a cane, the elbow should form a 25-degree angle. This allows for maximum weight transfer.

3. **The answer is E** *[see X.B]*.
   A vaporizer produces moisture by heating water to produce steam. A humidifier also produces moisture; however, it works by mechanically creating small water particles. A nebulizer is used to deliver liquid to the mouth and throat. A ventilator is used to assist in breathing. A peak flow meter is used to detect airway constriction.

4. **The answer is B** *[see VII.B.1]*.
   Shields are pads that are placed in the underwear and held with adhesive strips. They are used for patients with light incontinence problems.

5. **The answer is B** *[see XI.A.1]*.
   Oral temperature is taken by inserting the bulb of the thermometer under the tongue and sealing the lips around the thermometer for 3 to 4 mins.

6. **The answer is C** *[see XII.B]*.
   The French scale is used to measure the diameter of a urinary catheter. The Leur scale is used to measure syringe tip size. The gauge scale is used to measure needle diameter. The metric scale is a general system of measurement.

7. **The answer is D** *[see VIII.D.3]*.
   An extrication collar (also known as a Philadelphia collar) is used to immobilize the neck. It is commonly used in emergency situations. Soft or foam cervical collars provide mild support and remind the patient to keep the neck straight. Hard or rigid cervical collars provide moderate support but allow some movement.

8. **The answer is A** *[see VII.A.3]*.
   Overflow incontinence is caused by obstruction of the bladder. Urge incontinence is caused by uncontrolled bladder contractions. Stress incontinence is caused by increases in intra-abdominal pressure. Functional incontinence is related to physical or psychological problems. Transient incontinence is caused by medications, urinary tract infections, or mental impairments.

9. **The answer is D** *[see IX.A.1–2]*.
   Lower bowel obstruction, malignancy of the colon or rectum, and diverticulitis may all require a colostomy. Ulcerative colitis and Crohn disease may require an ileostomy. The treatment of a duodenal ulcer would not include a colostomy or an ileostomy.

10. **The answer is C** *[see V.B.1.d]*.
    Pregnancy tests detect hCG in the urine. This is secreted after the embryo has implanted in the uterus. Ovulation-prediction tests detect LH. Progesterone, estrogen, and follicle-stimulating hormone are all involved in controlling the menstrual cycle.

Over-the-Counter Otic, Dental, and Ophthalmic Agents

JENNIFER D. SMITH, CONNIE LEE BARNES

I. OTIC OVER-THE-COUNTER (OTC) PRODUCTS

A. The ear can be divided into three distinct parts: the external ear, the middle ear, and the inner ear.

    1. The external ear is typically thought of as the part of the ear one can see. However, being made up of the auricle, the external auditory canal (the ear canal), and the outer surface of the tympanic membrane (the ear drum), the external ear extends much farther.

    2. The **middle ear** is an air-filled chamber that provides direct access to the inner ear and indirect access to the nose and throat by way of the eustachian tube. The middle ear houses three small bones (malleus, incus, and stapes) known as the ossicles. When sound strikes the eardrum, it vibrates, transmitting the sound vibrations to the ossicles, which in turn transmit the sound to the inner ear.

    3. The **inner ear** is a delicate structure composed of auditory and vestibular components. The auditory component (the cochlea) is responsible for hearing. The vestibular component (the semicircular canals and the vestibule) is responsible for maintaining balance and equilibrium.

B. **Common ear disorders**

    1. **Excessive/impacted cerumen** (earwax). Contrary to current social beliefs, earwax does not need to be removed with objects such as fingers, towels, and cotton-tipped applicators because these objects typically cause impaction of the earwax, rather than its removal. Instead, the external ear has a unique self-cleansing mechanism. Ear canal skin is constantly shed and removed via lateral migration from the tympanic membrane (at a rate of 2 to 3 mm per day) to the external canal, where cerumen adheres to the shed skin and other debris. Movement such as chewing moves the cerumen outward where it is removed by drying, flaking, or simply falling out. The use of hearing aids or earplugs can block this outward migration, developing earwax impaction and leading to hearing loss.

        a. The **functions** of cerumen include the following:

            (1) Lubrication of the lining of the ear canal

            (2) Temporarily repelling water

            (3) Resistance to infection owing to its acidic nature (pH = 4–5), which creates an unfavorable environment for organism survival

            (4) Trapping dust, debris, and foreign objects

        b. **Epidemiology.** Aside from impaction caused by manipulation, some patient populations are more prone to experience impacted cerumen, including patients with an overproduction of cerumen, patients with narrowed ear canals, the elderly, and patients with mental retardation.

        c. **Symptoms** of impacted cerumen include earache, itching of the ear, reflex cough, dizziness, vertigo, tinnitus, and compromised hearing.

        d. **Earwax-softening agents** may be used alone or followed by the use of an otic syringe (see I.C).

            (1) **Carbamide peroxide** 6.5% in anhydrous glycerin is the **only U.S. Food and Drug Administration (FDA) approved agent for cerumen removal**. When carbamide peroxide

makes contact with tissue enzymes, oxygen is released, producing a foaming action. This **foaming action softens impacted cerumen**.

    (a) Available agents. Murine, Debrox, Mack's

    (b) Instructions for use. Patients **aged 12 and older** should tilt the head sideways and instill 5 to 10 drops into the ear. The applicator tip should not be inserted into the ear canal. Patients should keep the head tilted to the side (or insert cotton) for several minutes to increase contact time with the cerumen. Repeat the process **twice daily for up to 4 days**. For children < 12 with suspected cerumen impaction, a medical provider should be consulted.

  (2) Olive oil (sweet oil) is used to soften earwax and alleviate itching.

  (3) Mineral oil, recommended as 2 drops in the affected ear(s) once per week, has been used to liquefy the cerumen, thus aiding in its removal.

  (4) Docusate sodium given 15 mins before provider in-office irrigation has shown efficacy, but no data exist to support the superiority of docusate sodium over carbamide peroxide.

  (5) Hydrogen peroxide is a component of carbamide peroxide and has weak antibacterial properties. As an otic solution, hydrogen peroxide may be diluted 1:1 with warm water and instilled in the ear to aid in cerumen softening and removal.

  (6) Ear candles (coning candles), are made of paraffin-coated fabric wound into a foot-long cone that are inserted into the ear canal and lit with a match. However, no data support this dangerous process for efficacy. Furthermore, complications may include external otitis, temporary hearing loss, and burns.

  e. Patients with perforated tympanic membrane, ear drainage, ear pain, or a rash in the ear should be referred to a health care provider. In the office, providers may use various devices or irrigating systems to remove impacted cerumen.

2. Vertigo is a loss of equilibrium in which one might describe a room as spinning. As described in I.A.3, the vestibular compartment of the inner ear is responsible for maintaining balance and equilibrium. The autonomic system may become involved if the vertigo is severe, producing dizziness, pallor, sweating, and nausea. Patients expressing symptoms of vertigo (aside from motion sickness) should be referred to a medical provider.

3. Tinnitus may be described by patients as a ringing, buzzing, hissing, whistling, or humming noise lasting from seconds to minutes. Tinnitus has been linked to a variety of causes, including Ménière disease, head injuries, otitis media, syphilis, temporomandibular-joint (TMJ) dysfunction, and certain medications (salicylates, nonsteroidal anti-inflammatory drugs, aminoglycosides, loop diuretics, and chemotherapeutic agents). If tinnitus is constant or severe, a medical consult is advised. Currently, there are no FDA-approved treatments for tinnitus.

4. External otitis, also referred to as otitis externa, is **inflammation of the external auditory canal** secondary to a bacterial or fungal infection.

  a. Cause. External otitis, frequently referred to as swimmer's ear, is thought to be most commonly the result of **local trauma** to the external canal (e.g., cotton-tipped applicators, fingers, sharp objects) or **prolonged exposure to moisture**. Prolonged exposure to moisture (e.g., humid environment, underwater swimming, diving) promotes maceration of the thin skin lining the ear canal, allowing bacteria to penetrate and grow. Trauma to the external canal lends itself to susceptibility to damage and thus easier infiltration of microorganisms. The predominant microorganisms isolated from patients with swimmer's ear are *Pseudomonas aeruginosa* and *Staphylococcus aureus*.

  b. Symptoms. Initial symptoms include **itching** and a sensation of **pressure/fullness in the ear**, followed by **pain**, an **otic discharge**, and a possible **decrease in hearing**. The pain may become quite intense, especially if the outer ear is touched or with movement of the jaw, such as chewing.

  c. Treatment is with a **prescription otic antibiotic** and **corticosteroid** if bacterial in origin and otic antibiotic alone if fungal in origin, as well as discontinuation of mechanical trauma and/or swimming (until resolution of infection). Oral antibiotics are not necessary unless the infection is unresponsive to otic treatment, the patient is immunocompromised, or a middle ear infection coexists. **External otitis should not be self-treated.**

  d. Prevention of external otitis is the key. Mechanical trauma to the ear by way of cotton-tipped applicators and fingers should cease immediately. Water should be removed as gently and

effectively as possible after swimming or showering/bathing using a towel around the edges of the ear or a hair dryer set on low heat. It may also be beneficial to tilt the head to the side to help expel water. If reoccurrence is frequent, one might consider using molded ear plugs, but consideration should be given to the risk of impacted cerumen with the use of such devices.

5. **Water-clogged ear** may be a contributing factor to external otitis owing to tissue maceration from prolonged periods of exposure to water; however, water-clogged ear is a separate disorder. Therefore, labeling of products approved by the FDA for the treatment of water-clogged ear may not allude to its use for prevention of external otitis. The only agent FDA approved as safe and effective as an ear-drying agent is isopropyl alcohol 95% in anhydrous glycerin 5%, approved for use in **patients 12 years of age and older**. A home solution of 50/50 isopropyl alcohol and white vinegar may also be used to dry the ear. Caution must be taken not to recommend self-treatment for water-clogged ear for patients with signs of infection, discharge or bleeding from the ear, ear surgery within the previous 6 weeks, or tympanostomy tubes.

6. **Furuncles**, also known as boils, are small abscesses surrounding the base of a hair follicle in the outer portion of the external ear canal. *Staphylococcus aureus* is typically the offending organism. Furuncles are usually self-limiting and may be managed with warm compresses and a topical antibiotic.

7. **Otitis media** is a bacterial infection that is most prevalent between the ages of 3 months and 3 years, owing to the length, angle, and function of the eustachian tube in children. Symptoms include ear pain, fever, fluid discharge from the ear, and possible decreased hearing. All patients with suspected otitis media must be referred to a medical provider for evaluation and treatment.

C. **Administration of otic agents**
   1. Instructions for use of otic drops
      a. Warm the solution by holding the bottle in the hand for a few moments.
      b. Tilt the head sideways with the affected ear upward.
      c. Pull the earlobe up and back to straighten the canal for adults and down and back to straighten in children.
      d. Use the other hand to squeeze the bottle of drops, carefully delivering the number of recommended drops into the ear canal. Caution should be taken not to insert the applicator into the ear canal.
      e. Keep the head tilted sideways for several minutes or place cotton in the ear to prevent the medication from draining out. If cotton is used, it must be large enough, so as not to become lodged in the ear, and should not be left in the ear for longer than 1 hr.
      f. Repeat the procedure on the opposite ear, if necessary.
   2. **Instructions for use of an otic syringe**
      a. Prepare a *warm* solution of plain water. Fill the otic syringe with the warm water solution.
      b. Straighten the ear canal using the appropriate method, as noted earlier. Tilt the head over a sink or basin to catch the outflow solution.
      c. Insert the tip of the otic syringe into ear, with the tip pointed slightly upward.
      d. Gently squeeze the bulb of the otic syringe to allow the solution to enter the ear. Allow the solution to drain from the ear into the sink or basin. If pain or dizziness occurs, remove the syringe and consult a medical provider.
      e. Repeat on opposite ear if necessary.

II. DENTAL OVER-THE-COUNTER PRODUCTS

A. **Dental anatomy.** Anatomically, the teeth are divided into two parts: the **crown** (above the gingival line) and the root (below the gingival line).
   1. **Enamel** is the crystalline calcium salts (hydroxyapatite) that cover the crown to protect the underlying tooth structure.
   2. **Dentin** is the largest part of the tooth structure, located beneath the enamel. It protects the dental pulp.
   3. **Cementum** is a bonelike structure that covers the root and provides the attachment of the tooth with the periodontal ligaments.
   4. **Pulp** consists of free nerve endings.

B. Common dental problems and OTC products

1. **Dental caries** (i.e., **cavities**) are formed by the growth and implantation of cariogenic microorganisms.
   a. **Causes**
      (1) **Bacteria** (primarily *Streptococcus mutans* and *Lactobacillaceae*) produce acids (e.g., lactic acid) that demineralize enamel. Initially, demineralized enamel appears as a white, chalky area and becomes bluish white and eventually brown or yellow.
      (2) **Diet** is another factor in the development of dental caries. Foods with a high concentration of refined sugar (i.e., sucrose) increase the risk of dental caries. Sucrose is converted by bacterial plaque into volatile acids that destroy the hydroxyapatite.
         (a) **Fructose** and **lactose** are less cariogenic than sucrose.
         (b) **Noncariogenic sugar substitutes** are xylitol, sorbitol, and aspartame.
   b. **OTC products** for dental caries include products that can alleviate the pain and sensitivity until the patient can get to the dentist. Examples of ingredients that are beneficial in this regard include lidocaine, benzocaine (e.g., Anbesol, Orajel), or an oral analgesic (e.g., aspirin, acetaminophen). FDA has issued a warning that the use of topical benzocaine is associated with a rare, but serious condition, methemoglobinemia.

2. **Plaque and calculus**
   a. **Causes**
      (1) **Plaque** is a sticky substance formed by the attachment of bacteria to the pellicle, which is a thin, acellular, glycoprotein (a mucoprotein coating that adheres to the enamel within minutes after cleaning a tooth).
      (2) **Calculus** (or **tartar**) is the substance formed when plaque is not removed within 24 hrs. The plaque begins to calcify into calculus when calcium salt precipitates from the saliva. Calculus can be removed only by a professional dental cleaning.
   b. **OTC products**
      (1) **Toothbrushes.** Soft, rounded, nylon bristles are preferred by dentists because hard bristles can irritate the gingival margins and cause the gums to recede. Manual toothbrushes vary in shape, size, design, and texture. Some toothbrushes have specially designed bristles that reach deep between teeth and along the gumline to remove stains and polish teeth and massage gums. Electric toothbrushes can benefit patients who require someone to clean their teeth for them or patients who have orthodontic appliances. Toothbrushes should be replaced when they begin to show wear or every 3 months, whichever comes first. Patients should replace their toothbrush after having an upper-respiratory infection.
      (2) **Irrigating devices** direct a high-pressure stream of water through a nozzle to the hard-to-clean areas by gently lifting the free gingiva to rinse out crevices. Two types are available: **pulsating** (i.e., intermittent low- and high-pressure water streams) and **steady** (i.e., constant and consistent water pressure), neither of which has shown superior irrigating ability.
         (a) Irrigating devices should serve as adjuncts in maintaining oral hygiene.
         (b) **Examples** include Interplak Water Jet, Hydro-Pik, and the Waterpik oral irrigator.
   c. **Dental floss** is available waxed, unwaxed, thick, thin, flavored, or unflavored. Some dental flosses are impregnated or coated with additives such as baking soda and fluoride. Also, several manufacturers are marketing floss made of materials with superior antishredding properties (e.g., Glide, Colgate Total). There are no differences among dental flosses in terms of plaque removal and prevention of gingivitis. There is no evidence of a residual wax film with the use of waxed dental floss.
      (1) The selection of dental floss depends on the characteristics of the patient, such as tooth roughness or tightness of tooth contacts (e.g., waxed floss is recommended for tight-fitting teeth because it can pass easily between the teeth without shredding).
      (2) The American Dental Association (ADA) recognizes approximately 35 brands as safe and effective including Butler, Johnson & Johnson, and Oral-B.
   d. **Dentifrices** are products that enhance the removal of stains and dental plaque by the toothbrush. These include toothpastes, antiplaque and anticalculus mouthwashes, cosmetic whiteners, desensitizing agents, disclosing agents, and dental gums.
      (1) **Toothpastes** are beneficial in decreasing the incidence of dental caries, reducing mouth odors, and enhancing personal appearance. Some toothpastes may contain the

antioxidant coenzyme Q10 (CoQ10; e.g., Perfect Smile Q10). **Ingredients** include the following:

(a) **Abrasives** are responsible for physically removing plaque and debris. Examples include silicates, sodium bicarbonate, dicalcium phosphate, sodium metaphosphate, calcium pyrophosphate, calcium carbonate, magnesium carbonate, and aluminum oxides. High-abrasive formulations are not advised for long-term use or for use by patients with exposed root surfaces.

(b) **Surfactants** are foaming agents that are incorporated into most dentifrices because their detergent action aids in removing debris. The **most frequently used** surfactants are **sodium lauryl sulfate** and **sodium dodecyl benzene sulfonate**. Sodium lauryl sulfate-containing dentifrices have been associated with an increase in the occurrence of canker sores. Dentifrices such as Oral-B Rembrandt Whitening Natural, Sensodyne, and Biotene do not contain sodium lauryl sulfate.

(c) **Humectants** prevent the preparation from drying. Examples include sorbitol, glycerin, and propylene glycol.

(d) **Suspending agents** add thickness to the product. Examples include methylcellulose, tragacanth, and karaya gum.

(e) **Flavoring agents** include sorbitol or saccharin.

(f) **Pyrophosphates** are found in tartar-control toothpastes. These products retard tartar formation; however, they form an alkaline solution that may irritate the skin. Some patients might experience a rash around the outside of the mouth. These patients should use regular toothpaste and only occasionally brush with tartar-control toothpaste (e.g., Colgate Tartar Protection with Whitening). Tartar-control toothpastes do not penetrate below the gumline, where tartar does the most damage.

(g) **Fluoride** is anticariogenic because it replaces the hydroxyl ion in hydroxyapatite with the fluoride ion to form fluorapatite on the outer surface of the enamel. Fluorapatite hardens the enamel and makes it more acid resistant. Fluoride also has demonstrated antibacterial activity.

  (i) Fluoride is **most beneficial** if used from birth through **age 12 or 13** because unerupted permanent teeth are mineralizing during that time. Whether or not a patient receives fluoride depends on the concentration in his or her local drinking water (*Table 19-1*).

  (ii) **Common fluoride compounds** in toothpaste include 0.24% sodium fluoride and 0.76% or 0.80% sodium monofluorophosphate (e.g., Aim, Crest, Aquafresh, Colgate). The continuous use of stannous fluoride may cause tooth discoloration.

  (iii) A fluoride warning label, which recommends contacting a poison control center or seeking professional assistance if more quantity than used for brushing teeth

Table 19-1.   DAILY FLUORIDE SUPPLEMENT REQUIREMENTS FOR INFANTS AND CHILDREN, BASED ON CONCENTRATION OF FLUORIDE IN DRINKING WATER

Fluoride Concentration (ppm)	Age	Fluoride Supplement Required (mg/day)
> 0.6	6 months to 3 years	0
	3–6 years	0
	6–16 years	0
0.3–0.6	6 months to 3 years	0
	3–6 years	0.25
	6–16 years	0.50
< 0.3	6 months to 3 years	0.25
	3–6 years	0.50
	6–16 years	1.00

is ingested, is required by the FDA on fluoride-containing dentifrices because the federal agency lists fluoride as a toxic substance.

    (iv) The estimated toxic dose of fluoride is 5 to 10 mg/kg.

    (v) Acute fluoride toxicity causes nausea, vomiting, and diarrhea.

(2) Agents with **antiplaque** potential for inclusion in dentifrices include plant extracts (sanguinarine), metal salts (zinc and stannous), phenolic compounds (triclosan), and essential oils (thymol and eucalyptol).

    (a) **Triclosan** is an antimicrobial agent that has been demonstrated clinically to help prevent gingivitis, plaque, cavities, and tartar.

        (i) Colgate Total contains 0.24% sodium fluoride and 0.30% triclosan and is formulated with the polymer **Gantrez**, which works to prolong the contact of triclosan with oral structures.

        (ii) Therefore, Colgate Total continues to work in between brushings.

    (b) Colgate Total has been accepted by the ADA as efficacious.

(3) **Anticalculous dentifrices** include the ingredients zinc chloride, zinc citrate, and 33% pyrophosphate to prevent calculus formation.

    (a) The ADA does not evaluate anticalculus claims because it regards the inhibition of supragingival calculus as a nontherapeutic use.

    (b) The ADA has directed that the following statement appear on all package and container labeling for accepted fluoride dentifrice products with calculus-control activity: [*Product name*] has been shown to reduce the formation of tartar above the gumline but has not been shown to have a therapeutic effect on periodontal diseases.

(4) **Cosmetic whitening agents.** The **most common ingredient** in these products that is responsible for whitening the teeth is **10% carbamide peroxide** (i.e., in Gly-Oxide, Rembrandt Professional Bleaching System) and hydrogen peroxide (i.e., in Crest Whitestrips).

    (a) Carbamide peroxide is a white crystal that reacts with water to release hydrogen peroxide, which in turn liberates free oxides.

    (b) Some cosmetic whiteners may contain hydrogen peroxide in gel or liquid form.

    (c) Three methods of tooth bleaching exist: in-office bleaching, dentist-supported home bleaching, and OTC home bleaching.

        (i) Patients should be encouraged to perform tooth bleaching only with a dentist's supervision.

        (ii) Crest Extra Whitening uses a patented soft-silica technology. Owing to this technology, the product contains 50% more silica, which greatly enhances the removal of extrinsic stains without increasing abrasiveness.

        (iii) Colgate Luminous also contains a silica whitening technology and fluoride.

    (d) **Possible risks** associated with using whitening products include alteration of normal flora, tissue damage, tooth sensitivity, gingivitis, and potentiation of carcinogenic effects of other agents.

    (e) **Antiseptics** have been used as whiteners (e.g., Gly-Oxide).

(5) **Desensitizing agents** reduce the pain in sensitive teeth caused by cold, heat, acids, sweets, or touch. These products should be nonabrasive and should not be used on a permanent basis unless directed by a dentist.

    (a) Examples of **5% potassium nitrate compounds** include Colgate Sensitive, Sensodyne, Aquafresh Sensitive, and Crest Sensitivity.

    (b) Dibasic sodium citrate in pluronic gel and 10% strontium chloride were classified as class III pending further evidence of effectiveness.

(6) **Disclosing agents** aid in visualizing where dental plaque has formed. These products are for occasional use only and should not be swallowed. The FDA-approved product is a vegetable dye, Food, Drug, and Cosmetic (FD&C) Red No 3. Following use, the consumer should rinse the mouth with water and then expectorate.

(7) **Mouthwashes** may contain astringents, demulcents, detergents, flavors, germicidal agents, and fluoride. They can be used for cosmetic purposes, reducing plaque, or supplementing fluoride consumption.

    (a) **Cosmetic mouthwashes** freshen the breath. They are nontherapeutic and are not effective as an antiseptic agent. These mouthwashes are classified by their active

ingredients, alcohol content, and appearance. The most popular products are those that contain medicinal phenol and mint. The higher the percent of alcohol, the higher the effect of the flavor within the mouth.

(b) **Antiplaque mouth rinses.** Mouth rinses claiming anticalculus or tartar-control activity contain the same active ingredients as anticalculus dentifrices. Cool Mint Listerine has received the ADA seal of approval.

  (i) Cetylpyridinium chloride (CPC), a mouthwash ingredient, has been approved for class I for plaque and gingivitis treatment. Examples of products in this class include Cepacol, Scope, and Crest Pro-Health Rinse.

  (ii) Chlorhexidine is an active ingredient in some mouthwashes. An example is Colgate PerioGard.

  (iii) Staining is associated with the overuse of CPC and chlorhexidine.

  (iv) **Fluoridated mouthwashes** are used after cleaning the teeth and should be expectorated. Nothing should be put into the mouth for 30 mins after using these mouthwashes. The ADA has approved the following products: ACT Anti-Cavity Fluoride Rinse, ACT for Kids, and Colgate Phos-Flur Rinse.

(8) **Dental gums** are promoted to reduce plaque, whiten teeth, possibly reduce the risk of tooth decay, and freshen breath. Chewing gum is associated with increased salivary flow, which apparently produces a beneficial buffering effect against acids in the oral cavity.

  (a) Some contain baking soda as a mild abrasive cleaner and to neutralize acid.

  (b) Calcium may be added to help remineralize the teeth and prevent cavities.

  (c) These gums also contain xylitol, a sweetener that is less likely to cause cavities than sugar or sorbitol. Examples are Trident, Xtra Care, and Smart Mouth.

  (d) These gums are not a substitute for good oral hygiene, including brushing and flossing, but may be useful for people who are unable to brush after lunch.

  (e) It is not known if these products have any advantage over regular sugarless gum.

3. **Gingivitis** is inflammation of the gingiva. The gingiva may appear larger in size with a bluish hue caused by engorged gingival capillaries and a slow venous return.

  a. **Cause.** Gingivitis is caused by microorganisms that eventually damage cellular and intercellular tissues. **Chronic gingivitis** may be localized or generalized. The gums readily bleed when probed or brushed, and the patient should seek dental assistance.

  b. **OTC products** include anesthetics containing benzocaine (e.g., Orajel) to relieve the pain. FDA has issued a warning that the use of topical benzocaine is associated with a rare, but serious condition, methemoglobinemia. Mouthwashes may freshen the breath; however, it is important to consider the potential of these products to disguise and delay treatment of pathological conditions (e.g., gingivitis) before use. Also, acetaminophen (Tylenol) can be recommended. The patient should seek the advice of a dentist.

4. **Periodontal disease** is the result of chronic gingivitis left untreated.

  a. The periodontal ligament attachment and alveolar bone support of the tooth deteriorate.

  b. **Risk factors** include gender (men affected more than women), age (> 35 years old), smoking, lack of oral care and regular dentist visits, diabetes, hypertension, rheumatoid arthritis, and loss of anterior teeth.

  c. Periodontitis may be treated with prescription products:

  (1) Periostat (doxycycline hyclate, 20-mg capsules)

  (2) Atridox (doxycycline hyclate 10%) in the Atrigel Delivery System.

    (a) Atridox provides local antibacterial effects.

    (b) Low-dose doxycycline inhibits collagenase, an enzyme that destroys connective tissue in the gums, leading to tooth loss.

5. **Acute necrotizing ulcerative gingivitis (ANUG)** (also called **trench mouth**) is characterized by necrosis and ulceration of the gingival surface with underlying inflammation. This condition is usually seen in teens and young adults.

  a. **Signs** and **symptoms** of ANUG include severe pain, halitosis, bleeding, foul taste, and increased salivation.

  b. The **cause** of ANUG is unknown. It is postulated that it might be associated with the overgrowth of spirochete and fusiform organisms.

   c. **Risk factors** include anxiety, stress, smoking, malnutrition, and poor oral hygiene.
   d. **Treatment** consists of local debridement. Also, penicillin VK (penicillin V is a derivative of penicillin G; however, it is more stable in an acidic medium and, therefore, is better absorbed from the gastrointestinal tract) or metronidazole may be used in certain cases (e.g., widespread lesions).
   e. **OTC products** include acetaminophen and products with benzocaine (not eugenol because it may cause soft tissue damage). The patient should be advised to see a dentist. The use of salicylates is not recommended if the patient is predisposed to bleeding. Also, adequate nutrition, high fluid intake, and rest are essential. Rinsing the mouth with warm normal saline or 1.5% peroxide solution might be helpful for the first few days.

6. **Temporomandibular joint syndrome** is caused by an improper working relationship between the chewing muscles and the TMJ.
   a. **Signs** and **symptoms** include a dull, aching pain around the ear, headaches, neck aches, limited opening of the mouth, and a clicking or popping noise upon opening the mouth.
   b. **Risk factors** include bruxism (i.e., grinding the teeth) and occlusal (i.e., bite) abnormalities.
   c. **Treatment** consists of moist heat applied to the jaw, muscle relaxants, bite plates or occlusal splints, a diet of soft foods, correcting the occlusion, or surgery.
   d. **OTC products** that can help relieve the pain include oral analgesics (e.g., acetaminophen, ibuprofen).

7. **Teething pain.** The ADA has not accepted any product for teething pain. A **frozen teething ring** can provide symptomatic relief. Persisting pain may be treated with a local anesthetic such as benzocaine (found in Anbesol Baby and Baby Orajel). If a teething child presents with a fever, a physician should be contacted.

8. **Xerostomia** (i.e., dry mouth) is caused by improper functioning of the salivary glands (as in Sjögren syndrome and diabetes mellitus). **Artificial saliva** is available as an OTC product. The ADA has approved the following artificial saliva products: Moi-Stir, Salivart, Biotene Oral Balance.

C. **Common oral lesions and OTC products**
   1. **Canker sores** (also called **recurrent aphthous ulcers or recurrent aphthous stomatitis**)
      a. The **cause** of canker sores is unknown. Studies suggest that the sores may be caused by hypersensitivity to bacteria found in the mouth or dysfunction of the immune system initiated by minor trauma or stress. This is why physicians or dentists may use prednisone or a topical steroid to reduce allergic reaction or have the patient rinse with a compounded suspension. Peridex and Listerine appear to help decrease bacteria in the mouth.
      b. **Lesions** can occur on any nonkeratinized mucosal surface in the mouth (i.e., tongue, lips) and usually appear gray to yellow with an erythematous halo of inflamed tissue surrounding the ulcer. Most lesions persist 7 to 14 days and heal without scarring.
      c. **OTC products** can control the pain of canker sores, shorten the duration of current lesions, and prevent new lesions. Products include **protectants**, **local anesthetics**, and **debriding and wound-cleansing agents**.
         (1) **Protectants** include Orabase, denture adhesives (see II.F.2), and benzoin tincture. Denture adhesives are not approved for this use by the FDA.
         (2) **Local anesthetics**, such as benzocaine or butacaine, are the **most common anesthetics** found in these OTC products.
            (a) The FDA has approved the following ingredients:
               (i) Benzocaine (5.0% to 20%)
               (ii) Benzyl alcohol (0.05% to 0.1%)
               (iii) Dyclonine (0.05% to 0.1%)
               (iv) Hexylresorcinol (0.05% to 0.1%)
               (v) Menthol (0.04% to 2.0%)
               (vi) Phenol (0.5% to 1.5%)
               (vii) Phenolate sodium (0.5% to 1.5%)
               (viii) Salicyl alcohol (1.0% to 6.0%)
            (b) Examples of OTC local anesthetics for oral use include Anbesol, Blistex, Campho-Phenique, Orajel, Zilactin-B, and Zilactin-L.
            (c) The use of products containing substantial amounts of menthol, phenol, camphor, and eugenol should be discouraged owing to their ability to irritate tissue.

(d) Aspirin should not be retained in the mouth or placed on an oral lesion in an attempt to provide relief.

(e) **Prescription products.** Amlexanox (Aphthasol) has been approved for the treatment of canker sores.

   (i) It is applied four times daily after meals and at bedtime.

   (ii) Advise patients to start using the product as soon as they notice symptoms and to continue until the ulcer is healed, approximately 10 days.

(f) Gelclair is indicated for local management and relief of oral pain associated with aphthous ulcers. It provides oral pain relief by acting as a protective adherent barrier over the surface of the mouth and throat.

   (i) Patient should use one packet at least three times a day or as needed.

   (ii) Advise patients to mix one packet with 3 tablespoons of water, swish for a minute, then expectorate. Do not eat or drink for approximately 1 hr after treatment.

(g) **Orphan Drug products. Thalidomide** is indicated for aphthous ulcer and stomatitis in severely immunocompromised patients.

(3) **Debriding and wound-cleansing agents** include 10% to 15% carbamide peroxide, 3% hydrogen peroxide, and sodium bicarbonate. The FDA considers these active ingredients to be safe and effective for debriding or wound-cleansing agents for oral health care.

2. **Cold sores/fever blisters** (also called **herpes simplex labialis**) are caused primarily by the herpes simplex virus type 1 (HSV-1). HSV-1 is contagious and is thought to be transmitted by direct contact. An outbreak may be provoked by stress, minor infection, fever, or sunlight. Cold sores usually occur on the lips and are recurrent, often arising in the same location.

   a. **Presentation.** An outbreak is preceded by burning, itching, or numbness. Red papules of fluid-containing vesicles then appear, and these eventually burst and form a crust. These sores are typically self-limited and heal in 10 to 14 days without scarring.

   b. **OTC products** for cold sores include products that contain softening compounds (e.g., emollient creams, petrolatum, protectants), which keep the cold sore moist to prevent it from drying and fissuring. Local anesthetics in nondrying bases (e.g., Orabase, with benzocaine) decrease pain. Highly astringent bases should be avoided. The ADA contraindicates caustic agents (e.g., phenol, silver nitrate), camphor and other counterirritants, and hydrocortisone for the treatment of cold sores. Lesions should be kept clean by gently washing with mild soap.

   (1) **Docosanol 10%** cream (**Abreva**) is indicated for the treatment of cold sores. It prevents the cold sore infection from entering healthy cells. It is approved by the FDA to shorten healing time and duration of symptoms. Patients should apply the cream at the first sign of an outbreak and continue to apply the cream five times a day until the lesion is healed.

   (2) **Viractin** (2% tetracaine) is used for the temporary relief of pain and itching associated with cold sores.

   (3) If a **secondary infection** develops, bacitracin or Neosporin antibiotic ointments should be recommended. If necessary, the patient should consult a physician for a systemic antibiotic prescription.

   (4) A lip **sunscreen** should be used for patients whose cold sores appear to be caused by sun exposure.

   (5) The essential amino acid L-lysine has been used in oral doses of 300 to 1200 mg daily to accelerate recovery or suppress recurrence of cold sores. However, studies have produced conflicting data regarding L-lysine and its effect on the duration, severity, and recurrence rate of cold sores.

   c. **Prescription products**

   (1) **Valacyclovir (Valtrex)** is indicated for the treatment of herpes labialis.

   (2) **Acyclovir cream 5% (Zovirax)** is indicated for the treatment of cold sores in adults and adolescents > 12 years of age. Therapy should be initiated at the onset of sign and symptoms and applied five times per day for 4 days. Acyclovir is also available as an oral and ointment formulations.

   (3) **Penciclovir cream 1% (Denavir)** is an antiviral medication for the treatment of cold sores in adults and children 12 years of age and older. Patients should apply the cream every 2 hrs while awake for 4 days, beginning at the first sign of tingling or swelling.

D. Common oral infections and OTC products

1. **Candidiasis** (also called **thrush**) is caused by the fungus *Candida albicans*, which is the most common opportunistic pathogen associated with oral infections. Thrush has a milky curd appearance, and affected patients should contact a physician.

2. **Oral cancer.** The most common oral cancer is **squamous cell carcinoma**, which can appear as red or white lesions, ulcerations, or tumors.

   a. **Signs** and **symptoms** include a color change in the tongue, a sore throat that does not heal, and persistent or unexplained bleeding. Patients with any of these signs should contact a physician or a dentist.

   b. **Risk factors** include smoked and smokeless tobacco as well as alcohol.

   c. **Treatment** consists of eliminating use of tobacco and alcohol in any form (e.g., alcoholic beverages, mouth rinses with alcohol). Also, treatment generally includes **wide local excision** for small lesions and **en bloc excisions** for larger lesions (in continuity with radical neck dissection if lymph nodes are involved). Radiation, alone or combined with surgery, may be appropriate. Chemotherapy may be used as palliation or as an adjunct to surgery and radiation.

   d. **OTC medications** should not be administered until after checking with a physician. For example, OTC medications used for inflammation can increase the effects of methotrexate. Chemotherapeutic agents can produce many possible side effects that require immediate medical attention (e.g., chest pain, inflammation, unusual bleeding). Some examples of side effects that usually do not require medical attention include nausea, vomiting, loss of appetite or hair, and trouble sleeping. OTC medications can be useful in these cases; however, nausea and vomiting are treated by prescription medications such as ondansetron or metoclopramide. Nonpharmacological measures, such as avoiding disturbing environmental odors and vestibular disturbances, might be helpful in minimizing nausea and vomiting.

E. Recommended standard prophylaxis for prevention of endocarditis

1. **Amoxicillin** 2.0 g orally 30 to 60 mins before the procedure for adults, and 50 mg/kg orally for children, is the recommended standard prophylactic regimen for all dental, oral, upper respiratory tract, and esophageal procedures.

2. For patients who are **allergic to penicillin**, the recommended **alternative oral regimens** include the following:

   a. **Clindamycin**, 600 mg for adults; 20 mg/kg for children

   b. **Cephalexin**, 2.0 g for adults; 50 mg/kg for children

   c. **Azithromycin** or **clarithromycin**, 500 mg for adults; 15 mg/kg for children, 30 to 60 mins before the procedure

F. OTC denture products

1. **Denture cleansers** are either **chemical** or **abrasive** in respect to their cleansing ability.

   a. **Chemical** denture cleansers include alkaline peroxide, alkaline hypochlorite, or dilute acids.

   (1) **Alkaline peroxide** is the **most commonly used** chemical denture cleanser and is available as tablets or powders. It causes oxygen to be released, which creates a cleansing effect. Alkaline peroxide does not damage the surface of acrylic resins; however, it may bleach them.

   (2) **Alkaline hypochlorite** (i.e., bleach) dissolves the matrix of plaque but has no effect on calculus. It is both bactericidal and fungicidal. A **disadvantage** of alkaline hypochlorite is that it **corrodes metal denture components**. It can also bleach acrylic resin. Therefore, it should not be used more than once a week.

   b. **Abrasive** denture cleansers are available as gel, tablet, paste, or powder (e.g., silicates, sodium bicarbonate, dicalcium phosphate, calcium carbonate).

   (1) Dentures should not be soaked in hot water because the heat could distort or warp the appliances.

   (2) The ADA accepts the following denture cleansers as safe and effective: Efferdent and Polident.

2. **Denture adherents** contain materials (e.g., karaya gum, pectin, methylcellulose) that swell, gel, and become viscous to promote adhesion, which increases the denture attachment to underlying soft tissues.

   a. **Disadvantages.** As the use of denture adherents increases, the soft tissue deteriorates. Denture adherents can also provide a medium for bacterial and fungal growth. Daily use of denture adherents is not recommended.

   b. The ADA accepts the following denture adherents as safe and effective: Fixodent, Sea-Bond, Super Poli-Grip, and Effergrip.

G. **Pharmacist's responsibilities to the patient using OTC oral products**

1. **Refer** a patient to a dentist if the oral complaint involves an abscess with fever, swelling, malaise, lymphadenopathy, or purulent exudate.

2. **Remind** patients that cold and canker sores, with appropriate treatment, are usually a self-limiting problem.

3. Patients should be informed about **how to use recommended products**, the duration of use, the expectations of using the product, and the procedure to follow if the product is ineffective.

4. If a nonprescription product does not improve a condition, or if the condition worsens, use of the product should be discontinued and a physician or dentist should be contacted.

III. OPHTHALMIC OTC PRODUCTS

A. **Anatomy of the eye**

1. The **sclera**, also known as the white of the eye, functions to protect intraocular contents and maintain the shape of the eye.

2. The **cornea** is the main refracting surface of the eye.

3. The anterior chamber of the eye houses a continuous supply of **aqueous humor**, which is produced in relation to the intraocular pressure. The aqueous humor is responsible for nourishing the cornea.

4. The **iris** is the colored part of the eye that regulates the entrance of light through the pupil.

5. The **pupil** is the contractile opening at the center of the iris that dilates and constricts in response to light.

6. The **lens** is found directly behind the iris and pupil and is responsible for enabling the eye to accommodate, focusing for near and distance vision. The lens continues to grow throughout life, gradually becoming thicker over time. The lens is therefore susceptible to the degenerative effects of aging, most noticeably evident in the fifth decade of life as the inability to focus and refocus for near and distance vision.

7. Approximately two-thirds of the volume of the eye is occupied by the **vitreous humor**. As one ages, the gel-like characteristics of the vitreous humor is lost and shadows are cast by various cells, giving the illusion of "floaters."

8. The **retina** is composed of the optic disc, the retinal vessels, and the macula. The optic nerve enters the retina through the optic disc. The macula is responsible for central vision and the remaining parts of the retina are responsible for peripheral and color vision.

9. The **optic nerve**, also known as the second cranial nerve (CN II), transmits impulses from the retina to the brain.

B. **Ophthalmic formulations**

1. **Vehicles** provide increased viscosity, thereby enhancing contact time of the product. Vehicles commonly found in ophthalmic products include carboxymethylcellulose (CMC), povidone, polyvinyl alcohol (PVA), and hydroxypropyl methylcellulose (HPMC).

2. **Preservatives** provide antimicrobial activity for ophthalmic preparations and include benzalkonium chloride (BAK), chlorhexidine, methylparaben, propylparaben, ethylenediaminetetraacetic acid (EDTA), and sorbic acid.

3. **Antioxidants** prevent product deterioration. Common antioxidants found in ophthalmic preparations include edetic acid, sodium bisulfite, sodium metabisulfite, sodium thiosulfate, and thiourea.

4. **Wetting agents** reduce surface tension of the lens and include polysorbate 20, polysorbate 80, poloxamer 282, and tyloxapol.

5. **Buffers** are used in ophthalmic preparations to maintain a pH between 6.0 and 8.0. Buffers include acetic acid, boric acid, hydrochloric acid, phosphoric acid, potassium bicarbonate, potassium borate, potassium citrate, sodium acetate, sodium bicarbonate, sodium bisphosphate, sodium borate, sodium carbonate, sodium citrate, sodium hydroxide, and sodium phosphate.

6. **Tonicity adjusters** ensure an isotonic agent. These agents include dextrose, glycerin, potassium chloride, propylene glycol, and sodium chloride.

C. **Nonprescription ophthalmic agents**

1. **Ophthalmic demulcents (artificial tears)** are used to **hydrate and lubricate the eye** by stimulating tear production and decreasing tear evaporation. Products typically include one or more of the following as an active ingredient: **cellulose derivatives** (i.e., carboxymethylcellulose sodium,

hydroxyethyl cellulose, hydroxypropyl methylcellulose), **dextran 70**, **gelatin polyols** (glycerin, polyethylene glycol 300 & 400, polysorbate 80, propylene glycol), **polyvinyl alcohol**, or **povidone**. Formulations are available as drops or gels and include products such as Genteal, Clear Eyes Tears, Refresh, TheraTears, Moisture Eyes, and Visine Pure Tears. Initial dosing is recommended as two times daily, up to four times daily, as needed. However, solutions may be used hourly, if clinically indicated. To reduce ocular irritation, preservative-free artificial tears should be recommended to patients who will need to use the medication frequently.

2. **Ophthalmic emollients** include white petrolatum, mineral oil, and lanolin, which act to lubricate and hydrate the eye (e.g., Artificial Tears Ophthalmic Ointment, Lacri-Lube S.O.P. Ophthalmic Ointment). As an ointment, these agents are able to **provide increased contact time with the ocular surface but may result in blurred vision**. If possible, blurred vision may be minimized (or less noticeable) by decreasing the amount of ointment instilled into the eye or by administering the ointment at bedtime. Initial dosing is recommended as two times daily, but may be used as often as every few hours, or only occasionally, depending on patient response. Preservative-free ophthalmic ointments may reduce ocular irritation in patients requiring frequent dosing. When using eye drops and ointment, **drops should be instilled into the eye before applying ointment**.

3. **Vasoconstrictors** (decongestants) work by producing a **temporary constriction of the conjunctival blood vessels**, thereby reducing eye redness. Available ophthalmic vasoconstrictors include naphazoline, phenylephrine, tetrahydrozoline, and oxymetazoline. These agents **may have a rebound effect (congestion) if used in excess** or for extended durations and should be avoided in patients with narrow-angle glaucoma. Available products include Opti-Clear (tetrahydrozoline), Visine Original (tetrahydrozoline), and Visine L.R. (oxymetazoline).

4. **Antihistamines** may be used for the treatment of ophthalmic conditions associated with allergic rhinitis. Pheniramine and antazoline are nonprescription ophthalmic antihistamines but are only available in combination with the ophthalmic decongestant naphazoline. Ketotifen (e.g., Zaditor, Claritin Eye, Zyrtec Itchy Eye), is the only available nonprescription ocular antihistamine and mast cell stabilizer indicated for the temporary prevention of itching of the eye due to allergic conjunctivitis.
   a. Typical dosing of ophthalmic antihistamines is one to two drops in each eye three to four times daily.
   b. Ophthalmic antihistamines should not be recommended in patients with glaucoma or patients at high risk of developing narrow-angle glaucoma, as pupil dilation associated with the use of these agents may cause this disorder.
   c. Side effects of these agents may include burning, stinging, itching, foreign body sensation, dry eye, lid edema, and pupil dilation. Patients using ketotifen drops should also be advised of the possible adverse effect of bloodshot eyes.

5. **Astringents decrease ocular inflammation**. The only FDA-recommended astringent is **zinc sulfate**. Currently, there are no OTC ophthalmic products containing zinc sulfate.

6. **Irrigant solutions** work to **rinse and remove debris and contaminants** from the eye, while maintaining ocular moisture (e.g., Advanced Eye Relief Eye Wash).

7. **Hyperosmotic agents** include sodium chloride as the active ingredient (e.g., Muro-128) and function to increase the tonicity of the tear film, eventually eliminating excess fluid from the cornea.

D. **Eye disorders**
   1. **Dry eye,** also known as keratoconjunctivitis sicca, is a common condition in which patients complain of a foreign body sensation, ophthalmic itching, decreased tear production, redness, pain, and difficulty moving the eyelids. Symptoms are the result of a deficiency to produce aqueous, mucin, or lipid tear film components, which may be attributable to certain disease states (e.g., thyroid disease, Parkinson disease), infection, or medications (e.g., antihistamines, oral contraceptives). Nonprescription treatment for dry eye includes the use of **ophthalmic demulcents during the day and ophthalmic emollients at night**.
   2. **Conjunctivitis** is inflammation of the conjunctiva which may be caused by bacterial or viral infection, allergy, or environmental factors.
      a. **Allergic conjunctivitis** symptoms affect both eyes and include redness, mild edema of the eyelid, excessive tearing, extreme itching, stringlike mucoid discharge, and chemosis. Nonprescription treatment recommendations include avoidance of the allergen if feasible, cold compresses, vasoconstrictors, and antihistamines. Nonprescription ophthalmic products containing a combination of a vasoconstrictor and an antihistamine are available (e.g., Opcon A, Visine-A).

    b. The causes of **bacterial conjunctivitis** depend on a patient's age. Approximately one-quarter of patients presenting with bacterial conjunctivitis will have **concomitant otitis media**. Therefore it is prudent for all children presenting with a purulent ocular discharge on waking in the morning and abrupt onset of redness to have their ears examined for otitis media. **Treatment for bacterial conjunctivitis is prescription only**.

    c. **Viral conjunctivitis** is most often attributable to the **adenovirus** and is **highly contagious**. More commonly known as **"pink eye,"** individuals often experience an upper respiratory infection or are exposed to another individual with viral conjunctivitis before the onset of symptoms (e.g., pink eye, thick ocular discharge, extreme tearing, foreign body sensation). **Treatment is supportive** and may include cold compresses, ophthalmic demulcents, and topical vasoconstrictors.

3. **Chemical burns** can result from medications, chlorinated swimming pools, or exposure to toxic fumes or irritants (e.g., hairsprays, battery acid, vinegar, oven cleaners, lye). **Treatment includes immediate and continued irrigation** of the eye(s) with saline or sterile water and emergency attention from a physician or eye care specialist.

4. **Corneal edema** is characterized by **halos or star bursts** around lights, which are the result of an underlying disorder (e.g., damage to the eye). Once diagnosed by a physician, **hyperosmotic agents** such as Muro solution or ointment may be used to **draw the fluid away from the cornea**. Dosing should begin with a 2% solution used four times daily with the addition of a 5% ointment used at nighttime if needed. If unresolved, the 2% solution may be changed to a 5% solution with continued use of the ointment.

5. A **hordeolum**, more commonly known as a **sty**, is an infection of the glands of the eyelids caused by *Staphylococcus aureus*. Sties present as painful, red, and edematous but may be relieved by the application of **warm compresses** for 10 to 15 mins three to four times daily. Topical antibiotics may be required. Stye, an ophthalmic emollient, may be erroneously assumed to be for the treatment of a sty, but is only marketed for the relief of the symptoms (stinging, itching) associated with a sty.

6. A **chalazion**, simply a **granuloma**, may involve the glands of the eyelids or the surrounding area but is **not infectious**. When in its early stages, the inflammation may be relieved by **warm compresses** applied for 10 to 15 mins three to four times daily. If not resolved within 1 week, provider consultation is appropriate, and surgical excision may be necessary.

7. **Blepharitis** is a **bilateral inflammation of the eyelid margins**, attributable to *Staphylococcus*, seborrheic dermatitis, or a combination of the two. Blepharitis may be identified by red, scaly, thickened eyelids with possible loss of the eyelashes. Staphylococcal blepharitis requires antibiotic treatment, but seborrheic blepharitis may respond to lid hygiene with warm compresses for 15 to 20 mins two to four times daily, followed by lid scrubs with a mild detergent or purchased product (e.g., OCuSOFT Lid Scrub).

E. **Antioxidants**

1. The antioxidant vitamins include vitamin A (retinol and β-carotene), vitamin C, and vitamin E. **β-carotene 50 mg** every other day may prevent the development of cataracts, especially in smokers. However, the **use of antioxidants in patients who smoke increases the risk of lung cancer and should**, **therefore**, **not be recommended**. **Vitamin C** has been studied for the prevention of cataracts. However, insufficient data in published trials limits the recommendation of this supplement for this purpose.

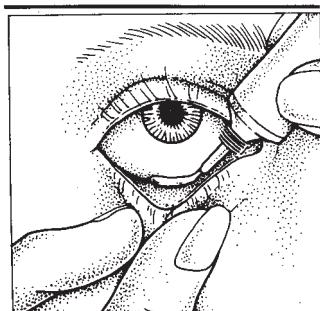
2. **Lutein**, an antioxidant pigment that functions to filter and protect the visual apparatus and its vascular supply, may be beneficial for improvement in vision in patients with dry age-related macular degeneration and for prevention of cataracts. However, more data by way of large randomized controlled trials are necessary to assess safety and efficacy of this supplement.

3. Patients with moderate and advanced age-related macular degeneration (ARMD) have shown a reduction in the progression of the disease and its associated vision loss with antioxidants plus zinc, as well as a combination of the following supplements: vitamin C 500 mg, vitamin E 400 IU, β-carotene 15 mg, zinc oxide 80 mg, and copper 2 mg. Ocuvite PreserVision, a formulation of the earlier antioxidants, zinc, and copper, is a dietary supplement currently under patent based on the promising results of the National Eye Institute's (NEI's) landmark Age-Related Eye Disease Study (AREDS). Studies of patients with mild or borderline ARMD have not shown benefit from antioxidant plus zinc supplementation. Therefore, this formulation should be **recommended only to patients who are nonsmokers** (owing to an increased risk of lung cancer) **with a diagnosis of moderate or advanced ARMD**.

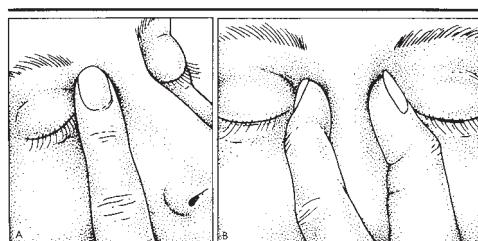
F. **Contact lenses**
1. **Types of contact lenses**
   a. **Hard contact lenses** were the first "original" contact lens, which were made of polymethyl-methacrylate (PMMA). Because of the hydrophobic nature of PMMA, the permeability of oxygen is limited, thus restricting the once-common use of hard contact lenses.
      (1) A **spectacle blur**, the inability to see well with glasses after removal of the contact lens, may occur with the use of hard lenses. The small diameter of the lens may also contribute to loss of the lens from the eye.
      (2) Care of hard contact lenses includes cleaning between the fingertips, soaking, and wetting with each removal of the lens from the eye. Furthermore, care must be taken to avoid scratching and chipping the surface of the contact lens.
   b. **Rigid gas-permeable (RGP) lenses** infuse oxygen permeability of soft contact lenses with the features of the hard contact lenses. RGP lenses are generally thicker than soft lenses, but more oxygen is delivered to the cornea by these agents.
      (1) The RGP lenses are available in daily- and extended-wear versions, approved for up to 7 days of wear.
      (2) Care of the RGP lens includes cleaning the lens in the palm of the hand with a surface-active cleaning product and an enzymatic product. The lens should then be soaked for a minimum of 4 hrs in a conditioning solution before reinsertion.
   c. **Soft lenses** are more comfortable and easier to remove than other contact lenses, however, the visual improvement noted may not be as significant as that which is seen with RGP or hard lenses. **Soft lenses should not be worn when applying topical ophthalmic products**, except those products specifically formulated for such use (e.g., rewetting solution).
      (1) Extended-wear soft contact lenses are approved for 7 days of continuous wear, although some (e.g., Focus Night and Day) may be used for 30 days continuously. Of note, not all patients will be able to tolerate the lens placement for 30 days.
      (2) Daily-wear soft contact lenses are designed to be worn for 1 day, up to 3 months, depending on the lens chosen. Because the lenses will be discarded within a short period, an enzymatic solution is generally not necessary for this type of lens, but general cleaning and disinfecting each time they are removed from the eyes is advisable. Sleeping in these lenses is not recommended.
2. **Solution ingredients** are generally specific to the type of contact lens chosen (i.e., soft, hard, or RPG). Therefore, the patient should ensure the product selected is in accordance with the type of lens worn.
   a. **Cleaning solutions** act to remove residue (e.g., debris, oils) from the contact lens by nonionic or amphoteric surfactants. If not cleaned regularly, the residue will build and harden, creating an ocular irritant, and possibly an ophthalmic infection. A homemade cleaning solution of baking soda and distilled water may be used, but is not typically recommended owing to the increased risk of ocular infection and difficulty in removing the agent from the lens. Available products are for hard lens (e.g., Lobob) or soft lens (e.g., AQuify).
   b. **Soaking solutions** are used to provide an aseptic environment for the lens once removed from the eye and may also aid in removal of residual contaminant on the lens not removed during cleaning (e.g., ReNu Fresh No Rub Formula). Soaking solutions generally have a higher concentration of preservative than wetting agents, but the lens should be thoroughly rinsed before insertion.
   c. **Wetting solutions** are applied directly to the lens before insertion into the eye. The function of the wetting solution is to transition the lens surface from hydrophobic to hydrophilic, provide lubrication, and enhance fingertip adhesion to allow for easier insertion. Wetting solutions are not necessary for insertion if the patient has significant tearing immediately after insertion of the lens. Saliva should not be used in place of a wetting solution because of the potential for infection.
   d. **Multipurpose products** are generally a solution composed of a cleaning solution, soaking solution, and wetting solution for ease of use with contact lenses (e.g., Biotrue Multi-purpose Solution for Soft Contact Lens, Opti-Free Replenish). However, a multipurpose product may not be as efficacious in the removal of the residue or providing adequate lubrication as the use of the three individual agents.
   e. **Rewetting solutions** may be used to clean and moisten the surface of the contact lens while the lens is still in the eye (e.g., Clear Eyes CLR).

    f. **Conditioning solution** is essentially an enhanced wetting solution, providing improved comfort and wettability of the lens (e.g., Boston Conditioning Solution).
  G. **Instillation of eye medication** (*Figure 19.1*)

    1. Wash hands.

    2. Shake suspensions to evenly distribute ingredients.


Guidelines for Instilling Eye Medications:

Follow these general guidelines when instilling eye medication:


- Shake suspensions or "milky" solutions to obtain the desired medication level.
- Wash hands thoroughly before and after the procedure.
- Ensure adequate lighting.
- Read the label of the eye medication to make sure it is the correct medication.
- Assume a comfortable position.
- Do not touch the tip of the medication container to any part of the eye or face.
- Hold the lower lid down; do not press on the eyeball. Apply gentle pressure to the cheek bone to anchor the finger holding the lid.

- Instill eye drops before applying ointments.
- Apply a 1/2-inch ribbon of ointment to the lower conjunctival sac.

- Keep the eyelid closed, and apply gentle pressure on the inner canthus (punctal occlusion) near the bridge of the nose for 1 or 2 mins immediately after instilling eyedrops.
- Using a clean tissue, gently pat skin to absorb excess eyedrops that run onto cheeks.
- Wait 5 to 10 mins before instilling another eye medication.

Figure 19-1. Guidelines for instilling eye medication. Reprinted with permission from Smeltzer SC, Bare BG. *Brunner & Suddarth's Textbook of Medical-Surgical Nursing.* 10th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2004.

3. Hold the lower eye lid down to form a pouch between the lid and the eyeball.
4. **Always apply eye drops before applying eye ointment.** Dispense the recommended number of drops into the pouch for eye drops. Keep the eyelids closed and apply gentle pressure to the inner canthus for 1 to 2 mins. Wait 5 to 10 mins before instilling another eye medication.
5. Ointments should be applied to the lower conjunctival sac as a 1/2-inch ribbon. To minimize blurred vision, a decreased amount of ointment may be applied to the eye. Blurred vision will be less noticed by the patient if the ointment is administered at bedtime, if feasible.

Study Questions

Directions for questions 1-17: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following nonprescription products is approved by the U.S. Food and Drug Administration (FDA) for treatment of impacted cerumen?

   (A) olive oil
   (B) carbamide peroxide
   (C) isopropyl alcohol 95% in anhydrous glycerin
   (D) docusate sodium

2. Which of the following otic conditions can be treated with a nonprescription agent?

   (A) vertigo
   (B) tinnitus
   (C) external otitis
   (D) water-clogged ear

3. Which of the following conditions is appropriate for the use of isopropyl alcohol 95% in anhydrous glycerin?

   (A) treatment of impacted cerumen
   (B) treatment of water-clogged ears
   (C) prevention of external otitis
   (D) treatment of external otitis

4. All of the following are true regarding carbamide peroxide *except* which one?

   (A) Carbamide peroxide softens earwax by the foaming action produced when oxygen is released.
   (B) Carbamide peroxide is safe for pharmacist recommendation in patients age 6 years and older.
   (C) Appropriate dosing for carbamide peroxide is 5 to 10 drops in the ear two times daily.
   (D) Carbamide peroxide should be used for a maximum of 4 days unless otherwise directed.

5. All of the following are true regarding external otitis *except* which one?

   (A) Initial treatment for external otitis is an oral antibiotic and corticosteroid.
   (B) Symptoms of external otitis include otic itching, pressure and fullness in the ear, pain, and otic discharge.
   (C) Mechanical trauma to the ear with cotton-tipped applicators can contribute to increased susceptibility to external otitis.
   (D) External otitis is also referred to as swimmer's ear.

6. Which of the following is an appropriate counseling tip for administration of otic drops?

   (A) Pull the earlobe up and back to straighten the ear canal for children.
   (B) Pull the earlobe down and back to straighten the ear canal for adults.
   (C) Fill the otic syringe with hot water.
   (D) If cotton is used, it should not be left in the ear for longer than 1 hr.

7. All of the following are true regarding ophthalmic formulations *except* which one?

   (A) Vehicles enhance contact time of the ophthalmic product.
   (B) Antioxidants prevent product deterioration.
   (C) Wetting agents reduce surface tension of the lens.
   (D) Tonicity adjusters are used to maintain a pH between 6.0 and 8.0.

8. Which of the following is appropriate treatment of diagnosed corneal edema?

   (A) hyperosmotic agent
   (B) vasoconstrictor
   (C) antihistamine
   (D) ophthalmic demulcent

9. Which of the following is also known as "pink eye"?

(A) allergic conjunctivitis
(B) bacterial conjunctivitis
(C) viral conjunctivitis
(D) environmental conjunctivitis

10. All of the following are antioxidants used for the treatment and/or prevention of ophthalmic disorders *except*

(A) vitamin D.
(B) β-carotene.
(C) vitamin C.
(D) lutein.

11. Which of the following solutions may be used to clean and moisten the surface of the contact lens while the lens is still in the eye?

(A) cleaning solution
(B) wetting solution
(C) soaking solution
(D) rewetting solution

12. Which of the following is true regarding ophthalmic antihistamines?

(A) Pheniramine and tetrahydrozoline are the only two nonprescription ophthalmic antihistamines available.
(B) Ophthalmic antihistamines are available only in combination with naphazoline.
(C) Ophthalmic antihistamines may cause burning, stinging, dry eyes, or mydriasis.
(D) Ophthalmic antihistamines may produce rebound congestion if used in excess or for extended durations.

13. Which of the following is the only astringent used in nonprescription ophthalmic agents that is recommended by the U.S. Food and Drug Administration (FDA)?

(A) edetic acid
(B) benzalkonium chloride
(C) zinc sulfate
(D) povidone

14. The definition of a surfactant (an ingredient in toothpaste) can best be described by which of the following statements?

(A) It prevents drying of the preparation.
(B) It removes debris by its detergent action and causes foaming, which is usually desired by the patient.
(C) It physically removes plaque and debris.
(D) It determines the texture, dispersiveness, and appearance of the product.
(E) It adds flavor to the preparation, which makes it more appealing to the patient.

15. A 16-year-old girl stops by a pharmacy on her way home from school. She says to the pharmacist, "I have been using Crest Whitestrips daily to bleach my teeth in preparation for my spring formal. However, my teeth are becoming very sensitive." Each of the following statements is advice that the pharmacist might suggest *except* which one?

(A) There is a possibility that you may damage the gingival tissue and tooth pulp.
(B) Oxidizing agents may have the potential for mutating or enhancing the carcinogenic effects of other agents (e.g., tobacco).
(C) Bleaching teeth is best done under dental supervision.
(D) Tooth sensitivity is not related to the frequency of use for such products.
(E) The most common ingredient in products responsible for teeth whitening is hydrogen peroxide, which can cause sensitivity.

16. All of the following products may be recommended by a pharmacist for the treatment of canker sores *except*

(A) benzocaine.
(B) Zilactin-B.
(C) Bayer aspirin placed directly on the oral lesion.
(D) Anbesol.
(E) Orajel.

17. The U.S. Food and Drug Administration (FDA) has approved which ingredient for protection against painful sensitivity of the teeth caused by cold, heat, acids, sweets, or contact?

(A) dicalcium phosphate
(B) sodium lauryl sulfate
(C) 5% potassium nitrate
(D) zinc chloride
(E) calcium carbonate

Directions for questions 18–20: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

A   if **I only** is correct
B   if **III only** is correct
C   if **I and II** are correct
D   if **II and III** are correct
E   if **I, II, and III** are correct

18. Which of the following compounds is/are considered a suspending agent (an ingredient in dentifrices)?

I. dicalcium phosphate
II. karaya gum
III. methylcellulose

19. Cold sore treatment might include which of the following ingredients?

    I. benzocaine
   II. docosanol
  III. camphor

20. Pharmacists can recommend over-the-counter (OTC) drug treatment for which of the following ear conditions?

    I. Swimmer's ear
   II. Accumulated earwax
  III. Water-clogged ears

Answers and Explanations

1. The answer is B *[see I.B.1.d.(1)].*
Carbamide peroxide is the only FDA-approved agent for cerumen removal. Olive oil, docusate sodium, and mineral oil are used to remove cerumen, but are not FDA approved. Isopropyl alcohol 95% in anhydrous glycerin is FDA approved for water-clogged ears, but not cerumen removal.

2. The answer is D *[see I.B.1.d; I.B.2–4].*
Patients exhibiting symptoms of vertigo, aside from motion sickness, should be referred to a medical provider. There is no FDA-approved treatment for tinnitus. External otitis (swimmer's ear) should be treated with a prescription otic antibiotic and corticosteroid. Only impacted cerumen and water-clogged ears may be treated with nonprescription products.

3. The answer is B *[see I.B.5].*
Isopropyl alcohol 95% in anhydrous glycerin is FDA approved only for treatment of water-clogged ears. Labels on products of isopropyl alcohol 95% in anhydrous glycerin should not claim to be used for treatment or prevention of external otitis (swimmer's ear) because this is a separate disorder from water-clogged ears. Treatment for impacted cerumen is carbamide peroxide.

4. The answer is B *[see I.B.1.d.(1)].*
Carbamide peroxide softens earwax through its foaming action when oxygen is released. It is labeled for ages 12 and older. Therefore, for children, age 12 with suspected cerumen impaction should be seen by a medical provider. Patients should instill 5 to 10 drops of carbamide peroxide into the ear two times daily for up to 4 days.

5. The answer is A *[see I.B.4.].*
External otitis is referred to as swimmer's ear. Although prolonged exposure to moisture is the typical cause of external otitis, mechanical trauma, such as the use of cotton-tipped applicators, fingers, or sharp objects in the ear, may cause the external ear canal to be more susceptible to damage and microorganism infiltration. Patients with external otitis may present with otic itching, a sensation of pressure or fullness in the ear, pain, or an otic discharge. Initial treatment is with an otic antibiotic and corticosteroid, not an oral antibiotic. Oral antibiotics are indicated when the infection is unresponsive to otic treatment, the individual is immunocompromised, or a middle ear infection coexists.

6. The answer is D *[see I.C].*
The earlobe should be pulled up and back to straighten the canal for adults and down and back to straighten the canal in children. Only warm water should be used in the otic syringe, as cold or hot water may induce dizziness. If cotton is used in the ear to retain the medication, it must be large enough to remove easily and should not be left in the ear for longer than 1 hr.

7. The answer is D *[see III.B].*
Buffers are used in ophthalmic preparations to maintain a pH between 6.0 and 8.0. Tonicity adjusters ensure the product is isotonic.

8. The answer is A *[see III.D.4].*
Once diagnosed by a physician, corneal edema is treated with hyperosmotic agents such as Muro solution or ointment to draw the fluid away from the cornea.

9. The answer is C *[see III.D.2].*
Viral conjunctivitis is most often attributable to the adenovirus and is more commonly known as "pink eye."

10. The answer is A *[see III.E].*
The antioxidant vitamins examined for the prevention and/or treatment of ophthalmic disorders include vitamin A (retinol and β-carotene), vitamin C, and vitamin E. Lutein is an antioxidant pigment that functions to filter and protect the visual apparatus and its vascular supply. Lutein is therefore thought to be beneficial for improvement in vision in patients with dry age-related macular degeneration and prevention of cataracts. Vitamin D is not an antioxidant vitamin.

11. The answer is D *[see III.F.2].*
Rewetting solutions are the only contact lens solutions that may be used while the lens is still in the eye.

12. **The answer is C** *[see III.C.4].*
    Currently, there are three available ophthalmic antihistamines: ketotifen, pheniramine, and antazoline. Pheniramine and antazoline are only available in combination with the ophthalmic decongestant naphazoline. Ophthalmic antihistamines may cause burning, stinging, dry eyes, or mydriasis. Vasoconstrictors, not antihistamines, may produce rebound congestion when used in excess or for extended durations.

13. **The answer is C** *[see III.B].*
    Edetic acid is an antioxidant and benzalkonium chloride (BAK) is a preservative used in ophthalmic formulations. Zinc sulfate is the only FDA-recommended astringent. Povidone is a vehicle used in ophthalmic formulations.

14. **The answer is B** *[see II.B.2.d.(1)].*
    Sodium lauryl sulfate is used frequently as a surfactant in most dentifrices. Its detergent action aids in the removal of debris, and the foaming is usually desired by the patient. There is no evidence that surfactants possess anticaries activity or decrease periodontal disease. The FDA considers surfactants an inactive ingredient in dentifrices.

15. **The answer is D** *[see II.B.2.d.(4)].*
    Teeth-whitening agents usually contain a peroxide-based ingredient, which can penetrate the surface area of the tooth to whiten. Cosmetic agents can alter the normal flora or cause tissue irritation, gingivitis, and teeth sensitivity. Antiseptics have been used as cosmetic whiteners (e.g., Gly-Oxide) along with hydrogen peroxide (e.g., Crest Whitestrips).

16. **The answer is C** *[see II.C.1.c.(2)].*
    Local anesthetics can provide relief of canker sore pain. The most common local anesthetics found in OTC products include benzocaine and butacaine. Some examples are Anbesol, Zilactin-B, and Orajel. Aspirin should not be retained in the mouth before swallowing or placed in the area of the oral lesions because of the high risk for chemical burn with necrosis.

17. **The answer is C** *[see II.B.2.d.(5)].*
    Desensitizing agents should not be abrasive or used on a chronic basis unless directed by a dentist. The products approved by the ADA include the ingredients: 5% potassium nitrate, 10% strontium chloride, and dibasic sodium citrate 2% in pluronic gel.

18. **The answer is D (II, III)** *[see II.B.2.d.(1).D].*
    Suspending agents are products that add thickness to the dentifrices. Examples are tragacanth, karaya gum, and methylcellulose. Dicalcium phosphate is categorized as an abrasive product.

19. **The answer is C (I, II)** *[see II.C.2.a–b].*
    Cold sore treatment involves keeping the lesion moist with emollient creams, petrolatum, or protectants. Local anesthetics (e.g., benzocaine, dyclonine, salicyl alcohol) may be used. In addition, docosanol 10% cream (Abreva) and tetracaine 2% (Viractin) are available without a prescription for the treatment of cold sores. Topical counterirritants (e.g., camphor) and caustics or escharotic agents (e.g., phenol, menthol, silver nitrate) are not recommended because they may further irritate the tissue. Cold sores are usually self-limiting and heal within 10 to 14 days without scarring.

20. **The answer is D (II, III)** *[see I.B].*
    Swimmer's ear requires an otic antibiotic, which is by prescription only.

Over-the-Counter Dermatological Agents

LARRY N. SWANSON, RYAN S. SWANSON

I. CONTACT DERMATITIS

A. **Introduction**

1. **Types of contact dermatitis.** Contact dermatitis is one of the **most common** dermatological conditions encountered in clinical practice. It has traditionally been divided into **irritant contact dermatitis** and **allergic contact dermatitis** on the basis of the origin and immunological mechanism.

   a. **Irritant contact dermatitis** is caused by direct contact with a primary irritant. These irritants can be classified as absolute or relative primary irritants.

      (1) **Absolute primary irritants** are intrinsically damaging substances that injure, on first contact, any person's skin. Examples include strong acids, alkalis, and other industrial chemicals.

      (2) **Relative primary irritants** cause most cases of contact dermatitis seen in clinical practice. These irritants are less toxic than absolute primary irritants, and they require repeated or prolonged exposure to provoke a reaction. Examples of relative primary irritants include soaps, detergents, benzoyl peroxide, and certain plant and animal substances.

   b. **Allergic contact dermatitis.** Many plants, and almost any chemical, can cause allergic contact dermatitis. Poison ivy is a classic example of allergic contact dermatitis, which is classified as a type IV hypersensitivity reaction. This type of allergic reaction is T cell–mediated, and the following **sequence of events** must occur to provoke it:

      (1) The epidermis must come in **contact** with the hapten (i.e., the specific allergen).

      (2) The **hapten–epidermal protein complex** (i.e., the complete antigen) must form.

      (3) The antigen must **enter the lymphatic system**.

      (4) **Immunologically competent lymphoid cells**, which are selective against the antigen, must form.

      (5) On **reexposure** to the hapten, the typical, local delayed hypersensitivity reaction (i.e., contact dermatitis) occurs.

      (6) The **induction period**, during which sensitivity develops, usually requires 14 to 21 days but may take as few as 4 days or more than several weeks. **Once sensitivity is fully developed:**

         (a) Reexposure to even minute amounts of the same material elicits an eczematous response, typically with an onset of 12 hrs and a peak of 48 to 72 hrs after exposure.

         (b) Sensitivity usually persists for life.

            (i) Most contact allergens produce sensitization in only a small percentage of exposed persons.

            (ii) Allergens or substances such as poison ivy, however, produce sensitization in > 70% of the population (50% to 95% are sensitive to the poison ivy plant).

2. **General phases of contact dermatitis**

   a. **Acute stage.** Wet lesions, such as blisters or denuded and weeping skin, are evident in well-outlined patches. Also evident are erythema, edema, vesicles, and oozing.

  b. Subacute stage. In this phase, crusts or scabs form over the previously wet lesions. Allergic contact dermatitis and irritant contact dermatitis caused by absolute primary irritants produce both the acute and subacute stages.

  c. Chronic stage. In this phase, the lesions become dry and thickened (i.e., lichenified). Initially, dryness and fissuring are the signs. Later, erythema, lichenification, and excoriations appear. The chronic phase of contact dermatitis usually occurs more often with irritant contact dermatitis caused by relative primary irritants.

B. Toxic plants. Poison ivy and poison oak are the **most common causes** of allergic contact dermatitis in North America. These plants were formerly known as the *Rhus* genus, but they are now properly referred to as the *Toxicodendron* genus.

 1. Poison ivy (*Toxicodendron radicans* and *T. rydbergii*) grows as a vine or as a bush. It is found in most parts of the United States but is especially prevalent in the northeastern part of the country. Poison ivy is often identified by its characteristic growth pattern, described by the saying, "Leaves of three, let it be."

 2. Poison oak (*T. diversilobum*) is found in the western United States and Canada. It grows as an upright shrub or a woody vine. *T. toxicarium* is found in the eastern United States.

 3. Poison sumac (*T. vernix*) grows in woody or swampy areas as a coarse shrub or tree and is prevalent in the eastern United States and southeastern Canada.

C. Toxicodendron dermatitis. For dermatitis to develop, previous sensitization (a 5- to 21-day incubation period) caused by direct contact with a sensitizing agent is required (see I.A.1.b). An oleoresin, **urushiol**, is the active sensitizing agent in poison ivy, poison oak, and poison sumac. There are slight differences in the chemical structures of the sensitizing agent in each of these plants, but the three agents cross-react.

 1. Release of the urushiol oil. The plants must be bruised or injured to release the oleoresin. It is **present in** the **roots**, **stems**, **leaves**, and **fruit**. Urushiol may remain active on tools, toys, clothes, pets, and under fingernails if those items have had contact with the broken plants.

  a. Urushiol does not volatilize, so one cannot get dermatitis from just being near a poison ivy plant; direct contact is necessary. **Burning plants**, however, can cause droplets of oil carried by smoke to enter the respiratory system, which can cause significant respiratory distress.

  b. A cut or damaged poison ivy, poison oak, or poison sumac plant initially yields a **clear fluid** containing the oleoresin, which **turns to a black inky lacquer** on exposure to air within a few minutes. This change can be a means for confirming identification of these plants.

  c. Because the oleoresin can rapidly penetrate the skin, the affected **area must be washed with soap and water within 10 mins** after exposure to prevent the dermatitis eruption. Washing up to 30 mins after exposure is still useful in removing some of the oleoresin.

 2. If an individual has been **previously sensitized**, the lesions usually occur within 6 to 48 hrs after contact with the allergen.

 3. Typically, the **initial eruption** exists as small patches of erythematous papules (usually streaks). **Pruritus (itching) is the primary symptom.**

  a. Papules may progress to vesicles, which may then ooze and bleed when they are scratched. Secondary infection may then develop. Often the inflammation is severe, and a significant amount of edema occurs over the exposed area.

  b. The lesions may last from a few days to several weeks. Left untreated, the condition rarely persists longer than 2 to 3 weeks.

 4. Poison ivy dermatitis does not spread. New lesions, however, may continue to appear for several days despite lack of further contact with the plant. This reaction may be due to the following facts:

  a. Skin that has been minimally exposed to the antigen begins to react only as the person's sensitivity heightens.

  b. Antigen is absorbed at varying rates through the skin of different parts of the body.

  c. The person inadvertently touches contaminated objects or may have residual oleoresin—for example, underneath the fingernails.

 5. Poison ivy is not contagious. The serous fluid from the weeping vesicles are not antigenic. No one can "catch" poison ivy from another person.

D. **Treatment.** The treatment of irritant and allergic contact dermatitis focuses on therapy for the specific symptomatology.

1. A pharmacist should **refer a patient** with a poison ivy eruption to a physician if
   a. The eruption involves a large area of the body (about 25%).
   b. The eruption involves the eyes, genital area, mouth, or respiratory tract (some patients may experience respiratory difficulties if they inhale the smoke of burning poison ivy plants).

2. The **severity of the eruption** depends on
   a. The quantity of allergen that the patient has been exposed to
   b. The individual patient's sensitivity to the allergen

3. **For severe eruptions**, a patient should consult a physician, who may prescribe **systemic corticosteroids**.
   a. Systemic corticosteroids are the cornerstone of therapy. One should use sufficiently high doses to suppress this inflammation. Generally, it is recommended that prednisone be given in a dose of 60 mg/day for 5 days, then reduced to 40 mg/day for 5 days, then 20 mg/day for 5 days, then discontinued. Prepacked dosage packs of corticosteroids used over 6 days provide too low of a dose over too short period.
   b. Some blisters may be drained at their base. The skin on top of the blister should be kept intact. Draining the blister allows more topical medication to penetrate for an antipruritic effect. Baths and soaks [see I.D.4.b.(1).(b)] may be beneficial as well.

4. **For a less severe eruption**, the principal goals are to relieve the itching and inflammation and to protect the integrity of the skin.
   a. Several therapeutic classes of agents can be used **to relieve itching**.
      (1) **Oral antihistamines** (particularly H_1-receptor blockers) are perhaps the most commonly used agents for pruritus. Antihistamines act as antagonists of the H_1 receptor found on mast cells, preventing the release of histamine and the subsequent histamine-mediated allergic response. These agents are available both over-the-counter (OTC), such as diphenhydramine (Benadryl), as well as per prescription, such as hydroxyzine (Atarax). Relief from itching may also be due to the sedative effects of these agents. As such, antihistamines may be preferred in patients who have trouble sleeping due to pruritus but should be used with caution in patients who must be alert during daytime hours.
      (2) **Topical hydrocortisone** (e.g., Cortaid), which is available in concentrations up to 1%, is minimally useful for its antipruritic and anti-inflammatory effects. Patients should be cautioned against using topical hydrocortisone for more than 7 days without first consulting a physician to ensure proper diagnosis before prolonged corticosteroid use.
      (3) **Counterirritants** include camphor (0.1% to 3.0%), phenol (0.5% to 1.5%), and menthol (0.1% to 1.0%). These agents have an analgesic effect as a result of depression of cutaneous receptors. The exact antipruritic mechanism is not fully known, but a placebo effect may result from the characteristic medicinal odors of these agents.
      (4) **Astringents** are mild protein precipitants that result in contraction of tissue, which in turn decreases the local edema and inflammation.
         (a) The principal agent used is **aluminum acetate** (Burow's solution).
         (b) **Calamine** (zinc oxide with ferric oxide, which provides the pink color) may also be used. Calamine contracts tissue and helps dry the area, but the formation of the thick dried paste may not be tolerated by some people.
      (5) The application of **local anesthetics**—for example, benzocaine (5% to 20%)—may relieve itching. Relief may be of short duration (30 to 45 mins), but application of benzocaine may be especially useful at bedtime, when pruritus is most bothersome. There is some question about the frequency of the sensitizing ability of benzocaine (0.17% to 5.0%); because of this, many practitioners avoid recommending local anesthetics for contact dermatitis. Certainly, treatment should be discontinued if the rash worsens.
      (6) **Topical antihistamines**—for example, diphenhydramine (Benadryl cream or spray)—may provide relief of mild itching principally through a topical anesthetic effect rather than any antihistamine effect. Many would not recommend their use because they may also have a significant sensitizing potential, and in children with varicella infections

(in which the integrity of the skin is compromised), systemic absorption has occurred with symptoms of anticholinergic toxicity produced. Topical and oral diphenhydramine should not be used concurrently.

(7) Zanfel is a topical solution that claims to wash urushiol from the skin even after the oil has bonded. Little clinical evidence exists to support this claim, and the cost of the product (about $40 for a 1 oz tube) is prohibitive for many patients.

b. Basic treatment

(1) Acute (weeping) lesions (see I.A.2.a)

(a) Wet dressings work on the principle that water evaporating from the skin cools it and thus relieves itching. Wet dressings have an additional benefit of causing gentle debridement and cleansing of the skin.

(b) Burow's solution (Domeboro) in concentrations of 1:20 to 1:40 as a wet dressing or a cool bath of 15 to 30 mins for three to six times per day provides a significant antipruritic effect.

(c) Colloidal oatmeal baths (e.g., Aveeno) may also provide an antipruritic effect.

(d) Topical therapy that may hinder treatment

(i) Local anesthetics and topical antihistamines may sensitize.

(ii) Calamine may make a mess without doing much good.

(2) Subacute dermatitis (see I.A.2.b). **A thin layer of hydrocortisone cream or lotion (0.5% to 1%)** may be applied three to four times a day to treat subacute dermatitis. Supplemental agents, such as topical anesthetics, may be used as well.

(3) Chronic dermatitis (see I.A.2.c) is best treated with hydrocortisone ointment. This stage is observed more frequently in forms of contact dermatitis that involve continuous exposure to the irritant or allergen. Again, chronic use of hydrocortisone (i.e., more than 7 days) should be monitored by a physician.

E. Prevention

1. The best treatment for poison ivy contact dermatitis is to **prevent contact** with the offending cause. This approach involves avoiding the plant and wearing protective clothing.

2. **Barrier preparations. Bentoquatam** (Ivy Block), an organoclay, is the first poison ivy blocker approved by the U.S. Food and Drug Administration (FDA) as safe and effective for prevention of urushiol-induced dermatitis. It comes as a lotion that should be applied at least 15 mins before contact with the plant and then every 4 hrs for continued protection against urushiol. It should be applied to leave a smooth, wet, visible film on the skin. Ivy Block may be removed with soap and water. Because of its alcohol content, patients should be instructed to stay away from flame during application until the product has dried on the skin.

II. SCALY DERMATOSES

A. Overview

1. Scaly dermatoses are diseases affecting the outer layer of skin, known as the **epidermis**.

2. These dermatoses are also called "**hyperproliferative disorders**," as they are characterized by a greater-than-normal turnover rate of epidermal skin cells. The typical turnover rate for skin cells is 25 to 30 days, defined as the amount of time it takes to migrate from the stratum germinativum (innermost layer of the epidermis) to the stratum corneum (outermost layer of the epidermis).

3. The three primary scaly dermatoses are

a. Dandruff

b. Seborrheic dermatitis

c. Psoriasis

B. Etiology

1. The exact cause for the accelerated cell turnover seen in the scaly dermatoses is unknown.

2. Patients who suffer from scaly dermatoses are found to have higher levels of **_Pityrosporum_** (a fungus that is found in the normal flora of the skin and scalp). Although there may be a link between the scaly dermatoses and elevated levels of *Pityrosporum*, it is unclear if the fungus leads to the dermatosis or if the dermatosis allows for the fungus to grow at a more rapid pace.

C.   Dandruff
   1.   Clinical presentation
      a.   Cell turnover rate is 13 to 15 days.
      b.   Primarily characterized by **dry white/gray "flakes"** scattered over the **scalp**.
      c.   **Scaling** and **pruritus** are the most common symptoms of dandruff.
      d.   Dandruff does not appear until puberty or later and peaks in early adulthood.
      e.   More severe in cooler months and less severe during summer months.
      f.   Not a serious medical condition, but embarrassment to the patient is a real concern.
   2.   Treatment
      a.   Nonmedicated shampoos
        (1)   Many patients who suffer with **mild dandruff** may be able to control the condition simply by washing with a nonmedicated shampoo on a **daily basis**.
        (2)   Patients should be counseled to **scrub the scalp** thoroughly while shampooing.
      b.   Medicated shampoos
        (1)   Those who suffer with more **moderate-to-severe dandruff** should be counseled to use a medicated shampoo.
        (2)   Most medicated shampoos should be used at least **twice weekly** for the first **2 to 3 weeks**. Patients should then decrease to once weekly or once every other week to maintain dandruff control.
        (3)   To apply medicated shampoo, thoroughly **rub shampoo into scalp and hair**. Leave on for 5 mins, then rinse and repeat. Patients may be instructed to use a scalp scrubber to ensure adequate penetration of the shampoo on the scalp.
        (4)   **Cytostatic agents** work by decreasing the rate of epidermal cell turnover.
          (a)   Coal tar (DHS Tar, Neutrogena T/Gel)
            (i)   Mechanism of action is likely related to the ability of coal tar to cross-link with DNA and inhibit cell division.
            (ii)   Prolonged exposure to coal tar may be carcinogenic, although patients who use coal tar only for treatment of skin conditions such as scaly dermatoses should not be at risk.
            (iii)   May cause **photosensitivity** and **folliculitis**. Do not use on or near groin, anus, and axillae.
            (iv)   Can **stain** clothing and bedsheets, as well as skin and hair (particularly blonde, gray, and bleached hair).
            (v)   Possesses a strong, unpleasant **odor**.
            (vi)   Available as shampoo, lotion, cream, ointment, foam, and soap in strengths ranging from 0.5% to 5.0%.
          (b)   Pyrithione zinc (DermaZinc, Head & Shoulders Dry Scalp)
            (i)   Cytostatic activity prevents epidermal cell growth and multiplication. Also possesses antifungal activity.
            (ii)   May be applied to scalp and skin. Different concentrations are approved for different conditions. Use products with 0.3% to 2.0% concentration for brief washings, such as shampooing; use products with 0.1% to 0.25% concentration when instructing patient to apply to scalp or skin without washing off (e.g., creams and lotions).
          (c)   Selenium sulfide (Dandrex, Selsun Blue)
            (i)   Possesses cytostatic and antifungal activities.
            (ii)   May cause **discoloration** of blonde, gray, and bleached hair, especially with prolonged periods of application.
            (iii)   Can leave scalp unusually **oily**.
            (iv)   Available as shampoo, lotion, and foam in concentrations from 1.0% (OTC) to 2.25% (via prescription).
        (5)   **Keratolytic agents** work by dissolving or breaking down the outermost layer of skin, causing peeling of the stratum corneum.
          (a)   Salicylic acid (Ionil, Salex)
            (i)   Decreases skin pH, thereby increasing the movement of water into the stratum corneum, which loosens and removes epidermal cells.

      (ii) Available for the treatment of scaly dermatoses at concentrations between 1.8% and 3%.

    (b) Sulfur

      (i) Exhibits antimicrobial/antifungal activity, although exact mechanism of action is unknown.

      (ii) Approved as a single agent for the treatment of dandruff, but rarely marketed by itself; most commonly seen in sulfur/salicylic acid combination products (with sulfur concentrations between 2% and 5%).

    (c) Sulfur/salicylic acid combination product (MG217 Medicated Tar-Free Shampoo, Scalpicin Maximum Strength)

      (i) When used in combination, individual ingredients may not exceed FDA-approved limits for treatment of dandruff (i.e., up to 5% sulfur and 3% salicylic acid).

      (ii) Sulfur can react with metals (such as copper and silver), discoloring products containing these metals.

  (6) Ketoconazole (Nizoral A–D)

    (a) A common treatment option in dandruff and seborrheic dermatitis due to its activity against *Pityrosporum* (see II.B.2).

    (b) Directions for application are the same as the aforementioned, with the caveat to leave **at least 3 days** between each shampoo.

    (c) Avoid use in patients < 12 years old and those who are nursing or pregnant, as safety and efficacy of ketoconazole have not been established in this population.

    (d) Available as OTC-strength (1%) and prescription-strength (2%) shampoos.

  c. Patients who do not experience improvement in their condition after **8 weeks** of appropriate self-treatment should be referred to their physician.

D. **Seborrheic dermatitis**

  1. Clinical presentation

    a. Cell turnover rate is 9 to 10 days.

    b. Primarily characterized by **dull**, **greasy**, **yellowish-red scales**.

    c. Can affect the scalp, face, ears, back, upper chest, axillae, and groin (i.e., **areas with high concentrations of oil-producing glands**).

    d. As with dandruff, **scaling** and **pruritus** are most common symptoms of seborrheic dermatitis.

    e. Onset is typically after puberty, affecting men more often than women.

    f. More severe in cooler months and less severe during warmer months.

    g. Exacerbated by **poor health and stress**.

    h. Important for patients to understand that condition persists for life; there is no curative treatment.

    i. Infantile seborrheic dermatitis is known as **"cradle cap."**

  2. Treatment

    a. Medicated shampoos are the cornerstone of therapy in seborrheic dermatitis.

      (1) Medicated shampoos carry the same instructions for use in seborrheic dermatitis as they do for dandruff (see II.C.2.b).

      (2) However, not all agents approved for treatment of dandruff have been approved for the treatment of seborrheic dermatitis. The following agents are primarily used in the treatment of seborrheic dermatitis (see II.C.2.b for a fuller discussion of these agents):

      (a) Coal tar

      (b) Pyrithione zinc

      (c) Salicylic acid

      (d) Selenium sulfide

      (e) Ketoconazole

    b. Topical corticosteroids

      (1) OTC formulations of **hydrocortisone** (**1%**) may be used as adjunct therapy in seborrheic dermatitis.

      (2) Counsel patients to use hydrocortisone on affected areas two to three times daily as needed. Hydrocortisone should not be applied to large areas of the body nor on or near the eyes.

(3) Hydrocortisone should **not be used for more than 7 days** without first consulting with the patient's physician. Treatment with a prescription-strength corticosteroid may be indicated if a patient does not fully respond to hydrocortisone.

3. Cradle cap

a. Cradle cap is not a serious medical condition and generally resolves by the time the affected infant reaches 12 months.

b. For infants with cradle cap, **shampoo the scalp frequently** with baby shampoo.

c. In more severe cases, a small amount of emollient (such as mineral oil, baby oil, vegetable oil, or white petrolatum jelly) may be applied to the scalp to help loosen and remove crusts. Extreme caution must be taken to ensure the infant does not aspirate these emollients.

d. A **fine-toothed comb** or **soft brush** may also be used to remove excess scales.

e. Some cases of cradle cap may require treatment with a mild topical corticosteroid, such as hydrocortisone. This should be done only under the care of a physician, and application of a corticosteroid to an infant's face should be avoided.

E. Psoriasis

1. Clinical presentation

a. Cell turnover rate is 3 to 4 days.

b. Multiple forms of psoriasis exist, including plaque (80% to 90% of cases), inverse, guttate, pustular, erythrodermic, and nail psoriasis.

c. Primarily characterized by **light pink/maroon-colored plaques covered with silvery scales**.

d. Plaques are most commonly found on the **elbows**, **knees**, **back**, **scalp**, **and external ear canal**. **Fingernails and toenails** can also be affected, causing nails to appear thick and crumbling.

e. **Itching** and **irritation** are the most common symptoms of psoriasis, although many patients may be asymptomatic.

f. Affects men and women equally, and onset can occur at any age.

g. As with dandruff and seborrheic dermatitis, psoriasis is less severe during warmer months.

h. Triggered by several factors, including **infection**, **stress**, **and certain medications** (namely, nonsteroidal anti-inflammatory drugs, β-blockers, antimalarials, lithium, and withdrawal from corticosteroid therapy). **Smoking**, **alcohol use**, and **obesity** also increase the severity of the disease.

i. Most cases of psoriasis are mild in severity, but death can rarely result from very severe, extensive cases. **Psoriatic arthritis** is a leading cause of morbidity.

j. No curative treatment exists. **Remissions and exacerbations** characterize the disease course for most patients.

2. Treatment

a. Only **mild cases** are indicated for self-treatment.

(1) Nonpharmacological measures

(a) Patients should be counseled to **soak in lukewarm water** several times a week and to **apply emollients** (such as petroleum jelly) to the affected areas immediately after bathing.

(b) Overweight/obese patients should **lose weight**.

(c) Patients who smoke should be counseled on **smoking cessation strategies**.

(d) Alcohol consumption should be limited or avoided completely.

(e) Patients should take measures to **reduce levels of stress** in their life if possible.

(2) Coal tar and **salicylic acid** are indicated for the treatment of psoriasis, but may be preferred for those patients with psoriasis limited to the scalp area. These agents should not be applied to large areas of the body.

(3) Hydrocortisone may also be effective, but its use should be limited to small areas of the body and should not be used for more than 7 days without prior prescriber approval.

b. Moderate-to-severe disease (defined as affecting more than 5% to 10% of body surface area) requires physician management.

(1) Prescription-strength **topical corticosteroids** (e.g., betamethasone, clobetasol, fluocinonide, and triamcinolone) are considered first-line agents. See *Table 20-1* for a listing of relative strengths of topical corticosteroids.

(a) For the treatment of psoriasis, these agents are typically applied twice daily.

(b) Systemic side effects are more likely with longer courses of therapy (i.e., > 4 weeks).

Table 20-1	RELATIVE POTENCIES OF TOPICAL CORTICOSTEROIDS		
Low Potency	**Medium Potency**	**High Potency**	**Very High Potency**
Alclometasone (Aclovate)	Betamethasone valerate (Beta Derm, Valisone)	Betamethasone dipropionate (Diprolene)	Clobetasol (Temovate)
Desonide (DesOwen, Desonate)	Fluocinolone (Synalar)	Desoximetasone (Topicort)	Halobetasol (Ultravate)
Hydrocortisone (Cortaid, Cortizone)	Fluticasone (Cutivate) Hydrocortisone butyrate (Locoid) Hydrocortisone valerate (Westcort) Triamcinolone (Aristocort, Kenalog)	Fluocinonide (Lidex) Halcinonide (Halog) Mometasone (Elocon)	

      (c) These agents are available in several vehicles, such as foams, sprays, and shampoos, to ensure maximal absorption at varying sites of application across the body.

   (2) **Topical vitamin D analogs**—including calcipotriene (Dovonex) and calcitriol (Vectical)—may be used as monotherapy, although they may be more effective when used in conjunction with topical corticosteroids.

   (3) Tazarotene (Tazorac) is a **topical retinoid** available as both a cream and a gel for long-term treatment of psoriasis.

   (4) **Calcineurin inhibitors**—such as tacrolimus (Protopic) and pimecrolimus (Elidel)—are preferred when treating psoriasis of the face, armpits, anogenital area, or breasts, as this may avoid requiring patients to apply corticosteroids to these sensitive areas. However, these agents carry a **black box warning** due to a potential link to lymphoma and skin cancer.

   (5) Various **systemic therapies** are used in the management of moderate-to-severe psoriasis.

      (a) **Methotrexate** is given at low doses once a week to help manage psoriasis. It may be effective in treating psoriatic arthritis, as well. Methotrexate should be used cautiously (if at all) in patients with hepatic disease due to **hepatoxicity**. Methotrexate is classified as **FDA pregnancy category X**.

      (b) **Acitretin** (**Soriatane**) is a synthetic retinoid (a vitamin A derivative). This agent is normally reserved for patients with severe psoriasis. Acitretin is classified as **FDA pregnancy category X**. Because studies have shown that its parent chemical, etretinate, can be detected in the body up to 2 years after discontinuing therapy, it is recommended that women of child-bearing potential who have taken acitretin not conceive for 3 years following discontinuation of the medication.

      (c) **Immunosuppressive medications**—such as cyclosporine (Gengraf), azathioprine (Imuran), and hydroxyurea (Droxia)—may be used in patients with severe psoriasis when other therapies are not tolerated. Of these three agents, cyclosporine is the only one with FDA approval for treatment of psoriasis. Patients taking cyclosporine should be monitored for adverse effects, notably nephrotoxicity, hyperkalemia, and hypertension.

      (d) **Biologics** are emerging as a preferred treatment option for patients with moderate-to-severe psoriasis. These agents have been shown to quickly improve psoriasis symptoms. Limits to use of these therapies include their high costs and the fact that they are administered via intramuscular (IM) or intravenous (IV) route. Biologics that have been FDA approved for psoriasis include adalimumab (Humira), alefacept (Amevive), etanercept (Enbrel), infliximab (Remicade), and ustekinumab (Stelara).

(6) Ultraviolet radiation (UV) has long been recognized as a safe and effective treatment for managing psoriasis. Varying types of phototherapy are available to patients. All phototherapy treatment regimens should be initiated and managed by a physician or dermatologist.

III. FUNGAL INFECTIONS

A. **Overview**
   1. Fungal skin infections, also known as "**tineas**" or "**ringworm**" (due to its characteristic circular appearance), are some of the most commonly encountered dermatologic conditions. It is estimated that up to 20% of the American population may be infected with a tinea infection at any given time.
   2. Several factors may predispose people to becoming infected with a tinea. Fungi grow best in **warm**, **moist environments**. Tight clothing or shoes that are worn on a repeated basis may facilitate fungal growth. Sharing public showers or pools can also promote the spread of tinea infections. Patients with diseases or conditions that suppress the body's natural immune response (such as diabetes, poor personal hygiene, malnutrition, or a compromised epithelium) are at greater risk of contracting tinea infections.
   3. Nonprescription therapies usually work quite well in resolving many types of tinea infections completely.
B. **Pathophysiology**
   1. Tinea infections are typically **superficial**. The fungi that cause tineas thrive on dead skin cells within the stratum corneum. Skin, hair, and nails may all be affected by a tinea infection.
   2. The three most prevalent fungi in the United States that cause tinea infections are *Trichophyton*, *Microsporum*, and *Epidermophyton*.
   3. Fungi may be transmitted to an unaffected individual either through direct contact with an infected person or animal or through contact with a fomite.
C. **Clinical presentation.** Tineas are categorized by the area of the body they affect.
   1. **Tinea capitis** is also known as "ringworm of the **scalp**." Tinea capitis occurs more frequently in children than adults. This may be due in part to a lack of social inhibition in sharing items like brushes and combs. Epidermal gland secretions also increase at puberty and have a fungicidal effect.
   2. **Tinea corporis**, or "ringworm of the **body**," is not limited to a specific area of the body. Rather, tinea corporis may take on several clinical appearances and can affect any area of the body. Often, patients with tinea corporis are infected with one or more additional tineas.
   3. **Tinea cruris** is more commonly referred to as "**jock itch**." The intertriginous areas of the **groin** make it an ideal environment for fungal infections. For anatomical reasons, males are more likely to suffer from tinea cruris than females.
   4. **Tinea nigra** is perhaps the least common of the tineas. It is mainly seen in people who live in humid coastal areas and may be transmitted through sand. Tinea nigra is primarily found on fingers and feet.
   5. **Tinea pedis**, or "**athlete's foot**," is by far the most common tinea infection. Sports players and people who share pools or showers are at the greatest risk for contracting tinea pedis. Once present, athlete's foot is exacerbated in patients who continue to wear shoes and socks, fostering a warm and moist environment for the fungus to survive.
   6. **Tinea unguium**, or **onychomycosis**, is a fungal infection of the **nails**. Toenails are more frequently affected by tinea unguium than fingernails. Onychomycosis can ultimately lead to loss of the affected nail if not treated appropriately.
   7. **Tinea versicolor** is a chronic fungal infection of the skin. Tinea versicolor is caused by *Pityrosporum* (see II.B.2) and primarily affects people living in hot, humid climates.
D. **Treatment**
   1. **Nonpharmacological measures**
      a. To maintain proper hygiene and to minimize the likelihood of contracting a tinea or spreading a tinea to another person, patients should **wash their body daily** with soap and water.
      b. Any contaminated towels and clothing must be **washed in hot water**.
      c. Patients with tinea infections should be counseled to **avoid sharing towels**.
      d. Allow shoes and clothing to **dry completely** before wearing them.

    e. As much as possible, noninfected patients should **avoid direct contact** with and **avoid using the same showers** as people who have fungal infections.

    f. If a shower must be shared, patients should be counseled to **wear shower shoes/sandals** while in the shower.

2. Pharmacological therapies

    a. Nonprescription topical medications

      (1) Only three types of tinea infections respond to self-treatment with nonprescription therapies: **tinea corporis**, **tinea cruris**, and **tinea pedis**. All other tinea infections should be referred to a physician for evaluation and treatment.

      (2) Each of the antifungals listed in the following text is applied topically for 1 to 4 weeks. These agents are generally well-tolerated, and systemic side effects are rare.

        (a) Butenafine (Lotrimin Ultra) is available as a 1% cream. Butenafine should only be used in patients 12 and older.

        (b) Clotrimazole (Desenex AF Cream, Lotrimin AF Lotion) is also sold as a 1% cream, lotion, or solution. Some patients will experience mild burning and stinging with use of clotrimazole.

        (c) Miconazole (Cruex Antifungal Spray Powder, Micatin Jock Itch Cream) is a 2% powder, cream, or lotion and is closely related chemically to clotrimazole.

        (d) Terbinafine (Lamisil AT) is available as a 1% cream, gel, or spray. Like butenafine, terbinafine should only be recommended in patients age 12 and older.

        (e) Tolnaftate (Tinactin) is a 1% cream, gel, or powder that has served as the OTC standard of care for fungal infections for decades (prior to many of these other products being introduced). Tolnaftate is the only active ingredient that carries FDA approval for both the treatment and prevention of athlete's foot, when used on a daily basis.

        (f) Undecylenic acid (Cruex Cream, Fungicure Liquid) is marketed in concentrations of 10% to 25% and comes in multiple forms, including a cream, solution, powder, and spray. Products containing undecylenic acid and its salts carry an unpleasant odor, which may be unacceptable to some patients.

    b. Prescription treatment options. Patients who do not respond to self-treatment with any of the OTC therapies described previously **within 1 week** should be referred to their primary care provider for evaluation. If the condition shows improvement within the first week, patients are free to continue with self-treatment.

      (1) Topical antifungals are available for use in patients who do not experience resolution of their tinea infection with OTC therapies or who have a tinea infection that cannot be self-treated.

        (a) Ciclopirox (Loprox) is available as a cream, gel, or lacquer for the treatment of tinea corporis, cruris, pedis, versicolor, and unguium.

        (b) Econazole (Spectazole) 1% cream is indicated for the treatment of tinea corporis, cruris, pedis, and versicolor.

      (2) More severe fungal infections require treatment with **systemic therapies**.

        (a) The **azole antifungals** [**fluconazole** (Diflucan), **itraconazole** (Sporanox), **ketoconazole** (Nizoral), **posaconazole** (Noxafil), and **voriconazole** (Vfend)] are generally well-tolerated. The azoles may cause varying degrees of hepatotoxicity, and the class is notorious for its wide spectrum of drug–drug interactions.

        (b) Griseofulvin (Grifulvin V) is available as both an oral tablet and suspension. Because griseofulvin increases photosensitivity, patients taking this agent should avoid prolonged exposure to the sun.

        (c) In addition to its status as an OTC topical agent, **terbinafine** (Lamisil) is also available as a prescription oral antifungal. It is considered the first-line agent for onychomycosis.

IV. ACNE

A. Overview

    1. Definition. Acne vulgaris is a disorder of the pilosebaceous units, mainly of the face, chest, and back. The lesions usually start as open or closed comedones and evolve into inflammatory papules and pustules that either resolve as macules or become secondary pyoderma, which results in various sequelae.

2. **Incidence**
    a. Acne vulgaris is the **most common** skin disease of adolescence; it affects about 85% of all people between the ages of 12 and 24.
    b. It affects primarily adolescents in middle school and high school, then decreases in adulthood.
3. **Importance**
    a. Acne vulgaris is usually **self-limiting**.
    b. However, the condition is significant to adolescents because of heightened self-consciousness about appearance.
    c. A great majority of people do not consult a physician for treatment of acne; therefore, a pharmacist can play a significant role.

B. **Origins and pathophysiology**
1. The **pathogenesis** of acne vulgaris involves **three events**.
    a. **Increased sebum production**
        (1) Sebum secretion is regulated primarily by **androgens**, which are actively secreted in both sexes beginning at puberty.
        (2) One of these androgens, testosterone, is converted to **dihydrotestosterone** (**DHT**).
        (3) DHT levels induce the sebaceous glands to increase in size and activity, resulting in increased amounts of sebum.
    b. **Abnormal clumping of epithelial horny cells within the pilosebaceous unit**
        (1) Normally, keratinized horny cells are sloughed from the epithelial lining of the pilosebaceous duct in the hair follicles and are carried to the skin surface with a flow of sebum.
        (2) In the patient with acne, the keratinization process is abnormal, characterized by increased adherence and production of follicular epithelial cells. This process is called **retention hyperkeratosis**, and it results in obstruction of the outflow of the pilosebaceous unit.
    c. **Presence of *Propionibacterium acnes*** (a gram-positive anaerobe)
        (1) People with acne have skin colony counts of *P. acnes* that are significantly higher than the counts of those without acne.
        (2) *P. acnes* produces several enzymes, including lipases, that break down sebum triglycerides to short chain free fatty acids (FFAs), which are irritating, cause comedones, and result in inflammation.
2. **Sequence of acne lesion development**
    a. Mechanical blockage of a pilosebaceous duct by clumped horny cells results in a **closed comedo** (i.e., **a whitehead**).
    b. When a closed comedo develops, it can form either a papule or an **open comedo** (i.e., **a blackhead**). The **dark color** of the blackhead is attributed to a combination of melanin, oxidized lipid, and keratinocytes, **not** to **dirt**.
    c. The lesion may enlarge and fill with pus, which is then termed a pustule.
    d. In more severe cases of acne, papules may develop into nodules or cysts.
    e. The term *pimple* nonspecifically refers to whiteheads, blackheads, papules, and pustules.

C. **Clinical features**
1. **Location.** Acne vulgaris lesions usually occur on the face, neck, chest, upper back, and shoulders. Any or all types of lesions may be seen on a single patient.
2. **Symptoms.** This condition is usually asymptomatic; however, some patients may have pruritus or pain if large, tender lesions are present.
3. **Classification.** It is important to differentiate **noninflammatory** from **inflammatory** acne to determine the best treatment approach. There have been many rating or grading scales for acne severity (*Table 20-2*). **Cystic acne** is present when the follicular wall ruptures occur deeper in the dermis and nodules and cysts are seen. Because of the potential for scarring, cystic acne patients should be referred to a physician for treatment. Scarring occurs with hypertrophic ridges, keloids, or atrophic "ice pick" pits.

D. **Complicating factors.** Other factors have been implicated in the exacerbation of acne.
1. **Drugs and hormones**
    a. Many topical and systemic medications (e.g., bromides, iodides, topical coal tar products, androgens, phenytoin, progestins, lithium, corticosteroids) can be comedogenic and can make acne worse or can induce acnelike eruptions (i.e., acneiform lesions).

| TABLE 20-2 | ASSESSMENT OF ACNE SEVERITY |

Grade of Acne	Qualitative Description	Quantitative Description
Comedonal		
I	Comedonal acne	Comedones only, < 10 on face, none on trunk, no scars; noninflammatory lesions only
	Blackheads	Open comedo; dilated hair follicle with open orifice to skin
		Dark color may be caused by oxidation of melanin or compacted epithelial cells; presence of lipids may contribute
	Whiteheads	Closed comedo; dilated hair follicle filled with keratin, sebum, and bacteria with obstructed opening to the skin
Papulopustular		
II	Papular acne	10–25 papules on face and trunk, mild scarring; inflammatory lesions < 5 mm in diameter
III[a]	Pustular acne	More than 25 pustules, moderate scarring; size similar to papules but with visible, purulent core
IV[a]	Severe/persistent pustulocystic acne	Nodules or cysts, extensive scarring; inflammatory lesions > 5 mm in diameter
	Recalcitrant severe cystic acne	Extensive nodules/cysts

[a] Some overlap with previous grade of acne.

      b. Acneiform eruptions differ from true acne lesions in that apparently no comedones form, eruptions are usually acute, and the lesions usually are all in the same stage of development.

  2. Stress does not cause acne but may exacerbate it.

  3. Diet. There is little evidence to support a relationship between diet and acne. Many different foods have been blamed for acne, from chocolates and sweets to shellfish to nuts and other fatty foods. Conflicting evidence exists on the effect of chocolate upon acne, making it difficult to say definitively that chocolate does or does not affect acne. Most dermatologists today make the following recommendations regarding diet:

      a. The patient should eat a well-balanced diet. As with most other diseases, and as a matter of good health, excess fats and simple carbohydrates should be avoided.

      b. The patient who insists that certain foods cause exacerbation of acne should probably avoid those foods.

  4. Physical trauma or **irritation** can promote the rupture of plugged follicles, which can produce more inflammatory reactions. Scrubbing the face, wearing headbands, cradling the chin with the hand, and picking at the pimples can contribute to the primary inflammation process. **Gentle**, regular **washing** with soap and water can be beneficial.

  5. Cosmetics. Some cosmetic bases and certain cosmetic ingredients are comedogenic (e.g., lanolins, petroleum bases, cocoa butter). Preparations such as cleansing creams, suntan oils, and heavy foundations should be avoided.

  6. Menstrual cycle. Some women may notice flare-ups of acne during the premenstrual phase of the cycle. Fluctuations in the level of progesterone are the probable cause.

  7. Environmental factors. Very humid environments or heavy sweating lead to keratin hydration, swelling, and a decrease in the size of the pilosebaceous follicle orifice, which results in duct obstruction. The sun, as well as artificial UV light, can help acne by drying and peeling the skin, but both can also aggravate acne.

E. Treatment and care

  1. General

      a. Most patients can be treated successfully with either topically or systemically administered medications or both. Acne often improves when patients reach their early 20s.

      b. Even the most effective treatment programs may take several weeks to produce any clinical improvement. This aspect must be emphasized.

    c. People affected with acne should avoid anything that seems to worsen the condition (e.g., cosmetics, clothing, cradling the chin with the hand).

    d. The number and type of lesions should be roughly determined to assess further therapeutic responses.

    e. **Self-treatment with OTC agents** is appropriate only for patients with **noninflammatory grade I acne** of mild to moderate severity.

2. Cleansing recommendations

    a. Because many acne patients have oily skin, **gentle cleansing** two to three times daily is recommended for removing excess oil.

    b. Acne lesions cannot be scrubbed away. Compulsive scrubbing may actually worsen the acne by disrupting the follicular walls and thus setting the stage for inflammation.

    c. Mild facial soaps, such as Dove, Neutrogena, and Purpose, should be used to cleanse the skin.

    d. Medicated soaps containing sulfur, resorcinol, or salicylic acid are of little value because the medication rinses away rather than penetrates the follicle.

    e. Patients with mild comedonal acne might benefit from cleansers containing pumice, polyethylene, or aluminum oxide particles (e.g., Brasivol). However, patients with inflammatory acne or sensitive skin should avoid these products.

3. Approaches to treatment depend on the severity of the condition. Although acne cannot be cured, most cases can be managed successfully with topical treatment alone. Based on the pathogenesis of the condition, potential methods include

    a. **Unblocking** the sebaceous duct so that the contents can be easily expelled.

    b. **Decreasing** the amount of sebum that is secreted.

    c. **Changing** the composition of the **sebum** to make it less irritating by decreasing the population of *P. acnes*.

4. Nonprescription topical medications

    a. **Benzoyl peroxide** (2.5% to 10%)—for example, PanOxyl Aqua Gel—has traditionally been recognized as the most effective topical OTC agent for acne, and many OTC acne products contain it. For some time, benzoyl peroxide was considered a category III agent by the FDA, stemming from a lack of clear proof regarding its safety and efficacy. However, in 2010, benzoyl peroxide was reclassified as category I [agents that are generally recognized as safe and effective (GRASE)].

        (1) **Effects.** Benzoyl peroxide has irritant, drying, peeling, comedolytic, and antibacterial effects. The clinical response shows only minimal differences among the 2.5%, 5.0%, and 10% concentrations.

            (a) A **beneficial effect** should be noticed within about 2 weeks, but the usual length of a therapeutic trial is 6 to 8 weeks.

            (b) As for **adverse effects**, benzoyl peroxide may cause a burning or stinging sensation, which gradually disappears. Most of the adverse effects from this agent relate to its therapeutic effect of irritating and drying the skin. For this reason, the lowest concentration available should be chosen initially. About **2.5%** of patients will **develop a contact dermatitis** with its use.

            (c) The vehicle for benzoyl peroxide is also important in its overall activity. The alcohol gel vehicle tends to be more effective than the lotion or cream formulations.

            (d) Benzoyl peroxide can discolor certain types of fabric or clothing material and can also bleach hair.

        (2) **Mechanism of action.** Benzoyl peroxide has a dual mode of action, so it is effective against both inflammatory and noninflammatory acne.

            (a) Benzoyl peroxide decomposes to release oxygen, which is lethal to the *P. acnes* anaerobe.

            (b) As an irritant, it increases the turnover rate of epithelial cells, resulting in increased sloughing and promoting resolution of comedones.

        (3) **Application**

            (a) The affected area should be washed with mild soap and water, then gently patted dry.

            (b) The product should be massaged gently into the skin, avoiding the eyes, mouth, lips, and inside of the nose.

        (c) The product can be applied at night, left on for 15 to 20 mins to test sensitivity, then washed off.

        (d) If no excessive irritation develops, apply once daily for the first few days.

        (e) If drying, redness, or peeling does not occur in 3 days, increase application to twice daily.

        (f) If patients have to use benzoyl peroxide during the day, advise them to use a sunscreen and avoid unnecessary sun exposure.

    b. **Salicylic acid** (0.5% to 2.0%), an irritant keratolytic agent, results in increased turnover of the epithelial lining. Through this effect, salicylic acid probably promotes the penetration of other acne products.

    c. **Sulfur** (3% to 8%), **sulfur** (3% to 8%) **combined with resorcinol** (2%), **or resorcinol monoacetate** (3%)—for example, Clearasil Adult Care Acne Treatment Cream, Acnomel

        (1) Sulfur is a keratolytic agent and has antibacterial actions.

        (2) Sulfur traditionally has been recognized as a less desirable product because it may be acnegenic with continued use, and it has an offensive color and odor.

    d. **Resorcinol** is a keratolytic agent that has been recognized as safe and effective against acne **when the agent is combined with sulfur**.

F. **Prescription medications**, **both topical and systemic**, are included here for completeness and to put into perspective how OTC agents fit into acne therapy.

    1. **Topical prescription agents**

    a. **Tretinoin** (vitamin A acid, *trans*-retinoic acid, Retin-A) increases the turnover rate of nonadhering horny cells in the follicular canal, which results in comedo clearing and inhibits new comedo development.

        (1) **Effectiveness.** Tretinoin is probably the most effective topical agent for acne, especially acne characterized by comedones. It is best used for **noninflammatory** acne. Tretinoin also may be used in combination with antibiotics or benzoyl peroxide for management of inflammatory acne.

        (2) **Side effects.** Because of its irritant properties, tretinoin can cause **excessive irritation**, **erythema**, **peeling**, and increased risk for **severe sunburn**. There may be an initial exacerbation of the acne (pustular flare) at 2 to 4 weeks, but usually by 8 weeks, the patient will see marked improvement. Because this agent may cause photosensitivity, it should generally be applied at night.

        (3) **Application.** The cream formulation of tretinoin, which is less irritating than the gel form, should be used initially for patients with dryer skin. The patient with very oily skin may do well initially with the gel form. The retinoids should be applied 30 mins after washing because moisture on the skin increases absorption and irritation. To minimize irritation, initially such a product can be applied every other day for 2 weeks, then daily. Other irritating substances, such as strong abrasive cleaners and astringents, should be avoided during treatment with tretinoin. Newer microsize reformulations of this agent (Retin-A Micro, Avita) are less irritating.

    b. **Adapalene** (Differin) is a topical retinoid-like compound that is dosed once daily. It can be applied in the morning because of no photodegradation, and it has less potential for photosensitivity.

        (1) **Effectiveness**. It appears to cause less irritation than tretinoin with equivalent efficacy. Therapeutic results should be noticed in 8 to 12 weeks. It can be used as an alternative to tretinoin in individuals with mild to moderate acne.

        (2) **Side effects**. The same precautions that apply to tretinoin apply also for adapalene.

    c. **Tazarotene gel and cream** (Tazorac) is a retinoid prodrug for mild to moderately severe facial acne that is applied once daily in the evening. It has similar efficacy and precautions as tretinoin, and the dose-related **adverse effects** include itching, burning, stinging, and erythema (redness). The gel form appears to be more irritating than tretinoin. A pustular flare may occur at about 10 to 14 days after this product is begun.

    d. **Topical antibiotics: erythromycin** (Eryderm), **clindamycin** (Cleocin-T) and **tetracycline**. These topical antibiotics are most effective when used in combination with benzoyl peroxide or topical retinoids. Combination products containing benzoyl peroxide and erythromycin

(Benzamycin) and benzoyl peroxide and clindamycin (BenzaClin) are also available. When these antibiotics are used alone, bacterial resistance occurs rapidly. Benzoyl peroxide use in combination with these antibiotics protects against this resistance.

  (1) Mechanism of action. The mechanism of action apparently involves suppression of the *P. acnes* organism, which in turn minimizes the inflammatory response due to the acne.

  (2) Application. These antibiotics are applied directly to acne sites, thus minimizing serious side effects from oral administration.

  (3) Side effects. There are **minimal** side effects to these topically applied antibiotics. **Mild burning** or **irritation** may occur. Although daily topical **clindamycin** does not produce detectable levels in the urine after 8 weeks of administration, there is a potential risk of **pseudomembranous colitis**. **Tetracycline** can cause a **yellow staining of the skin**.

  e. Azelaic acid (Azelex) and **sodium sulfacetamide and sulfur** are additional topical agents that are less effective than the other topical prescription agents. These agents might be used when others are not tolerated or as adjuncts to other therapies.

2. Systemic prescription agents

  a. Oral antibiotics/anti-infectives are the most effective agents against inflammatory lesions because they suppress *P. acnes*. They may be used when topical combinations are not tolerated or have failed. Oral antibiotics have an onset of action of 3 to 4 weeks. They are prescribed for daily use over 4 to 6 months and then tapered and ultimately discontinued with acne improvement. Antibiotics do not affect existing lesions, but prevent future lesions through this effect. *P. acnes* resistance to antibiotic therapy has become an increasing problem; erythromycin resistance is the most commonly reported, and minocycline resistance is reported rarely. As noted previously, concomitant administration of benzoyl peroxide may decrease the incidence of resistance.

  (1) Tetracycline is the **most frequently used** oral antibiotic for acne. It is preferred because of its effectiveness, low toxicity, and low cost. This agent should be taken on an empty stomach; food, antacids, iron, and dairy products decrease absorption. Tetracycline also has direct anti-inflammatory effects in acne.

  (a) Initial dose is 250 mg, two to four times daily, gradually reduced to a maintenance dose of about 250 mg per day.

  (b) Side effects. The more common adverse effects include upset stomach, vaginal moniliasis, and photosensitivity.

  (2) Erythromycin (E-Mycin) may be used as an alternative to tetracycline.

  (a) Initial doses range from 500 to 2000 mg per day in divided doses. A maintenance dose ranges from 250 to 500 mg per day.

  (b) Side effects. The primary side effect associated with erythromycin is gastrointestinal distress.

  (3) Minocycline (Minocin) **or doxycycline** (Vibramycin). Either of these agents can be taken in doses of 50 to 200 mg per day. Because of greater lipid solubility and enhanced penetration into sebaceous follicles, these agents may be useful for refractory cases. Either can be taken if bacterial resistance is suspected to erythromycin or if intolerable gastric irritation occurs after oral tetracycline. These two agents can be taken with food. Side effects to minocycline, including dizziness or vertigo and headache, discoloration of skin and visceral tissue, and drug-induced lupus erythematosus, limit the use of this agent. Doxycycline may be photosensitizing and should be swallowed with adequate fluids to prevent esophageal ulcerations.

  (4) Trimethoprim-sulfamethoxazole (Bactrim, Septra) has been used successfully in patients with acne resistant to erythromycin or tetracyclines. Minocycline and doxycycline are preferred over this drug combination because of its side-effect profile. **Oral clindamycin** (Cleocin) is used rarely because of the risk of pseudomembranous colitis.

  b. Oral isotretinoin (Accutane) is a vitamin A derivative indicated for **severe nodulocystic acne**. A single course of therapy results in a long-term stable remission in > 80% of patients.

  (1) Mechanism of action. Although the exact mechanism is unknown, isotretinoin decreases sebum production and keratinization, and it reduces the population of *P. acnes*.

      (2) Dosage. Treatment is usually begun with a daily dose of 0.5 mg/kg and increased to 1 mg/kg given in two divided doses with food for the usual duration of 20 weeks. A micronized formulation allows for lower once daily dosing with no regard to food intake.

      (3) Side effects include

        (a) Mucocutaneous dryness. Cheilitis (i.e., inflammation of the lips), dryness of the nasal mucosa, and facial dermatitis may occur with isotretinoin use. These effects can be treated with topical lubricants. Dryness of the eyes can also occur, so people using isotretinoin should not wear contact lenses.

        (b) Elevated serum levels. Isotretinoin may elevate serum triglycerides and cholesterol, as well as liver enzymes.

        (c) Birth defects. Isotretinoin is a **potent teratogen** and should not be given to pregnant women. A strict risk management program for isotretinoin use requires physicians to register patients to document negative pregnancy tests before use. Physicians who prescribe this agent and pharmacies that dispense it must be registered in an electronic FDA system.

        (d) Psychiatric effects. There have been reports of depression, suicidal behavior, and suicide. Data are inadequate to establish a causal relationship between isotretinoin administration and depression and suicide. This information must be taken in the context that teenagers with acne may often be depressed related to their appearance.

   c. Antiandrogens and hormones

      (1) Estrogens can decrease sebum production through an antiandrogenic effect.

      (2) Some progestin agents in oral contraceptives (e.g., norethindrone, norgestrel) have androgenic activity that can stimulate sebum secretion resulting in acne. One of the progestins, **norgestimate**, is minimally androgenic, and when it is combined with **ethinyl estradiol** as a triphasic combination oral contraceptive agent (Ortho Tri-Cyclen), it is effective in the treatment of moderate acne in some women and is FDA approved for such. **Norethindrone acetate/ethinyl estradiol** (Estrostep) is also FDA approved for acne.

      (3) Spironolactone (**Aldactone**) is an oral antiandrogen which acts to decrease sebum production and may be used on a limited basis.

      (4) Corticosteroids. Although corticosteroids have been implicated as causing acne, they also can be used to treat severe acne. Intralesional injections of triamcinolone and systemic corticosteroids have been used for severe inflammatory acne and severe cystic acne, respectively. Prednisone (or its equivalent) in doses of 20 mg per day or higher may be used for a short period to quickly improve acne for important events like a wedding. Topical corticosteroids are not effective.

V. DRY SKIN

A. Overview

  1. The clinical term for dry skin is "**xerosis**."

  2. The incidence of dry skin increases with age. It is estimated that over 50% of adults suffer with dry skin.

  3. Dry skin occurs most often during the winter months.

B. Pathophysiology. Dry skin results when the stratum corneum does not retain enough water. This may result from several factors:

  1. Frequent washing and bathing (defined as multiple times in a day)

  2. Overuse of soap or other cleaning products that remove the skin's natural oils

  3. Environments with **excessively dry air and low humidity**

  4. Inadequate fluid intake

  5. Thinning of the epidermis (particularly in geriatric patients)

  6. Other chronic conditions, such as psoriasis, thyroid disorders, smoking, or malnutrition

C. Clinical presentation

  1. Dry skin is most frequently characterized by **pruritus**.

  2. Other signs of dry skin include a "**cracked**" **appearance to the epidermis**, **flaking or sloughing of skin cells**, and a **decrease in skin flexibility**.

D. **Treatment**
1. **Nonpharmacological measures**
   a. **Bathing**
      (1) Patients who suffer with dry skin should be counseled on bathing or showering for **brief periods** (3 to 5 mins) with **lukewarm** water.
      (2) When bathing, patients should wash with **bath oils** (such as mineral oil), **colloidal oatmeal products** (such as Aveeno Soothing Bath Treatment Formula), or **mild cleansers** with ingredients like petrolatum and glycerin (such as Cetaphil Gentle Cleansing Bar). Many of these products will make the tub and surrounding area slippery; care must be taken when getting in and out of the bathtub while using these therapies.
      (3) Immediately after stepping out of the bathtub or shower, patients should **pat themselves dry** with a soft towel (rather than rubbing all the moisture from their skin with a more aggressive drying technique).
   b. Patients with dry skin should be counseled to **drink at least 64 oz of water a day** (unless pre-existing medical conditions prevent them from doing so).
   c. Patients who smoke should be counseled on **smoking cessation** strategies. **Caffeine and alcohol should also be avoided**, as these can exacerbate dry skin.
   d. **Humidifiers** may be used to increase the moisture in the air around the patient, particularly in rooms of the house in which the patient spends lots of time (such as their bedroom).
   e. **Sunscreen** should be worn whenever the patient will be outdoors.
2. **Pharmacological therapies**
   a. **Emollients** (commonly referred to as **moisturizers**) soften and soothe the skin by filling the epidermis with tiny beads of oil. These products come in several different formulations, available in lotions, creams, and ointments. Emollients work best when applied to damp skin (immediately after exiting the shower, for example). Examples of emollient products include Eucerin Cream, Lubriderm Advanced Therapy Lotion, and Udderly Smooth Udder Cream. These products contain various combinations of multiple ingredients, including water, glycerin, mineral oil, and lanolin.
   b. **Humectants** draw moisture into the affected area from the air and surrounding tissue. Humectants are commonly added to emollient products. Examples include glycerin, sorbitol, and propylene glycol.
   c. **Keratin** is a protein that is found in the skin, hair, and nails. **Keratin-softening agents**, such as urea and lactic acid, can be found in single-ingredient products (such as Carmol 10 Lotion and Lac-Hydrin Five Lotion) or in combination with emollient products.
   d. **Astringents** suppress inflammation associated with dry skin, as well as clear away the "debris" of dead skin cells. Patients should be counseled to soak a washcloth in the astringent solution and apply it to the affected area for 15 to 30 mins several times a day. Aluminum acetate (Domeboro Astringent Solution) and witch hazel are the two most commonly recommended astringents.
   e. **Hydrocortisone** may be employed to treat the symptoms of inflammation and itching associated with dry skin, but it should not be used as monotherapy in the treatment of dry skin. Hydrocortisone should never be used for more than 7 days without first consulting with a physician; it is important to ensure that the patient's itching is not associated with a more serious underlying disorder.

VI. SUNLIGHT, SUNSCREENS, AND SUNTAN PRODUCTS

A. **Introduction.** Overexposure to sunlight damages skin. A suntan, which has traditionally been associated with health, is actually a response to injury. Of the three types of solar radiation, only the UV spectrum produces sunburn and suntan.
1. The **UV spectrum** ranges from 200 to 400 nanometers (nm). Natural and artificial UV light is further subdivided into three bands.
   a. **UVA** (320 to 400 nm) can cause the skin to tan, and it tends to be weak in causing the skin to redden. UVA is about 1,000 times less potent than a comparable dose of UVB in causing erythema, but it is only slightly blocked out by the ozone layer and reaches the earth's surface in 10 to 100 times the amount of UVB. Some have proposed that UVA be further subdivided

into UVA I (340 to 400 nm) and UVA II (320 to 340 nm). UVA I is less erythrogenic and melanogenic than UVA II or UVB. UVA II is similar in effect to UVB.

    (1) Uses. UVA is often used in tanning booths and in psoralen plus UVA (PUVA) treatment of psoriasis.

    (2) Disadvantages. UVA is responsible for many **photosensitivity** reactions, **photoaging**, and **photodermatoses**. UVA rays can also **penetrate deeply into the dermis** and augment the cancerous effects of UVB rays.

  b. UVB (290 to 320 nm) **causes the usual sunburn reaction** and stimulates tanning. It has long been associated with sunlight skin damage, including the various skin cancers. It is the **most erythrogenic** and **melanogenic** of the three UV radiation bands. Small amounts of this radiation are required for normal **vitamin D synthesis** in the skin.

  c. UVC (200 to 290 nm) does not reach the earth's surface because most of it is absorbed by the ozone layer. Artificial UVC sources (e.g., germicidal and mercury arc lamps) can emit this radiation.

2. The **visible spectrum** (400 to 770 nm) produces the "brightness" of the sun.

3. The **infrared spectrum** (770 to 1800 nm) produces the "warmth" of the sun.

B. Sunburn and suntan

  1. Sunburn is generally a **superficial burn involving the epidermis**. This layer is rapidly repaired while old cells are being sloughed off in a process called **peeling**. The newly formed skin is thicker and offers protection for the lower dermal layers.

    a. Normal sequence after mild to moderate sunlight UV radiation (UVR) exposure

      (1) Erythema occurs within 20 to 30 mins as a result of oxidation of bleached melanin and dilation of dermal venules.

      (2) The initial erythema rapidly fades, and true sunburn erythema begins 2 to 8 hrs after initial exposure to the sun.

      (3) Dilation of the arterioles results in increased vascular permeability, localized edema, and pain, which become maximal after 14 to 20 hrs and last 24 to 72 hrs.

    b. Manifestations range from mild (a slight reddening of the skin) to severe (formation of blisters and desquamation). If the effect is severe, the patient may experience pain, swelling, and blistering. Fever, chills, and nausea may also develop, as well as prostration, which is related to excessive synthesis and diffusion of prostaglandins.

  2. Suntan is the result of two processes:

    a. Oxidation of melanin, which is already present in the epidermis

    b. Stimulation of melanocytes to produce additional melanin, which is subsequently oxidized on further exposure to sunlight

      (1) With increased melanin production, the melanocytes introduce the pigment into keratin-producing cells, which gradually become darkened keratin and a full suntan in 2 to 10 days.

      (2) Tanning increases tolerance to additional sunlight and reduces the likelihood of subsequent burning. However, dark skin is not totally immune to sunburn.

      (3) There is little evidence to suggest that obtaining a "base tan" from a tanning booth will reduce the likelihood of sunburn.

C. Factors affecting exposure to UVR

  1. Time of day and season. The greatest exposure to harmful UVB rays occurs between 10 A.M. and 4 P.M. in midsummer. UVA rays are fairly continuous throughout the day and season.

  2. Altitude. Sunburn is more likely to occur at high altitudes. UVB intensity increases 4% with each 1,000-ft increase in altitude.

  3. Environmental factors. Atmospheric conditions (e.g., smog, haze, smoke) may affect (i.e., decrease) the amount of UVR reaching the skin. Although direct sunlight greatly reduces the amount of UV exposure needed to produce a burn, sunburn can occur without it. For example, sunburn can also develop on a cloudy day because there is some UVR penetration through cloud layers (60% to 80%). However, the **reflection of light rays** (e.g., by snow, sand, water) greatly **increases** the amount of UV **exposure to sunlight**.

  4. Predisposing factors. People with fair skin and light hair are at greater risk for developing sunburn and other UVR skin damage than their darker counterparts.

D. **Other reactions to sunlight (UVR) exposure**
1. **Actinic keratosis** is a precancerous condition and may occur after many years of excessive exposure to sunlight. Typically arising during middle age or later, this disorder manifests as a sharply demarcated, roughened, or hardened growth, which may be flat or raised, and it may progress to **squamous cell carcinoma**.
2. **Skin cancer.** Chronic overexposure to sunlight may lead to **squamous cell carcinoma**, **basal cell carcinoma**, or **malignant melanoma**.
   a. **Squamous cell carcinoma.** Lesions usually appear as thickened, rough, scaly patches, which can bleed, and most commonly develops from actinic keratosis. It accounts for about 15% of skin cancers.
   b. **Basal cell carcinoma.** This is the most common of all skin cancers and accounts for about 80% of skin cancers. It may appear as pearly or translucent bumps and originates in the basal cells.
   c. **Malignant melanoma.** Malignant melanoma originates from melanocytes and is the deadliest form of skin cancer, and its incidence has been increasing. Moles should be watched for indications of malignancy—the **ABCD**s are
      (1) **A**symmetrical shape
      (2) **B**order irregularity
      (3) **C**olor that is nonuniform
      (4) **D**iameter > 6 mm
   d. Malignant melanoma formation may be associated with intense, intermittent overexposure to the sun (sunburning).
3. **Drug-induced photosensitivity reactions**
   a. **Types**
      (1) **Photoallergy reactions** occur when light makes a drug become antigenic or act as a hapten (i.e., a photoallergen). These reactions also require previous contact with the offending drug. Photoallergy reactions are relatively **rare** and are associated more frequently with topically applied agents than with oral medications.
         (a) **Occurrence** of these reactions is not dose related. The patient is usually cross-sensitive with chemically related compounds.
         (b) **Rashes** are most prominent on light-exposed sites (i.e., face, neck, forearms, back of hands), and they usually occur, after an incubation period of 24 to 48 hrs of combined drug and sun exposure, as an intensely pruritic eczematous dermatitis (a severe rash).
      (2) **Phototoxic reactions** occur when light alters a drug to a toxic form, which results in tissue damage that is independent of an allergic response.
         (a) **Occurrence.** These reactions are usually dose related, and the patient usually has no cross-sensitivity to other agents.
         (b) **Rashes** often appear as an exaggerated sunburn and are usually confined to areas of combined chemical and light exposure.
   b. **Implicated drugs.** Many drugs have been implicated in causing photoallergy and phototoxic reactions: thiazides, tetracyclines, phenothiazines, sulfonamides, and even sunscreens. Some drugs may produce both types of reactions.
   c. **Prevention.** Standard sunscreens do not always prevent photosensitivity reactions caused by drugs. UV light above 320 nm (i.e., UVA light) has been implicated in inducing photosensitivity reactions, so a chemical or physical sunscreen must cover this spectrum (see VI.E.2).
4. **Photodermatoses** are skin conditions that are triggered or worsened by light within specific wavelengths. These conditions include polymorphous light eruption (PMLE), lupus erythematosus, and solar urticaria.
5. **Photoaging** is a skin condition that is not merely an acceleration of normal aging. UVA radiation is thought to be involved. The skin appears dry, scaly, yellow, and deeply wrinkled; it is also thinner and more fragile.

E. **Sunscreen agents.** People can protect their skin from harmful UVR by avoiding exposure to sunlight and other sources of UVR, wearing protective clothing, and applying sunscreen.
1. **Application and general information.** All exposed areas should be covered evenly and liberally (2 mg/cm^2, which requires about 1 oz of sunscreen per one total body application for an

average-size adult in a swimsuit) with sunscreen, optimally 30 mins [(2 hrs for para-aminobenzoic acid (PABA) and PABA esters)] before sun exposure to allow for penetration and binding to the skin.

a. **Substantivity.** Perspiration, swimming, sand, towels, and clothing tend to remove sunscreen and may increase the need for reapplication.

   (1) Substantivity is the ability of a sunscreen formulation to adhere to the skin while swimming or perspiring.

   (2) **Water resistant** labeling indicates that the formula retains its sun protection factor (SPF) after 40 mins of activity in the water, sweating, or perspiring.

   (3) Labeling a product as **very water resistant** indicates that the product retains SPF after 80 mins of activity in the water, sweating, or perspiring.

b. **Protection.** Sunscreen products vary widely in their ability to protect against sunburn; the SPF and UVA/UVB ray protection should be noted to determine the level of protection. Moreover, baby oil, mineral oil, olive oil, and cocoa butter are not sunscreens (but are often used to attain a tan).

   (1) **SPF** gives the consumer a guide for determining how the product will protect the skin from UV rays, principally UVB rays. An SPF of 30 blocks about 97% of the UVB rays. Scientific evidence shows a point of diminishing returns at levels > 30; any benefits that might be derived from using sunscreens with an SPF > 30 are negligible. The FDA's most recent monograph requires sunscreens with an SPF > 50 to be labeled as "SPF 50+," as clinical evidence suggests no additional UV protection above SPF 50. The American Academy of Dermatology recommends that adults and children use sunscreens with an SPF of **at least 30**.

      (a) **Definitions.** A **minimal sun protection product** has an SPF of 2 to less than 12; a **moderate sun protection product** has an SPF of 12 to less than 30; a **high sun protection product** has an SPF of 30 or more.

      (b) **Derivation.** SPF is defined as the **minimal erythema dose** (**MED**) of protected skin divided by the MED of unprotected skin. MED is the amount of solar radiation needed to produce minimal skin redness.

      (c) **Example.** A person who usually gets red after 20 mins in the sun and wants to stay in the sun for 2 hrs (120 mins) should apply a sunscreen with an SPF of 6 (120 mins ÷ 20 mins = SPF 6). An SPF 6 product should provide adequate coverage, provided it is not washed off (as from swimming) or dissolved by sweat. An SPF of 15 blocks approximately 93% of the UVB rays.

      (d) Until now, there has been **no generally accepted comparable term that measures UVA protection**, although a few have been proposed. One major concern is that people may be staying out in the sun longer when they use sunscreen products that have high SPF values. If inadequate UVA protection is provided in that product, these individuals may be exposing themselves to very high amounts of UVA, with the potential for significant overexposure to this form of UV radiation.

   (2) **Skin cancer prevention.** Sunscreen application has been shown to prevent squamous cell carcinoma, but it is not absolutely confirmed that their use prevents melanoma. In fact, some studies have found that individuals who regularly use sunscreen have a higher risk of this cancer (perhaps because they can stay out in the sun longer before burning and thus experience longer periods of sun exposure).

c. **Sensitivity.** Some people may be hypersensitive to sunscreen agents. Discontinue use if signs of irritation or a rash occur. Contact dermatitis may occur with some of these agents. If sensitive to benzocaine, procaine, sulfonamides, or thiazides, avoid PABA or PABA esters.

d. **Specific information**

   (1) Do not use these products on infants younger than 6 months of age (there is concern about absorption of these agents).

   (2) Do not use a product with an SPF < 4 on children younger than 2 years of age (there is concern that an SPF < 4 will not provide adequate protection).

   (3) Recommend sunscreen products that are broad-spectrum sunscreens (i.e., that block both UVB and UVA).

2. The two basic **types of sunscreen agents** are physical sun blocks and chemical sunscreens (*Table 20-3*).

   a. **Physical sun blocks** are opaque formulations that reflect and scatter up to 99% of light in both the UV and visible spectrums (290 to 700 nm). Examples include **titanium dioxide** and **zinc oxide**. These sun blocks are less cosmetically acceptable than chemical sunscreens because they have a greasy appearance, but they may be useful for protecting small areas (e.g., the nose). These sun blocks are also useful for photosensitization protection. Newer, more dilute versions of titanium dioxide products and microfine, transparent forms of zinc oxide are more cosmetically appealing. Red petrolatum covers a lesser spectrum (290 to 365 nm).

   b. **Chemical sunscreens** act by absorbing a specific portion of the UV light spectrum to keep it from penetrating the skin. They can be categorized on the basis of their spectra of UVR blockage and basic chemical classification. Five main groups of chemical sunscreens are available.

      (1) **PABA** and **PABA esters** primarily absorb UVB rays. Examples are *p*-aminobenzoic acid, padimate O, and glyceryl PABA.

      (2) **Cinnamates** primarily absorb UVB rays. Examples are cinoxate and octyl methoxycinnamate.

      (3) **Salicylates** primarily absorb UVB rays. Examples are ethylhexyl salicylate and homosalate.

      (4) **Benzophenones** absorb UVB rays and sometimes extend into the UVA range. Examples are oxybenzone and dioxybenzone. Because of their extension into the UVA range, they are somewhat protective against photosensitivity reactions.

      (5) **Dibenzoylmethane derivatives. Avobenzone (Parsol 1789)** or butyl methoxydibenzoylmethane, provides coverage over the entire UVA range although its absorbance decreases dramatically at 370 nm. Photosensitivity reactions from medications may not be completely prevented in the 370 to 400 nm range. In combination with other agents that cover the UVB range, reasonable protection for both the UVA and UVB ranges can be achieved. It is the only available agent that blocks UVA wavelengths up to 400 nm.

      (6) **Other chemical sunscreens. Phenylbenzimidazole sulfonic acid** does not match up with any of the classes mentioned. It covers just the UVB range 290 to 320 nm.

      (7) **Ecamsule**, an agent incorporated into a combination product (Anthelios SX) with avobenzone and octocrylene, protects against both UVA and UVB.

   c. **OTC sunscreen products.** Most sunscreen products on the market contain combinations of two or more of the classes of chemical sunscreen agents described in preceding sections. To get adequate UVA protection, choose a product with avobenzone or a product with titanium dioxide or zinc oxide.

VII. WARTS

A. **Overview**

   1. Warts are caused by the **human papillomavirus (HPV)**.

   2. It is estimated that 7% to 10% of people have some type of wart.

   3. Most warts will resolve on their own in as little as 6 months to as long as 5 years.

B. **Pathophysiology**

   1. HPV is transmitted from an infected individual to a noninfected individual via **skin-to-skin contact**. Infected skin cells that have been shed from the host's body may also transmit HPV. The virus enters the body through some type of break or tear in the epidermis. Individuals with HPV may also **autoinoculate** unaffected areas of their own body by picking or scratching at a wart and introducing viral particles into other areas with a compromised epithelium.

   2. The incubation period for HPV ranges from **1 to 9 months**. The infected individual typically does not realize he or she has been infected until the wart appears.

C. **Types and characteristics.** Warts are categorized by the area of the body they affect.

   1. **Common warts** (verruca vulgaris) are most often seen on the hands and fingers although they can be found in nail beds and on the face. Common warts have a scaly, dome-shaped appearance.

   2. **Flat warts** (verruca plana) primarily affect the hands, knees, faces, and necks of children and young adults. As implied by their name, these warts have a flat appearance and tend to be flesh-colored.

Table 20-3	FDA APPROVED SUNSCREEN INGREDIENTS[1,4-6]

Ingredient (*Brand*)	Coverage	Notes
Chemical Sunscreens		
Benzophenones		
Dioxybenzone	UVA/UVB (260–380 nm)	Some people may have sensitivity to the benzophenones.
Oxybenzone (*Shade Sunblock* products)	UVA/UVB (270–350 nm)	
Sulisobenzone	UVA/UVB (260–375 nm)	
Cinnamates		
Cinoxate (*RV Paque*)	UVB (270–328 nm)	Cinnamates do not adhere well to the skin and need good substantivity vehicles.
Octocrylene (*Ban de Soleil SPF 8 + Color*)	UVB (250–360 nm)	
Octyl methoxycinnamate (*Hawaiian Tropic* and *Coppertone* products)	UVB (290–320 nm)	
PABA and PABA esters		
Aminobenzoic acid (PABA)	UVB (260–313 nm)	Penetrates horny layer of skin for lasting protection. Has substantivity on sweating skin but not much in water.
Padimate O (*Total Eclipse* products)	UVB (290–315 nm)	Can cause contact dermatitis and photosensitivity reactions in some people.
Salicylates		
Homosalate (*Coppertone* products, and tanning oils with low SPF)	UVB (295–315 nm)	Salicylates are weak sunscreens, but have good substantivity. They are not easily removed by sweating or swimming.
Octyl salicylate (*Sundown Sunscreen, Nivea Sun*)	UVB (280–320 nm)	
Trolamine salicylate (found in some oils with low SPF)	UVB (260–320 nm)	
Miscellaneous		
Ecamsule (*Anthelios SX*)	UVA (320–340 nm)	Approved by the FDA in 2006. Ecamsule has been marketed in Canada and Europe as *Mexoryl*.
Ensulizole	UVB (290–320 nm)	
Menthyl anthranilate (*A-Fil*)	UVA/UVB (260–380 nm)	Weak UV sunscreen with its best effectiveness in the UVA range.
Avobenzone, also known as Parsol 1789 (some Neutrogena products have *Helioplex*)	UVA (320–400 nm)	Isn't stable in light so it must be mixed with a physical sunscreen like titanium dioxide. *Helioplex* is a patented combination of oxybenzone and avobenzone with stabilizers to prevent the breakdown of avobenzone when it is exposed to light.
Physical Sunscreens		
Red petrolatum (*RV Paque*)	UVA/UVB (290–365 nm)	These products may be comedogenic. New micronized products may be more desirable than older opaque products.
Titanium dioxide (*TI-Baby Natural*)	UVA/UVB (290–770 nm)	With a chance of systemic absorption, titanium dioxide should not be used on children younger than 6 mo or on open wounds.
Zinc oxide (*Sundown Sport Sunblock*)	UVA/UVB (290–770 nm)	

3. **Plantar warts** (verruca plantaris) are typically located on the soles of the feet. When positioned on a weight-bearing area of the foot, plantar warts can be especially painful. These warts may be surrounded by a thickened area of skin, making it easy to confuse plantar warts for calluses.

4. **Venereal warts** (verruca genitalia) are found on or near genitalia and the anus. In the United States, genital warts are the most common form of sexually transmitted disease (STD). Patients with venereal warts should never attempt self-treatment for their condition.

D. **Treatment**

1. **Nonpharmacological measures**

   a. Patients with warts should be counseled to minimize contact with the affected area to avoid spreading the virus to other areas of the body or to other people.

   b. Those patients that suffer with plantar warts should be counseled to wear footwear in any high traffic area. These patients should also use their own towel and bathmat when bathing.

2. **OTC treatment options**

   a. **Salicylic acid** is the only FDA-approved OTC medication for common and plantar warts in strengths ranging from 5% to 40%. Self-treatment should not exceed 12 weeks; if patients do not notice improvement by this time, they should be referred to their primary care physician. Salicylic acid is available in a collodion vehicle (Compound W Gel/Liquid) and pads (Dr. Scholl's Clear Away Discs).

   b. **Cryotherapy** may be used very cautiously in the treatment of common and plantar warts. Cryotherapy products are marketed as pressurized canisters containing dimethyl ether and propane (Wartner) or dimethyl ether, propane, and isobutane (Compound W Freeze Off). To use, apply a saturated applicator directly to the wart for 10 to 20 secs. This forms a blister under the wart that eventually causes the wart to fall off. Although most patients will experience wart resolution after a single treatment, the application may be repeated every 10 days as needed. A single wart should not be treated more than three times.

   c. **Occlusion** of the wart may be an effective OTC treatment option, as well. Duct tape is perhaps the most frequently recommended occlusive vehicle although further studies are needed to determine its true efficacy.

3. **Prescription treatment options**

   a. **Liquid nitrogen** may be applied as a form of cryotherapy under the supervision of a physician. Treatment with liquid nitrogen has a high success rate (with resolution of up to 75% of treated warts), but must be used with extreme caution. Adverse effects may include painful blistering, erythema, nerve damage, and hypopigmentation of the skin.

   b. **5-Fluorouracil (Efudex)** may be used topically for the treatment of flat warts. Treatment with 5-fluorouracil lasts from 3 to 5 weeks. The efficacy of this treatment option has yet to be determined.

   c. **Imiquimod (Aldara)** is a topical agent that is used to treat venereal warts. Imiquimod may be especially useful for those warts that are resistant to other treatments. Most patients will respond to treatment with imiquimod within a period of 4 weeks. Imiquimod is generally well-tolerated, with most adverse effects being local skin reactions. Rarely, systemic side effects may occur. Aldara is a fairly expensive treatment option.

VIII. CORNS AND CALLUSES

A. **Overview**

1. Corns and calluses are common foot disorders whose incidences increase with age.

2. Although corns and calluses are often not a serious medical concern, patients who are predisposed to having impaired blood flow to the extremities (e.g., patients with diabetes) may develop complications from untreated or improperly treated foot disorders.

B. **Pathophysiology**

1. Unlike warts, corns and calluses are not viral in origin.

2. **Friction** and/or **pressure** lead to areas of **hyperkeratosis** (thickening of the stratum corneum) on the foot.

3. Corns and calluses may result from an **uneven distribution of weight** on the feet, **ill-fitting footwear**, or **repeated mechanical rubbing of the affected area** against a shoe or other surface.

C. **Types and characteristics**
  1. **Corns**
    a. **Hard corns** (known as heloma durum) appear on areas over bony protrusions, such as the tops of toes or the bottom of the foot. Hard corns possess a glossy appearance with a cone-shaped center.
    b. **Soft corns** (known as heloma molle) are found in the interdigital spaces, most often between the fourth and fifth toes. These corns have a "soft" texture that results from perspiration in the interdigital spaces. Soft corns appear thick and white and are often more painful than hard corns.
  2. **Calluses** are areas of thickened skin, most commonly found on heels and the balls of the feet. Calluses are raised and yellowish-white in color, with borders that are not as clearly defined as those of corns. Because calluses are protective in nature, they are not painful when left intact.

D. **Treatment**
  1. **Nonpharmacological measures**
    a. Patients with corns and calluses may be instructed to **soak the affected foot in warm water for at least 5 mins every day**. This helps to loosen dead skin. Files and pumice stones may be **used with great caution** to remove the dead skin, but care must be taken to not remove too much skin. Any tool with a sharp blade should be avoided altogether.
    b. Pads of various types, shapes, and sizes are available to help alleviate the pressure placed on corns and calluses. Foam, moleskin, and medicated pads are the most common types of padding available for the treatment of corns and calluses. Patients must be counseled that padding will only exacerbate the corn or callus if they do not also replace the offending footwear.
    c. Some patients may need to be fitted with custom-made footwear for corns or calluses that are refractory to other treatment methods. These patients should be referred to a podiatrist or other foot-care expert.
  2. **Salicylic acid** (Dr. Scholl's Liquid Corn/Callus Remover, Freezone Corn and Callus Remover, Mediplast) is the only FDA-approved OTC treatment option for corns and calluses.
    a. Available in collodion and plaster vehicles in strengths ranging from **12% to 40%**.
    b. For collodion vehicles, apply 1 drop of salicylic acid to the affected area at a time until the area is completely covered. Repeat one to two times daily for up to 2 weeks.
    c. For plaster vehicles, cut the disk or pad to the size of the affected area. Leave on for 48 hrs, then remove. Repeat this process every 48 hrs for up to 2 weeks.
    d. Salicylic acid should be avoided in patients with diabetes or impaired circulation due to the potential of ulcer formation or inflammation of the affected area.

IX. PEDICULOSIS AND PEDICULICIDES

A. **Introduction.** Pediculosis is a skin infestation produced by blood-sucking lice. Lice are small, flat, wingless insects with stubby antennae and three pairs of legs that end in sharp, curved claws. **Three types of lice infest humans**.
  1. *Pediculus humanus capitis* (i.e., the head louse)
  2. *Pediculus humanus corporis* (i.e., the body louse)
  3. *Phthirus pubis* (i.e., the pubic, or crab louse)

B. **Life cycles.** The lice that infest humans pass through similar life cycles.
  1. **Location.** All lice need human warmth to survive.
    a. **Head** and **pubic lice** spend their entire cycle on the skin of the human host.
    b. **Body lice** live in clothing, coming to the skin surface only to feed.
  2. **Development**
    a. Each type of louse develops from **eggs** (**nits**) that incubate for about 1 week. When the small, gray-white, tear-shaped eggs hatch, the nymphs appear.
    b. In about 3 weeks, the **nymphs** mature; then the females start to lay eggs.
    c. Each type of louse survives about 1 month as a **mature adult**. During this time, the female head louse can produce three to six eggs a day.
  3. **Egg deposit**
    a. **Body lice** deposit their eggs on fibers of clothing, particularly in the seams. These lice can survive without food up to 10 days, and the eggs may remain viable for about 1 month. Daily clothing changes and boiling or ironing infested clothing can eradicate **body lice**.

  b. **Head** and **pubic lice** deposit their eggs on hair strands, about ¼ inch from the skin. Adult head lice can survive on inanimate objects for about 20 hrs; head lice nits may survive up to 10 days off the body.

C. **Incidence.** The incidence of lice infestations increases each year.

 1. More than 10 million cases of head lice occur each year in the United States.

 2. The bulk of these cases occur between September and November, when students are back in school.

 3. In outbreaks of head lice, 70% of cases occur in children younger than 12 years.

 4. Infestations tend to be more common in girls, presumably because of their greater tendency to share grooming items.

 5. Unlike the other two forms of lice, body lice are associated with improper hygiene and are often present in homeless people. This infestation is rare in the United States, especially when people follow proper hygiene routines.

D. **Medical problems**

 1. Both adult and nymph lice are blood sucking; they feed on humans by piercing the skin and introducing a small amount of saliva (which contains an **anticoagulant**) into the feeding area. All lice types feed on blood for about 30 to 45 mins every 3 to 6 hrs.

  a. The attachment of lice to the body causes an **erythematous papule**, which may **itch**.

  b. The female louse produces a sticky **cementlike secretion** that holds the eggs in place on the hair shaft so securely that ordinary shampooing does not remove it.

 2. Neither head nor crab lice transmit infections, but body lice transmit **typhus**, **relapsing fever**, and **trench fever**.

 3. Lice and humans have a true **parasitic relationship**; lice depend on the human host for shelter, food, and reproductive success. Once hatched, nymphs must have access to the human host within the first 12- to 24-hr period, if they are to survive.

E. **Methods of transmission**

 1. **Head lice** are most commonly **spread by head-to-head contact** with an infected person through hats, caps, scarves, pillowcases, communal combs and brushes, or clothing that is hung close together (e.g., on a coat rack).

 2. **Pubic lice** are **transmitted primarily through sexual contact**, but also through shared undergarments, towels, or toilet seats.

  a. The lice affect teens and young adults most often through sexual contact.

  b. Lice frequently coexist with other sexually transmitted diseases.

  c. Scratching in the genital areas may transmit pubic lice to other hairy regions, such as the eyelashes, eyebrows, sideburns, and mustaches.

F. **Signs and symptoms**

 1. **Head lice**

  a. Most patients have fewer than 10 lice.

  b. The most common sign is **head scratching**.

  c. **Skin redness around the nape** (i.e., **back**) **of the neck** and above the ears is usually seen.

  d. The lice can be identified by direct examination using wooden applicator sticks or a comb to part the hair, then looking at the hair through a magnifying glass.

  e. The lice appear as tiny brownish gray spots that are often difficult to see. The shiny, **whitish silver eggs**, which appear almost as grains of sugar, are more likely to be seen than the lice. The nits are initially **deposited** about **¼ inch from the scalp** on the hair shaft, and they may be **confused with dandruff or hairspray droplets**. Usually, hair grows at a rate of about ½ inch per month, so the duration of infestation can be assessed based on this information.

 2. **Pubic lice.** The primary symptom is scratching in the genital area.

 3. **Body lice.** The most common symptoms are bites and itching, which are commonly seen as vertical excoriations on the trunk area.

G. **Treatment**

 1. There are **three steps** in the treatment of **head and body lice.**

  a. Treat the lice and nits with a pediculicide agent.

  b. Control the symptoms of itching to prevent secondary infection.

  c. Clean the environment of potential lice and nits.

2. **Itching.** Pharmacists should advise patients that even after the causative organism and nits have been killed, itching may persist for several days. This aspect is very important because patients may decide to use pediculicides excessively, thinking that they have been ineffective when the itching continues. **Excessive use of pediculicides may result in excessive drying, which can cause further itching.**

3. Home remedies. Because of the social stigma attached to lice infestation, some individuals may resort to harmful home remedies. Examples of such uncomfortable, ineffective, and potentially dangerous approaches that should not be used include:
   a. Shaving the head and pubic area
   b. Applying heat to the infested area with a hair dryer
   c. Soaking the head in hot water for several minutes
   d. Soaking the area of infestation with gasoline or kerosene

4. **OTC pediculicide products** are considered first-line treatments and include
   a. **Permethrin** (Nix) is a pyrethroid (i.e., a synthetic version of a pyrethrin). It is indicated for the treatment of **head lice only**.
      (1) **Mechanism of action.** Permethrin kills by **disrupting ion-transport mechanisms at the nerve membranes**. Permethrin is a synthetic mixture of chemically altered pyrethrin isomers. Because not all eggs may be killed (it takes about 4 days for the nervous system of the louse to develop) with a single application of this agent or removed with a nit comb, it may be necessary to reapply the pyrethrin product within 7 to 10 days of the first application (because the usual hatching time of the eggs is 7 to 10 days). The American Academy of Pediatrics (AAP) now recommends routine retreatment of patients with head lice, typically on day 9.
      (2) **Application.** Permethrin comes in the form of a 1% **creme rinse** and should be applied like a conventional hair conditioner after the hair has been shampooed (use a shampoo with no conditioner), rinsed, and towel dried. The hair should be thoroughly saturated with undiluted permethrin (25 to 30 mL), which should **remain on the hair for 10 mins, then rinsed**.
      (3) **Effectiveness.** A single application is generally effective in killing lice. Because the agent is retained on the hair shaft, the product provides **continuing activity for up to 14 days**. This residual effect persists regardless of normal shampooing.
         (a) Even with the residual activity, there still may be the need for retreatment in 7 to 10 days.
         (b) **Comb hair** in the previously infested area **with a fine-toothed comb** to remove dead lice and eggs.
         (c) There is, at least theoretically, the speculation that because low-level residual amounts of this agent are retained on the hair, it may be possible that when suboptimal levels are present, some lice may survive and give rise to strains that are resistant.
   b. **Pyrethrins 0.17% to 0.33% with piperonyl butoxide 2% to 4%.** This product is safe and effective for the treatment of **head** and **pubic lice**. The combination of ingredients is an example of **pharmacological synergism**.
      (1) **Pyrethrins** have a **similar mechanism of action as permethrin**. These natural insecticides are derived from a mixture of substances obtained from the flowers of the **chrysanthemum** plant.
      (2) **Piperonyl butoxide** enhances the pediculicide effect of pyrethrins by **suppressing the oxidative degradation mechanisms of the lice**. Therefore, the length of time that the pyrethrins contact the lice is increased.
      (3) **Side effects** from either agent are **uncommon**.
         (a) **Contact dermatitis** (see I) is the most frequently reported side effect.
         (b) **Allergic reactions.** Because pyrethrins are derived from a plant (chrysanthemum), they may produce hay fever (i.e., allergic rhinitis) and asthma attacks in susceptible individuals. Thus, patients who have known allergies to ragweed or chrysanthemum plants should use this product with caution.
      (4) Common **trade names** for this product include RID maximum strength Shampoo, A-200 maximum strength Shampoo.

(5) **Directions for use (shampoo)**
  (a) **Apply the product**, **undiluted**, to the dry hair until it is entirely wet.
  (b) Allow the product to **remain on the head for 10 mins**.
  (c) **Rinse thoroughly** with warm water.
  (d) Dry the area, preferably with a disposable cloth.
  (e) **Comb hair** in the previously infested area **with a fine-toothed comb** to remove dead lice and eggs.
  (f) Do not exceed two applications within 24 hrs. It may be necessary to reapply the shampoo in 7 to 10 days [see IX.G.4.a.(1)].

c. **OTC pediculicide treatment failure.** Treatment failure with the use of the preceding agents has been reported. Speculations as to the cause of this treatment failure include failure to follow product instructions, noncompliance with nit removal, and head lice drug resistance. Studies support the theory that there are now "super lice" that have survived exposure to pyrethrins and permethrin; resistance to pyrethrins has been better documented.

5. **Prescription products** are included here to put into perspective how the OTC agents fit into therapy.

a. **Malathion** (Ovide) is an organophosphate cholinesterase inhibitor that has been widely used as a lawn and garden insecticide. Resistance has also become an issue with this agent.
  (1) **Mechanism of action.** Sulfur atoms in the malathion bind with sulfur groups on the hair, giving a residual protective effect against reinfestation.
  (2) **Application.** Malathion is prepared as a lotion in 78% alcohol; therefore, caution should be used near an open flame or a hair dryer. The product should be sprinkled on dry hair and left for 8 to 12 hrs before rinsing. A fine-toothed comb should be used to remove the dead lice and eggs.
  (3) No systemic **adverse effects** have been reported with topical use of this medication.
    (a) The alcoholic vehicle may produce stinging and possible flammability.
    (b) Although this agent may be effective, its unpleasant odor (owing to sulfhydryl compounds), the required time of 8 to 12 hrs on the scalp, and those points noted in IX.G.5.a.(3).(a) represent the main drawbacks.
  (4) Malathion is **contraindicated in children < 24 months**, as the scalp is more permeable, possibly leading to increased absorption of the medication. Safety and efficacy in children < 6 years old have not been established.

b. **Benzyl alcohol 5%** (Ulesfia) was approved by the FDA in 2009 for the treatment of head lice in children 6 months and older.
  (1) **Mechanism of action.** Benzyl alcohol works by asphyxiating head lice. This medication is not ovicidal; thus, retreatment is necessary to kill any lice that hatched from eggs.
  (2) **Application.** Lotion should be massaged into the hair and scalp. Ensure the patient's skin and eyes are protected from any excess medication that may drip from the top of the head. Allow the lotion to remain on the head for 10 mins, then rinse the lotion from the hair and scalp. Repeat in 7 to 9 days.
  (3) The most common adverse effects associated with this medication are temporary pruritus, erythema, pyoderma, and ocular irritation.

c. **Spinosad 0.9%** (Natroba) is a topical pediculicide that was approved by the FDA in 2011 for the treatment of head lice in patients 4 years and older.
  (1) **Mechanism of action.** Spinosad is an insecticide that paralyzes and ultimately kills head lice upon ingestion of the chemical by the lice.
  (2) **Application.** Spinosad is indicated for topical application only. The suspension should be applied to dry hair and scalp. Ten minutes following application, patients should be instructed to wash their hair and scalp with warm water. Repeat in 7 days if live lice are seen at that time.
  (3) The most common adverse effects associated with this medication are localized erythema, ocular erythema, and irritation at the application site.

    d. Lindane, or γ-benzene hexachloride, has fallen into disfavor because of the potential for toxicity and the fact that its efficacy is less than the other agents available (both prescription and OTC products). Resistance to this agent is widespread. Lindane is no longer recommended by the AAP for the treatment of head lice. Its use has been banned in California.

6. **Adjunctive therapy**
   a. **Nit removal**
      (1) The pediculicide products mentioned vary in their ability to kill the lice nits. To ensure successful therapy after pediculicide application, the nits should be removed with a **fine-toothed comb**. A sturdy **metal comb** (like the LiceMeister) is recommended by the National Pediculosis Association (NPA). Although some schools may have a "no nit" policy—that is, a child's hair and scalp must be free of nits before he or she is allowed to return to the classroom—missing school due to head lice is no longer endorsed by the AAP.
      (2) Although various substances have been used in an effort to dislodge the nits from the hair shafts, most, if not all, have been unsuccessful. A mixture of 50% vinegar and 50% water has been recommended, but its effectiveness has been questioned. A lice egg remover containing various enzymes comes as part of a kit, but challenges have been made to its effectiveness.
   b. **Treatment of other household members.** Once a lice infestation has been identified in one member of the household, all other members should be examined carefully. Everyone who is infested should be treated at the same time. Any family member that shares a bed with the infected individual should also be treated, even if live lice are not found on that family member.
   c. **Adjunctive methods for controlling lice infestations**
      (1) **Washable material items** such as linens, towels, hats, and clothing should be machine-washed in hot water and dried in a hot dryer to destroy lice and nits.
      (2) **Nonwashable material goods** should be dry-cleaned or sealed in a plastic bag for 2 weeks.
      (3) **Personal items** (e.g., combs, brushes) should be soaked in hot water (130°F) for at least 15 mins.
      (4) **Furniture and household items** (e.g., carpets, chairs, couches, pillows) should be vacuumed thoroughly. OTC spray products that contain pyrethrins are no more effective than vacuuming in terms of removing the risk of reinfestation.
   d. Pediculicides should not be used around the eyes. For **eyelash pubic lice infestations**, **petrolatum** applied five times a day has been used to supposedly "asphyxiate" lice, but this may only slow lice movement. Gentle removal with baby shampoo may be helpful.

H. **Head lice myths** are numerous. The following additional facts may reassure and inform patients and parents of patients.
   1. No significant difference in incidence occurs among the various socioeconomic classes or races.
   2. Hygiene and hair length are not contributing factors.
   3. Head lice do not fly or jump from person to person.
   4. Head lice do not carry other diseases.
   5. Head lice cannot be contracted from animals, and pets are not susceptible to *Pediculus humanus capitis*.
   6. The head does not have to be shaved to get rid of lice.
   7. Washing hair with "brown" soap is not effective.
   8. Head lice are unrelated to ticks.
   9. Hair does not fall out as a consequence of infestation.
   10. Head lice infestations can occur at any time of the year.

Study Questions

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A woman who has not been in the sun for 4 months develops redness on her chest after lying in the sun for 20 mins. The next day, she applies a suntan lotion and develops the same degree of redness on her back in 2 hrs and 20 mins. What is the likely sun protection factor (SPF) of the lotion she is using?

    (A) 14
    (B) 10
    (C) 12
    (D) 9
    (E) 7

2. Which of the following cleansing products would a pharmacist recommend for a patient with inflammatory acne?

    (A) an abrasive facial sponge and soap used four times a day
    (B) aluminum oxide particles used two times a day
    (C) sulfur 5% soap used two times a day
    (D) mild facial soap used two times a day

3. If a patient needs a second application of an over-the-counter (OTC) pyrethrin pediculicide shampoo, how many days after the first application should this be done?

    (A) 4 to 5
    (B) 6
    (C) 7 to 10
    (D) 14 to 21
    (E) 15 to 17

4. All of the following treatments for personal articles infested with head lice would be effective *except*

    (A) placing woolen hats in a plastic bag for 2 weeks.
    (B) using an aerosol of pyrethrins with piperonyl butoxide sprayed in the air of all bathrooms.
    (C) machine-washing clothes in hot water and drying them using the hot setting on the dryer.
    (D) dry-cleaning woolen scarves.
    (E) soaking hair brushes in hot water for 15 mins.

5. All of the following sunscreen agents or combinations of agents would likely help prevent a drug-induced photosensitivity reaction *except*

    (A) titanium dioxide.
    (B) octyl methoxycinnamate plus homosalate.
    (C) oxybenzone and padimate O.
    (D) zinc oxide.
    (E) padimate O plus avobenzone.

6. All of the following would be appropriate recommendations for an adult patient in the acute stage (i.e., blistering, weeping) of poison ivy contact dermatitis *except*

    (A) 60 mg per day of prednisone initially, then tapered over 15 days.
    (B) Burow's solution; 1:20 wet dressing to area for 15 to 30 mins, four times per day.
    (C) two soaks per day in Aveeno Bath Treatment.
    (D) two applications of Ivy Block.

7. Pharmacists educating patients about acne should mention all of the following *except*

    (A) eliminating all chocolate and fried foods from the diet.
    (B) cleansing skin gently two to three times daily.
    (C) using water-based noncomedogenic cosmetics.
    (D) not squeezing acne lesions.
    (E) keeping in mind that acne usually resolves by one's early 20s.

8. A 15-year-old male patient has been using benzoyl peroxide 5% cream faithfully every day for the past 2 months with no apparent side effects. All of the following can be said about this patient *except*

    (A) he has been using this product for a long enough time to determine if the dose and dosage form are going to have any benefit.
    (B) he should use this product no more frequently than every other day because of its irritating properties.
    (C) this starting dose and dosage form are useful, especially if he has dry skin or it is wintertime.
    (D) his scalp hair may look bleached if the product comes in contact with it.
    (E) the product would sting if it got into his eyes.

9. All of the following descriptions match the therapeutic agent for poison ivy *except*
   (A) calamine, phenolphthalein gives it the pink color.
   (B) Ivy Block, useful in preventing poison ivy dermatitis.
   (C) benzocaine, data regarding incidence of hypersensitivity are conflicting.
   (D) hydrocortisone, useful for its antipruritic and anti-inflammatory effects.

10. All of the following statements related to sun protection are true *except* which one?
   (A) The sun's intensity increases 20% when going from sea level to an altitude of 5000 ft.
   (B) Water-resistant labeling on a sunscreen product indicates that it will retain its SPF after 40 mins of activity in water, sweating, or perspiring.
   (C) Baby oil is not a sunscreen, but its application to the skin after tanning causes melanin to rise to the surface.
   (D) Per the FDA, a product with an SPF of > 50 must now be labeled SPF "50+".
   (E) The SPF is really only a measure of ultraviolet B (UVB) protection.

11. All of the following statements about sunscreens are correct *except* which one?
   (A) Malignant melanoma formation may be associated with intense, intermittent overexposure to the sun (sunburning).
   (B) Any benefits that might be derived from using sunscreens with an SPF > 30 are negligible.
   (C) Sunscreens are best applied immediately before going out in the sun.
   (D) Avobenzone provides sunscreen coverage for the UVA spectrum.
   (E) Basal cell carcinoma is the most common of all skin cancers and accounts for about 80% of skin cancers.

12. All of the following statements are proper counseling point for a patient suffering with dry skin *except*?
   (A) Avoid alcohol and caffeine, as these can exacerbate dry skin.
   (B) Following a bath or shower, pat the skin down with a towel, leaving bits of moisture on the skin.
   (C) Soak in a tub two to three times per week for at least 20 mins to allow for adequate water absorption into the skin.
   (D) Avoid extremely hot baths and showers.
   (E) Ensure adequate daily intake of water (about 8 oz glasses of water per day).

13. Dandruff is
   (A) the result of decreased turnover of epidermal cells.
   (B) typically not a serious medical concern.
   (C) also known as cradle cap.
   (D) rarely accompanied by pruritus.

14. All of the following are potential treatment options for psoriasis *except*
   (A) salicylic acid.
   (B) topical hydrocortisone.
   (C) coal tar.
   (D) ketoconazole.

15. Which of the following tinea infections is not appropriate for self-treatment and must be referred to a physician?
   (A) Tinea nigra
   (B) Tinea corporis
   (C) Tinea cruris
   (D) Tinea pedis

Answers and Explanations

1. **The answer is E** *[see VI.E.1]*.
   The SPF is the minimal erythema dose (MED) of protected skin divided by the MED of unprotected skin. Thus, 2 hrs and 20 mins (140 mins) divided by 20 mins equals an SPF of 7.

2. **The answer is D** *[see IV.E.2]*.
   For patients with inflammatory acne, the best product is a mild facial soap used two times a day. The soap should be gently rubbed into the skin with only the fingertips. Cleansing products that irritate already inflamed skin should be avoided.

3. **The answer is C** *[see IX.G.4.b.(5).(f)]*.
   Reapplication of pyrethrins with piperonyl butoxide should be within 7 to 10 days of the first application. Any lice nits that were not killed on the first application would have time to hatch and then be killed with the second application.

4. **The answer is B** *[see IX.G.4.a; IX.G.6.c]*.
   Pyrethrins with piperonyl butoxide in an aerosol form can be sprayed directly on inanimate objects (e.g., chairs, headrests) to kill head lice, but the combination should not be sprayed in the air like an aerosol deodorizer. Moreover, vacuuming the furniture would

probably be as effective as spraying it. The other selections are appropriate for personal articles infested with head lice.

5. **The answer is B** *[see VI.E.2; VI.D.3.c]*.
Octyl methoxycinnamate and homosalate protect against only UVB exposure. Because photosensitivity reactions are often associated with UVA radiation exposure, people also need sunscreen protection for this portion of the UV radiation band. The other agents listed cover at least part of both UVA and UVB spectra.

6. **The answer is D** *[see I.D.3–4; I.E.2]*.
Ivy Block is used as a barrier protectant for the prevention of poison ivy dermatitis, *not* for the treatment of an acute eruption. The other options are appropriate to recommend to someone suffering from the acute stage of poison ivy dermatitis.

7. **The answer is A** *[see IV.D.3]*.
Evidence does not show that acne definitively worsens from any particular type of food, including chocolate or fried foods. The other choices are pieces of information that the pharmacist should convey to a patient with acne.

8. **The answer is B** *[see IV.E.4.a]*.
Although the irritating properties of benzoyl peroxide might dictate applying it only every other day on initiating treatment, this patient has tolerated the agent on a daily basis for 2 months. Thus, there would be no need to decrease the application frequency. All of the other choices do apply to this patient's use of benzoyl peroxide.

9. **The answer is A** *[see I.D.4.a]*.
Ferric oxide provides the pink color of calamine. All of the other descriptions match their associated agents.

10. **The answer is C** *[see VI.C.2.; VI.E.1.a.(2); VI.E.1.b.; VI.E.1.b.(1)]*.
Baby oil is not a sunscreen, and it has no effect on melanin. SPF does measure UVB protection, and an SPF higher than 50 must be labeled SPF "50+". Water-resistant sunscreen products must retain their SPF value after 40 mins of water activity. The intensity of the sun does increase by 4% with each 1,000-ft rise in elevation.

11. **The answer is C** *[see VI.D.2; VI.E.1; VI.E.2.b; VI.E.2.b.(5)]*.
Optimally, sunscreens should be applied 1 to 2 hrs before exposure to the sun. This allows time for the product to bind to the stratum corneum, which provides better protection. The other responses are correct.

12. **The answer is C** *[see V.D.1.a–c]*.
Patients who suffer with dry skin should be counseled on bathing or showering for brief periods (3 to 5 mins) with lukewarm water.

13. **The answer is B** *[see II.A.2; II.C.1.c; II.C.1.f; II.D.1.i]*.
Dandruff is not typically a serious medical condition, but embarrassment to the patient is a real concern and must be considered when offering the patient treatment options.

14. **The answer is D** *[see II.E.2.a.(2)–(3)]*.
Ketoconazole is not an appropriate treatment option for psoriasis (the only scaly dermatosis for which ketoconazole is not indicated).

15. **The answer is A** *[see III.D.2.a.(1)]*.
Only three types of tinea infections respond to self-treatment with nonprescription therapies: tinea corporis, tinea cruris, and tinea pedis. All other tinea infections should be referred to a physician for evaluation and treatment.

Over-the-Counter Weight Control, Sleep, and Smoking-Cessation Aids

JENNIFER D. SMITH

I. WEIGHT CONTROL

A. Obesity is a growing epidemic in America, spanning all age groups from childhood to adulthood. The National Health and Nutrition Examination Survey (NHANES) 2007 to 2008 data revealed that at least 30% in most age groups of the U.S. population are obese. This is concerning because obesity is a health risk for several chronic disease states including, but not limited to, cardiovascular disease, stroke, type 2 diabetes, and arthritis. Consequently, this upward trend in obesity leads to growing U.S. health expenditures.

   1. The U.S. Preventive Services Task Force (USPSTF) determined that the body mass index (BMI) is a reliable and valid identifier for **adults** at increased risk for morbidity and mortality owing to overweight and obesity. The BMI is calculated as either weight (in pounds) divided by height (in inches squared) multiplied by 703 or as weight (in kilograms) divided by height (in meters squared). The following guidelines relate BMI to overweight and obesity:

      a. **Overweight** is defined as a **BMI between 25 and 29.9 kg/m^2**.

      b. **Obesity** is defined as a **BMI ≥ 30 kg/m^2** and is further divided into grades: Grade 1 (BMI 30 to < 35); Grade 2 (BMI 35 to < 40); Grade 3 (BMI ≥ 40).

   2. Truncal fat accumulation, measured by **waist circumference**, is a **risk factor for cardiovascular disease and other diseases** (e.g., type 2 diabetes, sleep apnea, knee osteoarthritis) regardless if the individual is considered obese. Waist circumference is **not a valid measurement in individuals with a BMI > 35 kg/m^2**. Individuals with the following waist circumferences are considered at increased risk for cardiovascular and other diseases:

      a. A waist circumference in **men > 40 inches** (102 cm)

      b. A waist circumference in **women > 35 inches** (88 cm)

B. **Management.** Diet and exercise (lifestyle modifications) are the recommended first approach to weight loss, as well as sustained weight control. Although it seems relatively simple to eat a well-balanced diet and exercise regularly, time constraints and ease of access to highly processed foods are hurdles that Americans face in the fight against the bulge.

   1. **Caloric restriction.** To reduce weight (and thus BMI), energy intake should be less than the energy expended.

      a. The approximate adult energy requirements, based on actual weight, may be roughly estimated as follows. A 120-lb active woman would require approximately 1800 kcal/day to maintain her current weight.

         (1) Bedridden or sedentary individuals: 10 to 12 kcal/lb

         (2) Moderately active individuals (walking at regular pace): 13 kcal/lb

423

          (3) Active individuals: 15 kcal/lb

          (4) Very active individuals: 20 kcal/lb

    b. To lose about 0.5 kg/week, a **deficit of 500 to 1000 calories (kcal) per day** must be met. A **safe rate of weight loss is considered to be 1 to 2 lb/week.**

    c. Several commercially available weight loss programs (e.g., Weight Watchers, Nutrisystem, and Jenny Craig) exist today. When compared to self-help weight loss programs, some commercially available programs have shown enhanced and sustained weight loss, which may be attributable to the social support provided.

2. Dietary fat absorption inhibitor. Currently, the only available nonprescription agent that is FDA approved for weight loss is **orlistat**, a dietary fat absorption modifier. Dietary modifications in combination with orlistat can produce clinically modest weight loss (approximately 5% of baseline weight). Orlistat has been available in prescription form (Xenical®) since 1999, and gained FDA approval for nonprescription status in 2007 under the brand name Alli®.

    a. Alli® is available for individuals 18 and older who are mildly to moderately overweight (**BMI between 25 and 28 kg/m^2**).

    b. Nonprescription dosing is **60 mg TID** (as compared to 120 mg TID for Xenical®) during or within 1 hr of each fat-containing meal. Dose-related efficacy is observed with orlistat up to 300 to 400 mg daily, but effects plateau thereafter.

    c. Onset of orlistat takes approximately 2 weeks and statistically significant weight loss has been observed in obese patients after 3 months. Thus, individuals should be counseled that weight loss may not be significant with orlistat and may take several months for noticeable results.

    d. The use of orlistat will result in **gastrointestinal adverse effects**, including soft or liquid stools which may be fatty or oily in appearance, increased defecation, fecal urgency, and abdominal pain. Adverse effects are directly related to the dose and inversely related to the fat content of the diet. Gastrointestinal adverse effects may lessen over time.

    e. Prescription doses of orlistat have been associated with decreased absorption of vitamins A, D, E, K, and beta-carotene. However, at doses $\leq$ 180 mg/day given for short periods (e.g., 2 to 3 months), reduced absorption of these vitamins has not been observed. Individuals using Alli for extended periods should be counseled to take a **multivitamin once daily at bedtime**.

3. Exercise can decrease the appetite and increase body metabolism. Exercise adds only modestly to initial weight loss but is a key component of **sustained weight loss**.

C. Dietary supplements. Retail sales of weight loss supplements in the United States exceed **a billion dollars** annually. Americans have begun to seek nonprescription weight loss products for various reasons.

1. Some individuals may view dietary supplements as a quick resolution to the growing epidemic, because the obtainment of desired or reduced body weight with long-term lifestyle changes is perceived as difficult. Many advertisements of weight loss products give inflated claims, offering rapid results with little to no modification in lifestyle habits. Some people view dietary supplements as natural and, therefore, mistakenly believe they are safe to use.

2. With the implementation of the Dietary Supplement Health and Education Act of 1994, manufacturers are **not required to demonstrate product safety and efficacy before marketing** supplements. Although manufacturers of dietary supplements do not have to demonstrate product safety and efficacy, they **do have to follow good manufacturing practices**. In 2007, FDA ruled that dietary supplements must be manufactured in a manner that ensures quality and must be properly packaged and labeled as specified in the manufacturing record. Still, the lack of evidence for product safety and efficacy raises concerns for health care providers who attempt to make appropriate recommendations to patients seeking nonprescription weight loss products.

3. The U.S. Food and Drug Administration (FDA) files action against manufacturers of supplements determined unsafe, falsely labeled, labeled with misleading claims, adulterated, or misbranded.

4. The Federal Trade Commission (FTC) takes action against manufacturers providing product advertising that is misleading or makes unsubstantiated claims.

5. Numerous single- and multiple-entity products are available on the market today, each under the scrutiny of the FDA and FTC. The most commonly seen ingredients in weight loss products currently marketed, organized by purported mechanisms of action, include the following:

a. **Increase energy expenditure**

(1) **Ephedra.** Contains supplements that were **banned by the FDA in April 2004** owing to unreasonable risks of illness or injury when used as labeled. Products formulated with ephedrine alkaloids (ephedra, ma huang, sida cordifolia, Pinellia) were removed immediately, although, unlike other dietary supplements currently available, ephedra-containing supplements did have convincing evidence for short-term weight loss.

(2) **Bitter orange** is an extract from the peel, flower, leaf, and fruit of the Seville orange. Typical dosage is about 1 g/day, standardized to 1.5% to 6.0% synephrine, a stimulating agent that is chemically similar to ephedrine. Currently, there are no data to support its efficacy as an agent for weight loss. If combined with other stimulants such as caffeine, bitter orange may be cardiotoxic.

(3) **Guarana** seed contains 2.5% to 7.0% caffeine and exerts a diuretic action. Effectiveness has been demonstrated only in combination with ephedrine. Tolerance and dependence can develop with chronic use.

(4) **Caffeine** is an FDA-approved product; efficacy of this agent for weight loss has been demonstrated only in combination with ephedrine, which has been removed from the market. Tolerance and dependence can develop with chronic use.

b. **Modulate carbohydrate metabolism**

(1) **Chromium**, an essential mineral, increases insulin sensitivity, lean body mass, and basal metabolic rate and decreases insulin blood levels and body fat. Chromium is used in weight loss products in the form of chromium picolinate, 200 to 400 mcg/day, with no reported significant adverse effects. Rhabdomyolysis and renal failure have been reported with the use of chromium picolinate in doses exceeding 1000 mcg/day. Although widely marketed, there have been no large, well-designed studies for the use of chromium in weight loss. Although its efficacy for weight loss remains uncertain, over 100 products marketed for weight loss contain chromium.

(2) **Ginseng**, in the form of Panax ginseng, may improve glucose tolerance, according to preliminary data. Although ginseng is found in at least 20 commercially available weight loss products, it has no demonstrated efficacy for weight loss in humans.

c. **Enhance satiety**

(1) **Guar gum**, a fiber derived from the Indian cluster bean, has been deemed relatively safe in doses of 7.5 to 30.0 g/day, however, it has not demonstrated efficacy for weight loss in at least 20 clinical trials. Adverse effects include abdominal pain, flatulence, and diarrhea.

(2) **Glucomannan** (*Amorphophallus konjac*) purportedly absorbs water in the gut, contributing to enhanced satiety and thus decreased caloric intake. Preliminary evidence has demonstrated that glucomannan (3 to 4 g/day) may be well tolerated and efficacious for weight loss. However, this agent can have a laxative effect.

(3) **Psyllium** forms a fibrous mass with a bulk laxative effect but has not demonstrated efficacy for weight loss. Potential adverse effects are significant, including esophageal obstruction and nephrotoxicity (if seeds are crushed, chewed, or ground, a pigment may be deposited in the renal tubules). If used, patients should be instructed to not crush, chew, or grind the seeds, and adequate fluids must be consumed.

d. **Increase fat oxidation or reduce fat synthesis**

(1) **L-Carnitine** is synthesized in the liver, kidney, and brain. It is fundamentally important for fatty acid transport for energy production. No trials demonstrate efficacy of L-carnitine for weight loss.

(2) **Hydroxycitric acid (HCA)** is derived from the rind of the brindle berry, a tropical fruit native to India. It is purported to inhibit mitochondrial citrate lyase, thereby suppressing acetyl coenzyme A and fatty acid synthesis. In doses of 300 to 3000 mg/day, HCA has been well tolerated, with adverse effects of headache and gastrointestinal symptoms reported. Efficacy of HCA remains questionable.

(3) **Green tea** contains a polyphenol, epigallocatechin-3-gallate, better known as **EGCG**. Each cup (8 oz) of green tea provides 10 to 80 mg of caffeine, contributing to the tea's diuretic action and central nervous system (CNS) stimulation (e.g., increased heart rate, increased blood pressure, anxiety). Green tea has demonstrated increased fat oxidation and thermogenesis but lacks data regarding efficacy in weight loss.

(4) **Vitamin B₅** has been postulated to induce weight loss; however, data are lacking to support this.

(5) **Licorice** safety and efficacy for weight loss remains unclear. Reported adverse effects of licorice include pseudoaldosteronism, hypertension, and hyperkalemia.

(6) **Conjugated linoleic acid (CLA)** is a group of *trans*-fatty acids, which is purported to alter body composition by increasing lean tissue deposition and decreasing triglyceride uptake in adipose tissue. In doses of 1.4 to 6.8 g/day, CLA may have efficacy in weight loss, especially in obese patients. Adverse effects include mild to moderate gastrointestinal symptoms. CLA may increase insulin levels and insulin resistance.

(7) Clinical trials of **pyruvate**, in doses of 6 to 44 g/day, have demonstrated weak evidence of its effectiveness for weight loss. Reported adverse effects include diarrhea and audible abdominal sounds.

(8) **Calcium** suppresses parathyroid hormone and 1,25-dihydroxyvitamin D to reduce fat synthesis and increase fat oxidation. Although some studies have linked calcium intake to weight loss, clinical trials have failed to demonstrate statistically significant results. Additionally, the Agency for Healthcare Research and Quality (AHRQ) produced an evidence report stating that clinical trials do not support weight loss due to calcium supplementation.

e. **Block dietary fat absorption. Chitosan**, a common ingredient in "fat-trapper" supplements, is derived from the exoskeleton of shellfish. In doses of 2.0 to 4.5 g/day, chitosan has not demonstrated clinically significant increases in fecal fat excretion or weight loss. Adverse effects include nausea, constipation, and flatulence. Furthermore, it is questionable if chitosan is safe in individuals with shellfish allergies.

f. **Increase water elimination. Dandelion** (*Taraxacum officinale*) seems to have a diuretic effect but has not been studied for weight loss in humans. At least 15 dietary supplements for weight loss contain dandelion.

g. **Miscellaneous. Spirulina** (blue-green algae) contains phenylalanine, an agent theorized to inhibit appetite. Spirulina was declared ineffective for weight loss in 1981 by the FDA, and no published studies have proven otherwise. At least 13 products for weight loss currently on the market contain spirulina.

II. SLEEP AIDS

A. **Normal sleep and sleep requirements**

1. Sleep requirements vary widely among individuals and change throughout the life cycle. The usual range of sleep time per night is 5 to 10 hrs, with an average of about 7.5 hrs. Newborns require a considerable amount of sleep time, up to 18 hrs. Adolescents typically do not become sleepy until after midnight and awaken very late in the morning (if allowed), but require a total of 9.5 hrs of sleep. The typical adult requires 7 to 8 hrs of sleep to feel adequately restored, but this time may diminish with aging.

2. **Polysomnography** is the predominant tool for characterizing sleep physiology, although guidelines from the American Sleep Disorders Association do not indicate it as useful in the diagnosis and management of patients with insomnia. Using polysomnography, researchers have identified five stages of sleep, subdivided into rapid eye movement (REM) sleep and non-REM sleep.

a. Non-REM sleep consists of four stages. Each stage is a progression into a deeper sleep; and stages 3 and 4 are considered deep, restorative sleep. If time spent in stages 3 and 4 of sleep is diminished (as seen with aging), then sleep quality is compromised.

b. REM sleep is considered stage 5 of sleep. Most dreaming occurs during REM sleep. If awoken while in REM sleep, dreams may be described in vivid detail.

B. Insomnia

1. **Definition.** Insomnia is defined as one or more of the following sleep-related complaints: difficulty in sleep initiation (arbitrarily defined as a delay of > 30 mins), difficulty in maintenance of sleep, shortened duration of sleep, or quality of sleep that results in adverse daytime consequences.

2. **Epidemiology.** Insomnia is the most common sleep disorder in the United States, affecting approximately 40% of the adult population. Those affected most include women, the less educated or unemployed, separated or divorced individuals, patients with chronic medical or psychiatric disorders, and substance abusers. Economic costs of insomnia are estimated to be $> \$90$ billion annually in the United States. Direct costs include prescription and nonprescription medications, as well as visits to a health care provider. Indirect costs include absenteeism, diminished productivity, fatigue-related automobile crashes, and industrial accidents.

3. Classification of insomnia by duration.
   a. **Transient insomnia** lasts < 1 **week** and is typically the result of acute situational stress or circadian issues such as jet lag or shift work. This type of insomnia is often self-limiting.
   b. **Short-term insomnia** lasts **1 to 3 weeks** and is attributable to situational stress (e.g., acute personal loss), often related to work and family life or to medical or psychological disorders. If short-term insomnia is not managed appropriately, it may progress to chronic insomnia because individuals become increasingly anxious and frustrated about the inability to sleep. There are no established predictors to determine if short-term insomnia will continue to become chronic insomnia.
   c. **Chronic insomnia** lasts > 3 **weeks.** People with chronic insomnia need further evaluation because the condition is often the result of a medical disorder (e.g., sleep apnea, restless leg syndrome, primary insomnia), psychiatric disorder, or substance abuse. Up to 40% of chronic insomnia cases are correlated with psychiatric disorders, particularly depression.

4. Classification of insomnia based on cause.
   a. **Primary insomnia** is the main pathological condition in which a patient experiences continued insomnia in the absence of a related medical or psychiatric condition. Its pathogenesis is unknown, but the condition is treatable. Idiopathic insomnia is the inability to obtain adequate sleep, possibly stemming from a misaligned circadian rhythm. Psychophysiologic insomnia is increased wakefulness associated with the bed environment.
   b. **Secondary insomnia** is more common than primary and can be attributed to the following:
      (1) Adjustment insomnia is associated with situational stress.
      (2) Inadequate sleep hygiene is associated with lifestyle habits that reduce the amount of quality sleep, such as noise in the bedroom or the use of caffeine.
      (3) Insomnia owing to a psychiatric disorder
      (4) Insomnia owing to a medical condition, which may include restless leg syndrome, chronic pain (arthritis), migraines, or cancer
      (5) Insomnia owing to substance abuse

5. Treatment
   a. **Nonpharmacologic intervention** is inexpensive and may be effective.
      (1) Maintain a regular schedule and do not nap; avoid sleeping in late after a poor night's sleep.
      (2) Use the bed only for sleep; avoid reading or watching television in bed.
      (3) If unable to initiate sleep (or go back to sleep) within 20 mins, engage in a relaxing activity (away from bed) until drowsy, and then return to bed.
      (4) Avoid exercise within 3 to 4 hrs of bedtime.
      (5) Minimize or avoid caffeine after noon.
      (6) Minimize or avoid alcohol, tobacco, or stimulants. Many people believe alcohol to be an agent for sleep induction; however, alcohol can act as a CNS stimulant, thereby increasing nocturnal awakenings.
   b. **Nonprescription drug therapy:** It has been estimated that 40% of patients with insomnia self-medicate with either alcohol or nonprescription medications in an effort to correct the condition. The sales of single-entity nonprescription hypnotics (e.g., diphenhydramine, doxylamine) have increased since that estimate was made, but the sales of nighttime analgesics (nonprescription hypnotic plus an analgesic, typically acetaminophen) have surpassed the

single-entity products. Currently, data supporting the safety and efficacy of complementary therapy as sleep aids are lacking.

(1) **Diphenhydramine**, an ethanolamine, blocks histamine$_1$ and muscarinic receptors, thus inducing sedation. Diphenhydramine is marketed as a nighttime sleep aid as Unisom SleepGels, Compoz, and Sominex.

    (a) Diphenhydramine may be dosed for sleep induction as **25 to 50 mg/night** in patients aged 12 and older. Doses **> 50 mg show no additional benefit,** but increased adverse effects. An initial dose of 25 mg may be recommended for patients over the age of 65 with no contraindications to the agent.

    (b) **Adverse effects** of diphenhydramine are **anticholinergic,** including dry mouth, blurred vision, constipation, and urinary retention. Diphenhydramine use should be avoided in patients with glaucoma (narrow-angle), benign prostatic hypertrophy, dementia, or cardiovascular disease.

    (c) The duration of sedation from diphenhydramine is 3 to 6 hrs. However, this may be extended in elderly patients or those with delayed metabolism.

    (d) The use of diphenhydramine for the alleviation of insomnia should be **limited to 7 to 10 consecutive nights**. If used longer than recommended, decreased efficacy may be noted and REM sleep may be suppressed.

    (e) Diphenhydramine is available in combination with aspirin or acetaminophen as a **nighttime analgesic**. Data are available to support the use of these agents in combination if pain is present. However, in the absence of pain, the addition of an analgesic simply provides increased opportunities for complications and drug misadventures.

(2) **Doxylamine**, like diphenhydramine, is an ethanolamine antihistamine which induces sleep through the blockade of histamine and muscarinic receptors. Therefore, adverse effects and duration of sedation are similar to diphenhydramine. There are currently no studies demonstrating enhanced efficacy or safety of doxylamine compared to diphenhydramine.

    (a) Doxylamine is dosed as **25 mg/night**.

    (b) Doxylamine is the active ingredient in Unisom Nighttime Sleep Aid Tablets. However, it should be noted that Unisom SleepGels contain diphenhydramine.

(3) **Melatonin**, a nocturnal neurohormone secreted by the pineal gland, has a **sleep-phase-shifting effect on circadian rhythm**. Recent trials have observed effectiveness of melatonin for sleep onset in patients with misaligned circadian rhythms attributable to shift work or jet lag.

    (a) Melatonin production decreases with age, possibly attributing to sleep disorders noted in elderly patients.

    (b) Melatonin production can be decreased by tobacco, alcohol, and certain medications (nonsteroidal anti-inflammatory drugs, calcium-channel blockers, steroids, benzodiazepines, and fluoxetine).

    (c) When exogenous melatonin is **given in the early evening, the circadian phase will be advanced**. Although this may be beneficial for individuals who experience difficulty in initiating sleep, melatonin given in this manner may worsen the problem of individuals who complain of difficulty in reinitiating sleep after awakening too early.

    (d) If melatonin is **given in the morning, the circadian phase is delayed**, offering the possibility that the patient may become sleepier earlier and awaken earlier. At present, it is unclear if continued administration of exogenous melatonin will suppress endogenous production.

    (e) Melatonin may be dosed as **0.3 to 5.0 mg during the day or at night**, depending on the desired effect. A physiologic dose of melatonin is 0.1 mg, an intermediate dose is 0.3 mg, and a pharmacologic dose is 3.0 mg. **Doses > 1 mg** may improve sleep efficiency but **have not demonstrated the ability to provide quality sleep restoration** as well as the intermediate dose.

    (f) Attributable to its short half-life (30 to 50 mins), melatonin should have **minimal, if any, residual effects the following morning**.

(4) **Valerian root**, derived from *Valeriana officinalis*, is classified as generally recognized as safe (GRAS) for food use in the United States. In doses of **600 mg/day,** valerian root

is purported to induce sedation through its blockade of γ-aminobutyric acid (GABA) breakdown. Adverse reactions of valerian root include vivid dreaming. Further research is necessary to determine the safety and efficacy of valerian root as a sleep aid.

(5) **Kava**, derived from *Piper methysticum*, is one of the most common dietary supplements used in the self-management of anxiety. It is theorized that if insomnia is caused by a state of hyperarousal, then management of anxiety and nervousness will help induce the desired sleep.

(a) A typical dose of kava is **120 mg/day**.

(b) Reported adverse effects of kava are significant, including diarrhea, extrapyramidal side effects, and hepatotoxicity. A recent FDA advisory has **recommended against the use of kava because of the reports of hepatotoxicity**, including hepatitis, cirrhosis, and liver failure.

III. SMOKING CESSATION

A. **Introduction.** More than 400,000 deaths annually are attributable to diseases directly linked to cigarette smoking, including atherosclerotic vascular disease, lung cancer, and chronic obstructive pulmonary disease. It is the most preventable contributor to morbidity and mortality in the United States and yet nearly one-third of the adult population (approximately 48 million adults) continues to smoke. The resulting economic burden is startling, estimated at $50 billion annually to treat smoking-related disorders and $47 billion for the loss of wages and productivity.

B. **Physiologic effects** of nicotine involve the CNS (e.g., enhanced relaxation, improved attention) and the cardiovascular system (e.g., elevated blood pressure, tachycardia). The manifestations of smoking become more pronounced as one ages and may include any or all of the following: deepening of the voice (an untoward effect in women); a constant, hacking cough; yellowed fingernails and surrounding skin from substances found in cigarette smoke; and premature aging of the skin, most noticeable on the face.

C. **Benefits of smoking cessation** are evident for both the patient and society.

1. Patient
   a. Decreased carbon monoxide levels
   b. Restoration of olfactory and gustatory senses within days
   c. Increased self-respect, sense of accomplishment
   d. Improved lung function (up to 30%) within 2 to 3 months
   e. Reduction in the risk of coronary heart disease (50%) after 1 year. After 2 years, the risk is equivalent to individuals who never smoked.
   f. Parallel risk of stroke to that of a nonsmoker within 5 to 15 years
   g. Progressive decline in the risk of lung cancer as number of years of abstinence increases. However, the risk will never be equivalent to one who never smoked.

2. Society
   a. Decreased health care costs for treatment of diseases directly linked to smoking
   b. Decreased work absenteeism owing to smoking-related disease
   c. Cleaner environment from decreased secondhand smoke and cigarette remains (e.g., ashes or butts of cigarettes) in public places

D. **Complications of smoking cessation.** Smoking is an addiction and, therefore, not easy to give up. Nicotine withdrawal symptoms include tobacco cravings, depressed mood, insomnia, irritability, inability to concentrate, anxiety, decreased heart rate, and increased hunger. Literature suggests that when individuals stop smoking without aid, all symptoms of nicotine withdrawal resolve within 30 days, except increased hunger, which persists past the 30-day cessation period.

E. **Tailored interventions** for smoking cessation should be offered to every patient who smokes. The U.S. Public Health Service endorses an approach known as the five As, developed in 1996 by the Agency for Healthcare Policy and Research.

1. **Ask** patients if they smoke.
2. **Advise** patients who smoke to quit.
3. **Assess** the patient's willingness to quit.
4. **Assist** the patient in efforts to quit through counseling and/or pharmacologic therapy. (The combination of counseling and pharmacologic therapy has proven to be the most successful method.)

5. **Arrange** follow-up within a short time frame.
6. To assess the patient's willingness to quit, the transtheoretical model of behavior change may be a useful tool. According to this model, patients are in one of five motivational stages to change their current behavior—that is, to stop smoking.
   a. **Precontemplation.** Patient is not ready to change current behavior.
   b. **Contemplation.** Patient is considering a change in current behavior in the future but not at the present time.
   c. **Preparation.** Patient is actively considering a change in current behavior and is actively engaged in seeking more information.
   d. **Action.** Patient is actively attempting to change behavior or has changed behavior within the last 6 months.
   e. **Maintenance.** Patient has sustained changed behavior for at least 6 months.
7. For patients in the precontemplation and contemplation stages, the health care professional should still advise the patient to quit smoking and repeat the assessment at future visits. For patients in the contemplation stage, the health care professional should assist the patient by offering a referral for smoking-cessation counseling and/or pharmacologic therapy. Behavior modification works best as a multidisciplinary approach, involving the health care provider, pharmacist, nurse, and dentist.

F. **Nicotine-replacement therapy**
1. **Overview.** Nicotine-replacement therapy (NRT) is a smoking-cessation aid used to ameliorate nicotine withdrawal symptoms by providing a **nontobacco, controlled-release amount of nicotine**.
   a. Research has demonstrated that the use of NRT in individuals who smoke > 10 cigarettes a day **can double the chances of successful smoking cessation**; but it is most successful when combined with other nonpharmacologic measures, such as counseling.
   b. Currently, three available dosage forms of NRT are approved by the FDA (gum, lozenges, and patches); however, **none is effective if the patient is not mentally ready to quit**. Furthermore, NRT is **FDA approved only for smoking cessation**, **not cessation of smokeless tobacco** (e.g., chewing tobacco, snuff).
   c. Self-care with NRT is appropriate for individuals who smoke less than 1.5 packs of cigarettes per day. This is on the basis that each cigarette contains approximately 1 mg of nicotine. Patients smoking greater than 1.5 packs per day should be referred to a health care provider for consideration of prescription therapy for smoking cessation or should be counseled to cut back to at least 1.5 packs per day to enhance success of NRT.
2. **Safety.** Although it is recommended by the U.S. Public Health Service that all people trying to abstain from smoking should receive pharmacotherapy support, not everyone is an ideal candidate.
   a. For patients with **acute cardiovascular disease** (e.g., stroke, acute myocardial infarction, unstable angina) and **pregnant or breastfeeding women**, **absolute abstinence from nicotine should be recommended**. However, if the patient makes an informed decision, under the supervision of a provider, a rapidly reversible preparation is advisable (e.g., gum or lozenge).
   b. In recent studies, NRT **appears to be safe in patients with stable cardiovascular disease**. Blood pressure should be monitored closely.
   c. The sale of NRT is **restricted to those older than age 18.** Therefore, adolescents desiring smoking cessation should consult a medical provider.
   d. Patients with **asthma or depression** are instructed to consult their physician before the use of NRT. The levels of certain medications used for management of these disease states (e.g., theophylline, imipramine) may be altered by smoking cessation. The nicotine found in NRT does not alter these levels.
   e. It is recommended that patients **do not smoke while using NRT** because the purpose of NRT is to alleviate symptoms while weaning from cigarettes. Although some studies have indicated that the combination may be safe, until further research is conducted, concomitant use of NRT and cigarettes should not be seen as permissible.
   f. Patients are advised on the labeling of NRT products not to combine two forms of NRT. However, a few small studies have shown combinations of NRT to be superior to either agent

Table 21-1	RECOMMENDED SCHEDULING OF NICOTINE GUM AND LOZENGES[a]

Weeks	Dose
1–6	1 piece gum or 1 lozenge every 1–2 hrs (at least 9/day)
7–9	1 piece gum or 1 lozenge every 2–4 hrs
10–12	1 piece gum or 1 lozenge every 4–8 hrs

[a]The recommended scheduling of nicotine polacrilex gum and lozenges is identical. If nicotine is needed past the 12-week schedule, a medical provider should be consulted.

alone. Therefore, some specialists in the field do recommend combination therapy. However, until further research is conducted in the form of well-developed, large trials, combination therapy with NRT should be discouraged unless prescribed by the supervising medical provider.

3. **Available forms of NRT**
   a. **Nicotine polacrilex gum** received FDA approval for prescription sales in 1984 and nonprescription status in 1995.
      (1) **Dosing.** Sold under the trade name Nicorette Gum, this product is available in a **2-mg dose** for individuals who smoke at least 30 mins after waking in the mornings and a **4-mg dose** for those who smoke within 30 mins of waking in the morning. The typical usage is **10 pieces daily**, with a maximum recommended usage of 60 mg/day for up to 3 months. The **strength of gum purchased does not change** instead, the number of pieces used decreases over the course of treatment (*Table 21-1*).
      (2) **Chew-and-park method.** The gum should be chewed slowly, releasing a peppery, tingling sensation, at which point the gum should be "parked" between the cheek and the gum to enhance buccal absorption of the nicotine.
      (3) **Adverse effects** most commonly reported are sore jaw and mouth, mouth ulcers, and dyspepsia.
      (4) **Counseling tips**
         (a) Slowly chew the gum until a peppery, tingling sensation is felt, then park the polacrilex gum between the cheek and the gum. Once the peppery, tingling sensation disappears, begin to slowly chew the gum again until the sensation returns. The gum should be parked in a different area than before. Once the gum loses the ability to produce the peppery, tingling sensation (approximately 30 mins), discard the gum.
         (b) **Do not eat or drink for 15 mins before using nicotine gum** because it requires a basic pH for proper release and absorption of the nicotine.
         (c) **Do not use other forms of NRT or smoke** while using the gum product, unless otherwise directed by a supervising provider.
         (d) The gum may be chewed at the beginning of the first day or at least 30 mins after the last cigarette was smoked.
   b. **Nicotine lozenges**, currently sold under the trade names Nicorette Lozenges and Nicorette Mini-Lozenges, deliver nicotine into the buccal mucosa when the individual sucks on the tablet, similar to a cough drop.
      (1) **Dosing.** The lozenges, like the gum, are dosed **based on the timing of the first cigarette**. If the first cigarette is craved within 30 mins of waking, the **4-mg** lozenge should be recommended. If the first cigarette craving is after 30 mins of waking, the **2-mg** lozenge should be recommended. The **strength chosen will not change** throughout the course of cessation; instead fewer lozenges will be consumed each day during the **12-week proposed schedule** (*Table 21-1*).
      (2) **Adverse effects.** If the lozenge is consumed too quickly or swallowed (rather than dissolved) dyspepsia may be experienced. Other reported adverse effects include insomnia, nausea, hiccups, coughing, headache, and flatulence.

(3) **Counseling tips**
  (a) **Avoid chewing** or biting the lozenge. Rather suck on the lozenge slowly, moving it from side to side, until it is completely dissolved (20 to 30 mins). If accidentally swallowed, wait at least 1 hr before using another lozenge.
  (b) **Do not use other forms of NRT and do not smoke** cigarettes while using this product, unless otherwise directed by a supervising provider.
  (c) The first lozenge may be taken at the beginning of the first day or at least 30 mins after the last cigarette was smoked.
  (d) **Do not take more than 20 lozenges per day** of either the 2-mg or 4-mg dose.
  (e) **Do not eat or drink for 15 mins before using nicotine lozenge** because it requires a basic pH for proper release and absorption of the nicotine.

c. **Nicotine patches** were introduced in 1992 and acquired nonprescription status in 1996. Comparative studies of the available formulations of NRT have revealed that most individuals prefer the patch over the gum or a prescription nicotine inhaler.
  (1) Availability and dosing: Nicoderm CQ is available in three strengths: 7, 14, and 21 mg. The patch should be **tapered**, depending on the starting dose.
    (a) NicoDerm CQ 21-mg patch may be recommended to an individual who smokes > 10 cigarettes per day and then tapered as follows: 21 mg/day for 6 weeks; 14 mg/day for 2 weeks; 7 mg/day for 2 weeks.
    (b) Those who smoke < 10 cigarettes per day may begin with the NicoDerm CQ 14-mg patch and taper as follows: 14 mg/day for 6 weeks; 7 mg/day for 2 weeks.
  (2) Application: The patch must be **placed on a clean, dry, and hair-free area** of the upper body (e.g., upper arm, back) and may be worn for **16 to 24 hr/day.** Patients with early-morning cigarette cravings may require 24-hr use. However, if insomnia or vivid dreaming occurs, the patch may be removed after 16 hrs. The patch should never be placed over wounds or open areas. Use with caution in patients with severe psoriasis or eczema.
  (3) Adverse effects: The most common adverse effect of the patch is **skin irritation**, but this may be reduced by rotating the patch site.

Study Questions

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. All of the following statements about dietary supplements are true *except* which one?
   (A) Manufacturers are not required to demonstrate product safety and efficacy before marketing supplements.
   (B) Adherence to good manufacturing practices is not mandatory for manufacturers of dietary supplements.
   (C) The U.S. Food and Drug Administration (FDA) files action against supplements determined unsafe.
   (D) The Federal Trade Commission (FTC) takes action against manufacturers who present misleading product advertising.

2. All of the following statements about chitosan are true *except* which one?
   (A) It is a common ingredient found in fat-trapper supplements.
   (B) It is derived from the Indian cluster bean.
   (C) Its safety is questionable for individuals with shellfish allergies.
   (D) It is purported to inhibit dietary fat absorption.

3. Jane is 36 years old and wants to lose weight. Her current body mass index (BMI) is 32 kg/m^2, her waist circumference is 40 inches, and her weight is 202 lbs. She has lost a minimal amount of weight in the past using fad diets and nonprescription weight loss products but has been unable to maintain the weight loss. All of the following are true, *except*

    (A) Based on her BMI, Jane is considered obese.

    (B) Her waist circumference of 40 inches increases her risk for cardiovascular disease.

    (C) A safe rate of weight loss for Jane would be 1 to 2 lb/week.

    (D) Initiation of exercise will provide more weight loss than dietary intake changes.

    (E) Her weight is a risk factor for the development of type 2 diabetes.

4. Since the sudden death of his father 2 weeks ago, Bob has been unable to sleep at night. He has difficulty going to sleep and awakens early in the morning, unable to return to sleep. Which of the following would be the correct classification of Bob's current insomnia?

    (A) transient, primary insomnia

    (B) short-term, primary insomnia

    (C) transient, secondary insomnia

    (D) short-term, secondary insomnia

5. William works the swing shift at the local manufacturing plant. Based on a recommendation from a friend at work, William would like to try melatonin to help him get to sleep faster. Which of the following is true regarding William's use of melatonin?

    (A) An appropriate starting dose of melatonin is 5 mg/night.

    (B) William may experience continued drowsiness the following morning owing to melatonin's long half-life.

    (C) Recent trials have noted the effectiveness of melatonin in individuals participating in shift work.

    (D) Tobacco use will increase endogenous melatonin production.

6. Which of the following complementary alternative medicines (CAM) is most strongly associated with hepatotoxicity, including hepatitis, cirrhosis, and liver failure?

    (A) melatonin

    (B) kava

    (C) chitosan

    (D) valerian root

    (E) dandelion

7. Sylvia is 33 years old and wishes to purchase a sleep aid for her recent bout of insomnia (duration is 2 days). She has linked it to an overwhelming amount of stress she has been under lately at work, trying to meet deadlines, and her recent lack of sleep is not helping. She has no current medical conditions and takes a multivitamin daily. All of the following are true regarding Sylvia's taking diphenhydramine and doxylamine *except* which one?

    (A) Sylvia may benefit from diphenhydramine 50 mg used nightly.

    (B) Sylvia may use diphenhydramine for insomnia for up to 10 consecutive nights.

    (C) Sylvia may benefit from doxylamine 50 mg used nightly as needed.

    (D) Sylvia may experience anticholinergic side effects with the use of doxylamine.

8. Jill, a 22-year-old college student, has been encouraged by her health care provider to stop smoking. She tells her doctor that she wants to quit, but she does not want to gain weight right now or to sacrifice her grades as a result of an inability to concentrate during the day. According to the five As and the transtheoretical model of change, what is the next step Jill's health care provider should take?

    (A) Jill is in the precontemplation stage of change. Her provider should reassess her willingness to quit at the next visit.

    (B) Jill is in the contemplation stage of change. Her provider should reassess her willingness to quit at the next visit.

    (C) Jill is in the preparation stage of change. Her provider should reassess her willingness to quit at the next visit.

    (D) Jill is in the preparation stage of change. Her provider should offer her counseling and/or pharmacologic therapy for smoking cessation.

9. Zack is 55 years old and wishes to start taking nicotine lozenges to quit smoking. Which of the following is important in the recommendation and selection of nicotine lozenges?

    (A) number of cigarettes smoked daily

    (B) timing of his first urge for a cigarette

    (C) concomitant disease states and therapies

    (D) both the number of cigarettes smoked daily and concomitant disease states and therapies

    (E) both the timing of his first urge for a cigarette and concomitant disease states and therapies

10. All of the following are important counseling tips for the use of nicotine replacement therapies *except* which one?

    (A) Do not eat or drink within 15 mins of chewing nicotine gum.
    (B) The initial start of nicotine replacement therapy may be 30 mins after the last cigarette.
    (C) Skin irritation associated with the use of a patch may be minimized by rotating the patch site.
    (D) Patches should be removed after 8 hrs of use if the person experiences insomnia.

11. Wendy, a 45-year-old female, is seeking advice about the use of Alli® for weight loss. Her current weight is 228 lbs and her height is 5′6″. At her last provider visit, her provider suggested she set a weight loss goal of 2 lbs per week through diet and exercise. Wendy has type 2 diabetes and hypertension, both of which are well controlled. Which of the following would be appropriate information to provide Wendy?

    (A) Orlistat may assist in modest amounts of weight loss, but noticeable results may not be evident for several months.
    (B) Orlistat is contraindicated in individuals with diabetes mellitus.
    (C) Orlistat is taken as 1 capsule three times daily 1 hr after a fat-containing meal.
    (D) Orlistat may reduce the absorption of fat-soluble vitamins, thus a multivitamin should be taken when nonprescription orlistat is initiated.

Answers and Explanations

1. **The answer is B** *[see I.C]*.

   Manufacturers of dietary supplements (DS) are not required to demonstrate product safety and efficacy before marketing. Previously, manufacturers of DS were not required to adhere to good manufacturing practices. However, in 2007, FDA ruled that DS must be manufactured in a manner that ensures quality and the DS must be properly packaged and labeled.

2. **The answer is B** *[see I.C.5.e]*.

   Derived from the exoskeleton of shellfish, chitosan is purported to block dietary fat absorption and thus is a common ingredient found in fat-trapper supplements. Because it is derived from the exoskeleton of shellfish, the safety of chitosan in individuals with shellfish allergies remains in question.

3. **The answer is D** *[see I.A.1–2; I.B.1.b–c; I.B.2]*.

   A BMI > 30 kg/m^2 is considered obese. Women with a waist circumference > 35 inches are at increased risk of developing cardiovascular disease, as well as type 2 diabetes, sleep apnea, and osteoarthritis. If Jane's BMI had been > 35 kg/m^2, her waist circumference measurement would not be valid for determining an increased cardiovascular risk. Diet and exercise are the best approach to weight loss; however, exercise only adds a modest amount of weight loss. Decreased dietary consumption will provide the most benefit in her efforts to lose weight. A reasonable weight loss is 1 to 2 lb/week.

4. **The answer is D** *[see II.B.3–4]*.

   Transient insomnia is insomnia lasting < 1 week, and short-term insomnia is insomnia lasting from 1 to 3 weeks. Primary insomnia is a pathological condition in which the patient experiences continued insomnia in the absence of a related medical or psychiatric condition. Secondary insomnia can be attributed to a variety of situations, especially situational stress, such as the death of a loved one.

5. **The answer is C** *[see II.B.5.b.(3)]*.

   Melatonin effectiveness for sleep onset has been observed in recent trials in individuals participating in shift work. However, melatonin is not FDA approved for this purpose. An initial starting dose of melatonin is 0.1 to 0.3 mg in the evening for patients desiring improved sleep onset. Doses > 1 mg daily have not been able to demonstrate the quality sleep restoration seen in 0.3-mg doses. Melatonin has minimal, if any, residual effects the following morning, owing to its short half-life of 30 to 50 mins. Tobacco, alcohol, and certain medications can decrease endogenous melatonin production.

6. **The answer is B** *[see II.B.5.b.(5)]*.

   Kava, typically used for anxiety disorders, has been associated with hepatotoxicity, including hepatitis, cirrhosis, and liver failure. An FDA advisory committee has recommended against the use of kava because of the reports of hepatotoxicity.

7. The answer is C *[see II.B.5.b.(1)–(2)]*.

Diphenhydramine may be dosed as 25 to 50 mg nightly for a sleep aid used for up to 7 to 10 consecutive nights. The recommended dosage for doxylamine is 25 mg nightly. Both diphenhydramine and doxylamine are ethanolamine antihistamines. Therefore, anticholinergic effects may be experienced with the use of either agent.

8. The answer is B *[see III.E.6]*.

Jill is in the contemplation stage, as she is considering a change in the future, but she does not feel that this is the right time to begin a smoking cessation program. Therefore, Jill's provider should reassess her willingness to quit at her next visit, when, it is hoped that Jill will be ready to quit.

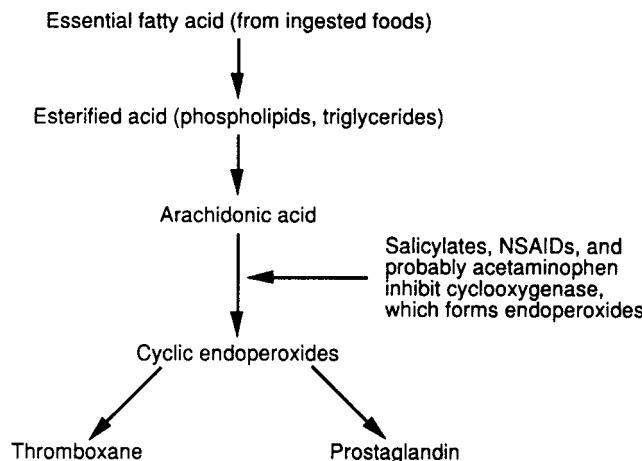
9. The answer is E *[see III.F.3.b]*.

Dosing is based on the timing of the first urge for a cigarette, either within or after 30 mins of waking up. Concomitant disease states should be considered as well. If the patient has hypertension, he will need to be monitored more closely while using nicotine replacement therapy. If he uses certain prescription medications for asthma or depression, his medication may need to be adjusted when he stops smoking.

10. The answer is D *[see III.F.3.a–c]*.

Nicotine patches should be worn for 24 hrs. If the patient develops insomnia or vivid dreams from the patch, it may be removed before bed, thus allowing only 16 hrs of exposure to the nicotine. Use of the patch for only 8 hrs is not an acceptable recommendation. Patch application sites should be rotated to avoid skin irritation and patients should be counseled not to eat or drink within 15 mins of chewing the gum.

11. The answer is A *[see I.B.2]*.

Orlistat may alter metabolic control, necessitating a change in diabetes medication dosing regimen; however, orlistat is not contraindicated in patients with diabetes. Orlistat is dosed as 1 capsule three times daily with a fat-containing meal, but for optimal effects, it should be dosed during or within 1 hr of the meal not after the meal. It is advisable to recommend a multivitamin to individuals who will be using doses of orlistat greater than 180 mg/day or who will be using orlistat for longer than 2 to 3 months. However, at initiation of nonprescription strength orlistat (60 mg thrice daily), a multivitamin has not been observed as necessary; however, it would be advisable if the individual does continue the medication past 2 to 3 months to recommend a MVI.


22 | Over-the-Counter Agents for Fever, Pain, Cough, Cold, and Allergic Rhinitis

JENNIFER D. SMITH, GERALD E. SCHUMACHER

I. ANALGESIC, ANTI-INFLAMMATORY, AND ANTIPYRETIC AGENTS.

Over-the-counter (OTC) analgesics and antipyretics relieve mild to moderate pain and reduce inflammation and fever. These agents are effective for somatic pain (e.g., musculoskeletal pain in the joints; pain from headache, myalgia, and dysmenorrhea; discomfort resulting from generalized inflammation), but they are not effective in reducing discomfort from the visceral organs (e.g., stomach, lungs, heart). Salicylates and nonsteroidal anti-inflammatory drugs (NSAIDs) reduce pain, inflammation, and fever, but acetaminophen generally is effective only for pain and fever.

A. Pathogenesis of pain. Intense stimulus (e.g., tissue injury) releases substances that sensitize pain receptors to mechanical, thermal, and chemical stimulation. This triggers pain receptors to send pain impulses over afferent nerve fibers to the central nervous system (CNS).

1. **Awareness** of pain occurs in the thalamus.
2. Pain **recognition** and **localization** occur in the cortex.
3. **Mechanism of analgesic, anti-inflammatory, and antipyretic action.** These agents inhibit (centrally, peripherally, or both) the biosynthesis of various **prostaglandins**, substances involved in the development of pain and inflammation as well as in the regulation of body temperature.

B. Salicylates

1. **Therapeutic uses**
   a. Salicylates are used to relieve mild to moderate pain and reduce inflammation and fever.
   b. Aspirin (acetylsalicylic acid), specifically, is also used to reduce the incidence of some forms of cardiovascular disease. Current evidence supports a modest reduction in the risk of strokes in women but notes less effect in men. On the other hand, evidence supports a significant reduction in the risk of myocardial infarction in men and women > 65 years but shows little effect on younger women.
   c. Men and women who have had a previous myocardial infarction, stable and unstable angina pectoris, or coronary artery bypass surgery, are candidates for aspirin use.
   d. No consensus has emerged on the prophylactic use of aspirin in healthy adults. The risks associated with aspirin use may outweigh the benefits of its widespread use.

2. **Mechanism of action**
   a. **Analgesic and anti-inflammatory actions.** The action of aspirin results from both the acetyl and the salicylate portions of the drug. Actions of other salicylates (e.g., sodium salicylate, salicylsalicylic acid, choline salicylate) result only from the salicylate portion of the agents.

Essential fatty acid (from ingested foods)

↓

Esterified acid (phospholipids, triglycerides)

Arachidonic acid

← Salicylates, NSAIDs, and probably acetaminophen inhibit cyclooxygenase, which forms endoperoxides

↓

Cyclic endoperoxides

↓ ↓

Thromboxane   Prostaglandin

Figure 22-1. Inhibition of prostaglandin formation by aspirin, nonsteroidal anti-inflammatory drugs (NSAIDs), and acetaminophen.

(1) These drugs **inhibit cyclooxygenase,** the enzyme that is responsible for the formation of precursors of prostaglandins (PGs) and thromboxanes from arachidonic acid (*Figure 22-1*).

(2) Analgesia is produced mainly by **blocking the peripheral generation of pain impulses** mediated by prostaglandins and other chemicals. Analgesia probably secondarily involves a reduction in the awareness of pain in the CNS.

b. Antipyretic action. The principal antipyretic action occurs in the CNS. Salicylates act on the hypothalamic heat-regulating center to produce peripheral vasodilation, which results from the inhibition of prostaglandin synthesis.

c. Antiplatelet and antithrombotic actions

(1) Antiplatelet. Aspirin (but not other salicylates, acetaminophen, or NSAIDs) **irreversibly inhibits cyclooxygenase in platelets,** which prevents the formation of the aggregating agent thromboxane A_2.

(2) Antithrombotic. At low doses, aspirin inhibits thromboxane A_2 formation but has a relatively small effect on prostacyclin. This results in blocking the platelet aggregating agent thromboxane A_2 while preserving the action of the aggregation inhibitor prostacyclin (prostaglandin I_2; PGI_2).

3. Administration and dosage

a. For **analgesia** or **antipyresis in adults**, 325 to 650 mg every 4 hrs or 650 to 1000 mg every 6 hrs should be administered as needed. The maximum daily dose is 4000 mg for no longer than 10 days for pain or 3 days for fever without consulting a physician.

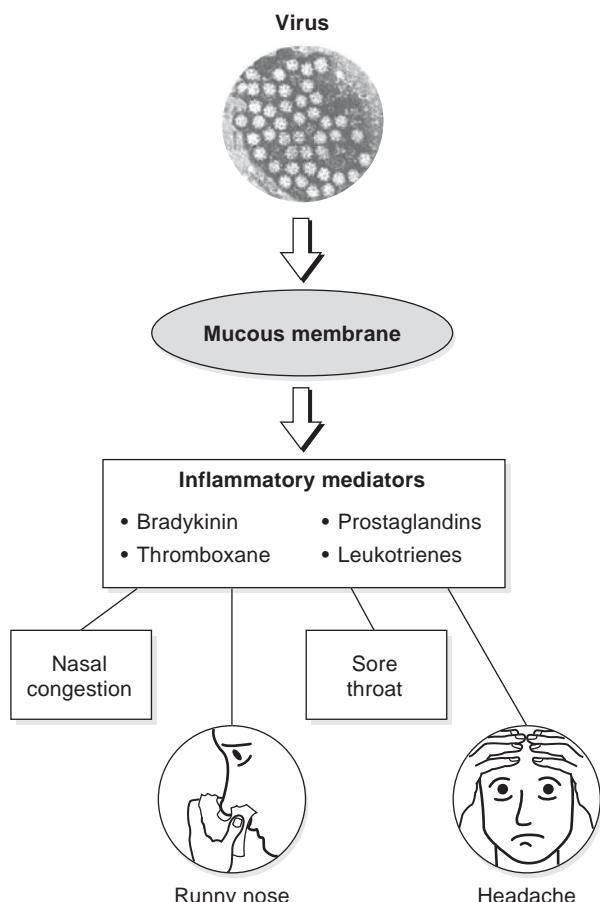
b. Child dosage depends on age. The dosages are 160 mg every 4 hrs for children 2 to 4 years of age and 400 to 480 mg every 4 hrs for children 9 to 12 years of age. Salicylates should be given for no longer than 5 days for pain, 3 days for fever, and 2 days for sore throat without consulting a physician.

c. The **antirheumatic dosage for adults** is 3600 to 4500 mg daily in divided doses.

d. For patients with **ischemic heart disease**, a 325-mg dose is given daily. Every other day is recommended for individuals with stable or unstable angina and evolving myocardial infarction. For patients without clinically apparent ischemic heart disease, the hemorrhagic complications associated with routine aspirin use may outweigh its benefit, unless individuals have established risk factors for atherosclerotic disease.

e. For patients at risk of stroke, an 81-mg dose is given daily or every other day. As described previously, the risks may outweigh the benefits.

f. Anti-inflammatory dosages. Although antipyretic and analgesic effects should appear within the first few doses, the anti-inflammatory effect may take 2 weeks or more to appear, even at high doses. The usual anti-inflammatory dosage of aspirin is 4000 to 6000 mg/day. The usual anti-inflammatory dosage of ibuprofen is 1200 to 3200 mg/day.

4. **Precautions**
    a. **Hypersensitivity** to aspirin occurs in up to 0.5% of the population.
        (1) Allergic reactions resulting in bronchoconstriction occur most frequently in people with **nasal polyps**.
        (2) **Cross-reactivity** with other NSAIDs occurs in > 90% of people. Cross-reactivity with acetaminophen occurs in 5% of people.
    b. **Contraindications.** Aspirin is contraindicated in patients with bleeding disorders or peptic ulcers. Also, aspirin should not be given to children or teenagers who have a viral illness, because Reye syndrome (i.e., fatty liver degeneration accompanied by encephalopathy) may occur.
    c. **Pregnancy.** Salicylates in chronic high doses are recommended with extreme caution during the last trimester of pregnancy because of
        (1) Potential bleeding problems in the mother, fetus, or neonate
        (2) Prolonging or complicating delivery
    d. **Gastrointestinal (GI) disturbances** resulting from the inhibition of the gastric prostaglandins occur in 10% to 20% of people at analgesic and antipyretic dosages. Anti-inflammatory regimens affect up to 40% of people. These effects decrease by using enteric-coated dosage forms and by taking salicylates with food or large doses of antacids. Buffered aspirin products contain insufficient buffers to counteract the adverse GI effects of aspirin.
    e. **CNS disturbances** such as tinnitus, dizziness, or headache may occur at anti-inflammatory doses in some patients.
    f. **Salicylism** (salicylate toxicity) may occur at anti-inflammatory doses. In addition to the CNS disturbances (see I.B.4.e), respiratory alkalosis, nausea, hyperthermia, confusion, and convulsions may occur.
5. **Significant interactions**
    a. Salicylates potentiate the effect of **anticoagulants** and **thrombolytic agents**.
    b. Salicylates potentiate (at anti-inflammatory doses) the effect of **hypoglycemics**.
    c. Salicylates potentiate the adverse GI reaction resulting from chronic **alcohol** or **NSAID** use.
    d. Aspirin may competitively inhibit the metabolism of **zidovudine**, resulting in potentiation of zidovudine or aspirin toxicity.
    e. **Caffeine** taken in conjunction with salicylates appears to enhance the analgesic effect.
C. **Acetaminophen**
    1. **Therapeutic uses.** Acetaminophen is used to relieve mild-to-moderate pain and to reduce fever. Guidelines from the American College of Rheumatology now recommend it as first-line therapy for osteoarthritis of the knee and hip. Because it has minimal anti-inflammatory activity, it cannot be used to treat the swelling or stiffness resulting from rheumatoid arthritis.
    2. **Mechanism of action.** The analgesic and antipyretic actions of acetaminophen are the same as those for aspirin (see I.B.2.a–b).
    3. **Administration and dosage.** Available dosage forms are 325 mg and 500 mg. A prolonged dosage form caplet of 650 mg is also available.
        a. For **analgesia** or **antipyresis in adults**, the dosage is 500 to 1000 mg three times daily as needed. The maximum daily dose is 4000 mg for no longer than 10 days for pain or 3 days for fever without consulting a physician. For osteoarthritis, 1000 mg four times daily is recommended.
        b. For **children age 6 years or older**, 325 mg is administered every 4 to 6 hrs as needed. The maximum daily dose is 1600 mg for no longer than 5 days for pain, 3 days for fever, or 2 days for sore throat without consulting a physician.
        c. **Routine use.** Acetaminophen is routinely used in patients who are
            (1) Sensitive to the GI disturbances caused by salicylates and NSAIDs
            (2) Prone to bleeding disorders
            (3) Hypersensitive to salicylates
    4. **Precautions**
        a. Patients with active alcoholism, hepatic disease, or viral hepatitis are at risk from chronic administration of acetaminophen. Toxicity is rare, but chronic daily ingestion of 5 g or more for longer than 1 month is likely to result in liver damage. Acute doses of 10 g or more are hepatotoxic.


b. Many OTC products contain acetaminophen in addition to other ingredients. It is important to counsel patients that the daily dosage limits cited in I.C.3.a–b apply to the total acetaminophen consumed from all products daily.

c. In light of both the increasingly common addition of acetaminophen to many OTC combination products and the concern for acetaminophen-induced liver toxicity, the U.S. Food and Drug Administration (FDA) is giving strong consideration to requiring prominent warning labels on all acetaminophen-containing products and reducing the adult daily dosage limit to 3250 mg. Chronic alcohol users would be recommended an even lower dose.

5. Significant interactions. Acetaminophen may competitively inhibit the metabolism of **zidovudine**, resulting in potentiation of zidovudine or acetaminophen toxicity.

D. NSAIDs. Currently, **ibuprofen** and **naproxen** are the only NSAIDs available without a prescription.

1. Therapeutic uses. NSAIDs are used to relieve mild-to-moderate pain and to reduce inflammation and fever. OTC drug use largely focuses on the analgesic and antipyretic indications of these agents. Maximum OTC drug dosage is generally recommended for osteoarthritis. As mentioned previously (see I.C.1), acetaminophen is recommended as initial treatment for osteoarthritis because of its safety profile, but NSAIDs are more effective for pain and inflammation. Their use is limited by greater frequency of adverse reactions (see I.D.4) than observed with acetaminophen.

2. Mechanism of action

a. Analgesic and anti-inflammatory actions. NSAIDs inhibit prostaglandin synthesis both peripherally and centrally. Like salicylates, these drugs inhibit cyclooxygenase (*Figure 22-1*). NSAIDs produce analgesia mainly by blocking the peripheral generation of pain impulses that are mediated by prostaglandins and other chemicals. Secondarily, analgesia probably involves a reduction in the awareness of pain in the CNS.

b. Antipyretic action. The principal antipyretic action is central. NSAIDs act on the hypothalamic heat-regulating center to produce peripheral vasodilation, which results from the inhibition of prostaglandin synthesis.

3. Administration and dosage. The available OTC dosage forms of ibuprofen are a 200-mg tablet and a 100-mg per 5-mL oral suspension. Naproxen sodium OTC is available as a 220-mg (200 mg of naproxen) tablet.

a. For **analgesia** or **antipyresis in adults**, the dosage of **ibuprofen** is 200 to 400 mg every 4 to 6 hrs as needed. The maximum daily dose is 1200 mg for no longer than 10 days for pain or 3 days for fever without consulting a physician. For **naproxen sodium**, the recommended dose is 220 mg every 8 to 12 hrs as needed. The maximum daily dose is 660 mg.

b. For **rheumatoid arthritis dosage in adults**, **ibuprofen** is recommended to a maximum daily dosage of 3200 mg (administered on a 4- to 6-hr basis), **naproxen sodium** to a daily maximum of 1100 mg (divided doses every 8 to 12 hrs).

c. Naproxen sodium is not recommended for children < 12 years of age. **Ibuprofen** is available as a suspension for children 2 to 11 years of age.

4. Precautions

a. NSAIDs are contraindicated in patients with **bleeding disorders** or **peptic ulcers**.

b. NSAIDs are recommended with extreme caution during the last trimester of **pregnancy** because of:

(1) Potential adverse effects on fetal blood flow

(2) The possibility of prolonging pregnancy

c. GI disturbances resulting from the inhibition of the gastric prostaglandins occur in 5% to 10% of people at analgesic and antipyretic doses. Anti-inflammatory regimens (i.e., higher doses) affect up to 20% of people. These effects decrease when NSAIDs are taken with food or large doses of antacids. Ibuprofen is often preferred to aspirin by patients because ibuprofen causes fewer GI disturbances and bleeding events.

d. Renal toxicity during chronic administration is a significant concern, and may occur in the form of nephrotic syndrome, hyperkalemia, or interstitial nephritis.

e. There is a growing concern about the cardiovascular toxicity of NSAIDs. Although the risk is low, ibuprofen use is more risky than naproxen.

    5. Significant interactions
      a. NSAIDs potentiate the effect of **anticoagulants** and **thrombolytic agents**.
      b. NSAIDs potentiate (at anti-inflammatory doses) the effect of **hypoglycemics**.
      c. NSAIDs potentiate the adverse GI reactions resulting from chronic **alcohol** or **salicylate** use.
      d. **Caffeine** taken in conjunction with ibuprofen appears to enhance the analgesic effect.
      e. Hypersensitivity to **aspirin** can occur with NSAID use.
      f. OTC labeling for these agents cautions against use of combining NSAIDs.

II. THE COMMON COLD

  A. General. The common cold is generally a mild and self-limiting viral infection of the upper respiratory tract. Rather than typical epidemiologic measures, the prevalence of the common cold is expressed as the number of incidences per individual per year. Adults typically experience two to three colds per year; preschool children typically experience five to seven colds per year. Children < 5 years old who attend daycare or have frequent interactions with a number of other children may experience as many as 12 colds per year.

  B. Etiology. The coronaviruses, respiratory syncytial virus (RSV), and rhinoviruses are the most contributing pathogens of the common cold, and the rhinovirus is the most frequently associated pathogen. Other pathogens involved include influenza, parainfluenza, and adenoviruses.

  C. Pathogenesis. Pathogenic events of the common cold caused by the rhinovirus begin when a small dose of virus is deposited into the nose or the eye either by direct contact or by aerosol transmission (*Figure 22.2*).
    1. Mucociliary action transports the virus to the adenoid where the virus is able to attach to the intracellular adhesion molecule (ICAM) receptors on lymphoepithelial cells. There, the

Figure 22-2. Pathogenesis of the common cold.

virus begins to replicate, triggering the release of inflammatory mediators, including histamines, kinins, certain prostaglandins, and several interleukins (e.g., interleukin 1 [IL-1], IL-6, and IL-8).

2. Within 8 to 12 hrs of viral entry into the nose or eye, the inflammatory mediators and parasympathetic nervous system reflex mechanisms lead to nasal congestion, rhinorrhea, sore throat, headache, and stimulation of cough and sneezing reflexes.

D. Symptoms

1. Once viral contact has been made, a scratchy throat may develop within 1 to 2 days.

2. A sore throat is followed by a thin, watery discharge, known as rhinorrhea, and sneezing. Within 1 to 2 days, the thin, watery discharge may become thick and purulent.

3. A dry, nonproductive cough may develop between days 3 and 5, often evolving into a productive cough.

4. The general peak of cold symptoms is 2 to 4 days, and the median duration of the common cold is 7 to 13 days.

E. Nonpharmacologic treatment includes adequate fluid intake, adequate rest, increased humidification, and/or nasal irrigation.

F. Pharmacologic treatment: Recommendations in the cough and cold aisles have changed significantly over the past few years. Previously, it was acceptable to treat the pediatric patient younger than the age of 2 for cough and cold symptoms, despite lack of data supporting this use. In 2008, an FDA public health advisory was released that nonprescription cough and cold products should not be used for individuals younger than the age of 2 due to serious and potentially life-threatening effects. In response, many manufacturers withdrew products that contained labeling for individuals younger than the age of 2, and many voluntarily relabeled their products for use in children ages 4 and older.

   1. **Decongestants**, also known as sympathomimetics, are the primary treatment for nasal congestion. Decongestants are available as topical or oral delivery (*Table 22-1*).

      a. Mechanism of action. Both oral and topical decongestants produce vasoconstriction by stimulating α-adrenergic receptors, thereby reducing the volume of blood circulated to the nasal mucosa and decreasing mucosal edema.

      b. Administration and dosage

        (1) Topical. Available nonprescription topical decongestants include sprays (phenylephrine and oxymetazoline) and inhalers (levmetamfetamine and propylhexedrine) and are labeled for individuals ages 6 years and older.

          (a) Phenylephrine (topical; Neo-Synephrine): 0.25% to 1%, every 4 to 6 hrs

          (b) Oxymetazoline (topical; Afrin, Neo-Synephrine 12 hrs, Nostrilla, Mucinex NS, Vicks Sinex 12 hrs): 0.05%, every 10 to 12 hrs

          (c) Levmetamfetamine (inhaler; Vicks Vapor Inhaler):

            (i) Ages 6 to 12 years: 1 inhalation in each nostril NMT every 2 hrs

            (ii) Ages 12 years and older: 2 inhalations in each nostril NMT every 2 hrs

          (d) Propylhexedrine (inhaler; Benzedrex): 2 inhalations in each nostril NMT every 2 hrs

        (2) Oral decongestants available in the United States include pseudoephedrine and phenylephrine. Pseudoephedrine is the key ingredient in the illegal manufacturing of methamphetamine, thus the sale of pseudoephedrine has been restricted, placing it behind pharmacy counters in all states. Phenylephrine is not as easily converted into methamphetamine and thus is more readily available to consumers who are seeking relief from congestion.

          (a) Pseudoephedrine

            (i) Ages 2 to 5 years: 15 mg every 4 to 6 hrs; maximum dose 60 mg/24 hr

            (ii) Ages 6 to 12 years: 30 mg every 4 to 6 hrs; maximum dose 120 mg/24 hr

            (iii) Ages 12 and older: 30 to 60 mg every 4 to 6 hrs or for sustained release 120 mg every 12 hrs; maximum dose 240 mg/24 hr

          (b) Phenylephrine

            (i) Ages 2 to 5 years: 2.5 mg every 4 hrs

            (ii) Ages 6 to 12 years: 5 mg every 4 hrs

            (iii) Ages 12 and older: 10 mg every 4 hrs

Table 22-1 AVAILABLE TOPICAL AND ORAL DECONGESTANTS

Agent	Products	Dosing	Avoid Use In . . .	Comments/Counseling Points
			Topical Decongestants	
Oxymetazoline	Afrin, Neo-Synephrine 12 hrs; Vicks Sinex 12 hrs; Mucinex Full Force; and Mucinex Moisture Smart	2–3 sprays q10–12h	Questionable use in hypertension or receiving MAOI May exacerbate: hyperthyroidism, intraocular pressure, coronary heart disease, prostatic hypertrophy	Use for only 3–5 days owing to potential for rebound congestion (rhinitis medicamentosa) Oxymetazoline is long acting Adverse effects: cardiovascular and CNS stimulation; burning; stinging; sneezing
Phenylephrine	Neo-Synephrine	2–3 gtt q4h		
Prophylhexedrine	Benzedrex	6+ years: 2 inhalations, no more than every 2 hrs		
Levmetamfetamine	Vicks Vapor Inhaler	6–12 years: 1 inhalation, no more than every 2 hrs 12+ years: 2 inhalations, no more than every 2 hrs		Lacks vasopressor effect; thus not contraindicated in patients with hypertension, thyroid disease, diabetes, narrow-angle glaucoma, or difficulty in urination owing to enlarged prostate
			Oral decongestants	
Pseudoephedrine	Sudafed	2–6 years: 15 mg q4–6h 6–12 years: 30 mg q4–6h 12+ years: 60 mg q4–6h: SR 120 mg q12h	Hypertension May exacerbate: hyperthyroidism, intraocular pressure, coronary heart disease, prostatic hypertrophy	Pseudoephedrine is absorbed well orally; however, phenylephrine has low oral bioavailability Adverse effects: cardiovascular (↑ BP, arrhythmias, tachycardia) and CNS stimulation (restlessness, insomnia, anxiety, hallucinations)
Phenylephrine	Sudafed PE	2–6 years: 2.5 mg q4h 6–12 years: 5 mg q4h 12+ years: 10 mg q4h		Concomitant use with TCA may affect BP (↑ or ↓), depending on specific decongestant

BP, blood pressure; *CNS*, central nervous system; *gtt*, drops; *MAOI*, monoamine oxidase inhibitor; *qh*, *every hour*; *TCA* tricyclic antidepressant.

c. **Precautions.** Only **under the advice of a medical provider**, and **with extreme caution** should decongestants be **recommended to patients with disease states that are sensitive to adrenergic stimulation**, including coronary heart disease, hypertension, thyroid disease, diabetes, narrow-angle glaucoma, and difficulty in urination owing to an enlarged prostate gland. Levmetamfetamine is different than the other available nasal decongestants because it lacks a vasopressor effect and, therefore, does not need to carry the warning for patients who are sensitive to adrenergic stimulation.

d. **Significant interactions.** Patients currently taking tricyclic antidepressants or monoamine oxidase inhibitors (**MAOIs**) or who are **within 2 weeks of discontinuation should avoid the use of oral and topical decongestants** owing to an increased effect on blood pressure.

e. **Counseling points**

(1) **Topical decongestants** cause localized vasoconstriction; so if used appropriately, systemic side effects should be minimal. However, given the difficulty of administration, systemic side effects are often seen with topical decongestants. *Table 22-2* provides advice for patient counseling on device selected.

(2) Patients using **topical nasal decongestants** should be cautioned to **limit use of the product to 3 to 5 days** to avoid **rhinitis medicamentosa**, a worsening of symptoms directly related to the extended use of the product. Treatment of this condition is to slowly withdraw the topical decongestant and begin oral decongestants. Topical normal saline may also be used to relieve irritated nasal passages.

(3) To avoid spread of infection, patients should be counseled not to share topical nasal decongestants with others.

(4) Topical decongestants may cause a temporary **burning or stinging sensation** when used and may also **increase nasal discharge**.

(5) Efficacy of topical decongestants may be diminished in the patient who has severely obstructed nasal passages because their use requires the ability of the medication to be delivered to the nasal mucosa.

TABLE 22-2   PATIENT COUNSELING INFORMATION FOR NASAL DECONGESTANTS

Drops	Spray (Atomizer)	Inhalers	Metered-Dose Pump (Spray)
• Blow nose • Squeeze rubber bulb on dropper and withdraw medication from bottle • Recline on bed and hang head over side (preferred) *or* tilt head back while standing or sitting • Place drops into each nostril and gently tilt head from side to side to distribute drug • Keep head tilted back for several minutes after instilling drops • Rinse dropper with hot water	• Blow nose • Remove cap from spray container • For best results, do not shake squeeze bottle • Administer one spray with head in upright position • Sniff deeply while squeezing bottle • Wait 3–5 mins, then blow nose • Administer another spray if necessary • Rinse spray tip with hot water, taking care not to allow water to enter bottle • Replace cap	• Blow nose • Warm inhaler in hand to increase volatility of medication • Remove protective cap • Inhale medicated vapor in one nostril while closing off other nostril; repeat in other nostril • Wipe inhaler clean after each use • Replace cap immediately • *Note*: Inhaler loses its potency after 2–3 months even though aroma may linger	• Blow nose • Remove protective cap • Prime metered pump by depressing several times (for first use), pointing away from face • Hold bottle with thumb at base and nozzle between first and second fingers • Insert pump gently into nose with head upright • Depress pump completely, and sniff deeply • Wait 3–5 mins, then blow nose • Administer another spray if necessary • Rinse spray tip with hot water, taking care not to allow water to enter bottle • Replace cap

(6) Once opened, **nasal inhalers should be discarded after 2 to 3 months** because the active ingredient dissipates, even when the product is tightly capped.

(7) Pseudoephedrine may cause hypertension and palpitations. Close monitoring should be observed in high-risk individuals.

(8) Pseudoephedrine readily enters the CNS and may, therefore, cause **insomnia**, restlessness, anxiety, or hallucinations. In individuals who are sensitive to this effect, the last dose should be given at least 4 to 6 hrs prior to bedtime.

(9) Notify a health care provider if symptoms worsen or do not improve within 7 days.

2. Nasal strips (Breathe Right) are bandagelike in appearance and function to physically open the nasal passages. Formulations include nonmedicated or with menthol.

  a. Instructions. Place the strip between the bridge and tip of the nose. As the strip attempts to resume a flattened shape, the nares are pulled into a more opened state.

  b. Uses. **Ideal in pregnancy**, **children**, and **in the elderly who take numerous medications**.

3. Decongestion alternatives (e.g., Coricidin HBP and its related line of products) are marketed for patients who are unable to take oral or topical nasal decongestants.

  a. Chlorpheniramine, an antihistamine, is typically the ingredient in these products.

  b. Antihistamines fail to target the primary problem: obstruction of the nasal passages.

4. Antihistamines

  a. Use

  (1) First-generation antihistamines are appropriate for the treatment of rhinorrhea, sneezing, and a nonproductive cough, but have no effect on nasal congestion. **Only first-generation antihistamines are appropriate for treatment of the common cold symptoms**. Second-generation antihistamines have preferential peripheral H_1-receptor binding, thus limiting the anticholinergic activity that is necessary to treat common cold symptoms. (*Table 22-3*).

  (2) Many providers advise against treating children for rhinorrhea and sneezing with the common cold owing to the increased risk of adverse effects. The best advice to a caregiver seeking treatment of a runny nose for a child < 6 years of age is to simply let it run its course because the cold is a self-limiting viral infection.

  b. Administration and dosing. **First-generation antihistamines are not FDA approved for treatment of common cold symptoms in children younger than age 6**.

  (1) Brompheniramine (not currently available as a single-entity product)
   (a) Ages 6 to 12 years: 2 mg every 4 to 6 hrs; max dose 12 mg/24 hr
   (b) Age > 12 years: 4 mg every 4 to 6 hrs; max dose 24 mg/24 hr

  (2) Chlorpheniramine (Chlor-Trimeton, Actifed)
   (a) Ages 6 to 12 years: 2 mg every 4 to 6 hrs; max dose 12 mg/24 hr
   (b) Age > 12 years of age: 4 mg every 4 to 6 hrs; max dose 24 mg/24 hr

  (3) Diphenhydramine (Benadryl)
   (a) Ages 6 to 12 years: 12.5 to 25 mg every 4 to 6 hrs; max dose 150 mg/24 hr
   (b) Age > 12 years: 25 to 50 mg every 4 to 6 hrs; maximum dose 300 mg/24 hr

  c. Precautions

  (1) Patients with narrow-angle glaucoma and benign prostatic hypertrophy should avoid first-generation antihistamines because the anticholinergic activities may exacerbate their condition.

  (2) Children and the elderly are most susceptible to the adverse effects of antihistamines; thus they are at increased risk of experiencing nightmares, anxiety, restlessness, unusual excitement, or irritability.

  d. Counseling points

  (1) Owing to **anticholinergic** properties, first-generation antihistamines may cause dry mouth (cotton mouth), blurred vision, difficulty in urination, constipation, irritability, and dizziness.

  (2) Patients taking first-generation antihistamines typically experience **sedation**, so caution should be taken driving or operating heavy machinery until one can identify how he or she will react to the ingredients. Of note, chlorpheniramine is the least sedating of the first-generation antihistamines.

  (3) Although first-generation antihistamines cause sedation in the adult patient, **children may experience paradoxical CNS stimulation**.

Table 22-3　OTC TREATMENT OF ALLERGIC RHINITIS

Agent	Product(s)	Dosing	Avoid Use In . . .	Comments/Counseling Points
		Nonsedating (second-generation) antihistamine		
Loratadine	Claritin Alavert Tavist ND	2–6 years: 5 mg q24h 6+ years: 10 mg q24h		No anticholinergic activity Penetrates poorly into CNS; free of sedating effects at usual doses Liver/kidney disease may need lower dosage
Cetirizine	Zyrtec	2–5 years: 2.5–5.0 mg qd 5+ years: 5–10 mg qd		No anticholinergic activity May cause CNS depression Liver/kidney disease may need lower dosage
Fexofenadine	Allegra	2–12 years: 30 mg q12h 12+ years: 6 mg q12h Or 180 mg q24h		Avoid concomitant administration with antacids containing aluminum and magnesium Avoid giving with fruit juices Take ER formulation on empty stomach Kidney disease may need lower dosage
		Sedating (first-generation) antihistamines		
Chlorpheniramine	Chlor-Trimeton, Actifed	2–6 years: 1 mg q4–6h 6–12 years: 2 mg q4–6h 12+ years: 4 mg q4–6h	Narrow-angle glaucoma MAOI use Prostatic hypertrophy Use caution in emphysema and chronic bronchitis	Largest side effect is drowsiness, followed by typical anticholinergic side effects Children and elderly may experience paradoxical stimulation Older adults are likely to have CNS depressive side effects, including confusion and hypotension *Photosensitizing:* Advise patients to wear sunscreen and protective clothing
Diphenhydramine	Benadryl	2–6 years: 12.5–25 mg q4–6h 12+ years: 25–50 mg q4–6h		

(Continued on next page)

Table 22-3 Continued.

Agent	Product(s)	Dosing	Avoid Use In . . .	Comments/Counseling Points
			Ocular antihistamines (in combination with naphazoline)	
Pheniramine	Naphcon A Opcon-A Visine-A	1–2 gtt TID–QID	Narrow-angle glaucoma: pupil dilation can cause angle-closure glaucoma	*Side effects:* burning, stinging, itching, foreign body sensation, dry eye, lid edema, and pupil dilation
Antazoline	Vasocon A	1–2 gtt TID–QID		
			Ocular Antihistamines	
Ketotifen	Zaditor	1–2 gtts BID	Narrow-angle glaucoma: pupil dilation can cause angle-closure glaucoma	*Side effects:* burning, stinging, itching, foreign body sensation, dry eye, lid edema, and pupil dilation
			Mast cell stabilizer	
Cromolyn sodium	Nasalcrom	*6+ years:* 1 spray in each nostril 3–6 times daily		Most efficacious if started before seasonal symptoms May take 3–7 days for initial response and 2–4 weeks for maximal response *Side effects:* sneezing, nasal stinging, burning Drug of choice in pregnancy for sneezing and rhinorrhea

BID, two times a day; CNS, central nervous system; gtts, drops; MAOI, monoamine oxidase inhibitor; qd, every day; QID, four times a day; TID, three times a day.

5. **Expectorants**
   a. **Mechanism of action. Expectorants**, also known as mucolytic agents, work to loosen sputum and thin bronchial secretions by irritating the gastric mucosa and stimulating secretions of the respiratory tract. This increases the volume of the respiratory fluid and thins mucus. Therefore, it is logical to use expectorants only to **treat a productive cough**.
   b. **Administration and dosing.** The only available expectorant is **guaifenesin**, approved for patients aged 2 years and older.
      (1) **Ages** 2 to 5 years: 50 to 100 mg every 4 hrs; maximum dose 300 mg/day
      (2) **Ages** 6 to 12 years: 100 to 200 mg every 4 hrs; maximum dose 1.2 g/day
      (3) **Ages > 12 years: Extended-release tablets (Mucinex) 600 to 1200 mg every 12 hrs; Immediate-release 200 to 400 mg every 4 hrs;** maximum dose 2.4 g/day
   c. **Precautions.** Guaifenesin is generally well tolerated, but side effects may include **nausea and vomiting**, dizziness, headache, rash, or diarrhea.
   d. **Counseling tips**
      (1) For enhanced efficacy in the loosening of mucus or phlegm in the lungs, patients should **drink an ample amount of water** when taking guaifenesin.
      (2) If symptoms worsen (development of fever, rash, or unremitting headache) or no improvement is noted in 7 days, consult a medical provider.
6. **Antitussives** are recommended for a nonproductive cough.
   a. **Dextromethorphan** (DM)
      (1) **Mechanism of action.** DM is considered equipotent to codeine as a cough suppressant and works centrally in the medulla to increase the cough threshold. However, data demonstrating its efficacy as a cough suppressant are lacking.
      (2) **Administration and dosing.** Available as a dextromethorphan hydrobromide and dextromethorphan polistirex—an extended release formulation.
         (a) Patients 4 to 6 years of age: (maximum dose 30 mg/day)
             (i) DM hydrobromide: 2.5 to 5 mg every 4 hrs or 7.5 mg every 6 to 8 hrs
             (ii) DM polistirex: 15 mg every 12 hrs
         (b) Patients 6 to 12 years of age: (maximum dose 60 mg/day)
             (i) DM hydrobromide: 5 to 10 mg every 4 hrs or 15 mg every 6 to 8 hrs
             (ii) DM polistirex: 30 mg every 12 hrs
         (c) Patients > 12 years of age: (maximum dose 120 mg/day)
             (i) DM hydrobromide: 10 to 20 mg every 4 hrs or 30 mg every 6 to 8 hrs
             (ii) DM polistirex: 60 mg every 12 hrs
      (3) **Precautions**
         (a) Dextromethorphan should not be recommended for patients taking a MAOI (Nardil or Parnate) or who are within 2 weeks of discontinuation of these agents because the combination may cause serotonergic syndrome.
         (b) Adverse effects are not generally seen at typical doses, but constipation, GI upset, abdominal discomfort, and dizziness may occur.
      (4) **Counseling points**
         (a) Reports of **intentional abuse of solid dosage forms of dextromethorphan for a euphoric effect have recently increased in the adolescent population** in the United States. Although adverse effects of dextromethorphan are generally benign in recommended doses, brain damage, seizures, loss of consciousness, irregular heart beat, and death have been reported with abuse of the drug. A national campaign has been initiated to promote parental awareness of this issue.
   b. **Codeine** is a schedule C-V drug in a cough syrup, thus its sale may be restricted in some states.
      (1) **Mechanism of action.** Codeine, like dextromethorphan, works centrally in the medulla to increase the cough threshold.
      (2) **Administration and dosing** of codeine is **not recommended for children < the age of 6 years**.
         (a) Ages 6 to 12 years: 5 to 10 mg every 4 to 6 hrs; maximum dose 60 mg/day
         (b) Age > 12 years: 10 to 20 mg every 4 to 6 hrs; maximum dose 120 mg/day

(3) Precautions
- **(a)** **Adverse effects** include **drowsiness**, **nausea and vomiting**, excitement, abdominal discomfort, or worsening/aggravation of constipation.
- **(b)** An overdose of codeine may cause death from respiratory depression and cardiovascular collapse.
- **(c)** Caution should be used in recommending this product for patients with pulmonary disease or shortness of breath.

c. **Camphor and menthol** are the only FDA-approved topical antitussives.
- **(1)** **Administration and dosing**
  - **(a)** Topical ointments containing 4.7% to 5.3% camphor or 2.6% to 2.8% menthol are FDA approved for alleviation of cough. Likewise, steam inhalants containing 6.2% camphor or 3.2% menthol are approved for use in steam vaporizers.
  - **(b)** Menthol or camphor ointment may be applied as a thick layer rubbed into the throat and chest. A warm, dry cloth may be used to cover the area. Application may be repeated up to three times daily or as directed by supervising physician.
  - **(c)** A menthol and camphor patch may be applied to the throat or chest of patients > 2 years of age. If the patient has sensitive skin, the patch may be applied to clothing covering the throat or chest, but the patch may not adhere to some types of polyester clothing. Clothing should be left loose so that vapors reach the nose and mouth. The patch should be removed, and a new patch applied, if needed, up to three times daily.
  - **(d)** Menthol or camphor steam inhalants may be added directly to the water (1 tablespoon per 1 quart of water) in a hot steam vaporizer, bowl, or basin. Vapors should be breathed in. This process may be repeated up to three times daily or as directed by supervising provider.
  - **(e)** Menthol (5 to 10 mg) is also effective as an antitussive available in oral lozenges or compressed tablets. Menthol stimulates cold sensory receptors, producing a sensation of coolness and a local anesthetic effect on the respiratory passageways, thus engendering a soothing, antitussive effect.
- **(2)** **Counseling.** Per FDA, all topical or inhalant products containing camphor or menthol must warn patients that their **use near a flame**, **in hot water**, **or in a microwave oven may cause the products to splatter and cause serious burns to the user**.

7. **Intranasal normal saline**, available in drops and sprays, may be used to moisten nasal membranes and assist in the removal of encrusted secretions.
   - a. Typical use is two to three sprays in each nostril as needed. Some products may be used as a spray when held upright or as drops when held upside down.
   - b. Intranasal normal saline may be **recommended** for use in all patients, including **infants** and **pregnant women**, unless directed otherwise by a physician.

8. **Local anesthetics** (e.g., benzocaine, phenol, menthol) in the form of lozenges and sprays may be useful in the alleviation of a sore throat. Mouthwashes have been recommended for use in the past; however, owing to localized action in the oral cavity, the pharyngeal wall may not be affected by these products. Because a sore throat is the initial symptom of many other illnesses, care should be taken to recommend products for sore throat alleviation only to patients who have concurrent symptoms of the common cold. **If the throat is red and inflamed**, **unusually painful**, **or has persisted for several days**, **the patient should be referred** to a primary care provider for further evaluation.

9. **Analgesics** are occasionally indicated in the treatment of common cold symptoms when sore throat, myalgia, and/or headache exist. Acetaminophen, ibuprofen, or naproxen sodium may be recommended, with consideration given to patient allergies, concurrent medications and disease states, and age.

10. **Combination products**
    - a. Numerous products are available that contain various combinations of antihistamines, decongestants, analgesics, expectorants, and antitussives. Certain product name designations help identify the ingredients.

   (1) *Nighttime* and *p.m.* usually signify that the product contains diphenhydramine, chlorpheniramine, or doxylamine.

   (2) *Sinus* usually signifies a decongestant (e.g., pseudoephedrine, phenylephrine) and/or an analgesic (e.g., acetaminophen).

   (3) *Cough* usually signifies that the product contains dextromethorphan.

   (4) *Nondrowsy*, *a.m.*, and *daytime* usually indicate that the product contains a decongestant (e.g., pseudoephedrine, phenylephrine) and typically does not contain an antihistamine.

   (5) *Allergy* signifies that the product contains an antihistamine.

   (6) *Cold* and *flu* indicate that the product may contain any combination of ingredients, including a decongestant, antihistamine, cough suppressant, and/or antipyretic.

  b. Combination products may be useful for simplicity of dosing and adherence if patients are experiencing a variety of symptoms that can be alleviated by one product. For example, if a patient has a dry, hacking, nonproductive cough, and nasal congestion, he or she may benefit from a combination product of dextromethorphan and pseudoephedrine. However, it would be a shotgun approach to recommend a product containing an analgesic and expectorant in combination with other ingredients for this patient.

  c. Disadvantages to combination products occur when previously treated symptoms resolve, but the patient continues to treat other symptoms with the same product. This adds unnecessary medication(s) to the regimen, increasing the risk of adverse events. Combination products can also be difficult to recommend when selecting the appropriate product for patients with coexisting medical conditions.

 11. Complementary therapy

  a. Zinc gluconate's effects on the duration or severity of the common cold have been studied. Results have been mixed, lending to what remains a controversial subject.

   (1) Mechanism of action. Current literature describes several possible mechanisms by which zinc may exert its effect, but such means remain unclear.

   (2) Availability and dosing. Despite its controversial use, a number of zinc products have been formulated, including tablets, capsules, chewing gums, lozenges, nasal gels, nasal sprays, and nasal swabs.

    (a) Selected formulations should be initiated within 24 to 48 hrs of the onset of symptoms.

    (b) Lozenges are recommended every 2 hrs for the duration of the cold.

    (c) Nasal sprays, swabs, and gels have been withdrawn from the market due to reports of permanent anosmia associated with the products.

  b. Vitamin C. Only a small number of studies have demonstrated the ability of vitamin C (dose > 1 g/day) to reduce the frequency or severity of the common cold. The clinical significance of the results of these studies remains questionable.

  c. Echinacea has been used as a popular remedy for the common cold since the late 1800s. Unfortunately, current literature does not give definitive supportive evidence for the efficacy of Echinacea in the prevention and/or treatment of the common cold.

   (1) Obstacles in studying Echinacea lie in the fact that three different species of *Echinacea* exist, each with a different phytochemical composition. The composition may further be altered, depending on the part of the plant used and the time of year the plant is harvested.

   (2) Current literature suggests that for Echinacea **to retain an immunostimulant effect, it should not be taken for longer than 2 to 3 weeks at a time**.

G. Exclusions to self-treatment of the common cold

 1. Fever > 101.5°F

 2. Chest pain

 3. Shortness of breath

 4. Worsening of symptoms or development of additional symptoms

 5. Concurrent underlying chronic cardiopulmonary diseases

 6. AIDS or chronic immunosuppressant therapy

 7. Frail patients of advanced age

III. ALLERGIC RHINITIS

A. **Introduction.** Rhinitis is an inflammation of nasal membranes, characterized by the **four cardinal symptoms**: **nasal congestion**, **rhinorrhea**, **sneezing**, **and nasal itching**.
   1. Risk factors for allergic rhinitis include the following:
      a. Family history of atopy
      b. Higher socioeconomic class
      c. Exposure to indoor allergens (animals and dust mites)
      d. Positive allergy skin prick test
   2. Allergic rhinitis may be classified as seasonal, perennial, episodic, or occupational. Seasonal and perennial, or a combination of the two, are the most frequent classifications.
      a. Seasonal: Symptoms may occur with repetitive and predictable seasonal symptoms.
      b. Perennial: Symptoms persist throughout the year without regard to season changes.
      c. Combination: Symptoms persist throughout the year with seasonal exacerbations.

B. **Etiology.** There are five main triggers for allergic rhinitis: pollens, molds, dust mites, animal allergens, and insect allergens. These allergens trigger an immunoglobulin E (IgE) mediated immunological reaction.
   1. Seasonal allergic rhinitis is typically caused by pollens and molds.
   2. Perennial allergic rhinitis is typically caused by dust mites, molds, and animal allergens.

C. **Pathogenesis.** Patients become sensitized to allergens; on subsequent exposure, the allergens trigger a genetically predetermined immune response that results in the symptoms of allergic rhinitis. Allergic rhinitis may then be characterized by early- or late-phase responses.

D. **Signs and symptoms.** The presence of itchy, watery eyes, and/or nasal pruritus is what differentiates allergic rhinitis from the common cold. Because children often cannot verbalize the symptoms of allergic rhinitis, it is important to recognize these signs.
   1. Repercussions of nasal pruritus include the following:
      a. **Gothic arch**, a steady upward movement of the upper lip and teeth which may result in an overbite, as a result of the "allergic salute," characterized by the constant upward rubbing of the nose with the palm of the hand.
      b. **Allergic crease**, a visible transverse line appearing between the tip and the bridge of the nose, caused by constant rubbing.
   2. Ophthalmic conditions present in the individual with allergic rhinitis include allergic shiners, a darkening of the lower eyelid attributable to chronic nasal obstruction, and Morgan lines (also known as the Dennie sign), which are seen as pleats under the eyes, running parallel to the lower eyelid margins.
   3. Individuals with allergic rhinitis may also experience fatigue, irritability, and malaise. Owing to these symptoms, allergic rhinitis may be a contributing factor to poor schoolwork in children afflicted by this condition.

E. **Treatment.** The primary goal in the treatment of allergic rhinitis is to control the symptoms without altering the patient's ability to function. Treatment options include environmental control, nonprescription pharmacologic treatment, and prescription treatment. This section focuses on nonprescription treatment (see *Table 22-3*).
   1. The **best treatment remains avoidance of the allergen(s)**, once determined, although this is sometimes impractical. Environmental controls directed toward particular allergens can be the first initiative toward resolution of symptoms.
   2. **Antihistamines**, both first and second generation, are the mainstay of treatment for allergic rhinitis.
      a. First-generation antihistamines are limited in continuous treatment of allergic rhinitis owing to their frequent dosing and related sedation. Unlike treatment of the common cold, first-generation antihistamines may be used for allergic rhinitis symptoms in patients between the ages of 2 and 5 years. These agents remain the least expensive treatment option at this time; however, this aspect must be weighed against the ability to remain alert for work and school activities.
      b. Second-generation antihistamines are advantageous because of their preferential peripheral H_1-receptor binding. This allows for minimal CNS effects, minimal sedative effects, and minimal anticholinergic activity. Three nonprescription second-generation antihistamines are currently available on the market as single-entity products or in combination with pseudoephedrine: loratadine, cetirizine, and fexofenadine. Comparison of therapeutic effectiveness

among the three products remains unclear at this time. However, in dosing comparisons, loratadine and cetirizine can be given once daily, and fexofenadine can be given once or twice daily, depending on the dose.

(1) **Administration and dosing**
- (a) Loratadine (Claritin): adjust in hepatic and/or renal impairment
  - (i) Ages 2 to 6 years: 5 mg once daily
  - (ii) Ages 6 years and older: 10 mg once daily
- (b) Cetirizine (Zyrtec): adjust in hepatic and/or renal impairment
  - (i) Ages 2 to 6 years: 2.5 to 5.0 mg once daily
  - (ii) Ages 6 to 12 years: 5 to 10 mg once daily
  - (iii) Ages 12 and older: 10 mg once daily
- (c) Fexofenadine (Allegra): Available in 12 - or 24-hr dosing; adjust in renal impairment
  - (i) Ages 2 to 6 years: 30 mg twice daily (syrup only)
  - (ii) Ages 6 to 12 years: 30 mg twice daily
  - (iii) Ages 12 and older: 60 mg twice daily or 180 mg once daily

(2) **Drug Interactions:** Concomitant administration of **aluminum and magnesium containing antacids** (e.g., Maalox) **may decrease absorption and peak plasma concentrations of fexofenadine**. Extended release doses (once daily doses) of **fexofenadine should be taken on an empty stomach with water**. Avoid taking fexofenadine with fruit (e.g., grapefruit, orange, apple) juices because fruit juices reduce the bioavailability of fexofenadine by greater than 30%.

3. Oral decongestants are effective in relieving symptoms of nasal congestion but have no effect on other symptoms of allergic rhinitis such as rhinorrhea, pruritus, or sneezing.
   a. **Because treatment of allergic rhinitis is for extended periods**, **oral decongestants should be used for nasal congestion rather than topical decongestants** owing to the potential for rhinitis medicamentosa.
   b. The combination of a decongestant and an antihistamine has proven to be an optimal treatment regimen for allergic rhinitis.
   c. Consideration must be taken into account when recommending products containing pseudoephedrine to adolescents and adults participating in sports programs, because of the "doping" effect of these agents.

4. Ocular antihistamines may be used for the treatment of ophthalmic conditions associated with allergic rhinitis.
   a. Currently there are three ocular antihistamines available on the market: pheniramine, antazoline, and ketotifen. Pheniramine and antazoline are only available in combination with naphazoline (a decongestant). Ketotifen (Zaditor) became available as a nonprescription product in 2007 and is the only available ocular antihistamine that does not contain a decongestant.
   b. Avoid the use of ocular antihistamines in glaucoma, as pupil dilation may cause angle-closure glaucoma.
   c. Side effects may include burning, stinging, itching, foreign body sensation, dry eye, lid edema, and pupil dilation.

5. **Cromolyn sodium** (e.g., Nasalcrom) is best used as a preventive measure for the symptoms of allergic rhinitis but may also be used as treatment for all symptoms except nasal congestion. However, **maximum benefit**, when used as treatment, **will not be seen for 1 to 2 weeks**. When used for prevention, cromolyn sodium should be initiated approximately 1 week before allergen contact.
   a. Cromolyn sodium has a short duration of action and, therefore, must be **dosed three to four times daily**. This frequency in dosing may result in diminished adherence.
   b. Cromolyn sodium is approved for use in patients **2 years of age and older**.
   c. Seek medical care if symptoms worsen or no improvement is seen within 2 weeks.
   d. Adverse effects include a brief stinging or sneezing directly after administration.

F. **Exclusions to self-treatment of allergic rhinitis**
   1. Symptoms of otitis media or sinusitis
   2. Symptoms that suggest lower respiratory tract problems
   3. History of nonallergic rhinitis

Study Questions

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which statement concerning the use of over-the-counter (OTC) analgesic agents is true?

    (A) Aspirin is indicated for mild to moderate analgesia, inflammatory diseases, antipyresis, and prophylaxis for patients with ischemic heart disease.

    (B) Ibuprofen is indicated for mild to moderate analgesia, reduction of fever, and prophylaxis for patients with ischemic heart disease but not for inflammatory disorders.

    (C) Acetaminophen is indicated for mild to moderate analgesia but not for reduction of fever and osteoarthritis.

    (D) Naproxen sodium is indicated for mild to moderate analgesia, antipyresis, and prophylaxis for patients with ischemic heart disease.

2. Which statement concerning drug interactions with over-the-counter (OTC) analgesic agents is true?

    (A) Aspirin potentiates the effects of antihypertensives, cardiac glycosides, and anticoagulants.

    (B) Ibuprofen potentiates the effect of zidovudine, hypoglycemics, and aminoglycosides.

    (C) Acetaminophen potentiates the effect of zidovudine.

    (D) For naproxen sodium, the OTC dosage recommendations are similar to the prescription dosage.

3. All of the following statements concerning contraindications with chronic use of over-the-counter (OTC) analgesic agents are correct *except* which one?

    (A) Aspirin, ibuprofen, and naproxen sodium are contraindicated in patients with bleeding disorders, peptic ulcer, and the third trimester of pregnancy.

    (B) Aspirin, acetaminophen, and ibuprofen are implicated in Reye syndrome.

    (C) Acetaminophen is contraindicated in patients with active alcoholism, hepatic disease, or viral hepatitis.

4. Which statement concerning dosage recommendations for over-the-counter (OTC) analgesic agents is true?

    (A) Aspirin for analgesia or antipyresis in adults is 325 to 650 mg every 4 hrs or 650 to 1000 mg every 6 hrs, with a maximum daily dose of 4000 mg for no longer than 10 days for pain or 3 days for fever without consulting a physician; the antirheumatic dosage for adults is 3600 to 4500 mg daily in divided doses; and patients with ischemic heart disease should take 325 mg daily or every other day.

    (B) Ibuprofen for analgesia or antipyresis in adults is 300 to 600 mg every 6 to 8 hrs, with a maximum daily dose of 1800 mg for no longer than 10 days for pain or 3 days for fever without consulting a physician; the anti-inflammatory dosage for adults is 1800 to 3600 mg daily in divided doses.

    (C) Acetaminophen for analgesia or antipyresis in adults is 325 mg every 8 to 2 hrs, with a maximum daily dose of 2000 mg for no longer than 10 days for pain and 3 days for fever without consulting a physician; patients with ischemic heart disease take 325 mg daily or every other day.

5. Which of the following is an inhaler ingredient deemed safe and effective for nasal congestion?

    (A) oxymetazoline

    (B) phenylephrine

    (C) levmetamfetamine

    (D) pseudoephedrine

6. A 27-year-old presents with sneezing, rhinorrhea, and nasal itching, which started 2 days ago. She feels miserable with her symptoms, which worsen when she cleans the house. Her current medications include calcium carbonate and docusate sodium. Which of the following would be the *best* recommendation for immediate symptom alleviation?

    (A) chlorpheniramine

    (B) pseudoephedrine

    (C) topical nasal strips

    (D) intranasal cromolyn

7. A 48-year-old presents with a chief complaint of a dry, hacking cough, which started yesterday. He denies fever, chills, sore throat, or congestion. His only medical condition is hypertension, which is controlled with hydrochlorothiazide (HCTZ). What would be the *best* recommendation for alleviation of his cough?

   (A) dextromethorphan
   (B) phenylephrine
   (C) fexofenadine
   (D) guaifenesin

8. Which of the following is an appropriate candidate for self-treatment with codeine for cough?

   (A) 4-year-old with nonproductive cough
   (B) 6-year-old with nonproductive cough
   (C) 15-year-old with productive cough
   (D) 22-year-old with productive cough
   (E) 92-year-old with nonproductive cough

For questions 9–10: A 42-year-old male complains of a scratchy throat, nasal congestion, and a cough that started 2 days ago. When he coughs, he brings up yellow-white phlegm. He has hypertension and dyslipidemia. Current medications include simvastatin, lisinopril, hydrochlorothiazide, carvedilol, hydralazine, isosorbide dinitrate, and amlodipine.

9. Which of the following would be the *best* recommendation for this person's cough?

   (A) codeine
   (B) dextromethorphan
   (C) diphenhydramine
   (D) guaifenesin

10. Which of the following would be the *most* appropriate recommendation for his nasal congestion?

    (A) Oral pseudoephedrine
    (B) Oral phenylephrine
    (C) Topical oxymetazoline
    (D) Topical levmetamfetamine

11. A 22-year-old female presents with sneezing, watery and itchy eyes, and a runny nose. She has no significant medical history, but she is in the midst of final exams and must remain alert. What would be the *best* recommendation for her symptoms?

    (A) Fexofenadine
    (B) Diphenhydramine
    (C) Brompheniramine
    (D) Levmetamfetamine

Answers and Explanations

1. **The answer is A** *[see I.B]*.
   Aspirin is the only analgesic agent with an approved labeling for analgesia, antipyresis, inflammation, and prophylaxis for ischemic heart disease.

2. **The answer is C** *[see I.C]*.
   Acetaminophen may competitively inhibit the metabolism of zidovudine, resulting in potentiation of zidovudine or acetaminophen toxicity. As for the other choices, OTC dosage levels are generally one-half the prescription dosage; aspirin is not commonly recognized to interact with antihypertensives or cardiac glycosides; nor is acetaminophen expected to interact with aminoglycosides.

3. **The answer is B** *[see I.B.4.b]*.
   Aspirin is the only analgesic agent associated with the development of Reye syndrome.

4. **The answer is A** *[see I.B.3; I.C.3; I.D.3]*.
   The aspirin dosage OTC recommendations are correct; the levels for acetaminophen are too low, and for ibuprofen, too high. In addition, acetaminophen does not carry an ischemic heart disease prophylaxis recommendation.

5. **The answer is C** *[see II.F.1.b.(1)]*.
   Levmetamfetamine is an inhaler ingredient that has been deemed by the FDA as safe and effective as a nasal decongestant. It is currently found in Vicks Vapor Inhaler. Oxymetazoline and phenylephrine are topical nasal decongestants found in pumps and drops but not in inhalers.

6. **The answer is A** *[see II.F.4; III.E.5]*.
   Rhinorrhea, sneezing, and nasal itching are symptoms of allergic rhinitis. Pseudoephedrine and topical nasal strips are indicated for nasal congestion, which she does not have. Both chlorpheniramine and intranasal cromolyn sodium are recommended treatments for the relief of sneezing and rhinorrhea. However, this patient needs immediate relief, and cromolyn sodium will take 1 to 2 weeks for noticeable symptom improvement.

7. **The answer is A** *[see II.F.6]*.
   The complaint is a dry, hacking cough, warranting the use of an antitussive rather than an expectorant (e.g., guaifenesin). Dextromethorphan is the only choice of antitussives provided.

8. **The answer is B** *[see II.F.6.b]*.

Codeine is appropriate for ages 6 and up for a non-productive cough. Although a 92-year-old with a non-productive cough fits this criteria, caution should be taken due to adverse effects associated with codeine.

9. **The answer is D** *[see II.F.5]*.

The patient is experiencing a productive cough, as noted by the yellow-white phlegm. An expectorant is the best agent for relief of a productive cough. The only available expectorant is guaifenesin, which works to loosen sputum and to thin bronchial secretions by irritating the gastric mucosa and stimulates secretions of the respiratory tract.

10. **The answer is D** *[see II.F.1.c]*.

Pseudoephedrine, phenylephrine, and oxymetazoline should be used cautiously in the patient with hypertension, particularly a patient on this many antihypertensive agents, due to stimulation of adrenergic receptors. Levmetamfetamine lacks a vasopressor effect and therefore is the least likely agent to affect his blood pressure.

11. **The answer is A** *[see III.E.2]*.

Levmetamfetamine, a nasal decongestant, would offer no benefit for the symptoms described. Although diphenhydramine and brompheniramine are first generation antihistamines, both would cause significant sedation when the patient needs to remain alert. Additionally, brompheniramine is not available as a single-ingredient product. Fexofenadine would alleviate the described symptoms without causing increased sedation.

Over-the-Counter Agents for Constipation, Diarrhea, Hemorrhoids, and Heartburn

23

JENNIFER D. SMITH

I. CONSTIPATION

A. General information

1. **Definition.** Constipation is defined as a decrease in the frequency of fecal elimination and is characterized by the passage of hard, dry, and sometimes painful stools. Normal stool frequency ranges from three times daily to three times per week. Patients may experience abdominal bloating, headaches, low back pain, and/or a sense of rectal fullness from incomplete evacuation of feces.

2. **Epidemiology**

   a. **Age.** Constipation is common in all age groups, however; there is a higher prevalence in people > 65 years of age.

   b. **Gender.** Women suffer from constipation more often than men.

3. **Causes.** Constipation can be caused by many factors, including the following:

   a. **Lifestyle. A diet** insufficient in fiber and/or inadequate fluid intake, **lack of exercise**, **and poor bowel habits**, such as failure to respond to the defecatory urge or hurried bowels (i.e., incomplete evacuation) can contribute to constipation.

   b. **Medications**, such as narcotic analgesics, diuretics, or anticholinergics (e.g., antidepressants, antihypertensives, antihistamines, phenothiazines, antispasmodics). In addition, nonprescription medications such as iron supplements, calcium- or aluminum-containing antacids, nonprescription nonsteroidal anti-inflammatory drugs (NSAIDs), and histamine-2 receptor antagonists (H_2RAs; i.e., ranitidine) may contribute to constipation.

   c. **Pregnancy** is a common contributor to constipation. The increased size of the uterus, hormonal changes, intake of calcium- and iron-containing prenatal vitamins, and a reduction in physical activity are all considered contributing factors.

   d. **Systemic disorders**, such as intestinal obstruction, tumor, inflammatory bowel disease, diverticulitis, hypothyroidism, hyperglycemia, irritable bowel syndrome, cerebrovascular disease, or Parkinson disease.

4. **Assessment** should include normal stool frequency, frequency and duration of the constipation, exercise routine, daily dietary fiber and fluid intake, presence of other symptoms, and current medications.

B. Treatment
   1. **Nonpharmacologic**
      a. Increase intake of fluids (at least eight 8-oz servings of noncaffeinated fluids daily) and fiber (e.g., whole-grain breads and cereals, beans, prunes, peas, carrots, corn). The recommended adult intake of fiber is 20 to 35 g/day, but individuals who are consuming inadequate amounts of fiber should increase the amount of fiber intake slowly to prevent gastrointestinal distress.
      b. Increase exercise to increase and maintain bowel tone.
      c. Bowel training to increase regularity (i.e., allowing regular and adequate time for defecation).
   2. **Pharmacologic** recommendations for simple constipation should begin as a **step-wise approach** with **bulk-forming laxatives** as first line, **hyperosmotic laxatives** as second line, and then **stimulant laxatives** if the previous recommendations were ineffective or intolerable. **Self-care** for the treatment of constipation should be **limited to 7 days**.
      a. Bulk-forming laxatives are natural or synthetic polysaccharide or cellulose derivatives that adsorb water to soften the stool and increase bulk, which stimulates peristalsis.
         (1) Availability. Bulk-forming agents include **psyllium** (e.g., Metamucil, Konsyl, Fiberall), **methylcellulose** (e.g., Citrucel), **calcium polycarbophil** (e.g., Konsyl Fiber caplets, FiberCon), and **wheat dextran** (e.g., Benefiber). All bulk-forming agents must be given with at least 8 oz of water to prevent choking.
         (2) Onset of action is slow and ranges from 12 to 24 hrs up to 72 hrs.
         (3) Adverse effects: Bloating, abdominal cramping, and flatulence
         (4) Warnings and counseling points
            (a) Bulk-forming agents should not be used if an obstructing bowel lesion, intestinal strictures, or Crohn's disease are present due to the potential to worsen the situation or result in bowel perforation. Additionally, because of the administration guidelines, bulk-forming laxatives may be inappropriate for individuals with severe fluid restrictions, such as those with heart failure or renal impairment.
            (b) Sugar-free formulations should be considered for individuals with diabetes but avoided in individuals with phenylketonuria.
            (c) The use of bulk-forming laxatives for constipation relief should be limited to 1 week; however, they can be used on a long-term basis for prevention.
      b. Hyperosmotic laxatives work by creating an osmotic gradient to pull water into the small and large intestines, resulting in increased peristalsis and bowel motility.
         (1) Availability
            (a) Glycerin (e.g., Fleet Glycerin Suppositories, Fleet Pedia-Lax) is only safe and effective when **used rectally**. Dosing for **ages 6 years to adult** is 2 g regular suppository or 5.4 g in liquid suppository; **ages 2 to 5 years** is 1 g regular suppository or 2.8 g in liquid suppository.
            (b) Polyethylene glycol 3350 (e.g., Miralax, Dulcolax Balance) is approved for self-care use in **ages 17 years and older**. It is dosed as **17 g**, stirred into 4 to 8 oz of fluid, **once daily**.
         (2) Onset of action varies greatly between the two nonprescription items in this class. **Glycerin** suppositories have an onset range of **15 mins to 1 hr and polyethylene glycol** has a longer onset of **1 to 3 days**.
         (3) Adverse effects. As expected, rectal burning may occur with glycerin products; polyethylene glycol causes adverse effects at excessive doses and can include diarrhea, nausea, bloating, cramping, and flatulence.
         (4) Warning. Avoid use in individuals with **kidney disease**, **irritable bowel syndrome**, during pregnancy, or while breastfeeding.
      c. Stimulant laxatives work by altering water and electrolyte transport by the intestines and by stimulating bowel motility (i.e., propulsive peristaltic activity). They are recommended for relief of constipation when an individual has failed or is intolerant to bulk-forming or hyperosmotic agents. However, stimulant laxatives are being used more frequently as first-line therapy for opiate-induced chronic constipation.
         (1) Availability. The two main classes of stimulant laxatives are anthraquinones (e.g., senna, sennosides) and diphenylmethane (e.g., bisacodyl).
            (a) Senna can be taken as single-entity products (e.g., Senokot, Ex-Lax, Perdiem, Fletcher's Laxative for Kids) or combined with a stool softener (e.g., Senokot-S, Peri-Colace) for relief of constipation. Senna is available as a standardized concentrate or

as sennosides, which are derived from the senna leaves. Adult dosing in solid oral formulations is 187 to 374 mg standardized concentrate and 8.6 to 17.2 mg sennosides. Senna is appropriate for self-care for pediatrics (**ages 2 and older**) and is available as a syrup, tablet, or chocolate chew.

    (b) **Bisacodyl** (e.g., Dulcolax, Correctol) is available in rectal and oral formulations. Adult doses are 5 to 15 mg by mouth or 10 mg rectally once daily. Pediatric dose (**ages 6 and older**) is 5 mg orally or rectally once daily.

(2) **Onset of action.** The onset of action of the oral preparation is within 6 to 12 hrs, but the rectal preparation onset of action is quicker, within 15 to 60 mins.

(3) **Adverse effects.** All stimulant laxatives can cause **abdominal cramping**. Electrolyte and fluid deficiencies, enteric loss of protein, malabsorption, and hypokalemia are additional possible adverse effects. The suppository form may cause rectal burning.

(4) **Warnings and counseling points**

    (a) Individuals with undiagnosed rectal bleeding or signs of intestinal obstruction should not use stimulant laxatives.

    (b) **Cathartic colon**, which results in a poorly functioning colon, has been associated with the chronic use of stimulant laxatives. However, there is no convincing evidence that chronic use impairs the colon in structure or function. Caution should still be taken with the chronic use of stimulant laxatives due to the other associated adverse effects noted above.

    (c) Sennosides may cause **discoloration of the urine** (pink/red, yellow, or brown), but this is a **harmless effect**.

    (d) Tablet formulations of **bisacodyl should not be crushed or chewed** due to the enteric coating. **Milk**, **H_2RA** (e.g., ranitidine, cimetidine, famotidine), **and antacids may erode this enteric coating** and should be separated in dosing by at least 1 hr.

d. **Emollient laxatives**, also known as **surfactants**, work by allowing water to move more easily into the stool. This creates a softer stool, which is easier to pass. Thus, these agents are particularly useful in those who must avoid straining to pass hard stools (e.g., recent myocardial infarction, rectal surgery). Emollient laxatives have very few side effects, but they are not as effective as other laxatives.

(1) **Availability.** Emollient laxatives are salts of the surfactant **docusate**. These products contain insignificant amounts of calcium, sodium, or potassium, and there are no specific guidelines for the selection of any one product. The products include **docusate sodium** (e.g., Colace) and **docusate calcium** (e.g., Kaopectate Stool Softener). Adult dosing is 50 to 300 mg/day and dosing for children **> 2 years of age** is 50 to 150 mg/day. Each dose should be **taken with at least 8 oz of water**.

(2) **Onset of action.** Slow onset of action (24 to 72 hrs).

(3) **Adverse effects.** Diarrhea and mild abdominal cramping are possible.

(4) **Warnings.** Use should be avoided in individuals with nausea and vomiting, symptoms of appendicitis, or undetermined abdominal pain.

e. **Saline laxatives**, which include **sodium and magnesium salts**, work to **draw water into the colon**. This class of laxatives includes **magnesium citrate**, **magnesium hydroxide** (e.g., Milk of Magnesia, Phillips caplets), and **sodium phosphate** (e.g., Fleet's Enema).

(1) **Onset of action is 30 mins to 3 hrs** when given orally and **2 to 5 mins when given rectally**.

(2) **Side effects include abdominal cramping**, **excessive diuresis**, **nausea and vomiting**, **and dehydration.** As much as 20% of magnesium may be absorbed from these products, which may lead to **hypermagnesemia in patients with preexisting renal impairment**. Excessive doses of magnesium result in diarrhea.

(3) **Warnings and counseling points**

    (a) The adult dose of magnesium citrate is consumption of one full bottle. Refrigeration of the product may increase palatability and help prevent crystallization.

    (b) Sodium-containing salts should be **avoided in those individuals with sodium restrictions** (e.g., heart failure, edema, renal failure) and magnesium-containing products should be avoided in individuals with severe kidney disease.

    (c) **Oral sodium phosphate (OSP)** products (e.g., Fleet's Phospho-Soda) have been sold for years as nonprescription products for constipation and for acute bowel evacuation.

However, the U.S. Food and Drug Administration (FDA) received numerous reports of acute phosphate nephropathy (**acute kidney injury**) associated with these products when used for acute bowel evacuation. FDA has allowed nonprescription OSP products to remain available for the treatment of constipation because acute kidney injury has not been reported at these doses. However, FDA has determined that nonprescription OSP products are not appropriate for bowel cleansing. In response, Fleet Laboratories voluntarily removed their OSP products from the market.

    f. Lubricant laxative. Mineral oil is the only available agent in this class. It works at the colon to increase water retention in the stool.

      (1) Availability. Mineral oil can be given **once daily orally or rectally**. The dose for adults (age ≥ 12 years) is 15 to 45 mL orally or 118 mL rectally and for children (age 6 to 11 years) is 10 to 15 mL orally or 59 mL rectally.

      (2) Onset of action. 6 to 8 hrs (oral dosing) and 5 to 15 mins (rectal dosing)

      (3) Adverse effects include anal seepage, which can result in itching and perianal discomfort.

      (4) Warnings and counseling points

        (a) Mineral oil can **decrease absorption of fat-soluble vitamins** (i.e., vitamins A, D, E, and K), so it should not be used on a chronic basis.

        (b) Mineral oil should be taken on an empty stomach. Because of possible **aspiration of mineral oil into the lungs (lipid pneumonitis)**, this agent should not be taken at bedtime. Those who are elderly, debilitated, or have dysphagia are at the greatest risk of lipid pneumonitis.

        (c) Emollients (e.g., docusate) may increase the systemic absorption of mineral oil, which can lead to **hepatotoxicity**. Thus **emollient and lubricant laxatives should not be given concomitantly**.

        (d) Mineral oil is contraindicated in persons with rectal bleeding, appendicitis, or age < 6 years.

C. Special populations

    1. Pediatrics. Constipation should be expected if there is a drastic change from baseline bowel function. Nonpharmacologic methods such as increasing the amount of fluid or sugar provided or increasing the bulk content of the diet (fruit, fiber cereals, vegetables) should be tried before medications are used. If nonpharmacologic methods do not work, those < 2 years of age should be referred to a medical provider. Glycerin suppositories may be used in those > 2 years of age.

    2. Pregnant. Constipation in pregnancy is common and can be the result of compression of the colon by the enlarged uterus, ingestion of prenatal vitamins containing iron and calcium, and the influence of progesterone can cause bowel hypomotility. Bulk-forming agents or stool softeners are appropriate to recommend during pregnancy.

    3. Geriatrics. The elderly tend to be at risk for constipation due to insufficient dietary (fiber) and fluid ingestion, concurrent disease states (e.g., hypothyroidism), and/or medications (e.g., opiates, anticholinergics). A **major concern** with the geriatric population is the possible loss of fluid that can be induced by aggressive laxative treatment (e.g., enemas, high-dose saline laxatives). Hyperosmotic or stimulant laxatives may be useful for initial treatment and bulk-forming laxatives for prevention, depending on concomitant disease states.

II. DIARRHEA

A. General information

    1. Definition. Diarrhea is defined as an increase in the frequency and looseness of stools compared to one's normal bowel pattern. The overall weight and volume of the stool is increased (> 200 g or mL/day), and the water content is increased to 60% to 90%. In general, diarrhea results when the intestine is unable to absorb water from the stool, which causes excess water in the stool.

    2. Classification. Diarrhea can be classified based on mechanism or origin.

      a. Classification by mechanism

        (1) Osmotic diarrhea occurs when excess water is pulled into the intestinal tract. Osmotic diarrhea ceases when the patient converts to a fasting state. This may be the result of hypermagnesemia, undigested lactose or fructose, or celiac disease.

(2) Secretory diarrhea occurs when the intestinal wall is damaged, resulting in an increased secretion rather than absorption of electrolytes into the intestinal tract. This can occur with the ingestion of bacterial enteropathogens (e.g., *Escherichia coli*, *Salmonella*, *Shigella*).

(3) Motility-related diarrhea occurs when food moves through the intestines at such a rapid pace (hypermotility) that insufficient time is allowed for water and nutrient absorption. Those with diabetic neuropathy, gastric/intestinal resection, or a vagotomy are susceptible to this type of diarrhea. Medications that can also cause hypermotility include parasympathomimetic agents (e.g., metoclopramide, bethanechol), digitalis, quinidine, and antibiotics.

b. **Classification by origin**

(1) Viral gastroenteritis is typically caused by the **noroviruses**, which are transmitted by contaminated water or food. Other attributable viruses include rotaviruses, adenoviruses, and hepatitis A virus. Diarrhea associated with viral gastroenteritis is usually self-limiting for 2 to 3 days but may last up to 2 weeks.

(2) Bacterial gastroenteritis typically results from consumption of contaminated water or food. Common contributors include *E. coli*, *Staphylococcus aureus*, *Vibrio cholerae*, *Shigella*, *Salmonella*, *Campylobacter*, and *Clostridium difficile*. Toxin-producing bacteria affect the small intestines, resulting in a watery stool. Invasive bacteria affect the large intestines, resulting in dysentery-like stools (e.g., extreme urgency to defecate, abdominal cramping, tenesmus, fever, chills, and small-volume stools that contain blood or pus). Onset of diarrhea may range between 1 and 72 hrs, depending on the infecting bacteria. Symptoms typically subside over 3 to 5 days.

(3) Protozoal diarrhea, caused by *Giardia lamblia*, *Entamoeba histolytica*, or *Cryptosporidium*, may be described as profuse watery diarrhea, which may be accompanied by flatulence and/or abdominal pain. This type of diarrhea is self-limiting, but may persist for several weeks. Due to the extent of fluid loss over an extended duration of time, individuals with protozoal-induced diarrhea are at risk for dehydration. Self-care is inappropriate for this type of diarrhea; infected persons should be referred to a medical provider.

(4) Diet-induced diarrhea. Diarrhea induced by foods results from food allergies, high-fiber diets, fatty or spicy foods, large amounts of caffeine, or lactose intolerance. The best treatment is prevention by avoiding troublesome foods.

B. **Evaluation**

1. **Assessment** of the individual should include age, onset and duration of diarrhea, description of stool (i.e., frequency, consistency, volume, and presence of blood or pus), other symptoms (i.e., abdominal pain, fever, chills), aggravating or remitting factors, recent travel, and medical history.

2. **Exclusions to self-care include:**

a. **Younger than 3 years** of age or **older than 60 years** of age (with multiple medical problems), pregnant or breastfeeding patients, and patients with HIV.

b. **Blood or mucus in the stools**

c. **High fever** ($> 101°F$ or $38°C$)

d. **Dehydration or weight loss** $> 5\%$ of total body weight; signs of dehydration—dry mouth, sunken eyes, crying without tears, dry skin that is not elastic like normal skin

e. **Duration of diarrhea > 2 days**

f. **Vomiting**

C. **Treatment**

1. **Nonpharmacological.** Normal dietary intake should be recommended during bouts of diarrhea. However, fatty foods, caffeinated beverages, foods rich in simple sugars, and spicy foods should be avoided. The most important recommendation for treating acute diarrhea is to keep the individual hydrated.

a. **Fluid and electrolyte replacement.** If mild to moderate fluid loss is present, oral rehydration solution (ORS) that contains water, salt, and sugar can be recommended. This solution can be made at home by adding salt, baking soda, and sugar to water (see *Table 23-1*) or purchased ready-to-use (e.g., Pedialyte). *Table 23-2* provides recommended doses for patient age and severity of diarrhea. If fluid loss is severe ($> 10\%$ loss of body weight) and/or severe vomiting persists, then intravenous rehydration is necessary and a referral to a medical provider is most appropriate.

Table 23-1	GUIDELINES FOR ORAL-REPLACEMENT THERAPY ESTABLISHED BY THE WORLD HEALTH ORGANIZATION (WHO)

Ingredients	Dose
Sodium chloride (table salt)	90 mEq (½ teaspoon)
Potassium chloride (potassium salt)	20 mEq (¼ teaspoon)
Sodium bicarbonate (baking soda)	30 mEq (½ teaspoon)
Glucose (sugar)	20 g (2 teaspoons)
Water	Enough to make 1 L of solution

     b. Fluids to be avoided in the dehydrated person include hypertonic fruit juices and carbonated or caffeinated beverages. These fluids may make the diarrhea worse and do not contain needed electrolytes (i.e., Na^+, K^+). Gatorade does not contain an equivalent electrolyte concentration to ORS, but may be sufficient in an individual with diarrhea who is not dehydrated.

2. **Pharmacologic. Although acute nonspecific diarrhea, including travelers' diarrhea, is typically self-limiting, antidiarrheals** may be used for symptom alleviation. Currently there are only two available nonprescription agents that the FDA has deemed to be safe and effective antidiarrheal agents: **loperamide and bismuth subsalicylate. Self-treatment of diarrhea** with these products **is limited to 2 days;** individuals experiencing longer bouts of diarrhea should be referred for medical care.

    a. Loperamide. Loperamide, an antiperistaltic agent, is approved as a nonprescription treatment for acute, nonspecific diarrhea, including traveler's diarrhea. **Loperamide** (e.g., Imodium A–D) provides effective control of diarrhea as quickly as 1 hr after administration.

       (1) Availability and dosing. Loperamide is available for **ages ≥ 6 years** in several oral formulations, including a syrup, capsule, and chewable tablet. The adult dose is 4 mg followed by 2 mg after each loose stool, not to exceed 16 mg/day. The dose for a child (ages 6 to 11 years) is also 2 mg after each loose stool, but the maximum dosage for ages 6 to 8 years is 4 mg/day, whereas the maximum dosage for ages 9 to 11 years is 6 mg/day.

       (2) Mechanism of action. Loperamide stimulates microopioid receptors on the circular and longitudinal musculature of the small and large intestines to normalize peristaltic intestinal movements. They slow intestinal motility and affect water and electrolyte movement through the bowel. Thus, the frequency of bowel movements is decreased, and the consistency of stools is increased.

       (3) Adverse effects. At recommended doses, loperamide is generally well tolerated. Side effects are infrequent and consist primarily of abdominal pain, distention, or discomfort; drowsiness, dizziness, and dry mouth.

Table 23-2	GUIDELINES FOR FLUID- AND ELECTROLYTE-REPLACEMENT THERAPY

| Age Group | Dose | |
	Mild (2–3 stools/day)	Moderate (4–5 stools/day)
> 5 years of age	2 L/first 4 hr, then replace ongoing losses	2–4 L/first 4 hr, then replace ongoing losses
< 5 years of age	50 mL/kg/first 4 hr, then 10 mL/kg or 1/2–1 cup per stool	100 mL/kg/4 hr, then 10 mL/kg or 1/2–1 cup per stool

(4) **Contraindications.** Loperamide should not be recommended to individuals presenting with symptoms of acute bacterial diarrhea (e.g., fever, chills, bloody diarrhea) as expulsion of the toxin is necessary. Neither should it be recommended in patients with colitis (potential for the development of toxic megacolon) nor in children < 6 years of age.

b. **Bismuth subsalicylate.** Bismuth preparations have moderate effectiveness against the prevention and treatment of traveler's diarrhea and nonspecific diarrhea, but doses required for relief are large and must be administered frequently, so these preparations may be inconvenient.

    (1) **Availability and dosing.** Bismuth subsalicylate (BSS) is available without a prescription in tablet and suspension formulations. Safety and efficacy data have not been reviewed for individuals < age of 12 years and should therefore only be recommended for self-care in **individuals ≥ 12 years of age.**

        (a) Chewable tablets or easy swallow caplets (e.g., Pepto-Bismol): 524 mg (two tablets) every 30 to 60 min; maximum of eight doses/day

        (b) Regular strength liquid (e.g., Pepto-Bismol Original): 524 mg (30 mL) every 30 to 60 mins; maximum of eight doses/day

        (c) Maximum strength liquid (e.g., Maalox Total Relief, Pepto-Bismol Maximum Strength): 1050 mg (30 mL) every hour; maximum of four doses/day

    (2) **Mechanism of action.** Bismuth salts work as adsorbents but also are believed to decrease secretion of water into the bowel. It is effective and can reduce the number of stools by 50%.

    (3) **Adverse effects.** BSS is relatively benign in recommended doses. The most remarkable adverse effect is **darkening of the tongue and stools** (caused by bismuth ion), which is a harmless effect occurring in > 10% of individuals ingesting BSS. In excessive doses, BSS may cause **ringing in the ears** or **neurotoxicity** (e.g., tremor, confusion, seizures, hallucinations).

    (4) **Contraindications.** BSS is not appropriate to recommend to individuals with hematological diseases (e.g., hypoprothrombinemia, hemophilia), **active GI** or **peptic ulcer disease,** documented **allergies to salicylates, children < 12 years** of age or within a **6-week period following varicella vaccination,** and those **taking warfarin therapy.**

c. **Probiotics, such as lactobacillus,** are living organisms that colonize in the gastrointestinal tract to promote health benefits. Lactobacillus is not an FDA-approved agent, but it does have some data in the relief of acute, nonspecific diarrhea, not including traveler's diarrhea. However, lactobacillus can only be **recommended for maintenance of normal gastrointestinal tract function.** There are four main species used—*Lactobacillus acidophilus, L. bulgaricus, L. reuteri,* and *L. GG*—with *L. acidophilus* regarded as the more commonly used species in the United States.

    (1) **Availability**. Several products containing lactobacillus are available with varying concentrations and dosing strategies. Some examples include the following:

        (a) **Bacid** contains **> 500 million units of *L. acidophilus*** per capsule and is dosed as two capsules twice to four times daily for adults and children.

        (b) **Culturelle** contains **10 billion units of *L. GG*** per capsule and is dosed as one capsule twice daily for adults and ½ to 1 capsule once daily for children.

    (2) **Mechanism of action.** Probiotics is a means by which an **exogenous species of bacteria** is introduced into the gut to **reestablish normal gut flora**. Lactobacillus produces lactic acid, thus creating an acidic environment that is unfavorable for pathogenic microorganisms.

    (3) **Adverse effects** are benign but can include **flatulence** with initiation (transient effect) and **constipation**.

    (4) **Contraindications.** Lactobacillus is not appropriate in any individual with **immunosuppression or valvular heart disease** due to the risk of bacteremia, those with a **milk allergy/sensitivity** because the product is dairy based or those younger than the age of 3 years.

d. **Lactase** (e.g., Lactaid) is indicated for individuals who have insufficient amounts of lactase in the small intestine. Thus, this agent is not appropriate to treat any cause of diarrhea other than a lactase deficiency. In the body, lactose (a disaccharide present in dairy products) must be broken down to glucose and galactose to be fully digested. If the lactase enzyme is unable to break down the lactose, water is drawn into the gastrointestinal tract and results in diarrhea. The dose of lactase-containing products is one to three caplets or tablets (depending on formulation) taken with first bite of meal or drink containing lactose. Titration of doses to higher levels may be required in some patients.

III. HEMORRHOIDS

A. **General information**
  1. **Definition.** Hemorrhoids are defined as abnormally large, bulging, symptomatic clusters of dilated blood vessels, supporting tissues, and overlying mucous membranes. Hemorrhoids can present in the lower rectum (internal hemorrhoids) or anus (external hemorrhoids). Simply, hemorrhoids represent downward displacement of anal cushions that contain arteriovenous anastomoses.
  2. **Epidemiology.** Hemorrhoids are common, with approximately 10% to 25% of the U.S. population affected. The risk of developing hemorrhoids increases with advancing age and peaks in individuals 45 to 65 years of age. The incidence of hemorrhoids in pregnant women is higher than that of nonpregnant women of similar age. Although they are considered a minor medical problem, they may cause considerable discomfort and anxiety.
B. **Types** of hemorrhoids are determined by their anatomical position and vascular origin.
  1. An **internal** hemorrhoid is an exaggerated vascular cushion with an engorged internal hemorrhoidal plexus located above the dentate line and covered with a mucous membrane.
  2. An **external** hemorrhoid is a dilated vein of the inferior hemorrhoidal plexus located below the dentate line and covered with squamous epithelium.
  3. A **mixed** hemorrhoid appears as a baggy swelling and exhibits simultaneous characteristics of internal and external hemorrhoids.
C. **Origin.** Although heredity may predispose a person to hemorrhoids, the exact cause is probably related to acquired factors.
  1. Situations that result in **increased venous pressure** in the hemorrhoidal plexus (e.g., chronic straining during defecation; small, hard stools; prolonged sitting on the toilet; occupations that routinely require heavy lifting; pelvic tumors; pregnancy) can transform an asymptomatic hemorrhoid into a problem.
  2. The hemorrhoidal veins are pushed downward during defecation or straining; with increased venous pressure, they **dilate** and **become engorged**. Over time, the **fibers** that anchor the hemorrhoidal veins to their underlying muscular coats **stretch**, which results in **prolapse**.
D. **Signs/symptoms**
  1. The **most common** sign/symptom of hemorrhoids is **painless bleeding** occurring during a bowel movement. The blood is usually bright red and may be visible on the stool, on the toilet tissue, or coloring the water in the toilet.
  2. **Prolapse** is the **second most common** sign/symptom of hemorrhoids. A temporary protrusion may occur during defecation, and it may need to be replaced manually. A permanently prolapsed hemorrhoid may give rise to chronic, moist soiling of the underwear. A dull, aching feeling may be heard as a complaint.
  3. **Pain** is unusual unless **thrombosis** involving external tissue is present.
  4. **Discomfort**, **soreness**, **pruritus**, **swelling**, **burning**, and **seepage** may also occur with hemorrhoids.
E. **Proper diagnosis is essential because other more serious conditions** may produce symptoms that mimic those of hemorrhoids and include **anal fissure** (small tear in the lining of the anus, **anal fistula** (abnormal connection between the mucosa of the rectum and the skin adjacent to the anus), **polyps** (tumor of the large intestine), or **colorectal cancer.**
F. **Treatment**
  1. **Nonpharmacologic**
     a. **Avoid straining** when defecating and avoid sitting on the toilet longer than necessary.
     b. **Increase dietary fiber**, **water intake**, **and physical activity**.
     c. **Sitz baths** for 15 mins, three to four times a day, can soothe the anal mucosa. Tepid water should be used, and prolonged bathing should be avoided. Epsom salts (magnesium sulfate) added to the bath or the application of an ice pack can help reduce the swelling of an edematous or clotted hemorrhoid.
  2. **Pharmacologic treatment. Nonprescription** agents are available for the treatment of burning, discomfort, inflammation, irritation, itching, pain, and swelling associated with hemorrhoids in individuals ages ≥ 12 years (*Table 23-3*). These products are simply palliative; they are not meant to cure hemorrhoids or other anorectal disease. Medical care should be sought if symptoms do

| Table 23-3 | GUIDE TO HEMORRHOIDAL THERAPY BASED ON APPROVED INDICATION FOR OTC ANORECTAL DRUG PRODUCTS |

Therapy	Burning	Discomfort	Irritation	Itching	Pain	Soreness	Swelling
Analgesic, anesthetic, antipruritic	Yes	Yes		Yes	Yes	Yes	
Astringent	Yes	Yes	Yes	Yes			
Keratolytic		Yes		Yes			
Local anesthetic	Yes	Yes		Yes	Yes	Yes	
Protectant	Yes	Yes	Yes	Yes			
Vasoconstrictor		Yes	Yes	Yes			Yes
Hydrocortisone		Yes		Yes			Yes

not improve after 7 days of treatment or if any of the following occur: bleeding, prolapse, seepage of feces or mucus, or severe pain. Available formulations include **ointments**, **creams**, and **suppositories**. Generally, the ointment or cream dosage form is believed to be superior to a suppository, which may bypass the affected area. Some formulations are available with rectal pipes, which are most efficient when the pipe has holes. The pipe allows insertion of the medication directly in the rectum and the openings allow the ointment to cover large areas of the rectal mucosa unreachable with the finger.

a. **Local anesthetics** work by blocking nerve impulse transmission.
   (1) **Availability.** FDA-approved **agents** include **benzocaine** 20% (e.g., Americaine), **pramoxine** 1% (e.g., Pramoxine Rectal Foam), and **dibucaine** 0.25% to 1.0% (e.g., Nupercainal).
   (2) **Adverse effects.** These agents may produce a hypersensitivity reaction with burning and itching similar to that of anorectal disease. Systemic absorption is minimal unless the perianal skin is abraded. As a result of its unique chemical structure, pramoxine exhibits little cross-sensitivity compared to the other local anesthetics.
   (3) **Warnings.** Allergic reactions may occur in some patients.

b. **Vasoconstrictors** are chemicals that resemble endogenous catecholamines. These agents cause arteriole constriction in the anorectal area to reduce swelling, but the mechanism by which they relieve itching, discomfort, and irritation is unknown.
   (1) **Availability. Phenylephrine** is the only FDA-approved vasoconstrictor found in non-prescription hemorrhoidal relief agents. It is one of the active ingredients in the line of Preparation H products available in ointment, gel, suppository, and cream.
   (2) **Adverse effects.** At recommended doses, the risk of individuals receiving enough systemic absorption from hemorrhoidal vasoconstrictors to develop cardiovascular or CNS effects is minimal; however, in those with cardiovascular disease, anxiety disorders, or thyroid disease, an agent that does not contain a vasoconstrictor is a prudent recommendation.
   (3) **Warnings/contraindications.** Avoid in individuals with **cardiovascular disease**, **hypertension**, **hyperthyroidism**, **diabetes**, and **prostate enlargement** because of the possibility of systemic absorption.

c. **Protectants** provide a **physical barrier** between the irritated skin and stool or anal seepage, thereby relieving the itching, irritation, discomfort, and burning. Protectants are often the bases or vehicles for other agents used for anorectal disease. Products include **aluminum hydroxide gel, cocoa butter, kaolin, lanolin, hard fat, mineral oil, white petrolatum, petrolatum, glycerin** (external use only), **topical starch, cod liver oil, shark liver oil, and zinc oxide**. When protectants are incorporated into the formulation of a nonprescription product, they should make up at least 50% of the dosage unit. If two to four protectants are used, their total concentration should represent at least 50% of the whole product. Lanolin, a derivative of wool alcohol, may be allergenic to susceptible individuals.

   d. **Astringents** lessen mucus and other secretions and protect underlying tissue through a local and limited protein coagulant effect. Action is limited to surface cells, but astringents provide temporary relief of itching, discomfort, irritation, and burning. Products considered to be safe and effective include calamine 5% to 25%, witch hazel 10% to 50% (external use only), and zinc oxide 5% to 25%.

   e. **Keratolytics** cause desquamation and debridement of the surface cells of the epidermis, which in turn allows hemorrhoidal medications to penetrate deeper into the tissues, and thus provide temporary relief of discomfort and itching. Products considered to be safe and effective include **aluminum chlorhydroxyallantoinate** (0.2% to 2.0%) and **resorcinol** (1% to 3%). Keratolytics are reserved for external use only and resorcinol should not be used on an open wound due to the potential for a serious hypersensitivity reaction. Of note, there are currently no marketed products for hemorrhoid relief that contain these agents.

   f. **Analgesics**, **anesthetics**, and **antipruritics** provide temporary relief of burning, discomfort, itching, pain, and soreness. Ingredients considered to be safe and effective for external use in the anorectal area include **menthol** (0.1% to 1.0%), **juniper tar** (1% to 5%), and **camphor** (0.1% to 3%). These agents should not be used to treat internal hemorrhoids.

   g. **Corticosteroids. Hydrocortisone (0.25% to 1.0%)** is the only FDA-approved corticosteroid for anorectal disorders. Hydrocortisone causes vasoconstriction, stabilization of lysosomal membranes, and antimitotic activity, which in turn may reduce the itching, inflammation, and discomfort in the anorectal area. Hydrocortisone concentrations $> 1\%$ are available by prescription only.

IV. HEARTBURN AND DYSPEPSIA

   A. **General information**

   1. **Definition.** Heartburn (pyrosis) is a form of indigestion that occurs when contents of the stomach flow backward into the esophagus (i.e., gastroesophageal reflux). Heartburn is generally a benign physiological process that occurs in normal individuals multiple times throughout the day. However, chronic heartburn can develop into gastroesophageal reflux disease (GERD), a more severe form of reflux that involves esophageal tissue damage. Dyspepsia is frequently defined as indigestion with symptoms of bloating, fullness, and nausea. The Rome III committee, an international committee, defines dyspepsia as one or more of the following symptoms: postprandial fullness, early satiety, or epigastric pain or burning.

   2. **Pathophysiology.** Heartburn is typically the result of a weakened or relaxed lower esophageal sphincter (LES). When the pressure in the stomach is enough to overcome the weak squeeze of the LES, the result is a backflow of stomach contents into the esophagus. Males or individuals older than the age of 50 years are more likely to develop heartburn. The following factors affect the tone of the LES and/or production of stomach acid:

   a. **Medications** that reduce LES tone include calcium-channel blockers (e.g., nifedipine, verapamil, diltiazem), nitrates, anticholinergic agents (e.g., tricyclic antidepressants, antihistamines), and oral contraceptives.

   b. **Foods** that reduce LES tone include chocolate, fatty foods, onions, peppermint, and garlic.

   c. **Smoking** (nicotine) reduces LES tone but can also stimulate stomach acid.

   d. **Stress** increases stomach acid.

   e. **Pregnancy and obesity** can create additional intra-abdominal pressure.

   3. **Symptoms.** Heartburn typically is described as a burning sensation or pain located in the lower chest. The pain may radiate higher in the chest, into the back, and into the throat or neck. Because the pain may radiate up into the chest, heartburn may be confused with pain associated with myocardial infarction (sweating associated with severe, crushing chest pain suggests a myocardial infarction and medical attention must be sought immediately). Symptoms usually occur soon after meals and when lying down at bedtime; patients may be awakened during the night with the pain. Pain on swallowing (odynophagia) may suggest severe mucosal damage in the esophagus.

   4. **Complications.** Patients with severe, uncontrolled reflux may suffer with bleeding from esophageal ulcers and pulmonary complications resulting from the aspiration of refluxed material into the upper airways and lungs. Patients who describe difficulty swallowing (i.e., dysphagia) may have an esophageal stricture, cancer, or a motility disorder.

5. **Exclusions to self-care include**
   a. Severe abdominal or back pain
   b. Unexplained weight loss
   c. Chest pain that is indistinguishable from ischemic pain
   d. Difficulty or pain on swallowing
   e. Presence or history of vomiting blood
   f. Black tarry bowel movements (if not taking iron or bismuth subsalicylate)
   g. Children < 12 years of age
   h. Possibility of being pregnant

B. **Treatment**
   1. **Nonpharmacological** interventions for heartburn and dyspepsia attempt to reduce or elimi-nate dietary and lifestyle factors that promote reflux. Specific recommendations include the following:
      a. Elevate the head of the bed 6 to 10 inches with blocks. This position improves esophageal clearance and reduces the duration of reflux. Just propping the head up with pillows may worsen symptoms by increasing abdominal pressure.
      b. Eat evening meals at least 3 to 5 hrs before going to bed to allow adequate time for gastric emptying.
      c. Avoid foods that reduce LES tone or irritate the esophagus (e.g., tomato-based products, coffee, citrus juices, and carbonated beverages).
      d. Reduce the size of meals and avoid lying down for at least 2 hrs after meals.
      e. Stop use of tobacco products and limit alcohol intake.
      f. Lose weight if appropriate.
      g. Avoid wearing tight-fitting clothing around the abdominal area.
   2. **Pharmacological.** The management of heartburn and dyspepsia may be viewed as a stepped-care approach, with antacids, nonprescription H_2RAs, and nondrug measures forming the basis for treatment. These measures may help alleviate symptoms in patients with mild to moderate heartburn and dyspepsia but cannot be expected to heal damaged esophageal mucosa or prevent complications.
      a. **Antacids.** Antacids are basic compounds that neutralize gastric acid, which increases the pH of refluxed gastric contents. As a result, the refluxed contents are not as damaging to the esophageal mucosa, and alkalinization of gastric contents increases LES tone.
         (1) **Availability and dosing.** Available antacids include **sodium bicarbonate** (e.g., Alka-Seltzer, Brioschi), **calcium carbonate** (e.g., Tums), **aluminum hydroxide** (e.g., Alternagel), and **magnesium hydroxide** (e.g., Milk of Magnesia). The adult dose is 40 to 80 mEq acid-neutralizing capacity (ANC) taken as needed for symptoms. If necessary, these doses may be titrated to a scheduled regimen, such as 40 to 80 mEq after meals and at bedtime. Patients should not take > 500 to 600 mEq ANC of antacid per day.
         (2) **Onset and duration of activity.** Antacids generally **relieve symptoms within 5 to 15 mins** of administration. Antacid suspensions generally dissolve more easily in gastric acid and therefore work quicker. In addition, sodium bicarbonate and magnesium hydroxide dis-solve quickly at gastric pH and provide rapid relief; however, calcium carbonate and alu-minum hydroxide dissolve slowly in stomach acid with a longer time frame for symptom relief (10 to 30 mins). The **duration of relief ranges from 1 to 3 hrs if taken 1 hr after meals** (duration of neutralization lasts only 20 to 40 mins if taken without food). Because of their short duration, patients may need to take four to five doses throughout the day for adequate symptom relief. **Antacids will not provide sustained neutralization of acid throughout the night**.
         (3) **Counseling**
            (a) Sodium bicarbonate contains 12 mEq of sodium per gram and is therefore contrain-dicated in patients with edema, congestive heart failure, renal failure, cirrhosis, and patients on low-salt diets.
            (b) **Calcium carbonate is the most potent** antacid ingredient but may cause consti-pation. **Aluminum hydroxide has the lowest neutralizing capacity** of all the ant-acids. Aluminum accumulation can be a problem in patients with chronic renal insufficiency.

    (c) **Magnesium hydroxide** rarely is used alone for heartburn because it frequently causes **diarrhea**. If used in renal failure patients, hypermagnesemia can occur rapidly.

    (d) **Combination products** with **aluminum and magnesium** (e.g., Maalox, Mylanta) provide the highest ANC per volume and are **used most frequently**. The predominant adverse effect of this combination is diarrhea.

    (e) **Patients with renal failure should avoid the use of all antacids.** Potassium and magnesium content of antacids should be considered for patients with cardiac disease.

    (f) Antacids can interfere with the absorption of many drugs. In general, antacids should be spaced at least 2 hrs apart from the administration of interacting drugs. This is often quite difficult to accomplish. Important clinical interactions with antacids may occur with the following drugs: tetracycline and quinolone antibiotics, iron supplements, and digoxin.

b. **H_2-Receptor antagonists (H_2RAs).** These medications inhibit gastric acid secretion by competitively blocking H_2-receptors on the parietal cell. By decreasing gastric acid secretion, the refluxed material is less damaging to the esophagus.

    (1) **Availability and dosing.** Available nonprescription agents are all **dosed as needed** for symptoms, **up to twice daily** and include **cimetidine** (Tagamet-HB) 200 mg; **famotidine** (Pepcid-AC) 10 to 20 mg (maximum dose is 40 mg/day); **ranitidine** (Zantac) 75 to 150 mg (maximum is 150 mg/day); and **nizatidine** (Axid-AR) 75 mg.

    (2) **Onset of action and duration.** The **onset of symptom relief is 1 to 2 hrs**, which is considerably longer than antacids; however, the duration of action can **last up to 10 hrs**.

    (3) **Counseling points**

        (a) All H_2RAs are **contraindicated** in individuals < **12 years of age**.

        (b) Nonprescription H_2RAs can be used for **relief or prevention** of heartburn.

        (c) **Cimetidine** may **impair** the **hepatic metabolism** and thus increase serum concentrations and the pharmacological effects of warfarin, phenytoin, and theophylline.

    (4) **Adverse effects.** These agents are extremely well tolerated. The **most common** adverse effects reported with nonprescription doses are **headache**, **diarrhea**, **dizziness**, and **nausea**.

c. **Proton pump inhibitors.** These agents provide complete acid suppression by inhibiting the hydrogen-potassium ATPase pump on the surface of the parietal cell. Proton pump inhibitors (PPIs) are an appropriate recommendation for individuals who have failed other "steps" in the treatment plan, or who are experiencing frequent heartburn (defined as heartburn occurring 2 or more days a week).

    (1) **Availability.** Nonprescription PPIs include **omeprazole** magnesium 20.6 mg (Prilosec OTC) and **lansoprazole** 15 mg (Prevacid 24 hrs).

    (2) **Onset of action and duration. Onset of action is 2 to 3 hrs,** but the **duration of relief is approximately 12 to 24 hrs.** Thus, PPIs should **not** be used **for immediate relief.**

    (3) **Adverse effects** include headache, constipation, abdominal pain, nausea, and diarrhea.

    (4) **Counseling points**

        (a) PPIs are activated by stomach acid and therefore should be **dosed 30 mins prior to a meal.** Optimal symptom relief may not be achieved if taken after a meal.

        (b) Drug interactions are attributable to effects on gastric pH and metabolism through the CYP3A4 and CYP2C19 pathways and include clopidogrel, vitamin K antagonists, and atazanavir.

        (c) PPIs for self-care are approved for **ages ≥ 18 years.**

        (d) As self-care, PPIs should only be recommended for the **14-day course** of therapy and **repeated no more often than every 4 months,** as necessary.

d. Bismuth subsalicylate (BSS) is FDA approved for the relief of upset stomach due to overindulgence of food and drink. Its mechanism of action for heartburn and dyspepsia is unknown. A more thorough review of BSS can be found in section II.C.2.b.

e. Combination H_2RAs and antacid (e.g., Pepcid Complete) may provide quick onset of relief (within 30 mins) and an extended duration of relief (8 to 10 hrs).

Study Questions

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which laxative should *not* be used to treat acute constipation because of its slow onset of action?

   (A) glycerin
   (B) bisacodyl suppository
   (C) psyllium
   (D) milk of magnesia

2. All of the following statements about emollient stool softener laxatives are true *except* which one?

   (A) They are not first-line treatment for the typical individual with acute constipation.
   (B) They are appropriate for individuals who should not strain by passing a hard stool.
   (C) They are known as surfactants and include docusate calcium and docusate sodium.
   (D) They are highly associated with the development of acute phosphate nephropathy.

3. Which of the following statements adequately describes bulk-forming laxatives?

   (A) They can cause diarrhea if not taken with at least 8 oz of water.
   (B) They are derived from polysaccharides and resemble fiber in mechanism of action.
   (C) They have a relatively fast onset of action of 4 to 8 hrs and duration of 12 to 24 hrs.
   (D) They produce a more complete evacuation of the bowels than stimulant products.

4. Which local anesthetic should be used to treat symptoms of pain, itching, burning, and discomfort in patients with an established lidocaine allergy?

   (A) tetracaine
   (B) dibucaine
   (C) pramoxine
   (D) benzocaine

5. Which of the following is the most common sign/symptom of hemorrhoids?

   (A) bleeding
   (B) pain
   (C) seepage
   (D) pruritus

6. Which of the following agents is designated as a safe and effective analgesic, anesthetic, and antipruritic by the FDA?

   (A) witch hazel
   (B) juniper tar
   (C) hydrocortisone
   (D) phenylephrine

7. All of the following symptoms associated with gastroesophageal reflux may be treated with nonprescription agents *except*

   (A) burning sensation located in the lower chest.
   (B) pain that is worse after meals.
   (C) pain or difficulty when swallowing.
   (D) pain that is worse in a recumbent position.

8. Which of the following is an appropriate nonpharmacological recommendation for patients with gastroesophageal reflux?

   (A) Eat larger but fewer meals.
   (B) Avoid meals high in protein.
   (C) Eat evening meals at least 3 hrs before bed.
   (D) Prop the head up with two pillows at night.

9. Which of the following would be the most appropriate to recommend for self-care to an individual wanting fast but extended relief from heartburn?

   (A) Proton pump inhibitor
   (B) H_2RA
   (C) Aluminum (+) Magnesium antacid
   (D) H_2RA (+) antacid

10. All of the following are acceptable uses of magnesium hydroxide *except*

   (A) heartburn.
   (B) dyspepsia.
   (C) hemorrhoids.
   (D) constipation.

Answers and Explanations

1. **The answer is C** *[see I.B.2]*.
   Glycerin and the bisacodyl suppository all produce stools in 30 mins to a few hours, whereas psyllium, a bulk-forming laxative, produces stool in 24 to 72 hrs in the same manner as a normal bolus of food or fiber.

2. **The answer is D** *[see I.B.2.d]*.
   These agents, known as surfactants (docusate calcium and docusate sodium), have a long onset of action (24 to 48 hrs); thus they should never be used for acute constipation but should be used mainly for patients who should not strain to pass hard stools (e.g., pregnant patients, postsurgical patients, postmyocardial infarction). Oral sodium phosphate (OSP), a saline laxative, has been associated with acute phosphate nephropathy, but not emollient laxatives.

3. **The answer is B** *[see I.B.2.a; I.B.2.c]*.
   Stimulant products result in a quicker, more complete, and often more violent evacuation of the bowel than do the bulk-forming agents. Bulk-forming agents are developed from complex sugars, similar to fiber, that provide bulk to increase gastrointestinal motility and water absorption into the bowel. However, patients must drink plenty of water to facilitate the absorption of water into the bowel, or they may become more constipated.

4. **The answer is C** *[see III.F.2.a.(2)]*.
   Because of its chemically distinct structure, pramoxine exhibits less cross-sensitivity compared to the other anesthetics and should be used in patients with a lidocaine allergy.

5. **The answer is A** *[see III.D.1]*.
   The most common sign/symptom of hemorrhoids is painless bleeding occurring during a bowel movement.

6. **The answer is B** *[see III.F.2.f]*.
   Juniper tar, menthol, and camphor are the only three agents deemed safe and effective as analgesics, anesthetics, and antipruritics by the FDA.

7. **The answer is C** *[see IV.A.5]*.
   Pain on swallowing often suggests severe esophageal mucosal damage, which would require prescription medications for healing. Difficulty on swallowing may indicate an esophageal stricture, cancer, or motor disorder. All of these conditions require diagnosis and treatment by a health care provider.

8. **The answer is C** *[see IV.B.1.a–g]*.
   Patients should be instructed to eat evening meals at least 3 hrs before going to bed. This allows sufficient time for gastric emptying, so that the volume of refluxed material will be smaller and less irritating to the esophagus.

9. **The answer is D** *[see IV.B.2.e]*.
   Proton pump inhibitors have an extended duration of action but a long onset of action, compared to antacids, which have a quick onset of action but a short duration of action. The combination of a H_2RA and an antacid (e.g., Pepcid Complete) allows for a quick onset of action (antacid) with an extended duration of action (H_2RA).

10. **The answer is C** *[see I.B.2.e; IV.B.2.a]*.
    Magnesium hydroxide (e.g., Milk of Magnesia) may be used for the symptomatic relief of heartburn, dyspepsia, and constipation. Magnesium hydroxide is most noted for its potential to cause diarrhea. Indirectly, it may provide relief from hemorrhoids if they are due to constipation but will not have a direct effect on alleviation of hemorrhoids.

24

Over-the-Counter Menstrual, Vaginal, and Contraceptive Agents

JENNIFER D. SMITH

I. MENSTRUATION AND MENSTRUAL PRODUCTS

A. **Introduction. Menstruation** is a physiological discharge of blood, endometrial cellular debris, and mucus through the vagina of a nonpregnant woman and is a result of the monthly cycling of female reproductive hormones. The menstrual cycle eliminates a mature, unfertilized egg and prepares the endometrium for the possible implantation of a fertilized egg the following month.

B. **Menstrual abnormalities**

1. **Dysmenorrhea**, which is painful menstruation, is the most common gynecologic problem in the United States.

   a. **Types**

      (1) **Primary dysmenorrhea** is pain associated with menstruation in the absence of identifiable pelvic disease. It is prompted by increased levels of prostaglandins in the menstrual fluids.

      (2) **Secondary dysmenorrhea** is associated with an underlying pelvic disorder. Possible causes include endometriosis, pelvic inflammatory disease (PID), and ovarian cysts.

   b. **Symptoms** of dysmenorrhea are primarily lower abdominal cramping and can often include nausea, vomiting, diarrhea, headache, and dizziness. Abdominal cramping usually begins at onset of menstrual flow or a few hours before onset.

   c. **Assessment.** Practitioners should **question the patient** about the following:

      (1) Current medications (including over-the-counter and herbals)

      (2) Age

      (3) Duration of dysmenorrhea

      (4) A description of the dysmenorrhea symptoms

      (5) History of pelvic disease (endometriosis, PID, ovarian cysts, infertility)

      (6) Allergy to aspirin or nonsteroidal anti-inflammatory drugs (NSAIDs)

      (7) Bleeding disorder

      (8) Exercise routine

   d. **Treatment.** Recommendation(s) should be based on the patient's assessment of the degree of pain. Pain associated with dysmenorrhea generally tapers within 2 days. Prolonged pain may be associated with an underlying problem, and patients should be referred to a physician.

      (1) **Nonpharmacologic** recommendations include rest, heat, wearing loose-fitting clothing, and exercise.

      (2) **Pharmacologic recommendations. NSAIDs** are used as the primary treatment of dysmenorrhea. Treatment with **aspirin** or **acetaminophen** can prove of benefit for the symptoms associated with primary dysmenorrhea; however, aspirin is not as potent as the other NSAIDs, and acetaminophen is not thought to prevent prostaglandin production to

a great extent although it can be helpful for treating the headache and backache that may accompany menstrual cramping. NSAID treatment provides relief for mild to moderate symptoms but will probably not help patients with severe symptoms.

(a) **Mechanism of action.** NSAIDs inhibit the synthesis and action of prostaglandins, which are responsible for the pain associated with dysmenorrhea.

(b) **Administration guidelines.** Begin therapy at the onset of pain; there is no proven value in beginning therapy in anticipation of dysmenorrhea. Acceptable recommendations include ibuprofen (e.g., Motrin, Midol Liquid Gels) 200 mg every 4 to 6 hrs (maximum 1200 mg/day) or naproxen sodium (e.g., Aleve, Pamprin All Day, Midol Extended Relief) 200 mg of naproxen every 8 to 12 hrs (maximum naproxen dose is 600 mg/day).

(c) **Adverse effects** are limited because of the brief duration of need. However, common adverse effects associated with NSAIDs include bleeding, upset stomach, abdominal pain, diarrhea, heart failure exacerbation, cardiovascular thrombic events, and dizziness. NSAIDs should be taken with food to decrease adverse gastrointestinal (GI) effects.

(d) **Warnings.** The lowest effective dose for the shortest duration needed should be recommended to lessen the potential risk for cardiovascular events. These agents are contraindicated in patients with an allergy to NSAIDs or active GI disease.

2. **Premenstrual syndrome (PMS)**

a. **Symptoms** (e.g., marked mood swings, fatigue, appetite changes, bloating, breast tenderness, irritability, feelings of depression) begin 1 to 7 days before the onset of menses.

b. **Nonpharmacological** therapy includes regular exercise, dietary modifications, and reduction of stress factors. Dietary modifications include avoiding alcohol and caffeine, which can increase irritability, and consuming a balanced diet of fruits, vegetables, and complex carbohydrates while avoiding salty foods and simple sugars (can exacerbate fluid retention). Patients experiencing symptoms abnormal to their cycle should be referred to a physician.

c. **Pharmacological treatment**

(1) **Combination products** are marketed for women (age 12 and older) with PMS symptoms. These products contain analgesics (e.g., acetaminophen, aspirin, ibuprofen, naproxen sodium), diuretics (e.g., caffeine, pamabrom), and/or an antihistamine (e.g., pyrilamine, diphenhydramine).

(a) **Diuretics** are recommended by the U.S. Food and Drug Administration (FDA) for use in eliminating water during premenstrual and menstrual periods. When **administered approximately 5 days before menses**, diuretics help relieve bloating, excess water, cramps, and tension. Included in this category are caffeine and pamabrom.

(i) **Caffeine** (e.g., Pamprin Max, Midol Complete), a **xanthine derivative**, promotes diuresis by inhibiting tubular reabsorption of sodium and chloride. The recommended dosage is 100 to 200 mg every 3 to 4 hrs. Side effects associated with caffeine use are GI disturbances and central nervous system (CNS) stimulation. Patients should be counseled to **limit the consumption of caffeine-containing foods or beverages** while taking this product.

(ii) **Pamabrom** (e.g., Aqua-ban, Midol Teen, Pamprin Cramp, Pamprin Multi-Symptom) is a theophylline derivative often used in combination with analgesics and antihistamines. The recommended dosage is 50 mg four times daily not to exceed 200 mg/day.

(b) Antihistamines, such as pyrilamine and diphenhydramine, are added to PMS products for their sedative effects although the need for sedation is questionable. At this time, there is insufficient evidence to recommend agents containing antihistamines (e.g., Pamprin Multi-Symptom, Midol Complete, Midol PM) for the alleviation of PMS symptoms.

(2) Daily **calcium supplementation** (equivalent to the recommended daily calcium intake for women of reproductive age) has been shown to reduce the emotional and physical symptoms of PMS.

(3) **Pyridoxine.** Although clinical trials do not support the efficacy of pyridoxine (vitamin B_6), it is being used for the treatment of PMS. Vitamin B_6 doses should be limited to 100 mg/day to prevent dose-associated neuropathy.

C. **Toxic shock syndrome (TSS)** is a rare but sometimes fatal illness often associated with menstruation.
   1. TSS can be categorized either as menstrual or nonmenstrual, with approximately two-thirds of cases associated with menstruation. TSS is known to occur in both men and women.
   2. The condition usually affects women < 30 years of age who use tampons. Women between the ages of 15 and 19 years are at the highest risk.
   3. TSS is characterized by an abrupt onset (8 to 12 hrs) of flu-like symptoms (e.g., high fever, myalgia, vomiting, diarrhea). Neurologic symptoms such as headache, agitation, lethargy, seizures, and confusion can also occur.
   4. TSS results from an exotoxin produced by *Staphylococcus aureus*.
   5. The **primary risk factor** for TSS is the **use of tampons**, but the use of barrier contraceptives (e.g., diaphragms, cervical sponges) also increases the risk.
   6. When TSS is suspected, patients should be hospitalized immediately. To lower the risk of TSS, women should use lower-absorbency tampons and alternate the use of tampons with feminine hygiene pads; however, to lower the risk to nearly zero, women should use sanitary pads instead of tampons.

II. VAGINAL PRODUCTS

A. **Vulvovaginal candidiasis**
   1. **General considerations**
      a. **Occurrence.** Approximately 75% of all women will experience vulvovaginal candidiasis (VVC), also known as a yeast infection, at least once, and 50% will have a second episode. Only 5% of women experience recurrent infections (four or more infections within a 1-year period).
      b. **Cause.** *Candida albicans* is responsible for up to 92% of infections. Infections owing to *C. glabrata* are increasing.
      c. **Predisposing factors.** Antibiotics, oral contraceptives containing high-dose estrogen, pregnancy, diabetes, poor postbowel movement hygiene, and immunosuppression increase the risk for infection.
      d. **Symptoms.** Can include a thick, white, "cottage cheese-like," nonmalodorous vaginal discharge; dysuria; vaginal burning; and pruritus.
   2. **Home diagnostics for VVC.** Currently, a color-keyed vaginal **pH monitor** (Vagisil) is available over-the-counter for women experiencing symptoms of VVC. VVC typically does not increase vaginal pH, but other infections such as bacterial vaginosis or *Trichomonas* may. Thus, essentially the purpose of the pH monitor is to rule out other bacterial infections and prevent erroneous treatment of an assumed yeast infection. The product is not intended to detect sexually transmitted infections.
      a. Indication. Women with symptoms of vaginal burning, itching, unpleasant odor, or unusual discharge.
      b. Use. Press wand against vaginal wall for 5 secs; compare color on the pH paper swab to the pH color chart
      c. Results. A pH of 4.5 in a symptomatic individual may be a yeast infection. A pH of 5.0 to 7.5 may indicate a different kind of vaginal infection.
      d. Counseling points
         (1) Menstrual blood can cause an elevated pH, indicating possible infection. Therefore, the test should not be performed during menstruation or for 5 days after menstruation.
         (2) Wait for 48 hrs after douching or sexual intercourse (72 hrs if a lubricant was used).
         (3) Recommended only for women with normal periods. Lack of estrogen (e.g., perimenopause or postmenopause, women who are nursing and have not restarted their period) may contribute to an elevated vaginal pH.
         (4) Symptomatic individuals with a pH of 5.0 to 7.5 should be referred for medical evaluation.
   3. Exclusions to self-care
      a. First episode of symptoms
      b. Pregnant
      c. Younger than 12 years of age
      d. Systemic symptoms such as fever
      e. History of recurrent vaginal yeast infections
      f. Discharge with a fishy odor (indicates bacterial vaginosis, most often caused by anaerobic bacteria) or a thin, malodorous purulent discharge (indicates *Trichomonas* infection)

4. **Pharmacologic treatment.** Products proven safe and effective for the treatment of VVC are imidazole derivatives with antifungal activity and include tioconazole, miconazole, and clotrimazole. Each agent is available in a variety of formulations, including intravaginal creams, suppositories, ovules, and ointments.

   a. The choice of product formulation is based on patient preference. One formulation is not more effective than another.

   b. **External vaginal creams**, mainly **used to treat vulvar symptoms of pruritus**, can be used in combination with intravaginal products. Many products are available as a "combination pack" including an internal cream, ovule, or suppository and an external cream.

   c. **For most available intravaginal products**, **application time should be recommended as bedtime to increase vaginal mucosa contact time**. However, external creams can be used any time of day.

   d. **Products are available as 1-, 3-, or 7-day treatment plans.** Available products include Monistat (miconazole 1-, 3-, and 7-day), Vagistat (tioconazole 1-day; miconazole 3-day), and Gyne-Lotrimin (clotrimazole 3- and 7-day). Efficacy rates for these products approach 80% to 90%.

      (1) Each product must be used for the consecutive number of days outlined for the product to be effective.

      (2) The formulated products for 1- and 3-day treatments are for user convenience and should not be misinterpreted for the time to symptom resolution.

      (3) **Symptoms of VVC typically do not resolve completely for 5 to 7 days.** Thus when 1- and 3-day products are purchased, the woman should be aware that she **may still experience symptoms after she has completed the treatment** but should resolve within several days. **If symptoms are still present after 7 days, a medical provider should be consulted.**

      (4) Products for internal use may come with prefilled applicators for single use or reusable applicators. Reusable applicators should be washed with soap and water each time.

   e. **Patient counseling**

      (1) Complete the course of therapy even if symptoms improve. Symptom improvement typically will not be seen for 5 to 7 days after initiation of treatment. Seek medical treatment if symptoms have not resolved after 7 days.

      (2) Wash vaginal area with mild soap before application.

      (3) Avoid sexual intercourse during therapy.

      (4) Avoid condoms and diaphragm use for 72 hrs after therapy is completed.

      (5) Continue use during menstrual period, but tampons should not be used during VVC treatment.

      (6) Sanitary pads can be used for leakage of intravaginal products.

      (7) Side effects can include burning or irritation.

      (8) Treatment of male partners is not necessary.

   f. *Lactobacillus acidophilus*, taken by mouth or as a vaginal suppository, has inadequate data at this time to make a sound recommendation for prevention or treatment of VVC.

5. **Prevention**

   a. Dry vaginal area well with a towel after bathing.

   b. Avoid tight or damp clothing.

   c. Wear cotton underwear.

   d. Use unscented soap to avoid irritation.

   e. Avoid douching.

   f. Decrease consumption of sucrose and simple sugars.

B. **Feminine hygiene products.** There are a variety of feminine hygiene products available for cleansing and controlling odor associated with normal vaginal discharge and products available for vaginal dryness. These products are not used to treat vaginal infections.

   1. Vaginal douches (Summer's Eve) irrigate the vagina and can be used for cleansing, for soothing as an astringent, or to produce a mucolytic effect.

   2. **Vaginal lubricants** are used for **immediate relief of vaginal dryness**, which can cause pain during intercourse. Vaginal lubricants are available as oil-, water-, or silicone-based.

      a. **Oil-based** lubricants typically contain baby oil or petroleum jelly and **should not be recommended for use with latex condoms** because they can deteriorate the latex. Additionally, oil-based lubricants can harbor bacteria in the vagina and lead to infections.

    b. Water-based vaginal lubricants (e.g., Astroglide, K-Y Jelly) are known to be compatible with latex condoms.

    c. Silicone-based vaginal lubricants (e.g., K-Y INTRIGUE) are longer lasting than water-based lubricants and are compatible only with latex condoms.

   3. Vaginal moisturizers. Unlike lubricants, which provide immediate relief, vaginal moisturizers (e.g., Replens, K-Y Silk-E) are for **chronic vaginal dryness**. Thus if used for intercourse, vaginal moisturizers need to be applied 2 hrs prior to allow for adequate lubrication.

III. OTC CONTRACEPTIVES

  A. Introduction. The **efficacy** and **pregnancy rates** for various means of contraception depend greatly on the **degree of compliance**. *Table 24-1* lists ranges of pregnancy rates reported for a variety of contraceptives.

  B. Methods of contraception that may make use of nonprescription products or devices include the following:

   1. Fertility awareness methods make use of information concerning the menstrual cycle to determine the days when intercourse is most likely to result in a pregnancy. Calculations of the period of fertility take into account the **sperm viability** in the female reproductive tract, which is

Table 24-1	PREGNANCY RATES FOR VARIOUS MEANS OF CONTRACEPTION (%)[a]	
Method of Contraception	**Typical[b]**	**Lowest[c]**
Oral contraceptives		
Combination (estrogen–progestin)	0.1–0.34	0.1
Progestin only	0.5–1.5	0.5
Mechanical/chemical		
Cervical cap[d]		
Multiparous	40	26.0
Nulliparous	20	9.0
Male condom without spermicide	12–14	3.0
Male condom with spermicide	4–6	1.8
Diaphragm[d]	20	6.0
Female condom	21	5.0
Intrauterine device	≤ 1–2	≤ 1.0–1.5
Levonorgestrel implants	≤ 1.0	≤ 1.0
Medroxyprogesterone injection	≤ 1.0	≤ 1.0
Spermicide alone	20–22	6.0
Other		
Rhythm (all types)	25	1–9
Vasectomy/tubal ligation	≤ 1	≤ 1
Withdrawal	40–50	30
No contraception	85	85

[a]During first year of continuous use.
[b]A typical couple who initiated a method that either was not always used correctly or was not used with every act of sexual intercourse, and who experienced an accidental pregnancy.
[c]The method of birth control was always used correctly with every act of sexual intercourse but the couple still experienced an accidental pregnancy.
[d]Used with spermicide.
Adapted with permission from Covington TR. *Nonprescription Drug Therapy: Guiding Patient Self-Care.* 4th ed. St. Louis, MO: Wolters Kluwer Health; 2005.

estimated to average **2 to 3 days** (up to 5 days), and the **fertile period of the ovum**, which is estimated to be **24 hr**. Recent studies indicate that conception is most likely to occur when couples have intercourse during a 6-day period ending on the day of ovulation. **Conception is highly unlikely if sexual intercourse occurs 6 or more days before ovulation or the day after ovulation**. These methods are based on reproductive anatomy and physiology and are applied according to the signs and symptoms naturally occurring in the menstrual cycle.

a. **Calendar method.** This method estimates the possible day of ovulation, based on documentation of prior menstrual cycle events. **Abstinence** should be practiced during the period around ovulation when there may be a fertilizable egg present. The calendar method is not as well-used as it once was and is not accurate for women with irregular cycles, women who are breastfeeding, or women with postponed ovulation.

b. **Temperature method.** Documentation of **basal body temperature (BBT)** can be made using a basal thermometer, which is available without a prescription.

   (1) Approximately 24 hrs prior to ovulation, there is a moderate drop in basal temperature followed by a rise in temperature 24 hrs after ovulation. The rise in temperature is thought to be the result of progesterone release, which indicates the occurrence of ovulation.

   (2) For this method to be successful, **abstinence** should be practiced **5 days after the onset of menses until 3 days after the drop** in basal temperature.

   (3) Because the basal temperature reflects the amount of heat radiation when the body is at its metabolic low, the temperature should be taken first thing in the morning (i.e., before any activity) after at least 5 hrs of restful sleep.

   (4) **The BBT** thermometer may be used **orally**, **vaginally**, **or rectally**, depending on the model selected.

   (5) False changes in BBT may be caused by infection, tension, a restless night, or any type of excessive movement.

2. **Spermicidal agents** are composed of an **active spermicidal chemical**, which immobilizes or kills sperm, and an **inert base** (e.g., foam, cream, jelly, gel, tablet, or suppository), which localizes the spermicidal chemical in proximity to the cervical os. The only FDA-approved spermicidal agent is **nonoxynol-9**. However, although it is spermicidal, it is **not a microbicide and therefore cannot be used alone for protection against sexually transmitted infections**.

a. **Dosage forms. Contraceptive spermicides**, which are available in several forms, offer the greatest variety within one specific method of contraception (*Table 24-2*).

   (1) **Creams**, **jellies**, **and gels** are used with a diaphragm. The concentration of spermicide is less than the necessary 8% to be employed as a single contraceptive method.

Table 24-2 SPERMICIDES[a]

Type (Product)	Comments
Film	Inserted by the female directly over the cervix; insert not less than 15 mins and not more than 3 hrs before intercourse; contraceptive protection begins 5–15 mins after insertion and remains effective no more than 3 hrs
Foam	Contraceptive protection is immediate; remains effective no more than 1 hr, additional dose is needed before any subsequent intercourse
Jellies, creams, gels	Contraceptive protection is immediate; used alone remains effective no more than 1 hr; when used with diaphragm or cap, keep diaphragm or cap in place for at least 6 hrs after last intercourse
Suppositories and tablets	Contraceptive protection begins 10–15 mins after insertion; remains effective no more than 1 hr

[a]The spermicidal agent in all listed products is nonoxynol-9.
Article adapted... Reprinted with permission from Hatcher RA. *Contraceptive Technology 1994–1996*. 16th ed. New York, NY: Irvington; 1994:180.
VCF, vaginal contraceptive film.

(2) Foams disperse better into the vagina and over the cervical opening but provide less lubrication than creams, jellies, and gels. They usually contain a higher concentration of spermicide (i.e., **the optimal concentration of 8% or higher**). Because of volume differences among brands, the dosage amounts vary. If vaginal or penile irritation develops, another brand should be tried.

    (a) The can should be shaken vigorously 20 times before use.

    (b) The foam should be inserted intravaginally about two-thirds the length of the applicator, and the contents should be discharged.

    (c) Foam should be reapplied during prolonged intercourse (i.e., lasting > 1 hr) and before every subsequent act of intercourse.

    (d) To ensure efficacy, the patient should wait at least 8 hrs before douching to avoid diluting the spermicide effect or "forcing" sperm into the cervix.

(3) Suppositories and foaming tablets. These agents are both small and convenient. Although solid at room temperature, suppositories melt at body temperature, whereas foaming tablets effervesce.

    (a) The tablets should be wetted and inserted high into the vagina 10 to 15 mins before intercourse. Intercourse must occur within 1 hr or the dose must be repeated. Each repeated act of intercourse requires insertion of another tablet/suppository.

    (b) To ensure efficacy, the patient should wait 6 to 8 hrs after the last act of intercourse before douching.

(4) Film comes as small paper-thin sheets (e.g., vaginal contraceptive film [VCF]). It is inserted on the tip of the finger into the vagina, and placed at the cervical opening 5 to 15 mins before intercourse.

(5) Sponge. The Today Sponge is a doughnut-shaped polyurethane device containing the spermicide nonoxynol-9. However, it may also provide contraceptive effects by serving as a mechanical barrier to the cervical entrance.

    (a) The sponge should **remain in place for at least 6 hrs** and up to 30 hrs. **Contraceptive benefits are for 24 hrs**, regardless of the frequency of intercourse during this period.

    (b) Increased risk of TSS with use (rare).

    (c) Not recommended for use during menstruation.

    (d) This method may have a higher pregnancy rate for women who have vaginally delivered a baby.

b. Side effects. Side effects are **minimal**, but may include sensation of warmth and rare allergic reactions (**contact dermatitis** with rash, stinging, itching, and swelling). If a suspected reaction occurs, one should be instructed to use another product because the issue might be the concentration of the spermicide or an additive specific to a given brand. There are no significant differences in birth defect rates between users and nonusers.

3. Male condoms are used to prevent transmission of sperm into the vagina.

a. Types. There are four different types of materials for male condoms, which include latex rubber, processed collagenous lamb cecum sheaths (lambskin), polyurethane, or polyisoprene. Condoms are labeled that they are intended to prevent HIV and other sexually transmitted infections, but caution that they do not completely eliminate the risk, particularly human papillomavirus (HPV) and herpes simplex virus (HSV).

(1) Latex condoms afford greater elasticity than lambskin and are more likely to remain in place on the penis.

    (a) Availability. Various types are available (e.g., lubricated, ribbed, colored), including some with spermicide (concentration much less than that of a vaginal spermicide product). It is doubtful that spermicide-lubricated condoms offer any better protection than plain latex condoms, and they have a shorter shelf life. There is a standard size, but smaller and larger versions are available.

    (b) Concerns. Latex rubber may cause an allergic reaction. An estimated 1% to 2% of the population is sensitized to natural rubber latex, and higher percentages are likely for those frequently exposed to latex (e.g., health care workers). The most common symptoms are genital inflammation with redness, itching, and burning. Sometimes, antioxidants or accelerators used during the manufacturing process may be the cause of the allergy.

(2) Lambskin condoms (e.g., Trojan NaturaLamb) are **not considered as effective as latex condoms** (and cannot be labeled as such) in preventing the transmission of STDs, including HIV. The lambskin condoms are structured to consist of membranes that reveal layers of fibers crisscrossing in various patterns. This gives the lambskin strength but also allows for an occasional pore. Therefore, lambskin **may allow HIV and hepatitis B virus**, which are smaller than sperm, to pass through.

    (a) Lambskin has less elasticity than latex, and lambskin condoms may slip off the penis.

    (b) Lambskin affords **greater sensitivity** than latex.

    (c) Lambskin condoms are more expensive than latex condoms.

(3) A **polyurethane condom** (e.g., Avanti, Trojan Supra) is **marketed for individuals who are allergic to latex**. Some evidence exists that slippage and breakage rates may be higher than for latex condoms. In contrast to the latex condom, petroleum-based products will not degrade the polyurethane.

(4) A **polyisoprene condom** (e.g., LifeStyles Skyn) is the newest material to be **marketed for individuals who are allergic to latex**. The condom is promoted as superior to polyurethane in malleability and comfort and does protect against most sexually transmitted infections.

  b. Advantages. The relative accessibility, ease of transport, and low cost make condoms an attractive method of contraception.

  c. Disadvantages. Condoms are **not 100% effective** against preventing pregnancy or the spread of sexually transmitted infections. Although accessible to purchase, male condoms are, for most, **not easily transportable**. Male condoms **should not be stored in wallets**, **glove compartments**, etc. because of the potential for deterioration of the condom. However, a new product, Trojan2GO, provides condoms packaged as "condom cards"—packaging that is resistant to breakdown and which can be easily carried in the wallet or pocket.

  d. Use. Condoms are now packaged with detailed instructions for proper application technique and disposal. A new condom should be used correctly each time.

  e. Counseling points

    (1) Proper lubrication can minimize the possibility of tearing and can be ensured by using either a lubricated condom or by applying a water-based lubricant to either the condom or the woman's genitalia. (*Note*: Petroleum jelly [Vaseline] should never be used because it causes deterioration of the rubber [latex] and is a poor lubricant.)

    (2) Condoms should never be reused.

    (3) Condoms should not be stored near excessive heat. Be sure to store condoms in a cool, dry place, out of direct sunlight. The glove compartment of a car is not a good place to store condoms. Do not store condoms in pockets, purses, or wallets for more than a few hours, unless packaging has been specifically designed for such purpose.

    (4) If the condom should break or leak, spermicide foam should be immediately inserted vaginally.

    (5) Do not buy or use condoms that have passed their expiration date.

    (6) Condoms are **not 100% effective** against preventing pregnancy or the spread of sexually transmitted infections. If a sexually transmitted infection is suspected, contact a health care provider or public health agency.

4. The **female condom** is a **disposable nitrile sheath** that fits into the vagina, and **provides protection from pregnancy and some sexually transmitted infections**. The original female condom (FC1) was made of polyurethane, an expensive material. In 2009, FDA approved a second-generation product, the nitrile female condom (**FC2**), which is made of **synthetic latex** and thus **less expensive** to manufacture than the FC1. Production of FC1 has ceased.

  a. The sheath resembles a plastic vaginal pouch and consists of an **inner ring**, which is inserted into the vagina near the cervix much like a diaphragm, whereas the **outer ring** remains outside the vagina, covering the labia. The condom is prelubricated, and additional lubricant (oil- or water-based) may be used if needed. It may be inserted up to 8 hrs before intercourse, and can be removed at any time after ejaculation. However, the FC should be removed prior to the woman standing up to prevent semen spillage.

    b. **Female condoms should not be used concurrently with a male condom** because the friction between the two condoms may **contribute to condom breakage**.

    c. The FC has a **higher pregnancy failure rate than male condoms**, but does appear to protect against some sexually transmitted diseases, including HIV and cytomegalovirus. However, these data are limited, and further research is necessary to determine the extent of protection these condoms afford against sexually transmitted infections.

    d. Female condoms should not be reused.

    e. A main complaint with the FC1 was a "squeaking" noise with use. The FC2 has less noise associated with it, but it still can make noise during intercourse.

5. The **diaphragm** is a contraceptive device that is self-inserted into the vagina to block access of sperm to the cervix. It requires a prescription and must be used in conjunction with a nonprescription spermicide to seal off crevices between the vaginal wall and the device.

6. The **cervical cap** is a prescription rubber device smaller than a diaphragm that fits over the cervix like a thimble. It is more difficult to fit than the diaphragm.

7. **Emergency contraception (EC) is the use of a medication or device after coitus to prevent pregnancy.** Currently, the only available nonprescription agent for emergency contraception is **levonorgestrel**, but it is only available for self-care in females **ages 17 and older**.

    a. **Mechanism of action.** The exact mechanism for EC is unknown but thought to be at least two or more of the following:

        (1) inhibit or delay ovulation

        (2) prevent implantation

        (3) inhibit fertilization

    b. **Availability and dose**

        (1) **Next Choice:** contains **two tablets of levonorgestrel 0.75 mg to be taken 12 hrs apart**

        (2) **Plan B One-Step:** contains **one tablet of levonorgestrel 1.5 mg to be taken as a single dose**

    c. Timing. Levonorgestrel for EC is **most efficacious when taken within 24 hrs of intercourse but can be taken up to 72 hrs after intercourse**. Some data demonstrate efficacy up to 120 hrs (5 days) after intercourse, but if used during this time frame, women should be aware that efficacy may be diminished.

    d. Safety. When used as emergency contraception, there are **no contraindications**, given the short duration of use. Adverse effects may include nausea, vomiting, cramping, or irregular bleeding. If vomiting occurs within 2 hrs of dosing, the dose may need to be repeated.

    e. **Counseling points**

        (1) Levonorgestrel EC should not be used for ongoing contraception.

        (2) EC is not effective against the prevention of sexually transmitted infections.

        (3) Levonorgestrel EC is most efficacious if taken within 24 hrs of unprotected intercourse.

        (4) Levonorgestrel EC is ineffective once implantation has occurred.

Study Questions

Directions for questions 1–8: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The most common cause of vaginal yeast infections is

    (A) *Candida albicans.*

    (B) *Candida glabrata.*

    (C) *Trichomonas.*

    (D) anaerobic bacteria.

2. A female complains of vaginal burning and itching with a distinct "fishy" odor. Which of the following would be the most appropriate recommendation?

    (A) Purchase the Vagisil pH monitor.

    (B) Referral to a medical provider.

    (C) Treatment with a 1-day VVC product.

    (D) Treatment with a 7-day VVC product.

3. Which of the following would be appropriate to counsel on for a woman who is purchasing a female condom?

(A) The FC2 is superior to the male condom for pregnancy prevention.
(B) The FC2 can protect against all sexually transmitted infections.
(C) The FC2 should be used concomitantly with a male condom.
(D) The FC2 can be inserted several hours prior to intercourse.

4. When assisting a female with the purchase of a vaginal pH monitor, which of the following should be discussed?

(A) The pH monitor is not recommended in postmenopausal women.
(B) An elevated pH indicates the presence of a yeast infection.
(C) The pH of a clean-catch morning urine sample should be used.
(D) The pH monitor can detect the presence of sexually transmitted infections.

5. Which of the following would be an appropriate counseling point for a female purchasing intravaginal miconazole?

(A) Avoid treatment during menstruation.
(B) All male partners should be treated.
(C) Avoid concomitant use of external creams.
(D) Side effects can include burning or irritation.

6. All of the following statements regarding contraceptives are correct *except* which one?

(A) Using the basal temperature method, intercourse should be avoided for a full 6 days after the noted temperature transition.
(B) If a condom should break or leak, one could recommend immediate insertion of a vaginal spermicide foam.
(C) Vaginal spermicides may kill many of the causative agents of sexually transmitted diseases (STDs), but they should not be relied on alone for STD prevention.
(D) Latex condoms can be labeled for the prevention of HIV transmission.
(E) Nonoxynol-9 is a safe and effective vaginal spermicide.

7. Which of the following agents can be used alone for protection against sexually transmitted infections?

(A) Contraceptive foam
(B) Contraceptive sponge
(C) Female condom
(D) Diaphragm

8. A 17-year-old female reports breakage of a condom last night during intercourse. She has not been using oral contraception because she smokes. Which of the following would be appropriate to counsel for this patient on Plan-B One-Step?

(A) She needs a prescription to purchase Plan-B One-Step.
(B) Take one tablet now and the second tablet 12 hrs later.
(C) Take Plan B One-Step within 72 hrs of intercourse.
(D) She is not a candidate for EC because of her tobacco use.
(E) She can use this continuously for back-up contraception.

Directions for questions 9–10: Each statement in this section is most closely related to **one** of the following drug types. The drug types may be used more than once or not at all. Choose the **best** answer, **A–D**.

A Diuretics
B Salicylates
C Nonsteroidal anti-inflammatory drugs (NSAIDs)
D Narcotic analgesics

9. The primary nonprescription pharmacological treatment for pain associated with dysmenorrhea

10. Recommended by the FDA for elimination of water before and during menstruation

Answers and Explanations

1. **The answer is A** *[see II.A.1.b]*.
   Candida albicans remains the most common cause. Infections caused by *C. glabrata* are increasing. *Trichomonas* and anaerobic bacteria cause other types of vaginal infections.

2. **The answer is B** *[see II.A.3.f]*.
   The symptoms of vaginal burning and itching are consistent with VVC; however, the distinct "fishy" odor is more indicative of bacterial vaginosis, which requires prescription treatment. Although a pH monitor may show that the vaginal pH is elevated with a bacterial infection, the woman would still have to seek medical care.

3. **The answer is D** *[see III.B.4.a]*.
   The FC should not be used concomitantly with the male condom because of the increased risk of breakage. Its pregnancy rates are higher than the male condom; and although it does protect against some sexually transmitted infections, it does not protect against all of them. The FCs can be inserted up to 8 hrs prior to intercourse.

4. **The answer is A** *[see II.A.2]*.
   The vaginal pH should not change with a yeast infection but may with other vaginal infections. The sample is taken by pressing a wand against the vaginal wall, not collecting a urine sample. The monitor is not recommended for women who lack estrogen (such as postmenopausal women) or for the detection of sexually transmitted diseases.

5. **The answer is D** *[see II.A.4.e]*.
   Intravaginal treatment for VVC can be used during menstruation and can be used in combination with external creams. It is not necessary for male partners to be treated. Side effects can include burning or irritation.

6. **The answer is A** *[see III.B.1.b]*.
   Intercourse should be avoided for a full 3 days after the noted temperature transition. All of the other statements are correct.

7. **The answer is C** *[see III.B]*.
   The diaphragm and spermicidal agents such as the contraceptive foam or sponge can be used alone to protect against pregnancy but cannot be used alone for prevention of sexually transmitted diseases.

8. **The answer is C** *[see III.B.7]*.
   Plan B One-Step is most efficacious when taken within 24 hrs of intercourse but can be used up to 72 hrs after with efficacy data. It is FDA approved as a nonprescription item for individuals ages 17 and up and is a single dose tablet, as opposed to Next Choice, which is a two-step process described in answer choice B. Smoking is not a contraindication to the use of this agent.

9. **The answer is C** *[see I.B.1.d.(2)]*.
   NSAIDs are approved by the FDA for the treatment of primary dysmenorrhea.

10. **The answer is A** *[see I.B.2.c.(1).(a)]*.
    For premenstrual and menstrual relief of water retention, bloating, and tension, the FDA has approved OTC diuretics.

25 Herbal Medicines and Nutritional Supplements

TERESA M. BAILEY

I. INTRODUCTION. Many of the drugs available on the market are derived from plants. Some of those include aspirin, atropine, belladonna, capsaicin, cascara, colchicine, digoxin, ephedrine, ergotamine, ipecac, opium, physostigmine, pilocarpine, podophyllum, psyllium, quinidine, reserpine, scopolamine, senna, paclitaxel, tubocurarine, vinblastine, and vincristine. Herb products are also derived from plants; however, these products are not considered drugs by the U.S. Food and Drug Administration (FDA).

A. Regulations
   1. The **Federal Food**, **Drug**, **and Cosmetic Act of 1938** mandated pharmaceutical companies to test drugs for safety before marketing.
   2. The **Kefauver–Harris Drug Amendments of 1962** mandated pharmaceutical companies to test drugs for efficacy before marketing.
   3. The **Dietary Supplement Health and Education Act of 1994** mandated the following:
      a. Dietary supplements are not drugs or food. They are intended to supplement the diet.
      b. Herbs are considered dietary supplements.
      c. Dietary supplements do not have to be standardized.
      d. The secretary of Health and Human Services may remove a supplement from the market only when it has been shown to be hazardous to health.
      e. Dietary supplements may make claims only regarding the effects on structure or function of the body. No claims regarding a particular disease or condition may be made.
      f. The following statement is required on the product label: "This product has not been evaluated by the FDA. It is not intended to diagnose, treat, cure, or prevent."
   4. **Final rule for Current Good Manufacturing Practices (CGMPs) for dietary supplements (2007)**
      a. Manufacturers are required to evaluate for identity, purity, strength, composition
   5. **German Federal Health Agency**
      a. In 1978, the German Federal Health Agency established Commission E.
      b. Commission E evaluates the safety and efficacy of herbs through clinical trials and cases published in scientific literature.
      c. There are > 380 published monographs on herbs.

B. Herbs considered unsafe for human consumption
   1. Carcinogenic herbs include borage, calamus, coltsfoot, comfrey, liferoot, and sassafras.
   2. Hepatotoxic herbs include chaparral, germander, kava, and liferoot.
   3. High doses of licorice for long periods may cause pseudoaldosteronism, a condition that may include headache, lethargy, sodium and water retention, hypokalemia, high blood pressure, heart failure, and cardiac arrest.
   4. Ma huang may cause myocardial infarction, strokes, or seizures.
   5. Pokeroot may be fatal in children.
   6. **Unsafe herbs according to the FDA.** In the 1990s, the FDA's Center for Food Safety and Applied Nutrition created the Special Nutritional Adverse Event Monitoring System Web site for dietary supplements. Unfortunately, by 1999 the site was no longer being updated and thus was eventually

deleted. According to the last update from that Web site, the following dietary supplements were considered unsafe by the FDA:

a. Arnica: muscle paralysis, death
b. American and European mistletoe: seizures, coma
c. Bittersweet and deadly nightshade: cardiac toxicity
d. Bloodroot: hypotension, coma
e. Broom: dehydration
f. Comfrey: cancer
g. Dutch and English tonka bean: hepatotoxicity
h. Heliotrope: hepatotoxicity
i. Horse chestnut: bleeding
j. Jimson weed: anticholinergic, hallucinations
k. Kava: hepatotoxicity
l. Lily of the valley: cardiac toxicity
m. Lobelia (nicotine): coma, death
n. Mandrake/mayapple: severe gastrointestinal symptoms
o. Morning glory: psychosis
p. Periwinkle: renal and hepatotoxicity
q. Snakeroot: reserpine derivative
r. Spindle tree: seizures
s. St. John's wort: drug interactions
t. Sweet flag: hallucinations, liver cancer
u. True jalap: purgative cathartic
v. Wahoo: seizures
w. Wormwood: seizures, paralysis
x. Yohimbe: renal failure, hypertension

II. COMMONLY USED HERBS

A. Black cohosh (*Cimicifuga racemosa*)
1. **Commission E indications.** Premenstrual symptoms, painful or difficult menstruation, and neurovegetative symptoms (hot flashes) caused by menopause
2. **Mechanism of action**
   a. Black cohosh has estrogen-like effects that are exerted by an unknown mechanism, different from an estrogenic mechanism.
   b. It does not appear to bind to estrogen receptors. Nor does it appear to upregulate estrogen-dependent genes.
   c. It does not affect the growth of estrogen-dependent tumors in experimental animals.
3. **Efficacy**
   a. Uncontrolled as well as double-blind, randomized, placebo-controlled clinical trials compared black cohosh to hormone therapy in perimenopausal and postmenopausal women with neurovegetative menopausal symptoms of different degrees of severity. The Kupperman menopausal index and psychiatric clinical and self-evaluation scales were significantly reduced after 3 months of treatment with black cohosh. Vaginal cytological parameters also improved in regard to estrogen stimulation. Black cohosh was shown to be superior to placebo and comparable to estriol, conjugated estrogens, and estrogen–progesterone therapy.[1]
   b. Black cohosh may not be effective in premenopausal breast cancer survivors with tamoxifen-induced hot flashes.[2]
4. **Contraindications/precautions**
   a. Pregnancy
   b. Unknown if suitable for patients for whom hormone replacement therapy is contraindicated, such as estrogen-receptor-positive breast cancer
   c. Commission E recommends that length of use should not exceed 6 months.
   d. Use caution in liver disease, such as hepatitis and fulminant liver failure.

5. **Drug interactions**
   a. Cisplatin (Platinol) efficacy may be reduced.
   b. Theoretically, black cohosh may interact with hepatotoxic drugs such as acetaminophen (Tylenol), carbamazepine (Tegretol), and isoniazid (Nydrazid) because it is an inhibitor of cytochrome P450 3A4 (CYP3A4) and CYP2D6 isoenzymes.
   c. A case reports a patient taking atorvastatin (Lipitor) developing significantly elevated liver function enzymes after black cohosh was initiated.[3]
6. **Side effects**
   a. Occasional intestinal problems may occur, such as nausea and vomiting; weight gain is possible.
   b. Liver toxicity may occur; liver function tests should be monitored periodically.
   c. Large doses of black cohosh may cause dizziness, nausea, severe headaches, stiffness, and trembling limbs.
   d. Does not seem to increase risk of endometrial hyperplasia.
7. **Dosage.** Remifemin is a standardized product that contains 20 mg black cohosh and is taken twice daily. It is standardized to 1 mg of 27-deoxyactein per tablet.

B. **Chaste tree berry (*Vitex agnus-castus*)**
   1. **Commission E indications.** Disorders of the menstrual cycle, breast swelling, and premenstrual symptoms
   2. **Mechanism of action**
      a. Chaste tree berry binds to dopamine receptors and inhibits prolactin secretion.
      b. One of its ingredients, linoleic acid, binds to estrogen receptors.
      c. It increases the pituitary gland's production of luteinizing hormone and inhibits follicle-stimulating hormone (FSH).
   3. **Efficacy.** One randomized, double-blind, placebo-controlled, parallel group study included 170 women with premenstrual syndrome.[4] *Vitex* was given 20 mg daily for three cycles. Self-assessment and clinical global impression significantly improved.
   4. **Contraindications/precautions**
      a. Pregnancy and lactation
      b. Hormone-sensitive conditions
   5. **Drug interactions**
      a. Theoretically, chaste tree berry may interact with medications that increase dopaminergic activity, such as bromocriptine (Parlodel) and levodopa.
      b. Theoretically, it may interact with medications that decrease dopaminergic activity such as the antipsychotics.
      c. Theoretically, it may interact with hormone-replacement therapy and oral contraceptives.
   6. **Side effects**
      a. Mild gastrointestinal upset
      b. Skin rash
      c. Irregular menstrual bleeding
   7. **Dosage.** Doses depend on the formulation. Typical dose range of chaste tree berry is 20 to 240 mg/day.

C. **Cranberry (*Vaccinium macrocarpon*)**
   1. **Commission E indications.** Recurrent urinary tract infections
   2. **Mechanism of action**
      a. Benzoic and quinic acids break down and form hippuric acid (bacteriostatic).
      b. Inhibition of *Escherichia coli* adherence to epithelial cells of urinary tract
   3. **Efficacy**
      a. A quasi-randomized, double-blind, placebo-controlled study included 153 women who received 300 mL of cranberry juice daily for 6 months.[5] Bacteriuria with pyuria occurred less often in the cranberry group (15%) versus placebo (28%).
      b. Cranberry has not been shown to be effective for treating an active urinary tract infection.
   4. **Contraindications/precautions**
      a. Nephrolithiasis
      b. Cranberry juice contains high amounts of salicylic acid and may trigger an allergic reaction in patients with an aspirin allergy or asthma.

      c. Discontinue 2 weeks before surgery.

      d. Ulcers, GERD

   5. Drug interactions

      a. Increased vitamin B_{12} absorption

      b. Potential to enhance elimination of renally excreted drugs by changing urine pH

      c. Cranberry juice may interact with warfarin, increasing the international normalized ratio (INR).

      d. May inhibit cytochrome P450 2C9. Drugs that are metabolized by CYP2C9 include amitriptyline (Elavil) and diazepam (Valium).

   6. Side effects

      a. Nausea, vomiting, diarrhea

      b. Nephrolithiasis

   7. Dosage. Recommended dose of cranberry is 300 to 400 mg twice daily using a standardized product to include 11% to 12% quinic acid per dose. Patients may also take 8 to 16 oz 100% cranberry juice daily. Drinking lots of fluids is recommended.

D. Dong quai (*Angelica sinensis*)

   1. Traditional Chinese medicine indications. Menstrual disorders, anemia, constipation, insomnia, rheumatism, neuralgia, and hypertension

   2. Mechanism of action

      a. Dong quai is only 1:400 as active as estrogen. However, it does not appear to produce any changes to the ovaries or vaginal tissue.[6]

      b. It contains seven different coumarin derivatives: oxypeucedanin, osthole, psoralen, angelol, angelicone, bergapten, and 7-desmethylsuberosin. Many coumarins have been shown to have vasodilatory and antispasmodic effects. One of the coumarins (osthole) is a central nervous system (CNS) stimulant.

      c. It inhibits experimentally induced immunoglobulin E (IgE) titers, suggesting that components of the plant may have immunosuppressive activity.

      d. It inhibits prostaglandin E_2 (PGE_2) release and, therefore, possesses analgesic, antipyretic, and anti-inflammatory actions.

      e. It has an antiarrhythmic activity similar to quinidine.

   3. Efficacy. A randomized, double-blind, placebo-controlled trial included 71 postmenopausal women (mean age, 52.4 years) who had FSH < 30 mIU/mL with hot flashes.[7] Women received three capsules of dong quai three times daily (equivalent to 4.5 g of dong quai root daily) or placebo for 24 weeks. Dong quai did not produce estrogen-like responses in endometrial thickness or in vaginal maturation or relieve menopausal symptoms. The study is criticized for using dong quai alone because in traditional Chinese medicine, dong quai is used in combination with four or more other herbs.

   4. Contraindications/precautions

      a. Pregnancy (uterine stimulant) and lactation

      b. Diarrhea

      c. Hemorrhagic disease; discontinue 2 weeks before surgery

      d. Hypermenorrhea

      e. Hypotension

      f. During cold or flu

      g. Allergy to parsley

      h. Breast cancer

   5. Drug interactions

      a. Dong quai interacts with anticoagulants such as warfarin (Coumadin)

      b. Antihypertensives (hypotension)

      c. Theoretically, may interact with hormone replacement therapy and oral contraceptives.

      d. Unknown if it interacts with other cardiovascular drugs such as procainamide (Pronestyl)

   6. Side effects

      a. Photodermatitis may occur in people collecting the plant.

      b. Burping, flatulence, and headache

      c. Safrole, found in the oil of dong quai, is carcinogenic and not recommended for ingestion.

      d. May stimulate breast cancer cells.

7. **Dosage.** A variety of doses are suggested. No standardized product is available. According to traditional Chinese medicine, dong quai alone may not be effective.

E. **Echinacea (*Echinacea purpurea*, *E. angustifolia*)**

1. **Commission E indications**

    a. Internal use: supportive therapy for infections of the upper respiratory tract (cold) and lower urinary tract

    b. External use: local application for the treatment of hard-to-heal superficial wounds and ulcers

2. **Mechanism of action.** Echinacea increases the body's resistance to bacteria by the following:

    a. Caffeic acid derivatives, which include cichoric acid, chlorogenic acid, and cynarin, increase phagocytosis and stimulate the production of immunopotentiating substances such as interferon, interleukins, and tumor necrosis factor.

    b. Polysaccharides, such as inulin, stimulate macrophages and inhibit hyaluronidase activity to decrease inflammation.

    c. Alkylamides, such as echinacein, have a local anesthetic effect and inhibit hyaluronidase activity to decrease inflammation.

    d. Echinacea has little or no direct bactericidal or bacteriostatic properties.

3. **Efficacy**

    a. **Treatment of common cold.** In a review of 26 controlled clinical trials evaluating echinacea's ability to strengthen the body's own defense mechanisms, it was found that 30 of 34 echinacea therapies were more effective compared to controls.[8]

    b. **Prevention of common cold.** Studies have shown that taking echinacea prophylactically to prevent the development of a cold does not seem to be effective.

4. **Contraindications/precautions**

    a. Echinacea is contraindicated in infectious and autoimmune diseases such as tuberculosis, leukosis, collagenosis, multiple sclerosis, AIDS, HIV, and lupus.

    b. Caution should be used in patients who are allergic to members of the ragweed or chrysanthemum family.

    c. The effects of echinacea in pregnancy, lactation, and children are unknown. Comparison with a control group suggested no increased risk of major malformations in 206 pregnant women.[9]

    d. Therapy should not exceed 8 weeks. Theoretically, prolonged use of echinacea may depress the immune system, possibly through overstimulation.

5. **Drug interactions**

    a. Unknown if echinacea interacts with immunosuppressants

    b. Echinacea inhibits cytochrome P450 1A2. Some drugs metabolized by CYP1A2 are caffeine (Cafcit) and theophylline.

    c. Echinacea induces and inhibits CYP3A4. Some drugs metabolized by CYP3A4 are midazolam (Versed), itraconazole (Sporanox), and fexofenadine (Allegra).

6. **Side effects**

    a. Nausea, vomiting, dizziness, tiredness

    b. Allergic reactions, acute asthma, leukopenia, and anaphylaxis

    c. May interfere with male fertility

7. **Dosage.** There are a variety of doses recommended. The most common dose is as the dried powder, 1 g or two 500-mg capsules orally three times daily. Recommended to use for 2 weeks only during a cold.

F. **Feverfew (*Tanacetum parthenium*)**

1. **Commission E indication.** Prophylaxis of migraine headaches

2. **Mechanism of action**

    a. Feverfew inhibits the release of 5-hydroxytryptamine (serotonin) from platelets, which may be the same mechanism as methysergide maleate (Sansert).

    b. It irreversibly inhibits prostaglandin synthesis through a different mechanism from that of the salicylates. It inhibits phospholipase A_2 by α-methylene butyrolactones (parthenolide and epoxyartemorin).

    c. There is an antithrombotic potential owing to a phospholipase inhibition that prevents the release of arachidonic acid.

3. **Efficacy.** An evaluation of five trials for the efficacy of feverfew in the prevention of migraines compared to placebo was conducted.[10] A variety of doses and durations were used. Some trials showed the number and severity of migraine attacks and the degree of vomiting was reduced with feverfew. The duration of attacks was unaltered. Other trials showed no benefit.

4. **Contraindications/precautions**
   a. Feverfew should be avoided in pregnancy, lactation, and children < 2 years of age.
   b. Contraindicated in individuals with allergies to chrysanthemums or ragweed.
   c. Contraindicated in patients with bleeding disorders. Discontinue 2 weeks before surgery.

5. **Drug interactions**
   a. Feverfew may interact with anticoagulants, increasing the risk of bleeding.
   b. Feverfew may inhibit the following cytochrome P450 isoenzymes: 1A2, 2C19, 2C9, and 3A4.

6. **Side effects**
   a. Gastric discomfort on oral consumption
   b. Contact dermatitis
   c. Minor ulcerations of oral mucosa, irritation of tongue, and swelling of lips may occur when fresh leaves are chewed.
   d. Palpitations
   e. Post-feverfew syndrome: Discontinuation of feverfew may produce muscle and joint stiffness and a cluster of nervous system reactions (rebound of migraines, anxiety, and insomnia).

7. **Dosage.** The usual dose of feverfew is 50 to 100 mg daily. A product containing at least 0.2% parthenolide is recommended.

G. **Fish oil**
1. **Purported uses.** Hypertension, hyperlipidemia, mental health, bipolar, psychosis, depression, anticoagulant, coronary heart disease, stroke
2. **Mechanism of action.** Fish oil contains omega-3 fatty acids, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). The human body cannot produce omega-3 fatty acids nor can it convert omega-6 fatty acids. Omega-3 fatty acids can form eicosanoids (prostaglandins, leukotrienes, lipoxins). Fish oil inhibits the synthesis of VLDL and triglycerides in the liver and studies have been shown to decrease triglycerides by 20% to 50% and increase HDL by 10%, but increase LDL by 0% to 45%.
3. **Efficacy.** Consuming fish oil, two servings of fatty fish per week, reduces the risk of developing primary or secondary cardiovascular disease.
4. **Contraindications/precautions.** Seafood allergy, bipolar disorder, bleeding, cardiac disease, depression, diabetes mellitus, hypertension, immunodeficiency
5. **Drug interactions**
   a. Anticoagulants/antiplatelets/thrombolytics. Increase bleeding
   b. Antihypertensives. Additive blood pressure reduction
   c. Xenical, Alli, Orlistat. Decreased fish oil absorption. Recommended to separate by 2 hrs.
6. **Side effects**
   a. Bleeding, ecchymosis (bruising), epistaxis (nosebleeds)
   b. Hypervitaminosis A, hypervitaminosis D
   c. Rash
   d. Dyspepsia, eructation (burping), nausea/vomiting, diarrhea
   e. Halitosis, dysgeusia (taste perversion)
7. **Dosage**
   a. Hypertriglyceridemia: 1 to 4 g/day orally in divided doses
   b. Hypertension: 4 g/day orally in divided doses
   c. Products providing eicosapentaenoic acid (EPA) 2.04 g and docosahexaenoic acid (DHA) 1.4 g daily are recommended.

H. **Flaxseed (*Linum usitatissimum*)**
1. **Purported uses.** Constipation, diarrhea, diabetes, menopause, hypertension, hyperlipidemia, coronary artery disease

2. **Mechanism of action**
   a. The seed coat gum of flaxseed is soluble fiber.
   b. Flaxseed contains fatty acids; of which, 55% are alpha-linolenic acid. The human body converts alpha-linolenic acid into omega-3 fatty acids, such as eicosapentaenoic (EPA) and docosahexaenoic acids (DHA).
   c. Lignans are phytoestrogens with weak estrogenic and anti-estrogenic effects.
3. **Efficacy**
   a. **Diabetes.** Flaxseed decreased A1c but did not decrease fasting blood glucose or insulin levels (Pan).
   b. **Hypercholesterolemia.** Flaxseed 40 to 50 g/day decreases LDL by 8% to 18% and decreases total cholesterol by 5% to 9%, but flaxseed does not affect HDL.
   c. **Menopause.** Flaxseed 40 g/day has been shown to significantly reduce hot flashes by about 35% and night sweats by about 44%.
4. **Contraindications/precautions.** Bleeding disorders, diabetes, gastrointestinal obstruction, and hormone-sensitive cancers
5. **Drug interactions**
   a. Anticoagulants/antiplatelets. Theoretically may have additive effects.
   b. Antidiabetic agents. Theoretically may have additive effects.
   c. Estrogens. Theoretically may have competitive effects.
   d. Flaxseed may decrease the absorption of oral drugs. It is recommended to administer medications an hour before or 2 hrs after taking flaxseed.
6. **Side effects**
   a. Soluble fiber causes bloating, flatulence, abdominal pain, diarrhea, constipation, dyspepsia, nausea.
   b. Allergic reactions
7. **Dosage**
   a. For hypercholesterolemia, baked goods (muffins or bread) containing flaxseed and ground flaxseed with 40 to 50 g of flaxseed per day
   b. For menopausal symptoms, 40 g daily of crushed flaxseed
   c. Adequate amount of fluid to prevent potential bowel obstruction

I. **Garlic (*Allium sativum*)**
   1. **Commission E indications.** Supports dietary measures for the treatment of hyperlipoproteinemia and to prevent age-related changes in the blood vessels (arteriosclerosis).
   2. **Mechanism of action**
      a. Garlic inhibits platelet function by interfering with thromboxane synthesis.
      b. It increases the levels of two antioxidant enzymes in the blood: catalase and glutathione peroxidase.
      c. Organic disulfides found in garlic oil inactivate the thiol enzymes such as coenzyme A (CoA) and hydroxymethylglutaryl (HMG) CoA reductase.
   3. **Efficacy**
      a. In a meta-analysis of eight studies evaluating the effect on blood pressure, the overall pooled difference in change of systolic blood pressure was 7.7 mm Hg lower with garlic than with placebo; diastolic blood pressure was 5.0 mm Hg lower with garlic.[11]
      b. In a meta-analysis of five studies evaluating the effect on total serum cholesterol, patients were excluded if they were receiving lipid-lowering drugs.[12] The overall pooled total cholesterol difference between garlic and placebo was −23 mg/dL (−29 to −17).
   4. **Contraindications/precautions**
      a. Caution in diabetes. Garlic may increase the release of insulin or enhance the response to insulin.
      b. Caution in pregnancy (emmenagogue and abortifacient) and lactation
      c. Caution in peptic ulcer disease and gastroesophageal reflux
      d. **Caution in bleeding disorders.** Discontinue 2 weeks before surgery
   5. **Drug interactions**
      a. Anticoagulants (increased bleeding)
      b. Protease inhibitor, saquinavir (decreased efficacy)
      c. Nonnucleoside reverse transcriptase inhibitors, such as nevirapine, efavirenz (decreased efficacy)

      d. Antihypertensives (hypotension)

      e. Antidiabetic agents (hypoglycemia)

      f. May induce the following cytochrome P450 isoenzymes: 2C9, 2C19, 3A4, 2D6, and 2E1. Caution should be used with contraceptive medications, cyclosporine, diltiazem, and verapamil (decreased efficacy).

      g. Isoniazid. Decreased efficacy.

  6. Side effects. Gastrointestinal discomfort (heartburn, flatulence), sweating, light-headedness, allergic reactions, and menorrhagia

  7. Dosage. Between 0.6 and 1.2 g dried powder (2 to 5 mg of allicin) daily or 2 to 4 g fresh garlic

  8. Comments

      a. Alliinase (the enzyme that converts alliin to allicin) is inactivated by acids. Enteric-coated tablets or capsules allow more absorption because they pass through the stomach and release their contents in the alkaline medium of the small intestine.

      b. Effective preparations include freeze-dried garlic power and aged garlic extract.

      c. Odorless garlic preparations may not contain the active compounds.

J. Ginger (*Zingiber officinale*)

  1. Commission E indications. Dyspepsia and prophylaxis of symptoms of travel sickness

  2. Mechanism of action

      a. Ginger promotes saliva and gastric juice secretion, which increases peristalsis and the tone of the intestinal muscle.

      b. It acts on 5-hydroxytryptamine 3 (5-HT$_3$) receptors in the ileum, similar to ondansetron.

      c. It inhibits thromboxane synthesis as a prostacyclin agonist.

  3. Efficacy. A double-blind study included 36 blindfolded subjects with high susceptibility to motion sickness who were given ginger 940 mg, dimenhydrinate 100 mg, or placebo for the prevention of motion sickness induced by a tilted rotating chair. Ginger subjects remained in the chair an average of 5.5 mins, dimenhydrinate 3.5 mins, and placebo 1.5 mins. The ginger group took longer to feel sick, but once sick, the sensations of nausea and vomiting progressed at the same rate in all groups.[13]

  4. Contraindications/precautions

      a. Bleeding disorders. Discontinue 2 weeks before surgery

      b. It is contraindicated for gallstone pain.

      c. It is recommended by the American College of Obstetricians and Gynecologists (ACOG) for use in pregnancy < 17 weeks of gestation with the following cautions: Ginger is a uterine relaxant in low doses and a uterine stimulant in high doses.

      d. Diabetes (hypoglycemia)

      e. Heart conditions may worsen because ginger has positive inotropic activity.

  5. Drug interactions

      a. Antiplatelets and anticoagulants (increased bleeding)

      b. Diabetic agents (hypoglycemia)

      c. Calcium-channel blockers (hypotension)

  6. Side effects are dermatitis, heartburn, and diarrhea.

  7. Dosage (for travel sickness). Daily dose is 2 to 4 g. Two 500-mg capsules taken 30 mins before travel, then one to two more capsules every 4 hrs as needed. The 1000 mg standardized extract is equivalent to

      a. 1 teaspoon fresh grated rhizome;

      b. 2 droppers liquid extract (2 mL);

      c. 2 teaspoons syrup (10 mL);

      d. 8 oz ginger ale, made with real ginger; and

      e. 4 cups ginger tea (made by steeping ½ teaspoon grated ginger for 5 to 10 mins in hot water).

K. Ginkgo (*Ginkgo biloba*)

  1. Commission E indications

      a. Treatment for cerebral circulatory disturbances resulting in reduced functional capacity and vigilance (vertigo, tinnitus, weakened memory, and mood swings accompanied by anxiety)

      b. Treatment of peripheral arterial circulatory disturbance such as intermittent claudication

2. **Mechanism of action**
   a. Ginkgo contains flavonoids (quercetin, kaempferol, and isorhamnetin) and terpenoids (ginkgolides A, B, and C and bilobalide).
   b. Flavonoids provide the antioxidant activity, reduce capillary fragility, and increase the threshold of blood loss from capillaries.
   c. Ginkgolides antagonize platelet-activating factor (PAF), which induces platelet aggregation, the degranulation of neutrophils, and the production of oxygen radicals.

3. **Efficacy**
   a. In a review of the clinical and pharmacological studies on ginkgo and cerebral insufficiency, eight were found to be of good quality.[14] Seven of the trials showed positive effects of ginkgo compared to placebo. Symptoms of cerebral insufficiency evaluated were difficulties of concentration and memory, absentmindedness, confusion, lack of energy, tiredness, decreased physical performance, depression, anxiety, dizziness, tinnitus, and headaches.
   b. A randomized, double-blind, placebo-controlled study included 202 patients with either Alzheimer disease or multi-infarct dementia. These patients were given ginkgo 40 mg three times daily or placebo for 1 year. Ginkgo had a statistically significant improvement by at least two points or better on the Alzheimer Disease Assessment Scale—Cognitive (a 70-point subscale) compared to placebo (50% vs. 29%). Ginkgo showed statistically significant improvement on the Geriatric Evaluation by Relative's Rating Instrument (37% vs. 23%). There was no difference between ginkgo and placebo on the Clinical Global Impression of Change Scale.[15]

4. **Contraindications/precautions**
   a. Epilepsy. Ginkgotoxin may cause neurotoxicity and seizures.
   b. Bleeding disorders. Discontinue 2 weeks before surgery
   c. Diabetes (hypoglycemia)
   d. Infertility. Caution in difficulty conceiving.

5. **Drug interactions**
   a. Ginkgo may potentiate the bleeding properties of antiplatelets/anticoagulants.
   b. Aminoglycosides (increased ototoxicity)
   c. Thiazide (increases blood pressure)
   d. Trazodone (Desyrel) (coma)
   e. Seizure threshold lowering drugs
   f. Anticonvulsants (decreased efficacy)
   g. Antidiabetic drugs (hypoglycemia)
   h. Ginkgo may mildly affect the cytochrome P450 isoenzymes 1A2, 2C19, 2C9, 2D6, and 3A4.

6. **Side effects**
   a. Gastric disturbances, headache, dizziness, and vertigo
   b. Toxic ingestion may produce tonic–clonic seizures and loss of consciousness
   c. Spontaneous bleeding; mild to severe (intracerebral hemorrhage)

7. **Dosage.** Recommended dose is 40 mg three times daily with meals for at least 4 to 6 weeks. Standardized preparations that contain 6% terpene lactones and 24% ginkgo flavone glycosides are recommended.

L. **Asian ginseng (*Panax ginseng*, *P. quinquefolius*)**
   1. **Commission E indications.** Tonic to combat feelings of lassitude and debility, lack of energy, and ability to concentrate, and during convalescence
   2. **Mechanism of action**
      a. At least 28 active ingredients, known as ginsenosides, have been identified.
      b. Ginseng effects vary with extract derivative, drying method, dose, duration of treatment, and animal species that were studied. Each ginsenoside produces different pharmacological effects on the CNS, cardiovascular system, and other body systems. Different ginsenosides are capable of producing biological effects in direct opposition with those produced by others. For example, the ginsenoside Rb_1 has been shown to have a suppressive effect on the CNS, whereas Rg_1 produces a stimulatory effect.

3. **Efficacy**
   a. A randomized, double-blind, placebo-controlled, crossover study included 50 male sports teachers who performed a treadmill exercise test. Volunteers received two ginseng capsules (Geriatric Pharmaton) daily for 6 weeks or placebo. Volunteers used energy more efficiently and had greater endurance while taking ginseng.[16] However, other studies have not shown Asian ginseng to be effective.
4. **Contraindications/precautions**
   a. Pregnancy and lactation
   b. Children
   c. Avoid in patients with hypertension, emotional/psychological imbalances, headaches, heart palpitations, insomnia, asthma, inflammation, or infections with high fever.
   d. Caution should be used in patients with a history of bleeding. Discontinue 2 weeks before surgery.
   e. Diabetes (hypoglycemia)
   f. Schizophrenia
   g. Caution should be used in patients with a history of breast cancer. Ginseng may stimulate breast cancer cells.
5. **Drug interactions**
   a. Ginseng may interact with phenelzine (Nardil), producing hallucinations and psychosis.
   b. Ginseng may decrease the INR of warfarin (Coumadin).
   c. Ginseng may interact with stimulants, including caffeine (Cafcit).
   d. Ginseng may interact with oral hypoglycemic and insulin, causing hypoglycemia.
   e. It is unknown whether ginseng interacts with hormonal therapy, antihypertensives, or cardiac medications.
   f. It may inhibit cytochrome P450 2D6. Caution should be used with drugs that are metabolized via cytochrome P450 2D6, such as amitriptyline (Elavil) and fluoxetine (Prozac).
   g. It may interfere with immunosuppressants such as cyclosporine (Sandimmune) or tacrolimus (Prograf).
6. **Side effects**
   a. Nervousness, excitation, insomnia
   b. Inability to concentrate with long-term use
   c. Diffuse mammary nodularity and vaginal bleeding may be caused by ginseng's estrogen-like effect in women.
   d. Hypertension, euphoria, restlessness, nervousness, insomnia, skin eruptions, edema, and diarrhea have been reported with long-term ginseng use with an average dose of 3 g ginseng root daily.
   e. Tachyarrhythmia due to increased QT interval
7. **Dosage.** 1 to 2 g crude herb daily or 100 to 300 mg ginseng extract three times daily. Standardized products that contain at least 4% to 5% ginsenosides are recommended.

M. **Milk thistle (*Silybum marianum*)**
   1. **Commission E indications.** Chronic inflammatory liver conditions and cirrhosis
   2. **Mechanism of action**
      a. Silymarin is believed to be the active component in milk thistle.
      b. Silymarin stimulates the activity of RNA polymerase A and is a potent antioxidant.
      c. Silymarin alters the outer liver membrane cell structure.
   3. **Efficacy.** In an evaluation of 13 trials for the efficacy of milk thistle in the treatment of alcoholic and/or hepatitis B or C virus liver diseases, milk thistle had no significant effect on overall mortality, complications of liver disease, or liver histology.[17] Liver-related mortality was significantly reduced with milk thistle when all trials were evaluated but was not significantly reduced when only high-quality trials were evaluated.
   4. **Contraindications/precautions**
      a. Avoid in pregnancy
      b. Allergy to chrysanthemums/ragweed
      c. Hormone-sensitive cancers
   5. **Drug interactions**
      a. Milk thistle may inhibit cytochrome P450 2C9 and 3A4.
      b. Milk thistle does not interact with indinavir (Crixivan).

6. **Side effects** include diarrhea and other gastrointestinal reactions (nausea, dyspepsia, flatulence) and allergic reactions.

7. **Dosage.** Recommended dose of milk thistle is 200 to 400 mg/day divided into three doses using a standardized product that includes 70% to 80% silymarin.

N. **Saw palmetto (*Serenoa repens*)**

1. **Commission E indications.** Treatment of micturition difficulties associated with benign prostatic hyperplasia

2. **Mechanism of action**
   a. Saw palmetto inhibits dihydrotestosterone to androgen receptors in prostate cells.
   b. It may inhibit testosterone-5-α-reductase, the enzyme responsible for the conversion of testosterone to dihydrotestosterone.

3. **Efficacy.** An evaluation of 30 studies evaluated saw palmetto in 5222 men with BPH during 4 to 60 weeks. Most of the studies compared to placebo; one study compared to finasteride, two studies compared to tamsulosin. The International Prostate Symptom Score and nocturia showed no significant difference to placebo, finasteride, or tamsulosin.[18]

4. **Contraindications/precautions**
   a. Avoid in pregnancy
   b. Avoid in children
   c. Discontinue 2 weeks before surgery

5. **Drug interactions**
   a. Theoretically, saw palmetto may interact with anticoagulants or antiplatelets.
   b. Theoretically, saw palmetto may interact with contraceptive drugs or hormone replacement therapy.

6. **Side effects**
   a. Intraoperative hemorrhage
   b. Headache
   c. Stomach upset, nausea, vomiting, diarrhea, constipation
   d. Acute hepatitis and pancreatitis

7. **Dosage.** Recommended 1 to 2 g saw palmetto or 320 mg of lipophilic extract daily, usually given 160 mg twice daily and taken with food. Products standardized to contain 90% free and 7% esterified fatty acids are recommended.

O. **St. John's wort (*Hypericum perforatum*)**

1. **Commission E indications.** In supportive treatment for anxiety and depression.

2. **Mechanism of action**
   a. **Some of the active ingredients** include hypericin, hyperin, hyperforin, melatonin, adhyperforin.
   b. Hypericin, flavonoids, and xanthones show in vitro irreversible monoamine oxidase inhibitor (MAOI) type A and B activity.
   c. St. John's wort may inhibit serotonin reuptake.
   d. St. John's wort may inhibit synaptic γ-aminobutyric acid (GABA) uptake and GABA receptor binding.

3. **Efficacy.** An evaluation of 37 trials for the efficacy of St. John's wort in the treatment of depression showed the herb may be more effective than placebo for mild-to-moderate depression.[19] St. John's wort may be as effective as other antidepressants for mild-to-moderate depression. St. John's wort may not be effective for major depression.

4. **Contraindications/precautions**
   a. Caution in fair-skinned persons when exposed to bright sunlight
   b. Caution in pregnancy (emmenagogue and abortifacient)
   c. No negative influence on general performance or the ability to drive a car or operate heavy machinery has been reported.
   d. Psychiatric conditions such as bipolar and schizophrenia may be exacerbated.
   e. Alzheimer disease. St. John's wort may induce psychosis
   f. Hypothyroidism. St. John's wort may increase thyroid-stimulating hormone.
   g. Anesthesia. St. John's wort may cause cardiovascular collapse.
   h. Surgical procedures. Discontinue 2 weeks before.
   i. Infertility. St. John's wort may inhibit oocyte fertilization and alter sperm DNA.

5. **Drug interactions**
   a. Antidepressants such as paroxetine (Paxil), sertraline (Zoloft), and nefazodone have been reported to cause serotonin syndrome when taken with St. John's wort.
   b. Antiretroviral (protease inhibitors and nonnucleoside reverse transcriptase inhibitors) levels may decrease.
   c. St. John's wort may decrease the efficacy of barbiturates.
   d. St. John's wort may increase the efficacy of clopidogrel (Plavix).
   e. Cyclosporine (Sandimmune) levels may decrease.
   f. St. John's wort may interact with other drugs metabolized through the cytochrome P450 isoenzymes 1A2, 2C9, 2C19, and 3A4.
   g. Digoxin (Lanoxin) levels may decrease.
   h. Irinotecan (Camptosar) and imatinib (Gleevec) levels may decrease.
   i. Methadone (Dolophine) levels may decrease.
   j. St. John's wort may decrease the efficacy of omeprazole (Prilosec).
   k. Oral contraceptives may have a decreased effect.
   l. St. John's wort may decrease the efficacy of HMG coenzyme reductase inhibitors (simvastatin).
   m. Tacrolimus (Prograf) levels may decrease.
   n. Theophylline levels may decrease.
   o. Triptans. Theoretically, St. John's wort may interact with the triptans.
   p. Verapamil (Calan, Covera-HS, Isoptin, Verelan) levels may decrease.
   q. St. John's wort may decrease the INR of warfarin (Coumadin).
   r. Serotonergic agents such as dextromethorphan, fenfluramine, narcotics.
   s. Anticonvulsants. Phenytoin, phenobarbital, mephenytoin.
6. **Food interactions**
   a. Older studies suggested that St. John's wort was an MAOI.[20]
   b. Newer studies suggest St. John's wort is a weak MAOI.[21]
   c. One case report published of MAOI-type food interactions such as tyramine-containing foods: cheeses, beer, wine, herring, and yeast.
7. **Side effects**
   a. Photodermatitis, allergic reactions
   b. Gastrointestinal irritations
   c. Tiredness, restlessness, sleep disturbances
   d. Elevated thyroid-stimulating hormone
   e. Elevated blood pressure
   f. Mania or hypomania
   g. May cause infertility
8. **Dosage.** Recommended 2 to 4 g daily in two to three divided doses. Standardized products containing 0.4 to 2.7 mg hypericin/day or 0.3% hypericin are recommended.

P. **Valerian (*Valeriana officinalis*)**
   1. **Commission E indications.** Restlessness and nervous disturbance of sleep
   2. **Mechanism of action**
      a. Several active compounds have been isolated from valerian and grouped into three categories: volatile oil, valepotriates, and alkaloids. It is believed that the sedative activity of valerian is secondary to the valepotriates.
      b. Valepotriates, valeranone 6, kessane derivatives 3a–f, valerenic acid 5a, and valerenal 5b have been reported to prolong barbiturate-induced sleeping time.
      c. Valerenic acid 5a has been shown to possess pentobarbital-like central depressant activity rather than muscle relaxant or neuroleptic effects. It has also been shown to inhibit the enzyme that triggers the breakdown of GABA.
      d. Valtrate and isovaltrate have exhibited antidepressant properties.
      e. Didrovaltrate possesses a tranquilizing ability similar to the benzodiazepines.
   3. **Efficacy.** A double-blind, randomized study included eight volunteers suffering from mild insomnia who received valerian aqueous extract 450 mg or 900 mg or placebo at bedtime. Valerian 450 mg significantly improved sleep quality, sleep latency, and sleep depth compared to placebo. The 900-mg dose offered no advantage over the 450-mg dose.[22]

4. **Contraindications/precautions**
   a. Caution while driving or performing other tasks requiring alertness and coordination is recommended.
   b. Pregnancy and lactation
   c. Surgery. Valerian may have an additive effect to anesthesia.
5. **Drug interactions**
   a. CNS depressants. Valerian may potentiate the sedative effect of barbiturates, benzodiazepines, opiates, alcohol, or other sedatives.
   b. Valerian inhibits cytochrome P450 3A4.
6. **Side effects**
   a. Headaches, hangover, excitability, insomnia, uneasiness, and cardiac disturbances
   b. Hepatotoxicity
   c. Toxicity includes ataxia, decreased sensibility, hypothermia, hallucinations, and increased muscle relaxation
   d. Patients may experience a benzodiazepine-like withdrawal, so doses should be tapered down slowly.
7. **Dosage.** Dried root: 2 to 3 g/cup, one to three times daily. Standardized to contain 0.8% to 1.0% valeremic acids/dose extract: 400 to 900 mg 30 to 60 mins before bedtime.

III. OTHER DIETARY SUPPLEMENTS THAT ARE POTENTIALLY SAFE

A. **Chondroitin**
   1. **Nonapproved indications.** Viscoelastic agent in ophthalmic procedures and the treatment of osteoarthritis
   2. **Mechanism of action**
      a. Chondroitin is made from shark and bovine cartilage. It concentrates in cartilage where it can be used in the synthesis of new cartilaginous matrix.
      b. It increases the RNA synthesis of chondrocytes, which may increase the synthesis of proteoglycans and collagens.
      c. It may inhibit leukocyte elastase activity. Leukocyte elastase is found in high concentrations in the blood and synovial fluid of patients with rheumatic diseases.
   3. **Efficacy.** A multicenter, double-blind, randomized study included 1583 patients with symptomatic knee osteoarthritis who received glucosamine 1500 mg daily, chondroitin 1200 mg daily, both glucosamine and chondroitin, celecoxib 200 mg daily, or placebo for 24 weeks. Glucosamine and chondroitin sulfate alone or in combination did not significantly reduce pain. The combination may be helpful in a subgroup of patients with moderate-to-severe knee pain.[23]
   4. **Contraindications/precautions**
      a. Previous hypersensitivity to chondroitin sulfate
      b. Bleeding disorders
      c. Use caution because chondroitin is usually produced from bovine cartilage (possible transmission of mad cow disease).
      d. Pregnancy and lactation
      e. Use caution in asthma; may exacerbate asthma
   5. **Drug interactions**
      a. May interact with heparin
      b. Theoretically, may interact with warfarin (Coumadin)
   6. **Side effects.** Nausea, epigastric pain, and headache
   7. **Dosage.** Recommended: 400 mg three times daily. Studies have shown that only 8% to 18% of oral chondroitin is absorbed.
B. **Coenzyme Q10 (ubiquinone or ubidecarenone)**
   1. **Nonapproved indications.** Heart failure (HF), hypertension, stable angina, ventricular arrhythmias, cancer, heart surgery, and periodontal disease
   2. **Mechanism of action**
      a. It is a naturally occurring coenzyme that has a predominant role in oxidative phosphorylation and synthesis of adenosine triphosphate (ATP), which is needed for muscle contraction and relaxation.

   b. Coenzyme Q10 is an antioxidant, a membrane stabilizer, and a cofactor in many metabolic pathways.

   c. It has been shown to reduce myocardial injury from ischemia and to reduce toxic myocardial damage from anthracyclines, such as doxorubicin (Adriamycin).

3. Efficacy

   a. Heart failure. One randomized, double-blind, placebo-controlled, multicenter study included 641 patients with New York Heart Association class III or IV chronic congestive heart failure who were receiving conventional treatment, such as digoxin (Lanoxin), diuretics, angiotensin-converting enzyme (ACE) inhibitors, and calcium-channel blockers.[24] Patients received coenzyme Q10 2 mg/kg/day for 1 year or placebo. The number of patients requiring hospitalization secondary to congestive HF was less in the coenzyme Q10 group ($n = 73$) versus placebo ($n = 118$); significance: $p < .001$. Episodes of pulmonary edema and cardiac asthma were reduced with coenzyme Q10 ($p < .001$).

   b. Statin-induced myalgias. Studies suggest that there is a 20% to 50% reduction in serum levels of coenzyme Q10 in hypercholesterolemic patients after a statin has been initiated. The reduction in coenzyme Q10 concentration is believed to be dose-related.[25] Several studies have evaluated the effect of coenzyme Q10 supplementation in patients taking statins. When coenzyme Q10 is given 30 to 300 mg/day, coenzyme Q10 serum concentrations significantly elevate.[25] However, a systematic review of studies showed **that exogenous coenzyme Q10 did not improve statin-induced myalgias.**[26]

4. Contraindications/precautions

   a. Hyper and hypotension

   b. Pregnancy and lactation

5. Drug interactions

   a. HMG reductase inhibitors may lower plasma concentrations of coenzyme Q10.

   b. Doxorubicin toxicity may be decreased.

   c. Antihypertensives (additive effect)

   d. Warfarin. Coenzyme Q10 is structurally related to vitamin K_2 so may have coagulant effects.

6. Side effects

   a. Rash and gastrointestinal disturbances, such as nausea, anorexia, epigastric pain, and diarrhea

   b. Elevations of serum aminotransferases have occurred with relatively high oral doses

7. Dosage. Depends on indication: 100 mg daily, up to 3000 mg daily in two to three divided doses.

C. Glucosamine hydrochloride

1. Nonapproved indication. Osteoarthritis

2. Mechanism of action

   a. Glucosamine is usually made from shellfish and enhances cartilage proteoglycan synthesis.

   b. It inhibits the deterioration of cartilage secondary to osteoarthritis.

   c. It maintains an equilibrium between cartilage catabolic and anabolic processes.

   d. It may have an anti-inflammatory action unlike cyclooxygenase.

3. Efficacy. A multicenter, double-blind, randomized study included 1583 patients with symptomatic knee osteoarthritis who received glucosamine 1500 mg daily, chondroitin 1200 mg daily, both glucosamine and chondroitin, celecoxib 200 mg daily, or placebo for 24 weeks. Glucosamine and chondroitin sulfate alone or in combination did not significantly reduce pain. The combination may be helpful in a subgroup of patients with moderate-to-severe knee pain.[23]

4. Contraindications/precautions

   a. Hypersensitivity to glucosamine or shellfish

   b. Diabetes. Glucosamine may impair insulin secretion.

   c. Pregnancy and lactation

   d. Asthma may be exacerbated.

5. **Drug interactions**
   a. Glucosamine may interact with antidiabetic agents.
   b. Glucosamine may induce resistance to antimitotic chemotherapy (etoposide [VePesid], doxorubicin).
   c. Theoretically, glucosamine may interact with warfarin.
6. **Side effects**
   a. Gastrointestinal side effects such as epigastric pain and tenderness, heartburn, diarrhea, and nausea
   b. CNS side effects such as drowsiness, headache, and insomnia
   c. Long-term side effects are unknown.
   d. Elevated blood glucose
7. **Dosage**. Recommended: 500 mg three times daily

D. **Melatonin**
   1. **Orphan drug status.** Treatment of circadian rhythm sleep disorders in blind people who have no light perception
   2. **Nonapproved indications.** Jet lag, insomnia, depression, and cancer
   3. **Mechanism of action**
      a. It is a hormone made from serotonin and secreted by the pineal gland. Melatonin controls the periods of sleepiness and wakefulness. It increases GABA receptor binding.
   4. **Efficacy**
      a. **Jet lag.** A randomized, placebo-controlled trial evaluated the effect of melatonin in 52 aircraft personnel. Melatonin was given either 5 mg daily 3 days before departure until 5 days after arrival (early group) or 5 mg daily upon arrival and for 3 additional days (late group). The late group had significantly less jet lag, fewer overall sleep disturbances, and a faster recovery of energy compared to the placebo group and the early group.[27]
      b. **Insomnia.** A meta-analysis on 17 randomized, double-blind, placebo-controlled trials that evaluated the sleep effect of melatonin in subjects showed that melatonin significantly decreased time to sleep onset, increased sleep efficiency, and increased total sleep duration compared to placebo.[28] Unfortunately, melatonin preparations were varied and study designs differed.
      c. **Children.** Melatonin may be effective in decreasing the time to sleep onset in children with neurodevelopmental disabilities. Melatonin does not improve total sleep time or nighttime awakenings.[29]
   5. **Contraindications/precautions**
      a. Avoid in pregnancy and lactation
      b. Melatonin may aggravate depressive symptoms.
      c. Melatonin may increase the incidence of seizures.
      d. Diabetes (hyperglycemia)
      e. Hypertension (exacerbated)
      f. Caution while driving or performing other tasks requiring alertness and coordination
   6. **Drug interactions**
      a. Selective serotonin reuptake inhibitors may increase melatonin serum concentrations.
      b. Other sedatives such as alcohol and benzodiazepines may exacerbate the sedative effects of melatonin.
      c. Melatonin may interfere with immunosuppressants.
      d. Antidiabetic agents may be less effective.
      e. Anticoagulants and antiplatelets (increased effect)
      f. Caffeine (theoretically, efficacy of melatonin may be decreased)
      g. Contraceptives (theoretically, efficacy of melatonin may be increased)
      h. Verapamil (increased melatonin excretion)
   7. **Side effects**
      a. Side effects include drowsiness, daytime fatigue, headache, and transient depression.
      b. Long-term side effects are unknown.
   8. **Dosage.** 0.3 to 5.0 mg at bedtime

Study Questions

Directions for questions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following herbs is known to cause cancer?

   (A) Chaparral
   (B) Comfrey
   (C) Ma huang
   (D) Licorice
   (E) St. John's wort

2. Which of the following is a correct statement?

   (A) Dietary supplements must be proven safe and effective before marketing in the United States.
   (B) The following statement is optional for labeling of herbal products: "This product has not been evaluated by the FDA. It is not intended to diagnose, treat, cure, or prevent."
   (C) Herbs must be standardized to be considered dietary supplements.
   (D) Dietary supplement manufacturers may claim that their products affect the structure and function of the human body.
   (E) Congress determines what is considered a supplement and what is considered a drug.

3. Tom would like to try echinacea to prevent cold and flu during the winter months. Which of the following statements is true about echinacea?

   (A) It is contraindicated in patients allergic to parsley.
   (B) It should be taken continuously only for 3 months.
   (C) It is contraindicated in patients with lupus and leukosis.
   (D) Prolonged use of echinacea will up regulate the immune system.
   (E) Side effects include headache, rash, and dizziness.

4. Mary has a family history of heart disease and wonders if garlic would be beneficial to her. Which of the following statements is correct about garlic?

   (A) Enteric-coated tablets release their contents in the stomach.
   (B) Side effects include heartburn, flatulence, and sweating.
   (C) The safety of garlic in pregnancy is unknown.
   (D) Garlic does not interact with warfarin.

5. An 80-year-old man takes warfarin for his mechanical heart valve. He would also like to take the following herbs: Asian ginseng, feverfew, garlic, and dong quai. Which of these herbs may decrease the effectiveness of warfarin?

   (A) Asian ginseng
   (B) Feverfew
   (C) Fish oil
   (D) Garlic
   (E) Dong quai

6. A 30-year-old female is 10 weeks pregnant with her second child. During her first pregnancy, she became depressed and was started on Prozac 20 mg every day. She is already beginning to notice early symptoms of depression during her second pregnancy. She would like to try St. John's wort for her depression. Which of the following statements is correct regarding St. John's wort?

   (A) The safety of St. John's wort in pregnancy is unknown.
   (B) St. John's wort is not helpful in treating mild depression.
   (C) St. John's wort may interact with serotonin reuptake inhibitors.
   (D) St. John's wort may interact with dairy products like milk and eggs.
   (E) St. John's wort decreases the effects of clopidogrel (Plavix).

7. A 65-year-old is interested in taking ginkgo. Which of the following statements is correct regarding ginkgo?

   (A) There are no contraindications with ginkgo.
   (B) There is a drug–herb interaction between ginkgo and aspirin.
   (C) Toxic effects include hypertension and cardiac arrest.
   (D) There is a drug–herb interaction between ginkgo and phenelzine.
   (E) Ginkgo is contraindicated in patients with gallstone pain.

8. A 20-year-old athletic man would like to take Asian ginseng to increase his physical stamina. His girlfriend suggested that he ask a pharmacist about the safety of Asian ginseng. Which of the following statements is not correct?

   (A) Asian ginseng may interact with phenelzine, warfarin, and digoxin.
   (B) Asian ginseng should be used with caution in patients with a history of breast cancer.
   (C) Asian ginseng may interact with stimulants, including caffeine (Cafcit).
   (D) Asian ginseng should be avoided in patients with hypertension.
   (E) Asian ginseng may cause bradycardia due to increasing the QT interval.

Answers and Explanations

1. **The answer is B** *[see I.B.f]*.
Comfrey may be carcinogenic. Chaparral may be hepatotoxic. High doses of licorice for long periods may cause pseudoaldosteronism. Ma huang may cause myocardial infarction, strokes, or seizures. St. John's wort has many drug interactions.

2. **The answer is D** *[see I.A.3.a–f]*.
The Dietary Supplement Health and Education Act of 1994 states that dietary supplements are not considered drugs or food. Because dietary supplements are not regulated as drugs, their safety and efficacy are not mandated by the FDA. Dietary supplements are intended to supplement the diet, do not have to be standardized, may make claims regarding only the effects on structure or function of the body. The following is the correct required labeling statement: "This product has not been evaluated by the FDA. It is not intended to diagnose, treat, cure, or prevent."

3. **The answer is C** *[see II.E.1–6]*.
Echinacea is contraindicated in infectious and autoimmune diseases such as tuberculosis, leukosis, collagenosis, multiple sclerosis, AIDS, HIV, and lupus. Caution should be used in patients who are allergic to members of the ragweed family. Therapy should not exceed 8 weeks. Theoretically, prolonged use of echinacea may depress the immune system, possibly through overstimulation. Side effects include nausea, vomiting, allergic reactions, anaphylaxis, and interference with male fertility.

4. **The answer is B** *[see II.I.1–8]*.
Garlic should be avoided in pregnancy because it is an emmenagogue and abortifacient. It may interact with anticoagulants, increasing the risk of bleeding. Side effects include gastrointestinal discomfort (heartburn, flatulence), sweating, light-headedness, allergic reactions, and menorrhagia. Enteric-coated tablets or capsules allow more absorption because they pass through the stomach and release their contents in the alkaline medium of the small intestine.

5. **The answer is A** *[see II.L.5.b]*.
Asian ginseng may decrease the INR of warfarin. Feverfew, fish oil, garlic, and dong quai may increase the INR of warfarin.

6. **The answer is C** *[see II.O.2–8]*.
St. John's wort is indicated by Commission E for depression and anxiety. St. John's wort should be avoided in pregnancy because it is an emmenagogue and abortifacient. St. John's wort interacts with many medications, including serotonin reuptake inhibitors. It may interact with clopidogrel by increasing its antiplatelet effects. Food interactions may be similar to those of the MAOIs (tyramine-containing foods: cheese, beer, wine, herring, and yeast).

7. The answer is B *[see II.K.1–6].*

Contraindications and precautions for ginkgo include diabetes, epilepsy, bleeding disorders, and infertility. Ginkgo may potentiate the bleeding properties of antiplatelets. Side effects include gastric disturbances, headache, dizziness, and vertigo. Toxic ingestion may produce tonic–clonic seizures and loss of consciousness.

8. The answer is E *[see II.L.6.e].*

Asian ginseng is capable of causing tachyarrhythmias due to QT interval prolongation. Asian ginseng's contraindications include patients with hypertension. Asian ginseng may interact with phenelzine, producing hallucinations and psychosis; may decrease the INR of warfarin; and may interfere with immunosuppressants. Siberian ginseng's contraindications/precautions include hypertension. It may interact with anticoagulants and antihypertensives and may inhibit cytochrome P450 isoenzymes.

Clinical Pharmacokinetics and Therapeutic Drug Monitoring

26

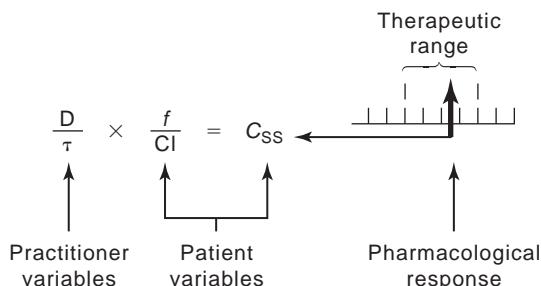
GERALD E. SCHUMACHER

I. INTRODUCTION

- **A. Objectives**
    1. **Therapeutic drug monitoring** (TDM) in a general sense is about using serum drug concentrations (SDCs), pharmacokinetics, and pharmacodynamics to individualize and optimize patient responses to drug therapy.
    2. **TDM** aims to promote optimum drug treatment by maintaining SDC within a **therapeutic range**—above, when drug-induced toxicity occurs too often; and below, when the drug is too often ineffective.
- **B. Definitions**
    1. Specifically, **TDM** is a practice applied to a small group of drugs in which there is a direct relation between SDCs and pharmacological response as well as a narrow range of concentrations that are effective and safe and for which SDCs are used in conjunction with other measures of clinical observation to assess patient status.
    2. **Clinical pharmacokinetics**, a term often used interchangeably with TDM, is more generally the application of pharmacokinetic principles for the rational design of an individualized dosage regimen.
    3. For definitions of the terms used and the concepts applicable in basic and clinical pharmacokinetics, see Chapter 5 on pharmacokinetics.
- **C. Rationale and reasons**
    1. **The rationale** for TDM makes three assumptions.
        a. Measuring patient SDC provides an opportunity to adjust for variations in patient pharmacokinetics by individualizing drug dosage.
        b. The SDC is a better predictor of patient response than dose.
        c. There is a good relation between SDCs and pharmacological response.
    2. **Reasons for measuring SDC**
        a. Drug levels are used in conjunction with other clinical data to assist practitioners in determining how a patient is responding.
        b. Drug levels provide a basis for **individualizing** patient dosage regimens.
        c. Drug levels assist in determining if a change in **patient-specific** pharmacokinetics has occurred during a course of treatment, whether as a result of a change in physiological state, a change in diet, or addition of other drugs.
        d. Assuring **drug compliance** is often cited as a reason for measuring SDC, but it is unreliable for this purpose. In truth, a noncompliant patient may outwit practitioners by manipulating preappointment behavior to induce an SDC that is nonreflective of the patient's drug-taking behavior.

499

II. APPLYING CLINICAL PHARMACOKINETICS IN TDM

A. **What the practitioner controls and does not control in TDM**


1. *Figure 26-1* shows the relation between dose rate of drug administered, pharmacokinetic variables, SDC, and pharmacological response.

2. Note that the only variables that the practitioner controls are the amount of drug administered and how often it is given. These variables may be manipulated to compensate for the patient's pharmacokinetic and pharmacodynamic variables (i.e., bioavailability, clearance, steady-state SDC, pharmacological response), which the practitioner does not control, to achieve some designated SDC that yields a pharmacological response usually observed within the drug's commonly accepted therapeutic SDC range.

B. **The concept of therapeutic range**

1. For many drugs, a specific serum concentration range can be designated for each drug that maximizes effectiveness and minimizes toxicity. The range of SDC is called the **therapeutic range** for the drug.

2. The notion of a therapeutic range is more a **probabilistic concept** than an absolute entity. It is probable that most patients will show effective and safe responses within the therapeutic range. However, a minority of patients will need SDC above or below the upper or lower limits, respectively, of the therapeutic range to achieve an effective response. Similarly, a minority of patients will not show toxicity at SDCs modestly above the therapeutic range, whereas others will show toxicity below the therapeutic range.

3. Therefore, TDM is about **individualizing** patient dosage regimens to achieve SDC within patient-specific therapeutic ranges for a drug. More often than not, a patient-specific range will fall within the generally stated therapeutic range.

C. **The concept of population pharmacokinetic values**

1. **A population pharmacokinetic value or parameter** refers to the mean (average) value noted for a given cohort of people (e.g., adults 20 to 60 years of age, patients with a defined range of renal impairment). Usually, this population value is normalized on a weight basis (e.g., amikacin volume of distribution in normal adults of 0.25 L/kg). When a population parameter is stated without defining the target population, it usually refers to adults; further, when the value also is not normalized (e.g., volume of distribution of amikacin of 15 to 20 L), it usually refers to adults of average weight (approximately 60 to 80 kg).

2. Hardly anyone is average. Individual values of the population studied are summed to determine a mean value that is then reported as the **population value**. Individualizing patient dosage regimens takes this into account by adjusting observed patient-specific values and responses to expected population measures.

3. So the practitioner starts the determination of a patient-specific dosage regimen by assuming that the patient behaves like the average member of his or her population with respect to pharmacokinetics, serum level, and expected response and uses population pharmacokinetic parameters to calculate the dosage regimen needed to meet the desired SDC objective.

4. If the patient is responding appropriately after administering the dosage regimen until steady state is reached based on using population values, then no adjustment in regimen is necessary.

5. If, however, the starting assumption of using average values turns out to be incorrect because the patient's response is either subtherapeutic or toxic due to patient-specific pharmacokinetic and/or pharmacodynamic values that are atypical for the population, the practitioner's only option (except for changing the drug) is to manipulate the practitioner-controlled input variables, **dose and frequency**, to bring the pharmacological response within the desired range.

Figure 26-1. Pharmacokinetic factors influencing serum drug concentration and pharmacological response. *f*, bioavailability; *Cl*, clearance; C_{ss}, steady-state serum drug concentration; *D*, dose; τ, frequency of administration of dose.

D. **Timing of SDC measurements**
   1. SDCs are sometimes measured **early in a course of therapy**, before steady state is reached, to determine patient-specific pharmacokinetic parameters, rather than relying on population values.
   2. More commonly, SDCs are measured **during a steady-state dosage interval** (τ_{ss}) because the objective is to determine if the SDC is within a desired therapeutic range—a range that has previously been determined almost invariably during τ_{ss}.
   3. Because SDCs are most commonly measured at steady state and referenced to values obtained at steady state, it is necessary to wait after starting drug administration until at least three to four assumed half-life ($t_{1/2}$) values (88% to 94% of reaching full steady state) so that SDC will be measured during a period when steady state may be assumed, for clinical purposes, to have been reached or approximated (e.g., approximately 90% of steady state or greater; so for an assumed $t_{1/2}$ of 6 hrs, wait 18 to 24 hrs after initiating drug treatment to measure SDC).
   4. If there are no changes in patient response, there is usually **no need to take subsequent daily SDC measurements**, once an appropriate SDC has been achieved. Only if something occurs that may be expected to alter the patient's pharmacokinetic values (e.g., coadministration of another potentially modifying drug, change in physiological state) are frequent measurements necessary.
   5. If a steady-state SDC (**C_{ss}**) is used appropriately to relate a patient's C_{ss} to a population or patient-specific therapeutic range, then it is important to note when during the steady-state dosage interval (τ_{ss}) the C_{ss} was measured in studies determining the therapeutic range. In other words, is the therapeutic range the practitioner is using as a basis for individualizing regimens based on C_{ss} measured **early** (apparent **$C_{max,ss}$**), near the **midpoint** (apparent **$C_{avg,ss}$**), or near the end (apparent **$C_{min,ss}$**) of τ_{ss}?
   6. **Errors** in interpretation occur when C_{ss} for a patient is measured at a time during τ_{ss} that is markedly different than the time used for establishing the therapeutic range (e.g., measuring C_{ss} in a patient 1 hr after giving a dose on an every 12-hrs regimen when the C_{ss} for the referenced therapeutic range was actually taken at the end of τ_{ss} [**$C_{min,ss}$**]).
   7. Errors in timing of C_{ss} are of greater concern for drugs with a short $t_{1/2}$ than for drugs with a long $t_{1/2}$. C_{ss} fluctuation during τ_{ss} is much greater in the former than the latter case.

III. TDM DRUGS AND COMMON CHARACTERISTICS

A. **TDM drugs**
   1. Drugs for which TDM is commonly used are noted in *Table 26-1*, along with the population therapeutic range.
   2. Drugs for which TDM is infrequently used in general situations but perhaps more commonly used by specialty practitioners or clinics are noted in *Table 26-2*.
B. **Common characteristics of TDM drugs.** Drugs that qualify for TDM have, as a minimum, the following characteristics in common:
   1. SDC is the most practical intermediate end point to be used when there is no clearly observable therapeutic or toxic end point.
   2. SDC is a reasonable proxy for drug concentration at the site of action.

Table 26-1	DRUGS OFTEN MONITORED USING SERUM DRUG CONCENTRATIONS

Drug	Therapeutic Range for C_{ss}
Amikacin	$C_{max,ss}{}^a$ = 20–30 µg/mL; $C_{min,ss}$ < 10 µg/mL
Cyclosporine	Varies with transplanted organ, time after transplant, time of sampling during dosage interval, and method of analysis
Digoxin	0.8–2.0[b] ng/mL
Gentamicin	$C_{max,ss}{}^a$ = 5–10 µg/mL; $C_{min,ss}$ < 2 µg/mL
Phenytoin	10–20 µg/mL
Tobramycin	$C_{max,ss}{}^a$ = 5–50 µg/mL; $C_{min,ss}$ = 2 µg/mL
Vancomycin	$C_{max,ss}{}^a$ = 30–50 µg/mL; $C_{min,ss}$ = 5–10 µg/mL

[a]End of 30- to 60-min infusion.
[b]Levels for atrial fibrillation often exceed 2 ng/mL.

Table 26-2	DRUGS MONITORED USING SERUM DRUG CONCENTRATIONS IN SPECIALTY SITUATIONS

Carbamazepine
Indinavin
Lithium
Methotrexate
Mycophenolate
Serolimus
Tacrolimus

3. The range of therapeutic and safe serum concentrations is narrow.
4. There is no predictable dose–response relation.
5. The pharmacological effect observed persists for a relatively long time. Acute, short, or intermittent effects are not well regulated by using serum drug levels.
6. A drug assay is available that is accurate, precise, specific, rapid, and relatively inexpensive.

IV. EQUATIONS FREQUENTLY USED IN TDM

A. **Linear pharmacokinetic drug clearance—normal renal function.** Linear clearance assumes that a **proportional** change in dose leads to the same **proportional** change in SDC. It also assumes that $t_{\frac{1}{2}}$ and drug clearance remain **constant** as the dose changes. See IV.D for an example of using some of the following equations.

1. **Estimating drug clearance (Cl)**

$$Cl = \frac{V}{1.4t_{\frac{1}{2}}} \tag{1}$$

where V is the apparent volume of distribution of drug.

2. **Maximum concentration ($C_{\text{max,ss}}$)** during τ_{ss}, when absorption is assumed to be much faster than elimination.

$$C_{\text{max,ss}} = \frac{(S)(f)(\text{dose}/V)}{1 - 10^{-0.3(\tau/t_{\frac{1}{2}})}} \tag{2}$$

where S is the fraction of the dosage form that is the active moiety and f is the bioavailability.

3. **Minimum concentration ($C_{\text{min,ss}}$)** during τ_{ss}, when absorption is assumed to be much faster than elimination.

$$C_{\text{min,ss}} = (C_{\text{max,ss}}) \left[10^{-0.3(\tau/t_{\frac{1}{2}})} \right] \tag{3}$$

4. **Average concentration resulting from intermittent administration ($C_{\text{avg,ss}}$)** during τ_{ss}

$$C_{\text{avg,ss}} = \frac{(S)(f)(\text{dose}/\tau)}{Cl} \tag{4}$$

where dose/τ is the amount of drug administered during each selected unit of time (e.g., hours, minutes).

5. **Steady-state concentration resulting from continuous administration ($C_{\text{inf,ss}}$).** For the same dose rate (dose/τ), ($C_{\text{avg,ss}}$) for intermittent administration **is the same as** ($C_{\text{inf,ss}}$) for continuous administration.

$$C_{\text{inf,ss}} = \frac{(S)(f)(\text{dose}/t_{\text{inf}})}{Cl} \tag{5}$$

B. **Linear pharmacokinetic drug clearance—impaired renal function**

1. **Estimating creatinine clearance from serum creatinine** when serum creatinine is assumed to be stable, not changing daily, and weight is expressed by the patient's total weight, unless total weight is equal to or more than 20% of ideal (lean) body weight, in which case ideal weight should be used in the calculation.

$$Cl_{\text{cr}} \text{ (mL/min, males)} = \frac{(140 - \text{age})(\text{weight})}{(Cr_s)(72)} \tag{6}$$

where Cr_s denotes serum creatinine in mg/dL and weight expressed in kg. The female value is 85% of the estimated male value in (6).

2. **Estimating prolonged drug $t_{1/2}$ or reduced drug Cl associated with reduced Cl_{cr}**

$$\frac{(Cl)_{ri}}{(Cl)_n} = \frac{(t_{1/2})_n}{(t_{1/2})_{ri}} = 1 - F + F[(Cl_{cr})_{ri}/(Cl_{cr})_n]$$ 　　(7)

where *ri* and *n* denote the renal impaired and normal conditions, respectively; *F* is the fraction of drug administered that is eliminated unchanged (unmetabolized); and Cl_{cr} represents creatinine clearance in mL/min. Important *F* values for some common TDM drugs are: aminoglycosides = 0.98, digoxin = 0.8, and vancomycin = 0.95.

3. **Using $C_{avg,ss}$ as a target** so that $C_{avg,ss}$ in the renal-impaired patient is maintained the same as $C_{avg,ss}$ in normals.

$$\frac{(dose/\tau)_{ri}}{(dose/\tau)_n} = \frac{dose_{ri} \times \tau_n}{dose_n \times \tau_{ri}} = 1 - F + F[(Cl_{cr})_{ri}/(Cl_{cr})_n]$$ 　　(8)

4. **Using $C_{max,ss}$ as a target** so that $C_{max,ss}$ in the renal impaired is maintained the same as $C_{max,ss}$ in normals.

$$\text{dose per } \tau_{ri} = (dose_L) [1 - 10^{-0.3(\tau_{ri}/t_{1/2ri})}]$$ 　　(9)

where $dose_L$ is a loading dose intended to achieve the same $C_{max,ss}$ in the renal impaired as in the normal patient.

C. **Nonlinear pharmacokinetic drug clearance—normal renal function. Nonlinear** clearance assumes that a proportional change in dose leads to a **disproportional** change in SDC. It also assumes that $t_{1/2}$ and Cl **change** as the dose changes and also as the amount of drug in the body from a given dose changes. Drugs exhibiting nonlinear clearance present a much greater challenge than linear clearance drugs because the assumptions in the latter case of proportional changes in dose yielding same proportional changes in C_{ss} and constant Cl and $t_{1/2}$ do not apply for nonlinear drugs. For nonlinear drugs, increases in dose lead to increases in $t_{1/2}$, decreases in Cl, and changes in C_{ss} that are excessive compared to the proportionate change in dose.

1. **Estimating drug clearance**

$$Cl = \frac{V_{max}}{K_m + C_{avg,ss}}$$ 　　(10)

where V_{max} is the maximum amount of drug that can be eliminated per unit of time (e.g., day) and K_m is the drug serum concentration at which the rate of elimination is 50% of V_{max}.

2. **Estimating $C_{avg,ss}$ resulting from a given dose/τ**

$$C_{avg,ss} = \frac{(K_m)(S)(f)(dose/\tau)}{V_{max} - (S)(f)(dose/\tau)}$$ 　　(11)

3. **Estimating dose/τ needed for a desired $C_{avg,ss}$**

$$dose/\tau = \frac{(V_{max})(C_{avg,ss})}{(K_m + C_{avg,ss})(S)(f)}$$ 　　(12)

D. **An example of applying some of the previous equations to developing and modifying dosage regimens**

1. A common dosage regimen for intravenous (IV) gentamicin is 1.7 mg/kg every 8 hrs (as a 30-min infusion). Regimens are usually adjusted to achieve $C_{max,ss}$ and $C_{min,ss}$ within 5 to 10 mcg/mL and less than 2 mcg/mL, respectively. Does the preceding regimen meet the target concentration objectives in normal patients? Assume the following population parameters in normals: $Cl = 0.09$ L/kg/hr, $t_{1/2} = 2.5$ hrs, $V = 0.25$ L/kg. For IV administration, $f = 1$, and $S = 1$ for the dosage form (label amount represents the actual amount of gentamicin).

2. **In normals**, using equations (2) and (3).

$$C_{max,ss} = \frac{(1)(1)(1.7 \text{ mg/kg})/(0.25 \text{ L/kg})}{1 - 10^{-0.3 \, (8 \text{ hr}/2.5 \text{ hr})}} = 7.6 \text{ mcg/mL}$$

$$C_{min,ss} = 7.6 \text{ mcg/mL} \times 10^{-0.3 \, (8 \text{ hr}/2.5 \text{ hr})} = 0.8 \text{ mcg/mL}$$

These values fall within the target concentration ranges for the average patient with normal renal function.

3. **In the renal impaired**, what should be done to modify the preceding regimen for a patient who is 60 years old, 70 kg, male, with a Cr_s of 2.5 mg/dL? In this patient, if the preceding regimen were used, the prolonged $t_{\frac{1}{2}}$ would yield $C_{max,ss}$ = 15.2 mcg/mL and $C_{min,ss}$ = 8.4 mcg/mL, values clearly above the target concentration ranges.

a. Using equation (6) for estimating Cl_{cr} in this patient.

$$Cl_{cr} = \frac{(140 - 60 \text{ yrs})(70 \text{ kg})}{(2.5 \text{ mg/dL})(72)} = 31 \text{ mL/min}$$

b. Then using equation (7) for estimating $t_{\frac{1}{2}}$ in this patient, assuming F = 0.98 and $(Cl_{cr})_n$ = 120 mL/min.

$$\frac{(2.5 \text{ hrs})}{(t_{\frac{1}{2}})_{ri}} = 1 - 0.98 + 0.98\,(31/120) = 0.27 (t_{\frac{1}{2}})_{ri} = 9.3 \text{ hrs}$$

c. Then, using equation (9), first determine a loading dose (D_L) to achieve the same $C_{max,ss}$ of approximately 8 mcg/mL as estimated in IV.D.2 for a patient with normal renal function:

$$D_L = (C_{max,ss})(V)/(S)(f)$$

$$D_L = (8 \text{ mcg/mL})(0.25 \text{ L/kg})/(1)(1) = 2 \text{ mg/kg}$$

Next, determine fraction of drug lost during τ, assuming a τ_{ri} of 24 hrs, and using the $(t_{\frac{1}{2}})_{ri}$ of 9.3 hrs estimated in IV.D.3.b.

$$\text{Fraction lost} = 1 - 10^{-0.3(\tau/t_{\frac{1}{2}})} = 1 - 10^{-0.3(24/9.3)} = 0.84$$

Lastly, calculate D per τ_{ri}:

$$\text{D per } \tau_{ri} = (D_L)[1 - 10^{-0.3(\tau/t_{\frac{1}{2}})}]$$

$$= (2 \text{ mg/kg})(0.84) = 1.7 \text{ mg/kg}$$

Thus, a D_L of 2 mg/kg followed by 1.7 mg/kg every 24 hrs is expected to maintain levels in this patient similar to that in normals.

V. EFFECT OF PHYSIOLOGICAL ALTERATIONS ON PHARMACOKINETIC VARIABLES

A. **General considerations.** It is apparent from *Figure 26-1* and the equations in section IV that any changes in pharmacokinetic variables result in changes in C_{ss} and perhaps pharmacodynamic outcomes. This may necessitate changes in D/τ compared to normals. For renal impairment, **quantitative** estimates of resulting changes in Cl and $t_{\frac{1}{2}}$, compared to normal values, are available using the equations in section IV. For hepatic, cardiac, pulmonary, and other impairments potentially inducing changes in normal pharmacokinetic variables, only **qualitative** estimates are possible.

B. **Renal impairment**, when marked, reduces drug clearance for drugs primarily dependent on the kidney for elimination. As noted in the equations in section IV.B, physiological markers like serum creatinine and creatinine clearance are used to estimate the changes in Cl and $t_{\frac{1}{2}}$ resulting from reductions in Cr_s and Cl_{cr}.

C. **Hepatic impairment** exerts a complex influence on drug pharmacokinetics. Two processes may be altered: blood flow rate in delivering drug to the liver and the capacity of enzymes to metabolize the drug. In general terms, moderate to severe hepatic impairment is expected to slow overall Cl and prolong $t_{\frac{1}{2}}$ for drugs highly dependent on the liver for elimination.

D. **Cardiac impairment**, when substantial, decreases hepatic and renal clearances, reduces volume of distribution, and may slow absorption for some drugs. The effect of compromised perfusion is most critical for drugs that are both highly dependent on the liver for clearance and efficiently metabolized by the liver in normal patients.

E. **Aging** results in reductions in renal (consistently) and hepatic (inconsistently) clearances. The clearance of drugs primarily dependent on the kidney declines by nearly 50% and the half-life nearly doubles over a 40- to 50-year period from young adulthood. On the other hand, some drugs primarily dependent on the liver for clearance show no age-related changes, whereas others do. Changes with age in absorption, volume of distribution, and serum protein binding of drugs show no consistent pattern.

F. From a clinical viewpoint, serum **protein binding** of drugs becomes an important issue in TDM for drugs bound more than 80% to serum proteins. Because hepatic and renal clearances, volume of distribution, and pharmacological response are mediated by the free (unbound) form of the drug in serum, interpatient variations in protein binding not only result in variations in pharmacokinetics in normals, but loss of serum proteins during renal and hepatic impairments may also result in modified drug clearance and pharmacological response.

VI. USING TEST PERFORMANCE CHARACTERISTICS IN TDM

A. Rationale and reasons

1. In TDM, the SDC functions like a diagnostic test to assist in classifying patient status.
2. On the one hand, the patient's SDC may be used, in conjunction with a population SDC cutoff value measure for the drug, which acts as a separator, to classify the patient as a member of either drug-induced toxic (patient SDC > upper cutoff value) or therapeutic (within therapeutic range) subpopulations.
3. Alternately, the patient's SDC may classify the patient as part of the therapeutic or subtherapeutic (SDC < lower cutoff value) subpopulations.
4. Although classifying patients in subpopulations is the most common use of SDC in TDM, a more informed application of SDC is to use the result to modify the clinician's probability of patient status. This is the use of SDC as part of a Bayesian approach to diagnostic test interpretation.

B. Test performance characteristics. Test performance indices are not perfect classifiers of patient status and should never be used as the sole measure for determining how the patient is reacting to the drug. A number of test performance indices characterize the accuracy of a diagnostic test to accurately classify patients as toxic, therapeutic, or subtherapeutic. Four of these indices are most useful in interpreting SDC.

1. **Positive predictive value (PPV)**
   a. **Comparing drug-induced toxic versus nontoxic patients (using upper SDC cutoff level).** PPV denotes the proportion of patients with a **positive test** (patient SDC > upper cutoff SDC) who are in a drug-induced **toxic** condition. So, the value of PPV represents the probability of a positive test being accurate in classifying the patient as toxic.
   b. **Comparing therapeutic versus subtherapeutic patients (using lower SDC cutoff level).** PPV denotes the proportion of patients with a **positive test** (patient SDC > lower cutoff SDC) who are **responding appropriately**. So, the value of PPV in this case represents the probability of a positive test being accurate in classifying the patient as therapeutic.

2. **Negative predictive value (NPV)**
   a. **Comparing drug-induced toxic versus nontoxic patients (using upper SDC cutoff level).** NPV denotes the proportion of patients with a **negative test** (patient SDC < upper cutoff SDC) who are **not** manifesting drug-induced **toxicity**. So, the value of NPV represents the probability of a negative test being accurate in classifying the patient as nontoxic.
   b. **Comparing therapeutic versus subtherapeutic patients (using lower SDC cutoff level).** NPV denotes the proportion of patients with a **negative test** (patient SDC < lower cutoff SDC) who are **subtherapeutic**. So, the value of NPV in this case represents the probability of a negative test being accurate in classifying the patient as subtherapeutic.

3. **Positive likelihood ratio (PLR).** In defining conditions as + or − (as in + = toxic and − = negative or + = therapeutic and − = subtherapeutic), **PLR** is the probability that a + **patient** has a + **test** divided by the probability that a − **patient** has a + **test** (e.g., the probability that a **toxic** patient has an SDC > cutoff divided by the probability that a **nontoxic** patient has an SDC > cutoff). The **higher** the **PLR,** the **more** discriminating the test.

4. **Negative likelihood ratio (NLR).** NLR is the probability that a + **patient** has a − **test** divided by the probability that a − **patient** has a − **test**. The **lower** the **NLR,** the **more** discriminating the test.

5. **Illustrating the use of PPV, NPV, PLR, and NLR.** For digoxin, using a test upper cutoff of 2 ng/mL, PPV is 0.59, NPV is 0.95, PLR is 7, and NLR is 0.2.
   a. **For PPV,** this means that the proportion of patients with a positive test result (SDC > upper cutoff) who truly have digoxin-induced toxicity is 59%. For an individual patient with SDC > cutoff, the probability of toxicity is 0.59.

b. For NPV, this means that the proportion of patients with a negative test result (SDC < upper cutoff) who truly are nontoxic is 95%. For an individual patient with SDC < cutoff, the probability of nontoxicity is 0.95.

c. For PLR, digoxin-induced toxic patients will have a positive test result seven times more often than do nontoxic patients.

d. For NLR, digoxin-induced toxic patients will have a negative test result 20% as often as will nontoxic patients.

e. These results suggest that a negative digoxin test result rules out toxicity (0.95) about 1.6 times (0.95/0.59) as effectively as a positive test rules in digoxin-induced toxicity (0.59). A positive test appears to be unreliable as an indicator of digoxin-induced toxicity, but a negative test appears to be highly predictive of nontoxicity. Furthermore, the PLR suggests that a positive SDC test is six times more likely to come from a digoxin-induced toxic than a nontoxic patient. On the other hand, the NLR implies that it is one-fifth as likely (0.2) that a negative test comes from a digoxin-induced toxic compared to a nontoxic patient.

f. Knowledge of test performance characteristics of SDC measures provides the practitioner with an index of the usefulness of the SDC in categorizing patients.

C. Using a Bayesian approach. Using SDC in conjunction with likelihood ratio information enhances the application of the SDC in decision making. A Bayesian approach to probability revision allows the practitioner to make a pretest assessment of patient status, order a diagnostic test, and use the probability information contained in the test result to revise the assessment of status.

1. The relation between pretest, test, and posttest assessment is shown in the following equation:

$$\text{(pretest odds)(likelihood ratio)} = \text{(posttest odds)} \tag{13}$$

where pretest refers to the pretest odds of the condition being present prior to obtaining the patient's SDC and posttest refers to the posttest odds of the condition being present after learning the SDC.

2. Odds are defined as + results divided by − results (+/−). **Probability** is defined as + results divided by total results (+/total, where total is the sum of + and − results).

3. Odds are converted to probability as follows:

$$\text{Probability} = \text{odds}/(1 + \text{odds}) \tag{14}$$

4. Probability is converted to odds as follows:

$$\text{Odds} = \text{probability}/(1 - \text{probability}) \tag{15}$$

5. An example of applying a Bayesian approach to modifying the probability of patient status. Using the digoxin test performance characteristics noted in VI.B.5:

a. Assume that a practitioner assesses by visual inspection that the probability of digoxin-induced toxicity in a patient is 0.25 (the pretest probability). She orders a serum digoxin concentration (SDC), and uses the measurement to revise her assessment of digoxin-induced toxicity in the patient (the posttest probability).

b. Further assume that the test performance characteristics for the SDC are: PLR = 7 and NLR = 0.2.

c. Using equations (13), (14), and (15), a pretest probability of 0.25 is the same as pretest odds of toxicity of ⅓ [0.25/(1 − 0.25)], using equation (15).

d. If the SDC test for the patient comes back positive (SDC > 2 ng/mL), then PLR = 7 is used to revise the odds of toxicity. If the SDC test is negative (SDC ≤ 2 ng/mL), then NLR = 0.2 is used.

e. Assume the patient's **SDC** = 2.4 ng/mL, then using equation (13) yields (⅓)(7) = 2.3. So, the posttest odds of toxicity are 2.3/1. Converting these odds to probability using equation (14): [2.3/(1 + 2.3)] = 0.71. The **posttest probability of toxicity is 0.71**. The pretest probability of 0.25 has nearly tripled (0.71/0.25) using the SDC as feedback.

f. Assume instead that the patient's SDC = **1.4 ng/mL**; then using equation (13) yields (⅓)(0.2) = 0.07. So, the posttest odds of toxicity are 0.07/1. Converting these odds to probability using equation (14): [0.07/(1 + 0.07)] = ~0.07. **The posttest probability of toxicity is 0.07**.

g. Although a positive SDC test nearly tripled the probability of toxicity earlier, a negative test cuts the probability to less than ⅓ of its pretest value. This demonstrates the usefulness of using SDC in combination with practitioner assessment as a guide to quantifying the probability of patient status.

VII. SUMMARY

A. TDM applies to a small number of drugs with a narrow range of effective and safe SDC wherein optimum drug treatment is promoted by maintaining SDC within a population or patient-specific therapeutic range, above which drug-induced toxicity occurs too often and below which the drug is too often ineffective.

B. A practitioner initiates drug treatment using a dose rate that assumes that the patient shows mean population values for the pharmacokinetic variables, even though it is expected that few patients will ever possess the mean value being used. If the resulting C_{ss} and/or pharmacological response is other than expected and the patient becomes at risk for subtherapeutic or drug-induced toxicity, it is likely due to the interpatient variability in pharmacokinetic values and pharmacodynamic response that characterizes the need for TDM; therefore, the dose rate is modified to produce a patient-specific C_{ss} that represents the best tradeoff of effectiveness and toxicity.

C. Timing of sampling of SDC is critical to reduce errors in interpretation of the measurement. SDC should be sampled at steady state, after postabsorption and postdistribution equilibrium is achieved, and a time during τ_{ss} that matches the time at which the therapeutic range was established.

D. The choice of $C_{max,ss}$, $C_{min,ss}$, $C_{avg,ss}$, or $C_{inf,ss}$ to estimate dosage regimens depends on the therapeutic range objective and, in the latter case, intravenous rather than intermittent administration.

E. For the renal-impaired patient, the dosage reduction factor is calculated to achieve, depending on the therapeutic range objective, a $C_{max,ss}$ or $C_{avg,ss}$ in the renal-impaired patient that is similar to that desired if the patient had normal renal function.

F. The SDC measure is more than a number used to relate the patient's value to a population therapeutic range. The SDC is a form of diagnostic test used: (1) to assist in classifying patient status and (2) as feedback to revise practitioner estimates of patient status. Therefore, it is important to know the predictive values and likelihood ratios of SDC tests.

Study Questions

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the one lettered answer or completion that is **best** in each case.

1. Define therapeutic drug monitoring. What is meant by the term TDM?

   (A) The use of drug serum concentration measurements for drugs in which there is (1) a correlation between serum concentration and response and (2) a narrow range of effective and safe concentrations, to assess patient status as an adjunct to clinical observation

   (B) The use of drug serum concentration measurements to determine population values for a drug's half-life value

   (C) The use of drug serum concentration measurements to assess the accuracy of the drug concentration assay

   (D) Observing the effects of drugs in human

   (E) Using drug serum concentration measurements to differentiate effective from ineffective drugs

2. The therapeutic range for digoxin is often stated as 0.8 to 2.0 ng/mL. What does this mean?

   (A) Fifty percent of people taking digoxin show a safe and effective response when the serum drug concentration is between 0.8 and 2.0 ng/mL.

   (B) Most people achieve the desired response to digoxin with minimum adverse effects when the serum digoxin concentration is maintained between 0.8 and 2.0 ng/mL. Fewer patients are managed effectively at < 0.8 ng/mL, but some may respond quite appropriately at lower levels. The frequency of adverse effects increases as the level increases above the upper limit of the therapeutic range, but a few patients are managed effectively without adversity above the range.

   (C) Twenty-five percent of people show an effective response to digoxin at < 0.8 ng/mL, and 75% show an effective response at 2.0 ng/mL.

   (D) Twice daily administration of digoxin, but not three times daily, requires that serum drug concentrations stay within 0.8 to 2.0 ng/mL.

   (E) Digoxin serum drug concentrations outside of the 0.8 to 2.0 ng/mL range are ineffective and/or unsafe.

3. Assume that for digoxin, the therapeutic range is cited as $C_{avg,ss} = 0.8$ to 2.0 ng/mL. If the patient is assumed to have an estimated digoxin $t_{1/2}$ of 48 hrs, how long would you wait to take a serum digoxin concentration measurement, and when during τ would you schedule it?

   (A) 28 days, then 3 to 4 hrs after the dose is administered
   (B) 14 days, then 6 to 8 hrs after the dose is administered
   (C) 7 days, then 10 to 14 hrs after the dose is administered
   (D) 3 days, then 1 to 2 hrs after the dose is administered
   (E) 1 day, then 18 to 22 hrs after the dose is administered

4. Differentiate linear from nonlinear drug clearance. What is the effect on TDM?

   (A) Linear drug clearance is first order, the Cl and $t_{1/2}$ are independent of drug dosage, and proportional changes in dose result in the same proportional changes in C_{ss}. Nonlinear drug clearance is zero order, Cl and $t_{1/2}$ change as dose changes (or as the amount of drug in the body changes), and proportional changes in dose yield disproportionate changes in C_{ss}.
   (B) Linear drug clearance presents fewer serum concentration peaks and troughs during the dosage interval than does nonlinear drug clearance.
   (C) Linear drug clearance is zero order, the Cl and $t_{1/2}$ are dependent on drug dosage, and proportional changes in dose do not result in the same proportional changes in C_{ss}. Nonlinear drug clearance is first order, and equations are not available to predict drug serum concentration from the dose rate.
   (D) Drugs with linear clearance have shorter $t_{1/2}$ values than drugs with nonlinear clearance.
   (E) Drugs with linear clearance are administered less often than drugs with nonlinear clearance.

5. What is the positive predictive value of a diagnostic test?

   (A) The fraction of patients with a positive outcome who have a positive test result.
   (B) Being more than 50% correct in predicting success or failure upon using a drug regimen.
   (C) The fraction of patients who achieve a successful response in using a drug.
   (D) The fraction of patients with a positive test result who turn out to have a positive outcome.
   (E) The probability that knowledge of a drug serum concentration results in a successful response to treatment.

6. A 70-year-old, 80-kg male with serum creatinine of 3 mg/dL is scheduled to start tobramycin therapy. What regimen is recommended to achieve $C_{max,ss}$ within 5 to 10 mcg/mL (use the midpoint of 7.5 mcg/mL for the calculation) and $C_{min,ss} < 2$ mcg/mL. Try an every 24-hr regimen to start and, if unsuccessful in achieving the target concentration goals, alter τ and recalculate. Assume in normals the following values: $t_{1/2} = 2.5$ hrs, $V = 0.25$ L/kg, $F = 0.98$, $S = 1$, $f = 1$, $Cl_{cr} = 120$ mL/min

   (A) A loading dose of 1.8 to 2.0 mg/kg followed by 1.0 mg/kg every day
   (B) A loading dose of 1.8 to 2.0 mg/kg followed by 1.5 mg/kg every day
   (C) 2.0 mg/kg every day
   (D) 1.0 mg/kg every day
   (E) 0.5 mg/kg every day

Answers and Explanations

1. **The answer is A** *[see I.B.1]*.

2. **The answer is B** *[see II.B]*.

3. **The answer is C** *[see II.D.3]*.
   If the patient's estimated $t_{1/2}$ is 48 hrs, 90% of steady state is expected to be achieved between 3 and 4 $t_{1/2}$ intervals or 6 to 8 days in this case. For clinical purposes, we choose 90% attainment of steady state as the minimum time to estimate drug accumulation. A level drawn at 7 days seems reasonable. Once a τ_{ss} has been selected, the time for scheduling a level should correspond with the reference time for the therapeutic range. In this case, $C_{avg,ss}$ was cited as the reference time, so a measurement scheduled for sometime near the midpoint of τ_{ss} (around 12 hrs) is reasonable.

4. **The answer is A** *[see IV.A–C]*.
   This presents challenges in TDM because for linear drugs, the clinician can expect a change in C_{ss} proportional to a change in dose, but for nonlinear drugs, this is not true.

5. **The answer is D** *[see VII.B]*.
   The positive predictive value of a diagnostic test is an index of how effective the test is in classifying patients correctly. For example, using a C_{ss} measure for a given drug, knowing that the positive predictive value is 0.8, given a group of patients with a C_{ss} above the test cutoff value, 80% of the patients will be accurately classified as having a positive outcome. If the test is being used to classify toxic versus nontoxic patients, 80% of the patients with C_{ss} above the test cutoff will experience drug-induced toxicity. If, instead, the test is being used to classify effective versus subeffective response in patients, 80% of the patients with C_{ss} above the test cutoff will experience effective response.

6. **The answer is B** *[see IV.D.3]*.
   Using the equation for estimating Cl_{cr} in this patient from IV.B.1:

   $$Cl_{cr} = (140 - 70 \text{ yrs})(80 \text{ kg})/(3 \text{ mg/dL})(72)$$
   $$= 26 \text{ mL/min}$$

   Then, using the equation for estimating $t_{1/2}$ in this patient from IV.B.2:

   $$\frac{(2.5 \text{ hrs})}{(t_{1/2})_{ri}} = 1 - 0.98 + 0.98 \ (26/120)$$
   $$= 0.23(t_{1/2})_{ri} = 10.9 \text{ hrs}$$

   Then, using equation [IV.D.3.c], first determine a loading dose (D_L) to achieve the desired $C_{max,ss}$ of 7.5 mcg/mL:

   $$D_L = (C_{max,ss})(V)/(S)(f)$$

   $$D_L = (7.5 \text{ mcg/mL})(0.25 \text{ L/kg})/(1)(1) = 1.9 \text{ mg/kg}$$

   Then, determine fraction of drug lost during τ, assuming a τ_{ri} of 24 hrs, and using the $(t_{1/2})_{ri}$ of 10.9 hrs estimated earlier using the equation in IV.D.3.c:

   $$\text{fraction lost} = 1 - 10^{-0.3(24/10.9)} = 0.78$$
   $$\text{fraction left} = 10^{-0.3(24/10.9)} = 0.22$$

   Lastly, calculate D per τ_{ri}:

   $$\text{D per } \tau_{ri} = (D_L)(\text{fraction lost per } \tau_{ri})$$
   $$= (1.9 \text{ mg/kg})(0.78) = 1.5 \text{ mg/kg}$$

   This dose of 1.5 mg/kg every 24 hrs is based on achieving an estimated $C_{max,ss} = 7.5$ mcg/mL, as noted earlier. To check the estimated $C_{min,ss}$ use equation (3) in [4.A.3]:

   $$C_{min,ss} = (C_{max,ss}) \ [10^{-0.3(\tau/t_{1/2})}]$$
   $$= (7.5) \ [10^{-0.3(24/10.9)}] = 1.6 \text{ mcg/mL}$$

   Thus, a D_L of 1.9 mg/kg followed by 1.5 mg/kg every 24 hrs is expected to attain the desired $C_{max,ss}$ and $C_{min,ss}$ levels in this patient. Of course, many estimates were made along the way (Cl_{cr}, $t_{1/2}$, V), so if the patient's $C_{max,ss}$ and $C_{min,ss}$ vary from what has been expected from the calculations, it is likely because of the estimates being at variance with the actual value(s) in the patient.

27 Pediatrics

MARCIA L. BUCK

I. PEDIATRIC PHARMACOTHERAPY

A. General considerations

1. Most pharmacists in community and hospital settings provide care for children. In the United States, children make up nearly one-third of the total population. Although children typically require fewer medications than adults because of their relative good health, approximately 30% of all prescriptions filled in community pharmacies are for pediatric patients. As a result, **pharmacists need to have a basic knowledge of pediatric pharmacotherapy to appropriately assess and monitor drug therapy**.

2. Providing care for children is often a challenge. There is **limited information on the selection**, **dosing**, **and monitoring of drugs** in this population. It is estimated that only 25% of the drugs available on the market in the United States carry a U.S. Food and Drug Administration (FDA)-approved indication for use in pediatric patients, although nearly 75% have been used to treat children. As a result, most pediatric dosing is considered off-label. Dosing information typically comes directly from case reports and small clinical trials published in the medical literature. In addition to being able to obtain pediatric-specific drug information, pharmacists must also be familiar with differences in pediatric pharmacokinetics and pharmacodynamics as well as the unique aspects of medication monitoring and compliance in this population.

B. Pharmacokinetic considerations

1. Unlike the relatively stable pharmacokinetic profile of most drugs in adults, children's **pharmacokinetic parameters change during maturation from neonates into adolescents** (*Table 27-1*). As a result, the pediatric population is a diverse and dynamic group. Each aspect of drug disposition is affected, including absorption, distribution, metabolism, and elimination. None of these processes is fully mature at birth, and they develop at different rates over the first years of life. The study of these changes is known as developmental pharmacology.

Table 27-1	AGE DEFINITIONS

Age Group	Age
Newborn	
Preterm or premature	< 36 weeks gestation[a]
Term	> 36 weeks gestation[a]
Neonate	< 1 month
Infant	1 month–1 year
Child	1–11 years
Adolescent	12–16 years

[a]Gestational age as measured from the time of the mother's last menstrual period.

2. **Drug absorption.** For most routes of drug administration, the greatest change in absorption takes place during infancy. Differences in drug absorption during this period may affect the choice of delivery method, dose, or monitoring.

    a. **Gastrointestinal absorption.** Oral drug absorption is most greatly altered during the first year of life. Several aspects of absorption are age dependent, including gastric pH, gastric emptying time, intestinal motility, bile salt production, and pancreatic enzyme function.

        (1) **Elevated gastric pH.** At birth, gastric pH is elevated to nearly neutral. This results from a relative decrease in gastric acid production and an overall decrease in the volume of gastric secretions. As a result, acid-labile drugs such as penicillin G may have a greater bioavailability in neonates than in older infants. Conversely, drugs that are weak acids such as phenobarbital (Luminal) and phenytoin (Dilantin) may not be as well absorbed. To compensate for this effect, neonates may require larger oral doses of these drugs than older infants to produce the desired therapeutic effect. Acid production rises steadily after birth but do not reach adult levels until 2 to 3 years of age.

        (2) **Prolonged gastric emptying and intestinal motility.** The rate of passage of drugs through the gastrointestinal tract is also important in determining the rate and extent of their absorption. Coordination of contractions within the stomach begins to improve shortly after birth, whereas intestinal peristalsis increases more slowly, over the first 4 to 8 months of life. As a result of this prolonged transit time, absorption of drugs may be significantly slowed.

            (a) **Preterm neonates typically have more delayed gastric emptying time than term neonates**, so that changes in oral absorption may be most pronounced in these patients. Clinical studies have demonstrated that peak acetaminophen (Tylenol) serum concentrations occur up to 2 hrs later in premature neonates compared to older infants.

            (b) **Breastfed infants empty their stomachs approximately twice as fast as formula-fed infants.** The increased caloric density of formula feedings delays gastric emptying.

        (3) **Bile salt and pancreatic enzyme production.** The rate of bile salt synthesis in preterm and term infants is approximately 50% of adult values. Decreased fat absorption from enteral feedings, as well as decreased drug absorption, can occur. For example, when lipid-soluble vitamin D is administered to infants, bioavailability is only 30% as compared with 70% in adults. The absorption of lipid-soluble drugs is further reduced due to lower levels of pancreatic enzymes.

        (4) Other factors affecting oral drug absorption include reduced splanchnic blood flow in the first month of life and reduced activity of intestinal metabolic enzymes, which alters the first-pass effect. In addition, neonates lack normal gut microflora. Although bacterial colonization normally occurs shortly after birth, it may be significantly delayed in preterm neonates who are being cared for in the sterile environment of an intensive care unit.

    b. **Percutaneous absorption**

        (1) Absorption of drugs through the skin is enhanced in infants and young children owing to better hydration of the epidermis, greater perfusion of the subcutaneous layer, and the larger ratio of total body surface area to body mass compared to adults.

        (2) In preterm neonates, the stratum corneum is also thinner, further increasing the potential for the absorption of topical products.

        (3) This route of administration should be used with caution in infants and young children to avoid overdosage. There are numerous accounts of toxicity resulting from percutaneous absorption. Repeated use of the skin cleanser hexachlorophene (Phisohex) has resulted in seizures in preterm neonates and application of povidone–iodine (Betadine) to prepare the skin for surgery or sterile procedures has caused iodine toxicity in infants. Repeated applications of topical hydrocortisone cream for diaper rash or eczema can produce adrenal axis suppression after as little as 2 weeks of use in an infant.

    c. **Intramuscular absorption**

        (1) The absorption of drugs administered by this route may be reduced in infants as a result of reduced blood flow to skeletal muscles. In addition, weak or erratic muscle contractions in neonates may result in reduced drug distribution. These factors may be partially offset

by the higher density of capillaries in skeletal muscle during infancy, which increases blood circulation.

(2) Intramuscular administration of drugs is generally discouraged in the pediatric population because of the pain associated with the injection and the risk of nerve damage from inadvertent injection into nerve tissue.

(3) This route is generally reserved for the administration of vitamin K where it produces a longer lasting depot-like effect to prevent hemorrhagic disease of the newborn, vaccines, and occasionally antibiotics when intravenous access is not available. If it is used, the volume should not exceed 0.5 mL for infants and younger children and 1.0 mL for older children.

d. Rectal administration. Absorption by this route is fairly reliable, even for preterm neonates. Administration may be complicated in infants; however, by the increased number of pulsatile contractions in the rectum compared to adults, making expulsion of a suppository more likely.

e. Pulmonary administration. Inhalation of medications is increasingly being used in infants and older children to avoid systemic exposure. Although developmental changes in the pulmonary vasculature and respiratory mechanics likely alter the pharmacokinetics of drugs given by inhalation, little is known about the effects of growth and maturation on this route of drug administration.

3. Drug distribution. Growth and maturation affect many of the factors that determine drug distribution. Body water content, fat stores, plasma protein concentrations, organ size and perfusion, hemodynamic stability, tissue perfusion, acid–base balance, and cell membrane permeability all undergo significant changes from infancy to adolescence.

a. Body water and fat content. Total body water content decreases with increasing age. This is primarily the result of a larger extracellular body water content in neonates and young infants that decreases with age. Approximately 80% of a newborn's body weight is water. By 1 year of age, this value declines to 60%, similar to that of an adult. Highly water-soluble compounds, such as gentamicin (Garamycin), have a larger volume of distribution in neonates than in older children. As a result, larger milligram per kilogram doses are often needed to achieve desired therapeutic concentrations. Conversely, body fat increases with age from 1% to 2% in a preterm neonate to 10% to 15% in a term neonate and 20% to 25% in a 1-year-old. Lipophilic drugs, such as diazepam (Valium), have a smaller volume of distribution in infants than in older children and adults.

b. Protein binding. Acidic drugs bind to **albumin**, whereas basic substances bind primarily to **α_1-acid glycoprotein** (AGP). The quantity of total plasma proteins, including both of these substances, is reduced in neonates and young infants. In addition, the serum albumin of newborns may have a reduced binding affinity. These two factors result in an increase in the free fraction of many drugs (*Table 27-2*). The increase in the free fraction may result in enhanced pharmacological activity for a given dose. **The relative decrease in serum proteins may also produce increased competition by drugs and endogenous substances**, **such as bilirubin**, **for binding sites**. Drugs that are highly bound to albumin, such as the sulfonamides, may displace bilirubin from its binding sites and allow deposition in the brain, referred to as kernicterus. As a result, these drugs are contraindicated in the first 2 months of life.

Table 27-2	PROTEIN-BOUND DRUGS WITH A HIGH FREE FRACTION IN NEONATES
Ampicillin (Principen)	Penicillin G (Pfizerpen)
Digoxin (Lanoxin)	Phenobarbital
Diazepam (Valium)	Phenytoin (Dilantin)
Lidocaine (Xylocaine)	Propranolol (Inderal)
Morphine (Duramorph)	Theophylline
Nafcillin (Nallpen)	

4. **Metabolism.** The most significant research in developmental pharmacology during the past decade has come in the area of drug metabolism. **Developmental changes have been identified for many phase I** (oxidation, reduction, hydroxylation, and hydrolysis) and **phase II** (conjugation) **reactions**. The maturation of metabolic function results in the need for age-related dosage alterations for many common therapies and may explain the increased risk for drug toxicity in infants and young children.

   a. The activity of **phase I enzymes**, **such as the cytochrome P450 (CYP) enzymes**, **changes significantly during maturation**. Activity of the primary isoenzyme present during the prenatal period, CYP3A7, declines rapidly after birth. This enzyme exists in barely measurable quantities in adults. It may appear early in fetal life to detoxify dehydroepiandrosterone and retinoic acid that are transferred across the placenta from maternal circulation. At birth, CYP2E1 and CYP2D6 levels begin to rise. Enzymes associated with the metabolism of many common drugs, including CYP3A4, CYP2C9, and CYP2C19, appear within the first weeks of life, but their levels increase slowly. The last of the enzymes to develop, CYP1A2, is present by 1 to 3 months of life. The activity of these enzymes does not appear to increase in a direct linear manner with age but varies over time. By 3 to 5 years of age, most patients have CYP isoenzyme activity levels similar to that of adults.

      (1) The altered pharmacokinetic profiles of drugs in children may, in large part, be explained by these developmental changes in the CYP enzyme system. One of the most well-studied enzymes is **CYP1A2**. This enzyme is nearly nonexistent in fetal liver cells, and activity is minimal in neonates. As a result, the rate of metabolism of caffeine in the neonate is slow, resulting in an elimination half-life of 40 to 70 hrs. Enzyme activity increases by 4 to 6 months of age. Within the first year of life it exceeds adult values, producing a caffeine half-life of approximately 5 hrs. Infants receiving caffeine (Cafcit) for apnea of prematurity or chronic lung disease must have periodic adjustments in their dose to account for these changes in metabolism and maintain therapeutic serum concentrations.

      (2) **Genetic polymorphism** also plays a significant role in determining metabolic function in children. Recent studies with atomoxetine (Strattera) have shown that children with reduced CYP2D6 function (i.e., poor metabolizers) had greater improvement in their attention deficit hyperactivity disorder (ADHD) symptoms than children who were extensive metabolizers, using a standard weight-based dose. The poor metabolizers also had an increased incidence of adverse effects as a result of having higher atomoxetine serum concentrations.

      (3) **Alcohol dehydrogenase** activity is only 3% to 4% of adult values at birth and does not achieve adult values until approximately 5 years of age. Because of this, newborns have a reduced ability to detoxify benzyl alcohol, a preservative found in many injectable products. Newborns exposed repeatedly to these products will accumulate benzyl alcohol, which may lead to a potentially fatal condition referred to as "gasping syndrome," with metabolic acidosis, respiratory failure, seizures, and cardiovascular collapse. Because of this risk, it is recommended that neonates receive preservative-free products or those containing alternative preservatives.

   b. **Phase II reactions** (conjugation with glycine, glucuronide, or sulfate to form more water-soluble compounds) also undergo considerable change during early childhood.

      (1) Uridine 5′-diphosphate glucuronosyltransferase (UGT) enzyme activity is minimal at birth. As a result, **glucuronidation is decreased in neonates**, compared with older children and adults. The rate of glucuronidation increases with increasing patient age. This can be seen in the decreasing half-life of morphine (Duramorph) during the first year of life, which mirrors the maturation of UGT2B7 function. The average half-life in a preterm neonate is 10 to 20 hrs, compared to 4 to 13 hrs in a neonate, 5 to 10 hrs in infants between 1 and 3 months of age, and 1 to 8 hrs in older infants and young children.

      (2) Unlike glucuronidation, **sulfation develops in utero and is well developed in the neonate**. Several of the sulfotransferases are present during gestation, where they metabolize hormones and catecholamines. The variation in the function of these two phase II reactions can be seen with the developmental changes in acetaminophen (Tylenol) metabolism. In early infancy, acetaminophen is converted primarily through formation of sulfate conjugates; but with increasing age, glucuronidation becomes the predominate form of metabolism.

c. Although most of the recent research into pediatric drug metabolism has focused on the development of enzyme function in neonates, several new studies highlight additional changes in metabolic function during adolescence. For example, lopinavir (marketed with ritonavir as Kaletra) pharmacokinetics undergoes significant age and gender-related changes at the time of puberty. Lopinavir clearance increases by more than 30% in boys after age 12, compared to minimal changes in clearance in girls after the onset of puberty.

5. **Elimination.** Development of renal function is a complex and dynamic process. Nephrons begin forming as early as the ninth week of gestation and are complete by 36 weeks. Although the functional units of the kidneys are present, their capacity is significantly reduced at birth. Glomerular filtration rate in neonates is approximately half that of adults. Values are further reduced in preterm neonates. Glomerular filtration rate increases rapidly during the first 2 weeks of life and typically reaches adult values by 8 to 12 months of age. Tubular secretion rate is also reduced at birth to approximately 20% of adult capacity but matures by 12 months of age.

    a. **Immature renal function results in significant alterations in the elimination of many drugs.** Pharmacokinetic studies for several drugs, including the aminoglycosides, digoxin (Lanoxin), and vancomycin (Vancocin), have shown a direct correlation between clearance and patient age. Prolongation of the half-life should be anticipated for all renally eliminated drugs administered to neonates and is most pronounced in preterm neonates.

    b. **To account for the reduced ability of a neonate to eliminate these drugs**, **longer dosing intervals are often required.** Failure to account for the reduction in renal function may result in drug accumulation and toxicity. Dosage adjustment is typically based on urine output, with values greater than 1 mL/kg/hr indicating adequate renal function. Although a trend towards increasing serum creatinine over a period of time may indicate worsening renal function, calculation of creatinine clearance is not routinely used to determine drug dosing in pediatrics. Creatinine values in neonates may be falsely elevated during the perinatal period due to transfer of maternal creatinine across the placenta, whereas values in older infants and young children may be low due to limited muscle mass and provide misleading assurance that renal function is adequate. As a result, the equations used for determining creatinine clearance, such as Cockcroft–Gault or Modification of Diet in Renal Disease (MDRD), are not considered appropriate for use in infants and children.

C. **Pharmacodynamic considerations.** Unlike the rapidly accelerating knowledge of the pharmacokinetic changes associated with development, less is known of the pharmacodynamic changes associated with maturation. Preliminary investigations of warfarin (Coumadin) pharmacodynamics have demonstrated a relationship between greater anticoagulant response and increasing patient age. Studies have suggested that neonates may have lower numbers of β-adrenergic receptors, reduced binding affinity, or conformational changes of the receptor binding site, which might explain their decreased responsiveness to dopamine and epinephrine for the treatment of hypotension. Future research in age-related pharmacodynamic changes is needed to optimize the safe and effective use of drugs in infants and children.

D. **Pediatric drug administration and monitoring.** Drug administration, including the selection of agent and dose as well as the preparation of the dose and therapeutic drug monitoring, is complicated in the pediatric population. Pharmacists caring for children must not only be knowledgeable about the changes in pharmacokinetics and pharmacodynamics described previously, but must also be able to use this information in the assessment of the appropriateness of a medication order or prescription. In addition, they should understand the need to carefully check all dosage calculations and be able to alter available dosage formulations when necessary to tailor them for infants and young children.

1. **Accurate dosage calculations are critical in the care of infants and children.** Pharmacists should use pediatric dosing information available in general drug references or pediatric-specific references such as *The Pediatric Dosage Handbook* (Lexi-Comp), the *Harriet Lane Handbook* (Mosby), or *Neofax* (Thomson Reuters). To account for differences in pharmacokinetic parameters, most pediatric doses are based on body weight. In the case of some drugs, such as chemotherapy, doses are based on body surface area (BSA). This value can be determined from the patient's height and weight, using either a nomogram or the following equation:

$$BSA \ (m^2) = \frac{height \ (cm) \times weight \ (kg)}{3600}$$

There is no absolute rule for when adolescent patients should start to be dosed as adults. In general, adult dosing guidelines may be used in patients weighing more than 40 to 50 kg or when the calculated weight-based pediatric dose exceeds the standard adult dose.

2. **The need to calculate pediatric doses introduces a greater risk for dosage errors.** Dosing errors have been found to be more common in medication orders for children than in any other patient population. Studies suggest a medication error rate of 5% to 15% in pediatric inpatients, with the greatest number of errors occurring during the ordering process. The need to calculate individual doses, along with potential decimal errors and transcription errors, increases the potential for mistakes. In addition, there is often a wide range of patient ages and weights within a single hospital or clinic. It is not uncommon to have patient doses vary by 10-fold, as an infant weighing 5 kg and an adolescent weighing 50 kg may be cared for by the same health care providers. Pharmacists practicing in a neonatal intensive care unit may have extremely low birth weight patients weighing as little as 0.5 kg alongside large infants with congenital or birth-related complications weighing 5 kg. All calculations should be double-checked, and orders outside of the normal pediatric dosage range verified with the prescriber. Computerized physician order entry (CPOE) with embedded clinical decision support and dose-checking software reduces the potential for errors but does not replace the need for order review by a trained pharmacist.

3. **Dosage formulations may need to be altered to make them useful for infants and children.** Because young children cannot typically swallow tablets and capsules, these solid dosage formulations must often be converted to oral solutions or suspensions. Several compounding resources, including *Extemporaneous Formulations for Pediatric, Geriatric and Special Needs Patients* (American Society of Health-System Pharmacists) and *Pediatric Drug Formulations* (Harvey Whitney Books), are available to provide pharmacists with formulations that have been tested to ensure drug stability. With coaching, most children can learn to swallow solid dosage forms between 6 and 8 years of age.

4. **Medications must be stored appropriately and doses measured accurately.** Families should be given complete instructions for the storage, use, and disposal of all medications for children. This should include instructions on the accurate measurement of oral liquids. Oral syringes are preferred for infants, but oral dosing spoons and cups may be used for older children. Written information, ideally targeted to the pediatric patient population as in *The Pediatric Medication Education Text* (American College of Clinical Pharmacy), is a useful adjunct to oral communication and allows families to provide detailed instructions to extended family members, preschool and school personnel, babysitters, and other care providers. Safe storage of all household medications should be stressed with all families as a part of good poison prevention practices.

5. **Intravenous (IV) medications may be prepared as more concentrated solutions because of the limits on fluid administration to infants and young children.** Although a typical adult may receive up to 4 to 5 L of IV fluids per day, the total daily fluid requirements for a preterm neonate may be as little as 20 to 50 mL. As a result of these limitations, medication volumes are typically minimized in order to allow more of the daily total to be used to provide either enteral or parenteral nutrition. Special equipment, such as syringe pumps and microbore tubing, is used to ensure accurate delivery of drugs in small fluid volumes. Currently available syringe pumps can deliver volumes as small as 0.1 mL over 1 hr. Smart pump technology, which incorporates dose checking and the ability to set dosing limits, has significantly reduced the frequency of IV medication errors in hospitalized pediatric patients. Microbore IV tubing is used to minimize the amount of dead space between the delivery device and the patient, further improving the accuracy of drug delivery. Pharmacists must also be capable of assessing literature on the compatibility with drugs and IV fluids because pediatric patients often have limited IV access, so that multiple solutions may need to be infused through the same IV site.

E. **Therapeutic drug monitoring** is often essential to optimizing drug therapy in infants and children. For most drugs, including aminoglycosides, antiepileptics, cyclosporine, methotrexate, tacrolimus, and vancomycin, the therapeutic ranges developed for and used in adults are also appropriate for monitoring pediatric patients. A potential complication in interpreting serum drug concentrations is the **presence of endogenous substances**, which may cross-react with analytical drug assays. This has been demonstrated for digoxin (Lanoxin) in neonates and infants, for whom endogenous digoxin-like reactive substances (EDLRS) may produce falsely elevated serum digoxin concentrations. Standard assay techniques can be modified to exclude EDLRS as a complicating factor.

F. **Pharmacists should also be aware of differences in adverse drug reactions between children and adults.** Most of the adverse reaction information available in drug product labeling or cited in pharmacy references has been obtained from clinical trials in adults. As several studies have demonstrated, the adverse reaction profile in children may be significantly different from that observed in older subjects. For example, severe dermatologic reactions to lamotrigine (Lamictal), including Stevens–Johnson syndrome, were infrequent during premarketing phase III clinical trials. When the drug was introduced into the market in the United States and began to be used in children off-label, a higher rate of dermatologic reactions was reported in children. Subsequent research revealed the incidence of severe dermatologic reactions to be 0.8% in children compared to 0.3% in adults. A reduction in the pediatric starting dose, along with recommendations for a more gradual dose escalation, has reduced the number of severe reactions. There are also adverse effects known to occur primarily in children due to pharmacokinetic differences. Valproic acid-induced hepatotoxicity has been reported most frequently in children less than 2 years of age, likely related to their reduced ability to eliminate the toxic 4-en-valproate metabolite. Other examples of drug reactions that occur more often in children than adults include the development of Reye syndrome, a derangement of cellular mitochondrial function resulting in liver failure following aspirin use, and the higher incidence of renal dysfunction with nonsteroidal anti-inflammatory drugs used during the first 6 months of life. Differences such as these further highlight the need for more clinical research in children.

G. In addition, **pharmacists should take an active role in promoting medication adherence (compliance) in children.** Several studies have shown adherence rates in pediatric patients to be 30% to 70%. It is surprising that some of the poorest adherence rates have been associated with chronic diseases such as asthma, epilepsy, and diabetes and in children requiring immunosuppressive therapy after organ transplantation. As in adults, counseling about medication adherence should include efforts to identify and overcome barriers to therapy, education about the importance of medical management, and programs to incorporate medication regimens into normal daily tasks. When working with families of younger children, pharmacists should also explore problems with dosage formulation (such as taste or texture aversion) and dosing frequency. Medications with once or twice daily dosing avoid the need for administration at school or day care and have been shown to increase adherence. In older children and adolescents, pharmacists should be aware of their growing need for autonomy and work with the patient and his or her family to foster the goal of self-care. Most children can begin to take an active role in their medication preparation and administration by the age of 12, although the age at which they can assume responsibility for their treatment varies considerably. As part of an interdisciplinary health care team, pharmacists can serve a vital role in improving medication adherence, reducing the likelihood of treatment failure and supporting a lifelong commitment to a healthy lifestyle among their pediatric patients.

Study Questions

Directions for questions 1–14: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

For questions 1–4: AH is a 1.2-kg female born prematurely at 30 weeks of gestational age. Her mother had an infection with a fever at the time of delivery. AH was admitted to the neonatal intensive care unit for presumed sepsis and placed on empiric antibiotic therapy with ampicillin (50 mg/kg IV every 12 hrs) and gentamicin (2.5 mg/kg IV every 8 hrs).

1. Which of the following variables will *most* likely be used to calculate doses for AH's antibiotics?
   (A) Height
   (B) Hepatic function
   (C) Weight
   (D) Age
   (E) Serum creatinine

2. After the administration of four doses of gentamicin, a serum concentration obtained 5 mins before the next dose was 2.5 mcg/mL. Which of the following answers best describes the pharmacokinetic differences observed in premature neonates (compared to older children and adults) that might explain this value?

(A) Larger volume of distribution, longer half-life
(B) Larger volume of distribution, shorter half-life
(C) Smaller volume of distribution, longer half-life
(D) Smaller volume of distribution, shorter half-life
(E) Similar volume of distribution, shorter half-life

3. Ampicillin may exhibit pharmacokinetic differences in AH because of its protein binding characteristics. Which of the following answers best describes the effect of AH's age on ampicillin protein binding?

(A) Increased protein binding, resulting in a greater free fraction
(B) Increased protein binding, resulting in a reduced free fraction
(C) Decreased protein binding, resulting in a greater free fraction
(D) Decreased protein binding, resulting in a reduced free fraction
(E) Decreased protein binding, resulting in no significant change in free fraction

4. As the pharmacist providing services for the neonatal intensive care unit, you evaluate medication orders and make recommendations to the medical team. Which of the following would be the *most* appropriate recommendation for AH's care?

(A) Change to oral antibiotics for better absorption.
(B) Double-check the calculations to avoid decimal errors.
(C) Dilute the gentamicin with a larger volume of IV fluids to make it easier to measure.
(D) Use a pediatric-specific therapeutic range for monitoring gentamicin.
(E) Change to sulfamethoxazole and trimethoprim (Bactrim) for single-agent antibacterial coverage.

5. Although the total body water content of an adult accounts for approximately 60% of body weight, the total body water content of a healthy newborn is

(A) 40%.
(B) 50%.
(C) 70%.
(D) 80%.
(E) 90%.

6. Administration of a sulfonamide antibiotic may displace bilirubin from binding sites on which of the following substances, leading to passage of bilirubin into the brain and the development of kernicterus?

(A) α_1-acid glycoprotein
(B) albumin
(C) β-adrenergic receptors
(D) uridine 5′-diphosphate glucuronosyltransferase
(E) sulfotransferase

7. Caffeine administered to neonates for the treatment of apnea of prematurity undergoes metabolism through which of the following cytochrome P450 enzymes, also the last major drug-metabolizing enzyme to develop after birth?

(A) CYP1A2
(B) CYP2C19
(C) CYP2D6
(D) CYP3A4
(E) CYP3A7

8. Both glomerular filtration and tubular secretion rates are reduced in infants compared to adults. Which list of drugs is the *most* likely to have prolonged clearance during infancy because of immature renal function alone?

(A) Amikacin, caffeine, and retinoic acid
(B) Acetaminophen, atomoxetine, and retinoic acid
(C) Acetaminophen, benzyl alcohol, and vancomycin
(D) Amikacin, gentamicin, and vancomycin
(E) Atomoxetine, lopinavir, and vancomycin

9. As a pharmacy manager in a children's hospital, you are responsible for implementing new technologies that have the potential to reduce medication errors in children. Which of the following has the *most* potential to reduce the largest number of errors?

(A) Bar-code scanning
(B) CPOE with dose-checking software
(C) Inventory management systems
(D) Smart pump technology
(E) Standard IV concentrations

10. You are counseling the grandmother of a 3-year-old boy who has a prescription for amoxicillin/clavulanate (Augmentin) to treat uncomplicated otitis media. Which of the following issues would be *least* likely to affect medication adherence (compliance)?

(A) Lack of education about the medication
(B) Cost
(C) Dosing interval (frequency)
(D) Taste
(E) Autonomy

Answers and Explanations

1. **The answer is C** *[see I.D.1]*.
   Most pediatric doses are based on body weight. This single variable incorporates growth and maturation while allowing a simple calculation for dose. Height is often difficult to measure accurately in children, and the calculation of body surface area is typically reserved for those drugs with narrow therapeutic indices, such as chemotherapy.

2. **The answer is A** *[see I.B.3.a; I.B.5]*.
   Aminoglycosides such as gentamicin exhibit a larger volume of distribution in neonates because of their larger body water content. Neonates also typically have a longer elimination half-life as the result of having reduced renal function during the first 6 months of life.

3. **The answer is C** *[see I.B.3.b; Table 27-2]*.
   Neonates have both a reduced quantity of plasma proteins as well as a reduction in the affinity of albumin to bind to other substances. As a result, the free fraction of many drugs, including ampicillin, is increased.

4. **The answer is B** *[see I.D; I.E]*.
   All pediatric orders should be carefully checked for calculation errors. Errors are more common in the pediatric population as the result of weight-based dosing and the need for mathematical calculations. The use of the oral route would not be advisable in this patient because of the potential reduced drug absorption. Likewise, the dilution of the dose with more IV fluid or the use of a sulfa drug would not be appropriate for this patient's age. Finally, the therapeutic range for gentamicin is the same in pediatric patients as in adults.

5. **The answer is D** *[see I.B.3.a]*.
   A healthy newborn will have total body water content approximately 80% of his or her body weight. The higher total body water content is the result of larger extracellular body water content. This value will decrease over the first year of life to reach adult values by 1 year of age.

6. **The answer is B** *[see I.B.3.b; I.B.4.b]*.
   Like bilirubin, sulfonamides and other acidic drugs bind to albumin in human serum. In contrast, basic substances bind to α_1-acid glycoprotein. Uridine 5′-diphosphate glucuronosyltransferase and sulfotransferase are metabolic enzymes involved in conjugation.

7. **The answer is A** *[see I.B.4.a]*.
   Caffeine is metabolized via CYP1A2 to demethylated xanthines: paraxanthine, theobromine, and theophylline. CYP1A2 is the last of the major drug-metabolizing enzymes to develop during infancy, reaching peak enzymatic activity by 4 to 6 months of life. The pharmacokinetic profile of caffeine during infancy has been extensively studied, with initial publications dating to the 1970s.

8. **The answer is D** *[see I.B.4–5]*.
   The aminoglycosides (amikacin, gentamicin, and tobramycin) and vancomycin are examples of drugs that undergo renal elimination and as a result have prolonged clearance in infants. Acetaminophen, atomoxetine, caffeine, lopinavir, and retinoic acid are metabolized. Their clearance is more heavily influenced by hepatic enzymatic activity than by glomerular filtration or tubular secretion rates.

9. **The answer is B** *[see I. D]*.
   Mistakes made during ordering account for the largest percentage of pediatric medication errors. The need to calculate the appropriate weight-based dose places the prescriber at risk for mathematical errors, including decimal errors resulting in 10-fold variations in dose. Dose-checking software, a common feature of the CPOE systems of many hospitals and many retail pharmacies, has been shown in several studies to significantly reduce prescriber errors. The other methods, although all associated with reductions in medication error rates, have produced less dramatic results.

10. **The answer is E** *[see I.G]*.
    Although the other options are all important aspects of counseling to enhance medication adherence in children, autonomy (the ability to provide self-care or give medications independently) would not be a consideration for a 3-year-old child. Autonomy becomes a much more critical issue in determining adherence in adolescence.

Geriatrics

28

ALAN H. MUTNICK

I. DRUG USE IN GERIATRIC PATIENTS. In 2000, more than 12% of the American population was > 65 years of age, representing more than 35 million Americans, while consuming approximately 30% of all health care costs. It is estimated that three out of every four elderly people are taking prescription medications. Anticipated total drug usage, including nonprescription medications, reveals that 50% of all drugs used in the United States are used by the geriatric population.

A. **Adverse drug reactions.** Geriatric patients are at increased risk for drug-induced adverse effects. Incidence of adverse drug reactions (ADRs) in patients older than 65 years is two to three times greater compared to younger patients. The risk is five times higher in people approaching age 90. One in five of all elderly patients experience an ADR. In some patients, these are overlooked because they mimic the characteristics of other diseases.

1. Factors that are responsible for the higher prevalence of ADRs in the geriatric population include polypharmacy, multiple disease states, altered pharmacokinetic disposition among the elderly (reduced drug elimination, increased sensitivity to drug effects, etc.), poor relationship with health care providers, increasing severity of illness, and poor patient compliance and supervision.

   a. Studies have shown that > 35% of geriatric patients living in the community use six or more medications; approximately one-half of patients residing in long-term care facilities use five or more medications. People 65 years and older use approximately 40% of the drugs prescribed and 50% of the over-the-counter (OTC) medications taken.

   b. Patients taking multiple medications have a greater chance of experiencing ADRs owing to drug–drug interactions and the potential for overlap or synergy between adverse effect profiles.

   c. Patients with multiple disease states are at higher risk for having a drug–disease state interaction.

   d. In addition to the aforementioned risk factors for developing an ADR, it is difficult to predict how geriatric patients will respond to any given medication owing to altered pharmacokinetic and pharmacodynamic profiles.

   e. Another issue complicating geriatric drug therapy is adherence. Factors that have been shown to increase nonadherence include poor relationships with health care providers, lower socioeconomic status, living alone, polypharmacy, complicated drug regimens, and multiple comorbidities. As many as 60% of geriatric patients do not take their medications as prescribed and may self-medicate as often as once a week. If patients are hospitalized, their prescribed drug doses may represent a significant overdosage or underdosage, which could cause unintended effects.

   f. Elderly patients can have diseases that make adhering to drug therapy difficult. Conditions that affect vision, such as macular degeneration or cataract formation, can make reading prescription labels and medication instructions troublesome. Hearing loss can prevent patients from understanding and health care professionals from effectively communicating medication information and patient instructions. Arthritis can add to the difficulty of opening medication bottles. In these instances, providing patients with medication or "pill" boxes and written medication lists may limit potential barriers to patient adherence. Recognizing these factors, pharmacists can increase adherence in elderly patients.

519

2. Pharmacists can provide recommendations to eliminate unnecessary drug therapy and monitor medication profiles to avoid potential drug–drug or drug–disease state interactions that may prove harmful. Efforts to optimize drug therapy, including simplifying and employing more cost-effective regimens, may ultimately afford better patient adherence.

B. **Pharmacokinetics.** Pharmacokinetic parameters may be altered in the elderly owing to age-related physiological changes. Specific age-related physiological changes affecting drug therapy are given in *Table 28-1*.

1. **Absorption.** Physiological changes that can alter absorption in the geriatric population include delayed gastric emptying, decreased splanchnic blood flow, elevated gastric pH, and impaired intestinal motility. Although the rate of drug absorption may be altered in some patients, the extent of absorption is rarely affected, and this represents the least affected parameter in the elderly.

2. **Distribution.** Several age-related physiological changes may affect drug distribution.

   a. Elderly patients have a decrease in total body water with a proportionate increase in body fat, causing water-soluble drugs (e.g., digoxin [Lanoxin®]) to have a smaller volume of distribution. Peak concentrations of water-soluble agents will be higher, and loading doses may need to be adjusted to incorporate this change.

   b. The volume of distribution of lipid-soluble drugs (e.g., diazepam [Valium®]; propranolol [Inderal®]) is increased due to the proportionate increase in body fat, which will result in their accumulation in fat stores and increasing their duration of action. For some patients, this will increase the risk of adverse effects due to prolonged sedation as well as greater predisposition to falls.

   c. The aging process has also been shown to affect the pharmacokinetics of drugs that are highly protein bound. Drugs that are highly bound to albumin (e.g., warfarin [Coumadin®]; phenytoin [Dilantin®]) may have a greater free concentration due to decreased albumin levels in the elderly who are chronically ill.

   d. Additionally, there are other substances, some medications as well as other substances within the body, that may alter binding affinity in the elderly to albumin, or albumin may even experience a change in configuration, which can also lower binding capacity. Competition for acidic binding sites could occur with accumulated endogenous substances, altering the free fraction of drugs.

| Table 28-1 | AGE-RELATED PHYSIOLOGICAL CHANGES AFFECTING DRUG THERAPY |

Factors	Change	Clinical Significance
Pharmacokinetic		
Gastrointestinal motility	↓	May affect the rate but not the extent of drug absorption
Gastric pH	↑	No significant change in drug absorption
Renal function	↓	Reduced elimination of renally excreted drugs
Serum albumin	↓	Decreased protein binding leading to an increased free fraction of drug
Phase I hepatic metabolism	↓	Potential accumulation of drugs metabolized by oxidation, reduction, or hydrolysis reactions
Body fat to lean muscle mass ratio	↑	Increased volume of distribution of fat-soluble drugs
Total body water	↓	Decreased volume of distribution of water-soluble drugs
Pharmacodynamic		
β-Receptor sensitivity	↓	Potential diminished response to β-blockers
Baroreceptor sensitivity	↓	Greater risk of orthostatic hypotension
Response to benzodiazepines and opioid analgesics	↑	Increased risk of adverse effects with typical doses

   e. Although α_1-acid glycoprotein (AGP) concentrations tend to increase with age, the increase in the concentrations of basic drugs (e.g., lidocaine [Xylocaine®]; propranolol [Inderal®]) that bind to AGP are usually clinically meaningful only in acutely ill patients.

   f. Based on available clinical literature, the elderly have a higher predisposition to the acute effects of medications when combinations of highly protein bound agents are given concomitantly without taking into account the drug–drug interaction taking place at protein binding sites. Drugs such as phenytoin (Dilantin®), diazepam (Valium®), propranolol (Inderal®), valproic acid (Depakene®), warfarin (Coumadin®), and salicylates require extra monitoring in the elderly in order to avoid the consequences associated with altered protein binding.

3. Renal excretion. Perhaps the best documented and most predictable age-related physiological change is the decline in renal function, specifically glomerular filtration rate and the tubular secretion rate.

   a. In patients without renal dysfunction, it is estimated that there is a 50% decline in renal function by age 80. Renal blood flow is reduced by approximately 10% each decade of life. Estimates of the serum creatinine level are the closest predictor of renal function that is currently available. As serum creatinine increases, there is a reciprocal reduction in creatinine clearance and glomerular filtration rate.

   b. Although serum creatinine may be the best predictor of renal function, it is not always accurate in the elderly because creatinine production also declines with age and with lower activity levels (such as being bedridden or debilitated).

   c. Medications primarily eliminated by the kidneys may have increased concentrations of both the active drug and its metabolites possibly leading to subsequent adverse effects. All renally eliminated drugs used in geriatric patients should be monitored for the need for dose reductions and potential toxicity.

   d. Cockcroft and Gault equation is a useful "estimate" of creatinine clearance, but its limitations in the elderly must be appreciated, due to reduced creatinine synthesis and consequential reductions in levels due to reduced muscle mass.

$$\text{Males: Creatinine clearance (mL/min)} = \frac{(140 - \text{age}) \times \text{weight kg}}{72 \text{ serum creatinine (mg/dL)}}$$

Females:
85% of male value (not applicable if serum creatinine > 5 mg/dL)

4. Hepatic metabolism. Age-related changes affecting the liver include a reduction in hepatic blood flow and a decline in hepatic metabolism.

   a. A reduction in phase I reactions (oxidation, reduction, and hydrolysis) occurs in the elderly and may prolong the activities of drugs metabolized by these enzymes. The long-acting benzodiazepine diazepam (Valium®), phenytoin (Dilantin®), cimetidine (Tagamet®), and certain analgesics, which depend on phase I reactions for metabolism, represent situations in which changes in hepatic metabolism may be important. The elimination half-lives of these agents would be prolonged and may result in drug accumulation and the predisposition to adverse drug effects.

   b. Phase II reactions (glucuronidation, acetylation, and sulfation) are relatively unchanged in the elderly. Several short acting benzodiazepines such as oxazepam (Serax®) and lorazepam (Ativan®) undergo phase II reactions and represent relatively safe agents to administer to the elderly for that reason.

   c. Liver blood flow has been demonstrated to fall approximately 50% between the ages of 20 and 80 years. This becomes a critical parameter for those drugs, which have high extraction rates by the liver such as propranolol (Inderal®), lidocaine (Xylocaine®), and the earlier tricyclic antidepressants. Such alterations in the rate of liver extraction would require careful titration to pharmacologic effect in order to avoid an excess response and the potential for toxicity.

   d. Liver volume and cell mass decrease in the elderly. It appears that this change in size enhances the reduced activity of oxidative and demethylation metabolism. Conjugation reactions do not appear to be affected by liver mass.

C. Pharmacodynamics

1. Geriatric patients can be more or less responsive to certain drugs compared to younger patients. Reasons for this may include altered receptor sensitivity, receptor number, or receptor response. Studies have shown that elderly patients may show a diminished response to β-blockers and β-agonists.

2. In contrast, geriatric patients have an exaggerated response to anticholinergic drugs—drugs affecting the CNS such as narcotics, analgesics, benzodiazepines, and warfarin. Elderly patients should be monitored carefully when taking these medications. Initiation of any of these therapies should be at lower doses than recommended for younger patients. Avoidance of these drugs may not be possible, but if better alternatives exist, they should be used first.

D. Drug therapy considerations

1. Drug therapy in geriatric patients is an involved process and can be very complex because of age-related changes in pharmacokinetics and pharmacodynamics.

2. Additionally, a lack of clinical trials designed to evaluate the safety and efficacy of drug therapy in the elderly population increases the problem.

3. The higher incidence of adverse effects in geriatric patients may be in part the result of the complexity of drug therapy and the relative lack of clinical trials in this population. *Table 28-2* lists several drugs and doses that should be avoided in the elderly owing to higher risks of adverse effects and/or lack of efficacy.

4. Owing to alterations in gait, balance, and mobility, falls and consequent adverse events are frequent occurrences in geriatric patients.

   a. The high prevalence of osteoporosis in the elderly results in an increased incidence of fractures. Complications associated with fractures, particularly hip fractures, are significant causes of morbidity and mortality.

   b. Medications causing orthostatic hypotension, drowsiness, dizziness, blurred vision, or confusion have the potential to cause or worsen postural instability and increase falls in the elderly.

   c. It is well established that many psychoactive agents, especially long-acting benzodiazepines, are associated with an increased risk of falls in the elderly. If a benzodiazepine must be prescribed, low-dose lorazepam (Ativan®) or oxazepam (Serax®) are better choices because of the lack of active metabolites and their metabolism involves phase II hepatic reactions only.

5. Geriatric patients tend to be sensitive to medications that possess anticholinergic effects. Dry mouth, urinary retention, blurred vision, constipation, tachycardia, memory impairment, and confusion are typical anticholinergic adverse effects associated with several classes of drugs (*Table 28-3*). These agents can also induce delirium in some people.

   a. When possible, drugs with anticholinergic effects should be avoided in the elderly. In those instances when this is not an option, the least anticholinergic agent should be chosen and initiated at the lowest effective dose. For example, if a tricyclic antidepressant is needed, desipramine (Norpramin®) and nortriptyline (Pamelor®) possess less anticholinergic activity than amitriptyline (Elavil®) and imipramine (Tofranil®) and therefore would be better initial therapeutic options.

   b. Frequent monitoring for and patient and family education on signs and symptoms of possible anticholinergic adverse effects is always warranted when these drugs are prescribed in the elderly.

E. General principles. To aid clinicians in providing appropriate geriatric drug therapy, some general principles have been developed.

1. Start with a low dose, and titrate the medication dose slowly.

2. Owing to reduced renal and hepatic function, the half-lives of many drugs are prolonged in the elderly. Selection of agents should involve consideration of the specific pharmacokinetics of each drug in the geriatric population.

3. Rapid dose escalations prevent attainment of the optimal therapeutic response because a steady-state concentration of the drug is not reached and increases the risks of developing an ADR.

4. The fewest number of drugs should always be used to treat patients.

5. Always evaluate possible drug toxicity. Geriatric patients can have atypical presentations of ADRs, which may manifest as CNS changes (e.g., altered mental status).

6. Review concomitant medications and diseases to evaluate the possible interactions with new drugs.

7. Reassess the need for each medication on a regular basis.

| Table 28-2 | TARGET DRUGS AND DOSES TO AVOID IN GERIATRIC PATIENTS |

Drug	Comments
Analgesics	
Pentazocine (Talwin)	Avoid; safer and more effective alternatives
Meperidine (Demerol)	Avoid; safer and more effective alternatives
Antidepressants	
Amitriptyline (Elavil)	Avoid; anticholinergic adverse effects, increased risk of falls, and QT prolongation; use nortriptyline or desipramine as alternatives
Amitriptyline, perphenazine (Triavil)	Avoid; use separate antidepressant and antipsychotic agents in appropriate geriatric doses as necessary
Doxepin (Sinequan)	Avoid; safer and more effective alternatives
Antiemetics	
Trimethobenzamide (Tigan)	Avoid; more effective alternatives available
Antihistamines	
Sedating OTC agents, cold preparations	Avoid; potent anticholinergic effects
Hydroxyzine (Atarax)	Avoid; potent anticholinergic effects
Cyproheptadine (Periactin)	Avoid; potent anticholinergic effects
Chlorpheniramine (Chlor-Trimeton)	Avoid; potent anticholinergic effects
Antihypertensives	
Hydrochlorothiazide (HydroDIURIL)	Doses > 25 mg/day should be avoided
Methyldopa (Aldomet)	Avoid; safer alternatives
Propranolol (Inderal)	Lipophilic nonselective β-blocker with increased potential for adverse effects; avoid; use a cardioselective β-blocker instead
Reserpine	Avoid; risk of adverse effects (e.g., sedation, depression)
Antipsychotics	
Haloperidol (Haldol)	Avoid unless indicated for psychotic disorder; use in small doses (1 mg); risk of sudden death in higher doses
Thioridazine (Mellaril)	Avoid unless indicated for psychotic disorder
Antispasmodics	
Belladonna	Avoid long-term use; anticholinergic adverse effects
Dicyclomine (Bentyl)	Avoid long-term use; anticholinergic adverse effects
Hyoscyamine (Pyridium)	Avoid long-term use; anticholinergic adverse effects

Table 28-2   Continued.

Drug	Comments
Decongestants	
Oxymetazoline (Afrin)	Daily use for > 3 days should be avoided
Phenylephrine (Neo-Synephrine)	Daily use for > 3 days should be avoided
Pseudoephedrine (Sudafed)	Avoid; anticholinergic effects and potential to raise blood pressure
H2 antagonists	
Cimetidine (Tagamet)	Avoid; adverse CNS effects
Hypoglycemic agents	
Chlorpropamide (Diabinese)	Avoid; long half-life can cause prolonged hypoglycemic episodes and can induce SIADH
Muscle relaxants	
Carisoprodol (Soma)	Risk of adverse events greater than potential benefits; all use should be avoided
Cyclobenzaprine (Flexeril)	Risks of adverse events greater than potential benefits
Methocarbamol (Robaxin)	Risks of adverse events greater than potential benefits
Orphenadrine (Norflex)	Risks of adverse events greater than potential benefits
NSAIDs	
Indomethacin (Indocin)	Avoid; CNS adverse effects; use alternative NSAID
Noncyclooxygenase selective NSAIDs	Avoid long-term use of naproxen, oxaprozin and piroxicam; increased risks of adverse effects
Platelet inhibitors	
Dipyridamole (Persantine)	Avoid; lack of efficacy and adverse effects (orthostatic hypotension) at high doses; aspirin is safer and more effective
Sedative hypnotics	
Long-acting benzodiazepines Chlordiazepoxide (Librium) Diazepam (Valium) Flurazepam (Dalmane)	Avoid; accumulation and increased risk of falls, sedation, and delirium
Short-acting benzodiazepines Alprazolam (Xanax) Oxazepam (Serax) Triazolam (Halcion)	Nightly use should be avoided; increased risk of falls, daytime sedation, and delirium
Meprobamate (Miltown)	All use should be avoided
Barbiturates	All use should be avoided; safer alternatives exist

CNS, central nervous system; *NSAIDs*, nonsteroidal anti-inflammatory drugs; *OTC*, over-the-counter; *SIADH*, syndrome of inappropriate antidiuretic hormone secretion. Modified with permission from Fick DM, Cooper JW, Wade WE, et al. Updating the Beers criteria for potentially inappropriate medication use in older adults. *Arch Intern Med.* 2003;163:2716–2724.

Table 28-3	DRUGS AND DRUG CLASSES POSSESSING ANTICHOLINERGIC EFFECTS

Antidiarrheal agents
  Diphenoxylate/atropine (Lomotil)
Antiemetics/antivertigo agents
  Meclizine (Antivert)
  Scopolamine (Transderm scopolamine)
  Trimethobenzamide (Tigan)
  Promethazine (Phenergan)
  Prochlorperazine (Compazine)
Antihistamines, sedating types
Antipsychotic agents
Antispasmodics
  Belladonna alkaloids
  Chlordiazepoxide/clidinium-Librax
  Dicyclomine (Bentyl)
  Hyoscyamine (Pyridium)

Propantheline (Pro-Banthine)
Oxybutynin (XL formulation has fewer effects) (Ditropan)
Tolterodine (Detrol)
Class Ia antiarrhythmic agents
  Disopyramide (Norpace)
  Quinidine
Parkinson's agents
  Amantadine (Symmetrel)
  Benztropine (Cogentin)
  Procyclidine (Kemadrin)
  Trihexyphenidyl-Artane
Skeletal muscle relaxants
  Cyclobenzaprine (Flexeril)
  Orphenadrine (Norflex)
Tricyclic antidepressants

Study Questions

Directions for questions 1–14: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following medications due to its lack of active metabolites and dependency on phase II hepatic reactions is least likely to cause a fall in a geriatric patient?

   (A) amitriptyline (Elavil®)
   (B) haloperidol (Haldol®)
   (C) benztropine (Cogentin®)
   (D) diazepam (Valium®)
   (E) oxazepam (Serax®)

2. Which of the following drugs would be expected to cause anticholinergic adverse effects in the elderly?

   (A) diazepam (Valium®)
   (B) ciprofloxacin (Cipro®)
   (C) tolterodine (Detrol®)
   (D) propranolol (Inderal®)
   (E) cimetidine (Tagamet®)

3. Which of the following antihypertensive agents should be avoided in elderly patients?

   (A) amlodipine (Norvasc®) 5 mg every day
   (B) atenolol (Tenormin®) 25 mg every day
   (C) benazepril (Lotensin®) 10 mg every day
   (D) hydrochlorothiazide (HydroDIURIL®) 25 mg every day
   (E) methyldopa (Aldomet®) 250 mg three times a day

4. Which of the following benzodiazepines is expected to cause the *least* amount of adverse effects in the elderly?

   (A) chlordiazepoxide (Librium®)
   (B) diazepam (Valium®)
   (C) flurazepam (Dalmane®)
   (D) lorazepam (Ativan®)
   (E) temazepam (Restoril®)

5. Which of the following factors is associated with an increased risk of noncompliance in the elderly?

   (A) Polypharmacy
   (B) Hypertension
   (C) Living with a spouse in an isolated environment
   (D) Expensive medications
   (E) Good relationship with physician

Directions for questions 6-7: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

    A if **I only** is correct
    B if **III only** is correct
    C if **I and II** are correct
    D if **II and III** are correct
    E if **I, II, and III** are correct

6. Which of the following pharmacokinetic parameters is most likely to affect the manner in which a drug will affect a geriatric patient?

    I. Drug absorption
    II. Phase I reactions within the liver
    III. Drug distribution

7. Which of the following statements regarding renal excretion in the geriatric patient is correct?

    I. All renally eliminated drugs should be monitored for the need for dose reductions in order to reduce potential toxicity.
    II. Cockcroft–Gault formula provides a good estimation of creatinine clearance in most patient populations.
    III. Serum creatinine is a very sensitive indicator of renal function in the elderly.

8. Patient AM is a 60-year-old obese Caucasian male who is about to be started on several renally eliminated drugs for various diseases he has been diagnosed with. Patient is 5′9″, weighs 220 lb, and has a serum creatinine of 2.0 mg/dL. What is Mr. AM's calculated creatinine clearance?

    (A) 56 mL/min
    (B) 128 mL/min
    (C) 47 mL/min
    (D) 109 mL/min
    (E) 100 mL/min

Answers and Explanations

1. **The answer is E** *[see I.D.4.b–c and I.B.4.b].*
Medications that can cause orthostatic hypotension, drowsiness, dizziness, blurred vision, or confusion have the potential to cause falls in geriatric patients. Psycho-active agents such as haloperidol along with long-acting benzodiazepines such as diazepam are associated with an increased risk of falls in the elderly. Additionally, agents that have high anticholinergic effects can cause blurred vision while also being capable of inducing delirium (amitriptyline [Elavil®]; benztropine [Cogentin®]). However, oxazepam is a short-acting benzodiazepine dependent on phase II reactions for metabolism, which are not affected by advancing age, and would be a suitable alternative in the elderly patient.

2. **The answer is C** *[see I.D.5.a; Table 28-3].*
Tricyclic antidepressants, antispasmodics, antiemetics, and Parkinson's agents represent the largest group of drugs possessing anticholinergic activity, which have the potential for inducing significant negative effects in the elderly. Blurred vision, urinary retention, constipation, dry mouth, tachycardia, and memory impairment are a few of the significant side effects associated with their use in the elderly. Tolterodine, an antispasmodic, works by antagonizing acetylcholine receptors, which aids patients with an overactive bladder. However, this anticholinergic effect can pose substantial problems in elderly patients due to the side effects associated with its use.

3. **The answer is E** *[see I; Table 28-2].*
The use of methyldopa should be avoided in elderly patients owing to risk of CNS adverse effects and hypotension. Hydrochlorothiazide should be avoided in elderly patient when doses are expected to exceed 25 mg per day.

4. **The answer is D** *[see I.B.4.a–b and I.D.4.c; Table 28-2].*
Chlordiazepoxide, diazepam, and flurazepam should be avoided in elderly patients owing to active metabolites and long-elimination half-lives. Lorazepam represents the safest alternative because of a relatively short half-life, absence of active metabolites, and it is dependent on phase II hepatic metabolism, which is minimally affected with aging while being devoid of phase I hepatic metabolism.

5. **The answer is A** *[see I.A.1.e].*
Lower socioeconomic status, living alone, polypharmacy, complicated drug regimens, poor relationships with health care providers, and multiple disease states are all risk factors for noncompliance in the geriatric population.

6. The answer is D; II and III are correct
[see I.B.1–4].
Phase I reactions (oxidation, reduction, and hydrolysis) can be reduced in the elderly, and several therapeutic classes such as benzodiazepines and select analgesics represent situations in which changes in hepatic metabolism may be important due to a prolongation of plasma half-lives with a resultant drug accumulation. Drug absorption has been shown to be altered in the elderly; however, the level of alterations has not yet been shown to affect the extent of absorption being reduced. Phase II reactions in the liver are represented by glucuronidation, acetylation, and sulfation and have not yet been shown to require therapeutic adjustments while dosing such agents.

7. The answer is C; I and II are correct
[see I.B.3.a–d].
The disposition of drugs administered to patients, which are eliminated renally, is the best documented age-related change, which occurs in the elderly. The need to monitor such agents and adjust their doses based on elimination characteristics will help reduce added accumulation and the tendency for toxicity in those with declining renal function. The elderly are predisposed to such effects as renal function is reduced with advancing age. The Cockcroft–Gault formula is a useful tool for estimating most patients' creatinine clearance, when given a serum creatinine; however, it must be recognized that it provides merely an estimate and might not reflect exact renal function

is all patient populations. The serum creatinine is used as an indirect measurement for renal function primarily due to its relationship to creatinine clearance and glomerular filtration rate. However, in the elderly due to reduced levels of muscle and consequent reductions in the degree of creatinine produced, normal levels of serum creatinine do not translate into normal levels of renal function.

8. The answer is A *[see I.B.3.d].*

$$\text{Creatinine Clearance (mL/min)} = \frac{(140 - \text{age}) \times (\text{weight kg})}{72 \times \text{serum creatinine (mg/dL)}}$$

$$\text{Creatinine Clearance (mL/min)} = \frac{(140 - 60) \times (100 \text{ kg})}{72 \times \text{serum creatinine (2.0 mg/dL)}}$$

$$\text{Creatinine Clearance (mL/min)} = \frac{(80) \times (100 \text{ kg})}{72 \times (2.0 \text{ mg/dL})}$$

$$\text{Creatinine Clearance (mL/min)} = \frac{8000}{144}$$

$$\text{Creatinine Clearance (mL/min)} = 55.6 \text{ mL/min} = 56$$

Women's Health

JULIE J. KELSEY

I. PREMENSTRUAL SYNDROME/PREMENSTRUAL DYSPHORIC DISORDER

- **A. Definition.** Premenstrual syndrome (PMS) occurs in many women from 2 to 14 days before the onset of menstruation. Women with PMS can experience abdominal bloating, weight gain, appetite changes, fatigue, tension, mastalgia, headaches, irritability, depressed or labile mood, anxiety, or be oversensitive to environmental stimuli. Women with premenstrual dysphoric disorder (PMDD) often have major depression, frequently have persistent anger, irritability, anhedonia, and feel overwhelmed or out of control.
- **B. Epidemiology.** PMS is quite common (up to 75%) and usually mild; however, 20% to 30% of women have clinically significant PMS that interferes with their normal routines. The more debilitating PMDD is seen only in 3% to 8% of menstruating women. Symptoms typically cease at or soon after the onset of menstruation.
- **C. Cause.** The exact cause of the conditions is unknown, but hormones likely play a role.
- **D. Treatment** is multimodal, including lifestyle and dietary changes, cognitive behavioral therapy, and pharmacological treatment.
  1. **Lifestyle/dietary changes.** Regular exercise, good sleep hygiene, and reduced sodium intake are often helpful.
  2. **Vitamin supplementation.** Some recommendations include 600 mg calcium twice daily, 200 to 400 mg magnesium daily, pyridoxine 50 to 100 mg daily, or vitamin E 400IU daily to decrease symptoms.
  3. **Analgesics.** Agents such as nonsteroidal anti-inflammatory drugs, including mefenamic acid (Ponstel) or acetaminophen for headaches, menstrual cramping, and breast tenderness.
  4. **Diuretics.** Spironolactone (Aldactone) may be helpful for fluid weight gain.
  5. **Oral contraceptives.** These may be helpful to reduce symptoms. Drospirenone-containing contraceptives (e.g., Yaz, Yasmin) may be most beneficial because of the similarity to spironolactone. A shortened hormone-free period also should be considered.
  6. **Antidepressants** (*Table 29-1*)**.** Agents may be taken throughout the cycle or only during the luteal phase (days 14 to 28). Relief of symptoms should occur in the first cycle. Meta-analyses have demonstrated that intermittent dosing is less effective than continuous dosing.

II. POLYCYSTIC OVARIAN SYNDROME

- **A. Definition.** Polycystic ovarian syndrome (PCOS) is a disorder of chronically abnormal ovarian function and hyperandrogenism (abnormally elevated androgen levels). PCOS is also called the Stein–Leventhal syndrome.
- **B. Epidemiology.** PCOS occurs in approximately 1 in 15 women (6% to 8%) and is the most common hormonal disorder in menstruating women. The syndrome was initially described 75 years ago based on the abnormal appearance of the ovaries and includes signs and symptoms of hyperandrogenism such as acne, hirsutism in 60% to 70%, male pattern baldness, menstrual disturbances (oligomenorrhea or amenorrhea), and dark and velvety skin (acanthosis nigricans). Obesity is present in approximately half of women affected by the syndrome.

| Table 29-1 | ANTIDEPRESSANTS FOR PREMENSTRUAL DYSPHORIC DISORDER |

Antidepressant	Recommended Doses
Fluoxetine (Prozac)	10–60 mg daily, 90 mg weekly
Sertraline (Zoloft)	50–150 mg daily
Paroxetine (Paxil)	20–30 mg daily
Citalopram (Celexa)	20–30 mg daily
Venlafaxine (Effexor)	50–200 mg daily (extended-release)
Duloxetine (Cymbalta)	60 mg daily (case reports only)
Clomipramine (Anafranil)	25–75 mg daily

C. **Cause.** Inappropriate gonadotropin secretion leads to insulin resistance and hyperinsulinemia as well as excessive androgen production.

D. **Complications.** Complications of PCOS include the development of diabetes, metabolic syndrome, increased cardiovascular risk factors (hypertension, dyslipidemia, and early markers of atherosclerosis), obstructive sleep apnea, infertility, endometrial hyperplasia in 30% to 50%, and an increased risk of endometrial carcinoma.

E. **Treatment** includes dietary and lifestyle changes and pharmacologic therapy to minimize disease manifestation.

1. **Dietary/lifestyle changes.** Weight loss of 5% to 10% can reduce insulin and androgen levels and restore regular menstrual cycles. A diet low in saturated fat, high in fiber, and containing low glycemic index foods is recommended. Regular exercise also helps improve insulin resistance.

2. **Oral contraceptives.** Regulation of the menstrual cycle can reduce androgen production and reduce the risk of endometrial hyperplasia and cancer.

3. **Metformin.** Metformin (Glucophage) cannot only slow the progression to type 2 diabetes in women with prediabetes, it also improves ovulation leading to more cycle regularity. It can also improve the likelihood of pregnancy in women trying to conceive. The minimum dose is 500 mg three times daily.

4. **Thiazolidinediones** have been studied to improve ovulation and increase the pregnancy rate in women with PCOS.

5. **Spironolactone.** Spironolactone decreases the incidence of hirsutism by 40% to 88%. Doses of 50 to 100 mg twice daily for 6 to 12 months have been used for this purpose. Women should not become pregnant while taking spironolactone.

6. **Clomiphene.** Clomiphene (Clomid, Serophene) alone is the initial therapy of choice for infertility. The combination of clomiphene and metformin is effective in many women with PCOS who are unable to conceive on their own.

III. DRUG USE IN PREGNANT PATIENTS. Most women would like to avoid pharmacologic therapy during pregnancy if at all possible. However, > 80% of women are exposed to substances such as medication during their pregnancies. Preexisting conditions and other problems occurring during the pregnancy may require continuation or initiation of drug therapy. In rare circumstances, fetal therapy can be administered through the mother. It is important to understand maternal pharmacokinetic changes, placental drug transfer, eventual disposition of the drug, and limitations of the FDA classification system to safely treat pregnant women.

A. **Fetal development.** The effects of drug therapy in pregnancy depend largely on the stage of fetal development during which the exposure occurs. Pregnancies are normally dated from the first day of the last menstrual cycle; however, when discussing fetal development, fertilization occurs on day 1.

1. **Weeks 1 to 2.** During the first days after fertilization, the zygote forms in the fallopian tube. Over the next few days, division of the zygote eventually results in the formation of the blastocyst, which

travels through the tube into the uterus. The blastocyst contains numerous types of relatively un-differentiated tissues that will ultimately become the fetus, the placenta, and the fetal membranes. Superficial implantation in the endometrium occurs within the first 5 days. During the second week, differentiation begins and the placenta has started to form. During these weeks, there is an "all or none" phenomenon. With no placenta to transfer substances to the blastocyst, there is no susceptibility to teratogens. Exposure to environmental agents during this time will have either little or no effect on the embryo or will destroy most cells, leading to pregnancy termination.

2. **Weeks 3 to 8.** It is during this time that the placenta becomes fully functional and organogenesis occurs. This is the most critical period of development, when the embryo is most susceptible to teratogens. All major organ systems develop structurally during these weeks. All are completely formed by the end of the ninth week, with the exception of the central nervous system (CNS). Major congenital anomalies, such as cardiac abnormalities, spina bifida, and limb defects occur during this time.

3. **Weeks 9 to 38 (the fetal period).** At the ninth week, the embryo is referred to as a fetus. Development during this time is primarily functional, with overall growth occurring throughout. The fetus may be at risk during exposure to potentially fetotoxic drugs or viruses. Exposure to a drug is generally not associated with major congenital malformations; however, minor congenital anomalies and functional defects may occur during this time.

B. **Placental transfer of drugs.** The placenta is the functional unit between the fetal and the maternal blood supply. There is no mixing of the two systems, but exchange of nutrients, oxygen, and waste products occurs primarily via passive diffusion. This process is driven by the concentration gradient between the two systems. There are a few substances that are actively transported across the placenta (e.g., amino acids); drugs that are structurally similar to these compounds will also be transported by this mechanism.

1. **Placental metabolism.** The placenta produces several pregnancy-related hormones that are mainly secreted into the maternal circulation. Some of the other substances produced by the placenta are enzymes that metabolize drugs. A common example of this is prednisone metabolism, so that very little steroid reaches the fetus.

2. **Factors affecting placental drug transfer.** For a drug to cause a teratogenic or pharmacological effect in the embryo or fetus, it must cross from the maternal circulation to the fetal circulation or tissues. Generally, the principles that apply to drug transfer across any lipid membrane can be applied to placental transfer of a drug. Most substances administered for therapeutic purposes have, by design, the ability to cross the placenta to the fetus. The critical factor is whether the rate and extent of transfer are sufficient to cause significant drug concentrations in the fetus. There are many factors that affect the rate and extent of placental drug transfer.

   a. **Molecular weight.** Low-molecular-weight drugs (< 500 Da) diffuse freely across the placenta. Drugs of a higher molecular weight (500 to 1000 Da) cross less easily. Drugs composed of very large molecules (e.g., heparin) do not cross the placental membranes.

   b. **Drug pK_a.** Weakly acidic and weakly basic drugs tend to rapidly diffuse across the placental membranes. Ionized compounds do not cross the placenta.

   c. **Lipid solubility.** Moderately lipid-soluble drugs easily diffuse across the placental membranes. It is important to note that many drugs have been formulated for oral administration and are designed for optimal lipid membrane transfer.

   d. **Drug absorption.** During pregnancy, gastric tone and motility are decreased, which results in delayed gastrointestinal emptying time. This typically does not affect drug absorption. However, nausea and vomiting, which are most common in the first trimester but may continue throughout pregnancy, may affect absorption.

   e. **Drug distribution.** The volume of distribution increases significantly during pregnancy and increases with advancing gestational age. The alteration in volume of distribution is the result of an increased plasma volume. Total body fluid (intravascular and extravascular volume) increases, as does adipose tissue. The placenta itself may also be a site for distribution. Hydrophilic drugs will have a higher volume of distribution leading to lower peak levels. Plasma concentrations of drugs that are widely distributed are usually lower than those with a small volume of distribution. Therefore, less drug is available to cross the placenta.

   f. **Plasma protein binding.** Placental transfer of a highly plasma-protein-bound drug is less likely because only the free drug crosses the placenta. During pregnancy, a reduction in the levels of

two major drug-binding proteins—albumin and AGP—is observed. A dilutional effect occurs with albumin and other protein concentrations, which can increase the free fraction of drugs.

    g. Physical characteristics of the placenta. As a pregnancy progresses, the placental membranes become progressively thinner, resulting in a decrease in diffusion distance. The placenta also expands, causing a greater surface area for the transfer of substances.

    h. Maternal pharmacokinetic changes. The dramatic increase in blood volume that occurs primarily during the first 30 weeks of pregnancy enhances blood flow through the kidneys and liver. Drugs that are excreted renally will experience a more rapid clearance, which could decrease the overall exposure time of the drug to the placenta. Metabolism of some drugs is increased, whereas others decrease; cytochrome P450 system enzymes 2D6, 2C9, and 3A4 increase in activity, whereas 1A2 and 2C19 are inhibited.

    i. Drug half-life. Drugs that remain in circulation longer have a higher likelihood of placental passage due to the prolonged exposure.

3. Teratogenic drugs

    a. Teratogens are defined as agents that increase the risk of or cause a congenital anomaly to occur. These defects can be structural, functional, or behavioral in nature. Women may blame a specific exposure during their pregnancy as the cause of a fetal anomaly; however, the defect may have no known cause, as is the case in 3% of all births in the United States.

    b. It may take years of exposures to actually link a specific drug to certain defects. Animal studies can only suggest potential problems in humans but are often the only source of information regarding safety of agents during early pregnancy. The dose that animals often receive exceeds the normal human dose, which diminishes the applicability of these data to humans.

    c. The fetus is unable to metabolize or eliminate drugs as quickly as the mother. Some substances may be excreted into the amniotic fluid and then resorbed in the fetal intestines after the fluid is swallowed. Therefore, some drugs may have a longer exposure time in the fetus, whereas others are eliminated more rapidly.

    d. Because fetal organ systems develop at different times, specific teratogenic effects depend mainly on the point of gestation when the drug was ingested.

    e. The teratogenic rate of substances indicates how frequently anomalies occur and over what exposure period. For example, one of the most potent known teratogens, thalidomide, had a teratogenic rate of 20% with a single exposure, yet only one-third of women who ingested the drug gave birth to affected infants. Other agents may increase the rate of specific defects over the general population, but the absolute incidence may be extremely low.

    f. The FDA developed a classification system that groups drugs according to the degree of their potential risk during pregnancy.[1]

        (1) Category A. Adequate, well-controlled studies in pregnant women have not shown an increased risk of fetal abnormalities.

        (2) Category B. Animal studies have revealed no evidence of harm to the fetus; however, there are no adequate and well-controlled studies in pregnant women. Or animal studies have shown an adverse effect, but adequate and well-controlled studies in pregnant women have failed to demonstrate a risk to the fetus.

        (3) Category C. Animal studies have shown an adverse effect, and there are no adequate and well-controlled studies in pregnant women. Or no animal studies have been conducted, and there are no adequate and well-controlled studies in pregnant women.

        (4) Category D. Studies—adequate, well-controlled, or observational—in pregnant women have demonstrated a risk to the fetus. However, the benefits of therapy may outweigh the potential risk.

        (5) Category X. Studies—adequate, well-controlled, or observational—in animals or pregnant women have demonstrated positive evidence of fetal abnormalities. The use of the product is contraindicated in women who are or may become pregnant.

    g. Problems with the current system. The current system was created in 1979 and has not been revised since its inception. With many agents there is a paucity of human data, despite the

---

[1]Federal Register, June 26, 1979;44(124):37434–37467.

fact the drug may carry a category B rating. Most newly marketed agents will be placed in category C, amid other agents with little data in humans or animals. This is the most difficult category to assess. Although there may be case reports of drug exposures, these tend to bias information toward fetal risk; most publish only outcomes with potential drug-related effects. Few drugs will ever be assigned a category A status because large, randomized, well-controlled trials are rarely conducted in pregnant women.

h. **Examples of teratogenic agents**

(1) **Vitamin A derivatives.** Drugs such as isotretinoin (Accutane) and etretinate (Tegison) are potent teratogens in humans. These agents should be discontinued several months before pregnancy.

(2) **Warfarin** (Coumadin) is most teratogenic in the first trimester (weeks 6 to 9), but can also cause malformations during the second and third trimesters as well. Early exposure is associated with a pattern of defects known as fetal warfarin syndrome. These defects can include hypoplasia of the nose and extremities, congenital heart disease, and seizures. CNS abnormalities are increased with later use. Heparins may be an appropriate substitute when anticoagulation is necessary; however, they are not as effective for preventing thrombosis in women with artificial heart valves.

(3) **Androgenic agents** can cause virilization of female fetuses, creating ambiguous genitalia. Finasteride (Propecia) can cause genital abnormalities in male offspring. Estrogen and progestins, fortunately, do not have this effect. Many women continue to take birth control pills during the first month or two after conception until the pregnancy is discovered.

(4) **Ethanol.** Alcohol consumed in large amounts for prolonged periods during pregnancy (> 4 to 5 drinks per day) is known to cause fetal alcohol syndrome (FAS). Features of FAS include growth restriction, craniofacial dysmorphology, and CNS malfunctions, along with various other abnormalities. At least 30% of women who abuse alcohol will deliver an infant affected by FAS. Moderate alcohol consumption (2 drinks per day) can also lead to similar defects, although usually not the complete syndrome. Even though the most problematic time is during the first 2 months of pregnancy, moderate drinking during the second trimester is associated with an increased rate of spontaneous abortions.

(5) **Antineoplastics.** Many agents in this class are associated with fetal anomalies after first trimester chemotherapy administration. Growth restriction often occurs regardless of the timing of exposure. Owing to the mechanism of action of these agents, many are embryocidal.

(6) **Anticonvulsants.** Drugs such as phenytoin (Dilantin), valproic acid (Depakene), and carbamazepine (Tegretol) have all been associated with fetal anomalies. However, maternal benefit from these agents often outweighs the risk to the fetus. Anticonvulsants should not be stopped during pregnancy, but if appropriate, they should be discontinued several months before fertilization. Valproic acid and carbamazepine can increase the risk of neural tube defects; women taking these agents should receive folic acid supplementation starting before conception. Toxic epoxide radicals are thought to be the mechanism of teratogenicity with several of these agents. Genetic alterations in the epoxide hydrolase enzyme activity can reduce or increase the severity of abnormalities.

(7) **Infections.** Viral infections, such as rubella, cytomegalovirus, parvovirus, coxsackie, and varicella can be associated with growth restriction, congenital anomalies, premature delivery, and potential embryo toxicity or fetal demise. Nearly all maternal infections have been thought to cause growth restriction.

(8) **Cigarette smoking.** Cigarettes contain many toxic and carcinogenic compounds in addition to nicotine. Nicotine is a potent vasoconstricting agent capable of reducing uterine blood flow and increasing uterine vascular resistance. Smoking not only increases the risk of a growth-restricted fetus but also increases the risk of spontaneous abortions, premature delivery, placental abruption, and premature rupture of the membranes. Small increases in defects of the heart, limbs and feet, skull, urinary system, abdomen, intestines, and muscles have also been associated with cigarettes. Smoking may also alter the effects of other substances, perhaps enhancing toxicity of both agents.

4. **Other problematic therapies.** Some agents given during pregnancy may result in pharmacological effects that are not necessarily toxic, yet need to be considered when medications are given during the later weeks of pregnancy.
   a. **CNS depression** may occur with barbiturates, tranquilizers, antidepressants, and narcotics. Also, anesthetics and other agents commonly given during labor may cause significant CNS and respiratory depression in newborns (e.g., magnesium sulfate or opioid analgesics).
   b. **Neonatal bleeding.** Maternal ingestion of agents such as nonsteroidal anti-inflammatory drugs (NSAIDs) and anticoagulants at therapeutic doses near term may cause bleeding problems in the newborn.
   c. **Drug withdrawal.** Habitual maternal use of barbiturates, narcotics, benzodiazepines, alcohol, and other substances of abuse may lead to withdrawal symptoms in newborns.
   d. **Constriction of the ductus arteriosus.** Maternal use of NSAIDs in the third trimester may cause the ductus arteriosus to close prematurely and could result in pulmonary hypertension in the newborn.

IV. DRUG EXCRETION IN BREAST MILK.
Today, more than 60% of women choose to breastfeed their infants. Of these women, 90% to 95% receive a medication during the first postpartum week, most commonly for pain control after delivery. It is important to understand the principles of drug excretion in breast milk and specific information on the various medications to minimize risks from drug effects in the nursing infant.

A. **Transfer of drugs from plasma to breast milk.** Drug transfer into breast milk is governed by many of the same principles that influence human placental drug transfer.
   1. Most drugs cross into breast milk via passive diffusion along a concentration gradient formed by the un-ionized drug content on each side of the membrane.
   2. Breast milk contents change throughout a feeding. Colostrum, the very first milk produced, is much higher in protein than mature milk and the fat content is minimal. Mature milk consists of foremilk at the beginning of a feeding and hindmilk at the end. The protein and fat content increase throughout the nursing session. Therefore drugs that partition into more lipid solutions will have the highest concentration in hindmilk.
   3. A milk to plasma ratio can be determined for specific agents when both blood and milk concentrations are known. Most drugs have a ratio < 1; lower numbers indicate that less drug crosses into breast milk. Because the milk to plasma ratio may change within a feeding, the average breast milk concentration is usually used, if available.
   4. It is possible to calculate the dose an infant receives if the breast milk concentration is known. A typical infant drinks 150 mL/kg/day. Multiplying the average concentration by the breast milk volume consumed will give the total daily exposure. It is important to remember that this drug must now be ingested by the infant, so the bioavailability of the drug is critical to calculate the actual daily dose. Doses < 10% of the maternal dose on a milligram per kilogram per day basis are preferable.
   5. Some medications are not absorbed orally but may pass into breast milk when administered intravenously to the mother. Although the drug may not enter the infant's blood, it may have effects on the gastrointestinal tract. For example, the bioavailability of gentamicin is negligible; however, it may cause diarrhea or sterilize the bowel.

B. **Drug factors.** The drug and its environment influence the rate and extent of drug passage into the breast milk.
   1. **Molecular weight.** Drugs weighing < 200 Da cross into milk easily. Larger molecules can dissolve in the lipid membrane or pass through small pores. Large molecules, such as insulin, do not cross into breast milk.
   2. **pH gradient.** Human milk is more acidic than plasma.
      a. Weak acids may diffuse across the membrane and remain un-ionized, allowing for passage back into the plasma. Lower amounts of these drugs will cross than those that are weak bases.
      b. Weak bases may diffuse into the breast milk and ionize, which causes drug trapping. This creates higher levels of drug in the breast milk; these drugs will have a milk to plasma ratio > 1. This effect though is not usually clinically significant, especially when the maternal serum concentration is very low.

3. **Drug pK$_a$.** Only the un-ionized form of a drug is able to pass through the lipid membrane.

4. **Plasma protein binding.** The free fraction of a drug is available to pass into the breast milk. In general, drugs with high plasma-protein-binding properties tend to remain in the plasma and pass into the milk in low concentrations. Milk proteins and lipids also may bind drugs when they are created in the mammary glands; this may represent another route of entry, rather than passive diffusion.

5. **Lipid solubility.** Lipid solubility is necessary for a drug to pass into the breast milk. Highly lipid-soluble drugs (e.g., diazepam [Valium]) may pass into the breast milk in relatively high amounts and, therefore, may present a significant dose of drug to the nursing infant.

6. **Equilibration.** Some drugs may rapidly equilibrate between maternal plasma and breast milk. These agents will diffuse across the membrane as the drug concentration changes in the maternal system. Other agents may never reach equilibrium between milk and plasma. These drugs tend to slowly diffuse into breast milk and will respond gradually to changes in maternal concentrations.

C. **Maternal factors.** Maternal pharmacology plays a significant role in the rate and extent of drug passage into breast milk. The extent of plasma protein binding and changes in the mother's ability to metabolize or eliminate the drug influence the amount of drug that is available to pass into the breast milk. Equally important are the maternal dose of the drug, the dosing schedule or frequency, and the route of administration.

D. **Drugs affecting hormonal influence of breast milk production.** The primary hormone responsible for controlling breast milk production is prolactin. A decrease in milk production may result in diminished weight gain in the nursing infant, the need for supplementation, or premature cessation of breastfeeding.

1. **Drugs that decrease serum prolactin levels.** Drugs such as bromocriptine have been used to suppress lactation in women who choose not to breastfeed. This practice has long been abandoned because myocardial infarctions, seizures, and stroke were attributed to its use. Other drugs include
   a. ergot alkaloids
   b. L-dopa

2. **Drugs that increase serum prolactin levels.** Metoclopramide (Reglan) has been useful therapeutically to enhance milk production. The following drugs are known to increase serum prolactin levels, but they are not used for this purpose. These drugs include
   a. methyldopa (Aldomet)
   b. haloperidol (Haldol)
   c. phenothiazines

E. **Factors to assess.** In assessing the safety of an agent during breastfeeding, several considerations should be addressed.
1. Inherent toxicity of the drug
2. Drug safety data in infants
3. Amount of drug ingested
4. Duration of therapy
5. Age of the infant or degree of prematurity
6. Drug pharmacokinetics in the mother and child

F. **Factors to minimize drug exposure to the infant.** One of the goals when using medications in the breastfeeding mother is to maintain a natural, uninterrupted pattern of nursing. In many instances, it may be possible to withhold a drug when it is not essential or delay therapy until after weaning. Other factors include

1. **Medication selection.** When a specific product is being selected, it is important to choose the agent that is distributed into the milk the least, if possible.
   a. Other desirable characteristics include a short half-life, inactive metabolites, and high protein binding.
   b. In addition, it is desirable to select agents with lower plasma concentrations, which may involve an alternative route of administration.
   c. Single doses may be preferable to a longer therapy course if the agent is contraindicated in breastfeeding. This can allow for the mother to pump and discard her milk for a defined time, often 12 to 24 hrs, rather than discontinue breastfeeding altogether.

2. **Maternal dose relative to infant feeding.** One of the goals of drug dosing in lactating women is minimal infant exposure to the drug. It is desirable to adjust the dosing and nursing schedules so that a drug dose is administered at the time of or immediately after the infant's feeding. Medications should be dosed before the infant's longest sleep.

G. **Examples of drugs that readily enter breast milk.** These agents should be used with caution in nursing mothers.

1. **Narcotics, barbiturates, and benzodiazepines.** CNS active agents, such as diazepam, may have a hypnotic effect on the nursing infant. These effects are related to the maternal dose. Alcohol consumption may have a similar effect.

2. **Antidepressants and antipsychotics.** These classes of drugs appear to pass into the breast milk; however, no serious adverse effects have been reported. The long-term behavioral effects of chronic exposure to these drugs on developing newborns are unknown.

3. **Anticholinergic compounds.** These drugs may result in adverse CNS effects in the infant and may reduce milk volume in the mother. Dicyclomine (Bentyl) is contraindicated in nursing mothers because it may result in neonatal apnea.

V. INCONTINENCE

A. **Definition.** Incontinence is defined as an inability to control urine or feces elimination. There are four major types of urinary incontinence: stress, urge (overactive bladder), overflow, and mixed (stress and urge incontinence).

B. **Epidemiology.** The reported incidence of urinary incontinence varies widely, ranging from 10% to 35% in women. Incontinence becomes more common as women age but is not a normal part of aging.

C. **Cause.** Gender, age, hormonal status, birthing trauma, and genetic differences in connective tissue all contribute to the development of incontinence.

D. **Diagnosis** is made with a voiding diary (frequency of urination, leakage of urine, symptoms during urination such as pain or discomfort, or the need to strain or splint to urinate), a physical examination, surgical and obstetric history, medication history, mental status examination in the elderly, and a urinalysis. Special diagnostic procedures, such as a cystourethrogram, can be performed if the initial diagnosis and treatment is ineffective.

E. **Stress urinary incontinence** (SUI) involves the involuntary loss of urine during physical activity that increases the intra-abdominal pressure (e.g., coughing, sneezing). This is usually caused by urethral underactivity, decreased tone of the urethral sphincter, or hypersensitivity of the bladder neck.

1. **Treatment** of SUI usually involves
   a. **Behavioral therapy.** Bladder retraining involves voiding on a schedule, usually hourly to start. Once this is managed without leakage, the time between voids is increased by 15-min intervals, until the elapsed time between voids is between 2 and 4 hrs. Pelvic floor muscle strengthening, known as Kegel exercises, can reduce incontinence by up to 50%.
   b. **Weight loss** of 5% to 10% can dramatically improve symptoms especially in the postpartum period when stress incontinence is a common problem.
   c. **Fluid restriction** to less than 2L daily.
   d. **Drug therapy**
      (1) **Vaginal estrogen** improves tone and blood supply of the urethral sphincter muscles increasing urethral closure pressure and increasing mucosal thickness, thus improving functioning.
      (2) **Alpha-adrenergic agents** induce muscle contraction in the bladder neck and urethra, increasing outlet resistance. Pseudoephedrine (Sudafed) is the remaining agent in this class.
      (3) **Duloxetine** (Cymbalta) which has a direct effect on the urethra (enhancing closure) via peripheral adrenergic activation (40 to 80 mg daily).
      (4) **Imipramine** (Tofranil), a tricyclic antidepressant, decreases bladder contractility and increases outlet resistance. Doses of 75 mg once daily and 25 mg three times daily have been successful in studies.
   e. **Surgical options.** Colposuspension elevates the bladder neck and the urethra, restoring the urethrovesical junction; sling procedures elevate the urethra and increase urethral

compression; or tension-free tape reduces urethral mobility or produces a kink in the urethra during increases in intra-abdominal pressure.

F. Urge incontinence is described by the sudden sense of needing to urinate followed by the loss of urine. This involuntary contraction of the bladder or bladder overactivity is known as detrusor instability. The detrusor is the muscle located in the bladder wall; relaxation allows bladder to expand. Another common symptom is frequent urination during the day and night.

1. **Treatment** of urge incontinence involves
   a. **Behavioral therapy.** Bladder retraining entails initially voiding every 1 to 1.5 hrs even if leakage or the urge to void occurs before this time, eventually increasing the interval by 30 mins until 3 to 4 hrs elapses between voids. Also, avoiding foods that may irritate the bladder such as caffeine, carbonation, acidic foods, and spicy foods is helpful.
   b. **Drug therapy**
      (1) **Anticholinergic agents** act on muscarinic receptors to decrease contractility. However, these agents have the potential to cause significant side effects, especially in the elderly. Extended-release formulations usually have lower anticholinergic effects.
         (a) **oxybutynin** (Ditropan, Ditropan XL, Oxytrol), 2.5 mg to 5.0 mg two to four times daily, 5 mg to 30 mg daily extended-release, 3.9 mg patch twice weekly.
         (b) **tolterodine** (Detrol, Detrol LA), 2 mg twice daily or 4 mg daily extended-release. The dose should be decreased by 50% in women taking CYP3A4 inhibitors.
         (c) **trospium** (Sanctura), 20 mg twice daily, adjusted to 20 mg daily in renal impairment or elderly women ($>$ 75 years).
         (d) **darifenacin** (Enablex), 7.5 to 15 mg daily, women with moderate hepatic impairment or taking CYP3A4 inhibitors should not receive more than 7.5 mg daily.
         (e) **solifenacin** (VESIcare), 5 to 10 mg daily with 5 mg daily recommended in women with renal impairment, moderate hepatic impairment, or in those taking CYP3A4 inhibitors.
      (2) **Flavoxate** (Urispas) is a urinary antispasmodic that can be helpful. Doses range from 100 to 200 mg three to four times daily.
   c. **Surgery.** Augmentation cystoplasty uses intestinal segments to improve the storage function of the bladder.

G. Overflow incontinence is a constant loss of urine or inadequate bladder emptying. This type of incontinence is not common in women. Women with neurological impairment who may not feel the urge to void are predisposed to this type of incontinence because of bladder overdistension. A post-void residual, measuring the urine volume remaining in the bladder after urination, can make this diagnosis. A blockage in the urethra can also cause overflow incontinence.

1. **Treatment**
   a. **Behavioral therapy.** Voiding or self-catheterization should occur at specific intervals to prevent overdistension. In severe cases of neurological impairment (such as significant dementia), the patient may require incontinence pads or long-term catheterization.
   b. **Drug therapy.** Tamsulosin (Flomax) may be helpful by relaxing striated and smooth muscle, decreasing urethral resistance, and relieving symptoms. Initial doses should be 0.4 mg daily with a maximum of 0.8 mg daily. It is important to note that some women receiving alpha-adrenergic blocking agents for hypertension develop incontinence.
   c. **Surgery.** Surgery may be required if a urethral blockage is the cause of incontinence.

VI. MENOPAUSE

A. Definition. Menopause is defined as the irreversible cessation of the reproductive cycle and menses after the ovaries permanently fail to respond to gonadotropins. Removal of the ovaries (oophorectomy) in premenopausal women and premature ovarian failure also will lead to menopausal symptoms. Menopause occurs naturally around age 51, but often occurs earlier in smokers due to increased estrogen metabolism in these women.

B. Symptoms. Symptoms of menopause are due to the lack of estrogen. They include vasomotor instability (hot flushes), atrophic changes of the vagina and urethra/bladder (symptoms of burning, itching, bleeding, dyspareunia/painful intercourse, or incontinence), and a menopausal syndrome (sleep disturbances and mood swings).

Table 29-2	EFFICACY OF NONHORMONAL THERAPY ON HOT FLASHES	

Therapy	Initial Dose	Study Results, % Decrease in Hot Flashes
Venlafaxine (Effexor)	75 mg XL daily	61% vs. 27% with placebo
Paroxetine (Paxil)	10 mg daily	50%–51% vs. 16% with placebo
Fluoxetine (Prozac)	20 mg daily	50% vs. 36% with placebo
Gabapentin (Neurontin)	300 mg TID	41% vs. 29% with placebo
Clonidine (Catapres)	0.5 mg PO BID or 0.1 mg/day TD weekly	37% vs. 20% with placebo 80% vs. 36% with placebo
Methyldopa (Aldomet)	250 mg BID	Visual analog scale improvement

PO, by mouth; *TID,* three times daily; *BID,* twice daily; *TD,* transdermal; *XL,* extended release.

C. **Treatment**
1. **Lifestyle changes.** Recommendations include lowering the core body temperature by dressing in layers, consuming cold food and beverages, and using cooling techniques, such as a fan or cold towels placed on the back of the neck.
2. **Hormone therapy.** Hormone therapy has become controversial in recent years but can be helpful in very symptomatic women. The lowest dose for the shortest duration is the current recommendation. Estrogen decreases the risk of colon cancer and decreases the risk of noninsulin dependent diabetes. However, combined hormone therapy can increase the risk for breast cancer, whereas estrogen alone does not appear to have this effect. Estrogen also increases cardiovascular risks and thromboses.
3. **Nonhormonal therapy.** Many other therapies have been studied for the treatment of vasomotor symptoms (*Table 29-2*).
4. **Herbal therapies/phytoestrogens.** Many therapies have been studied, but few agents have been shown to be more effective than placebo.
   a. **Black cohosh** possibly decreases hot flashes, but therapy should be limited to 6 months or less. Black cohosh can increase the density of breast tissue, making mammograms more difficult to interpret.
   b. **Red clover** has a small decrease in frequency of hot flushes over placebo.
   c. **Soy** has not been shown to be beneficial in many studies.
   d. **Other herbs.** Other herbs studied or recommended by some for hot flashes include ginseng, dong quai, damiana, licorice, motherwort, fennel, and evening primrose oil.

VII. OSTEOPOROSIS

A. **Definition.** Osteoporosis can be defined as an imbalance of osteoblast and osteoclast activity. Osteoblasts form bone, whereas osteoclasts break down bone (resorption). Receptor activator of nuclear factor kappa-B (RANK) and osteoprotegerin (OPG) are proteins that are intimately involved with bone remodeling. RANK is key for the differentiation and activation of osteoclasts. OPG has the opposite effect, blocking the effects of RANK by binding to the RANK ligand. The ultimate result of OPG is to decrease the activity of osteoclasts, thus preventing bone resorption.
B. **Epidemiology.** In 2009, approximately 13% of the American population was > 65 years of age, representing nearly 38 million Americans. The risk of a fracture doubles every 7 to 8 years in women older than the age of 50. Nonmodifiable risk factors for osteoporosis include female sex, age, low body mass index, small frame, family history of osteoporosis, menopausal status, and ethnicity/race. In an observational study, osteoporosis was diagnosed in different ethnicities. Women with highest risk to lowest rate of osteoporosis were Native Americans > Asians > Hispanics > Caucasians > African Americans. Risk factors that can be modified include alcohol intake > 3 servings per day, low activity level, smoking, and estrogen deficiency.
C. **Diagnosis.** Routine health care should include measuring height; vertebral fractures will shorten stature and having one vertebral fracture increases the risk for more. Screening for osteoporosis should be done in women 60 to 64 years with one major risk factor and all women > 65 years, women with a low trauma fracture, women who have lost > 0.5 inch of height within 1 year or > 1.5 inches

overall, and to monitor therapy. The World Health Organization developed the Fracture Risk Assessment tool (FRAX) to evaluate a woman's risk of having a hip or any major osteoporotic fracture over the next 10 years. It takes into account family history and many risk factors. It is only indicated in women > 50 years who have not started any drug therapy for osteoporosis. Peripheral bone mineral density scans can be done at community health screenings using heel ultrasonography on the nondominant foot. These screenings can help identify women who need further screening with a dual energy x-ray absorptiometry (DXA) scan. The DXA scan is the gold standard and bone mineral density (BMD) is measured at the hip and spine. The results generate a T score; a score of −1 to −2.5 indicates low bone mass/osteopenia and a score ≤ −2.5 makes the diagnosis of osteoporosis. A DXA scan should not be performed more frequently than every 1 to 2 years.

D. **Therapy**
1. **Lifestyle changes** are important to increase bone mass. Adolescent and young women need to build bone early in life. A healthy lifestyle incorporates weight bearing exercises such as walking and isometric exercises such as weight lifting, not smoking, and limiting alcohol and caffeine intake. Sunlight converts vitamin D into an active form in the skin, but adequate exposure is difficult for most women to achieve. Using suntan lotion negates the effect of sunlight and only more equatorial areas of the world have enough direct sunlight during the winter months.
2. **Calcium and vitamin D.** Adequate calcium ingestion may not occur with dietary intake and supplementation is often recommended. Vitamin D has been shown in studies to decrease the number of falls, thus reducing the number of fractures. The recommended intake of calcium according to the National Osteoporosis Foundation (NOF) is 1200 mg with 800 to 1000 international units of vitamin D for women older than age 50. Calcium therapy taken without vitamin D might increase the risk of myocardial infarctions.
3. **Bisphosphonates** are selected as first line in many women (*Table 29-3*). They are effective in reducing fractures in the hip and spine, working to decrease osteoclast activity. Oral dosing is complicated by their poor absorption when taken within 1 hr of a meal or beverage. They also require the woman to remain upright after dosing to prevent esophageal irritation and erosion. They can cause unusual side effects, such as jaw necrosis and atypical fractures of the femur. They are generally contraindicated in women with a creatinine clearance less than 30 mL/min. The duration of therapy is not completely established, although 5 years is recommended by some experts.
4. **Hormone therapy.** Estrogens inhibit bone resorption and promote bone formation. They reduce fractures in the hip, spine, and nonvertebral locations. Bone mass is maintained with conjugated equine estrogen doses of 0.3 mg daily. The higher the estrogen dose, the higher the increase in BMD; however, the lowest dose of estrogen should be used in naturally postmenopausal women to control vasomotor symptoms.
5. **Selective estrogen receptor modulators** (SERMs). Raloxifene (Evista) increases BMD spine and hip and reduces vertebral fractures. Raloxifene is helpful in women also needing protection against breast cancer, but the agent can cause menopausal symptoms in women due to its estrogen antagonism in selective tissues. The dose for prevention and treatment of osteoporosis is 60 mg daily.

Table 29-3   BISPHOSPHONATES FOR OSTEOPOROSIS TREATMENT AND PREVENTION

Bisphosphonate	Treatment Dose	Prophylaxis Dose	Fracture Reduction
Alendronate (Fosamax)	10 mg daily PO or 70 mg PO weekly	5.0 mg PO daily or 35 mg PO weekly	50% H, V, NV
Risedronate (Actonel)	5.0 mg PO daily or 35 mg PO weekly or 150 mg PO monthly	Same as treatment regimens	35%–45% V, NV
Ibandronate (Boniva)	2.5 mg PO daily or 150 mg PO monthly or 3.0 mg IV monthly	Same as treatment regimens	50% V
Zoledronic Acid (Reclast)	5.0 mg IV yearly	5.0 mg IV every other year	51% H, 70% V

H, hip fracture; *V*, vertebral (spine) fracture; *NV*, nonvertebral fracture; *PO*, by mouth; *IV*, intravenous.

Table 29-4	EFFICACY OF VARIOUS OSTEOPOROSIS MEDICATIONS			
Therapy	**↓ Hip Fx**	**↓ Spine Fx**	**↓ Nonspine Fx**	**↑ BMD**
Estrogen	34%	35%		5%[a]
Raloxifene		40%		
Bisphosphonates	40%	60%		3.3%–4.8%
Calcitonin		33%		1%
Teriparatide	35%	65%	35%	5%
Denosumab	40%	68%	20%	5%

Fx, fracture; *BMD*, bone mineral density.
[a] with 1.25 mg daily conjugated equine estrogens.

6. **Calcitonin.** Calcitonin (Miacalcin) works on osteoclasts to inhibit bone resorption. It helps maintain a normal calcium level in serum and increases bone stores. Calcitonin is helpful with the pain associated with vertebral fractures. It is most commonly administered intranasally but is also available in an injectable formulation for subcutaneous or intramuscular administration. Parenteral doses are 100 mcg every other day, whereas the intranasal is 200 mcg daily in alternating nostrils.

7. **Teriparatide.** Teriparatide (Forteo) is recombinant human parathyroid hormone that is administered subcutaneously daily (20 mcg). It stimulates osteoblast activity, increases gastric absorption and renal reabsorption of calcium, increases BMD in the hip and spine, and prevents vertebral fractures. It is not considered first line due to cost and a lack of long-term data. It must be kept refrigerated, making this therapy more difficult for some women.

8. **Denosumab.** Denosumab (Prolia) is a monoclonal antibody that binds to the RANK ligand, inhibiting osteoclast formation and activity. Essentially, it works like OPG. It is effective at reducing fractures of the hip, spine, and nonvertebral sites. Denosumab is a subcutaneous injection of 60 mg given every 6 months. It is indicated in women who have failed or are intolerant to other osteoporosis therapies (*Table 29-4*).

Study Questions

Directions for questions 1–8: Each of the questions, statements, or incomplete statements in these sections can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A 23-year-old woman was diagnosed with significant PMS in her teens, now presents with persistent irritation with her significant other resulting in frequent arguments. Possible therapies for her include all of the following *except*

    (A) sertraline 100 mg days 14 to 28.
    (B) paroxetine 30 mg daily.
    (C) venlafaxine XR 75 mg daily.
    (D) clonazepam 1 mg twice daily.
    (E) citalopram 20 mg daily.

2. The best therapy for an obese woman with PCOS to improve menstrual regularity will be

    (A) spironolactone.
    (B) metformin.
    (C) weight loss.
    (D) pioglitazone.

3. Which of the following therapies enhances osteoblast activity?

    (A) Calcium and vitamin D
    (B) Calcitonin
    (C) Denosumab
    (D) Teriparatide
    (E) Risedronate

4. Which of the following medications is safe to use in the third trimester of pregnancy?

   (A) Acetaminophen
   (B) Nonsteroidal anti-inflammatory drugs
   (C) Warfarin
   (D) OxyContin
   (E) Aspirin

5. Placental transfer of a drug is affected by all of the following characteristics *except*

   (A) molecular weight.
   (B) fetal gender.
   (C) gestational age.
   (D) lipid solubility of the drug.
   (E) plasma protein binding.

6. When selecting a benzodiazepine product for a woman who has chronic panic disorder, all of the following drug properties are desirable for breastfeeding her 8-month-old infant who was born at term *except*

   (A) hepatic metabolism to inactive metabolites.
   (B) a short half-life.
   (C) a rapid onset of action.
   (D) high lipid solubility.

7. Drug safety in pregnancy of a specific agent can be assessed best by

   (A) the FDA classification system, especially category C drugs.
   (B) case reports.
   (C) physician knowledge.
   (D) databases such as REPROTOX.

8. The primary difference between PMS and PMDD is

   (A) PMS has an earlier onset of symptoms.
   (B) PMS is more debilitating.
   (C) PMDD can be treated with antidepressants.
   (D) PMDD is more common.

Directions for questions 9–12: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

   (A) if **I only** is correct
   (B) if **III only** is correct
   (C) if **I and II** are correct
   (D) if **II and III** are correct
   (E) if **I, II, and III** are correct

9. The definition of polycystic ovarian syndrome includes

   I. hyperandrogenism
   II. diabetes
   III. obesity

10. Therapy for stress urinary incontinence can include

   I. oxybutynin
   II. tamsulosin
   III. imipramine

11. Behavioral therapy and bladder retraining is most helpful in which types of incontinence?

   I. stress incontinence
   II. urge incontinence
   III. overflow incontinence

12. According to the principles of drug excretion into the breast milk, which combination of the following properties would result in the *highest* drug concentration in breast milk?

   I. low molecular weight, moderately lipophilic
   II. low plasma protein bound, weakly basic
   III. highly plasma protein bound, weakly acidic

13. Following principles of teratogenicity, drug exposure during which of the following times could cause fetal abnormalities?

   I. first 2 weeks of gestation
   II. weeks 3 to 8 of gestation
   III. the fetal period

Answers and Explanations

1. **The answer is D** *[see I.D.6 and Table 29-1]*.
   Clonazepam can be used in premenstrual dysphoric syndrome but should be limited to women who have anxiety as the most prevalent symptom. That is not the case for this woman. All of the remaining agents are appropriate for PMDD. Luteal phase dosing has been studied and may not be as effective as daily therapy.

2. **The answer is C** *[see II.E.1.3-5]*.
   Weight loss of 5% to 10% can restore cycle regularity in more than 50% of women. Weight loss and an appropriate diet will also decrease insulin and androgen levels. Spironolactone is helpful for hirsutism but not cycle regularity. Metformin and thiazolidinediones have both been used to improve ovulation and thus cycle regularity. Metformin can also reduce the risk of diabetes development; however, weight loss in the long run will provide the most benefit to the patient.

3. **The answer is D** *[see VII.D.2-8]*.
Teriparatide increases bone mass by stimulating osteoblast activity. Estrogens also stimulate osteoblast activity, but other therapies work by inhibiting osteoclast activity. Denosumab involves the RANK ligand, which then inhibits osteoclast activity.

4. **The answer is A** *[see III.B.3.e.(1)–(2);III.B.4.a–d]*.
Acetaminophen is a safe and effective analgesic that can be used in therapeutic doses during pregnancy. NSAIDs may interfere with the onset or progress of labor when used in the third trimester. NSAIDs and warfarin, when used near delivery, may cause bleeding problems in the newborn infant. In addition, warfarin use in the third trimester may be associated with fetal CNS abnormalities. OxyContin use in the third trimester may induce neonatal withdrawal following delivery.

5. **The answer is B** *[see III.B.2]*.
Fetal gender does not affect placental transfer of a drug. The molecular weight and the lipid solubility of a drug greatly influence its ability to cross the placental membranes. Plasma protein binding affects the amount of free drug available to cross the placenta. Gestational age influences the volume of distribution of the drug as well as the thickness of the placental membranes.

6. **The answer is D** *[see IV.B.5; IV.F.1.a]*.
When any drug is used by a nursing mother, it is desirable to have the least amount of active drug available in the maternal circulation to diffuse into the breast milk. A rapidly acting (for maternal onset of action), rapidly eliminated (i.e., short half-life) drug with inactive metabolites is optimal. If the drug is highly lipid soluble, it is more likely to pass into breast milk.

7. **The answer is D** *[see III.B.3.f]*.
The FDA classification system does not assess risk well in category C drugs. Category A and to some extent category B drugs have been shown to be safest in pregnancy. Case reports of pregnancy exposures tend to bias data toward adverse outcomes. The best source of information is from available databases, such as REPROTOX or Teris, or with published books such as Brigg's *Drugs in Pregnancy and Lactation*.

8. **The answer is C** *[see I.A]*.
PMDD is more debilitating than PMS, usually due to major depression that can accompany the other symptoms. Several antidepressants are available for treatment of PMDD. The onset of symptoms varies with both conditions. PMS is much more common than PMDD.

9. **The answer is A (I)** *[see II.A,B]*.
The definition of polycystic ovarian syndrome includes hyperandrogenism and hyperinsulinemia. Insulin resistance is common and diabetes can result, but these conditions are not part of the diagnosis. Only half of the women with PCOS are obese.

10. **The answer is B (III)** *[see V.E.1.d.(4)]*.
Imipramine is helpful to paralyze the bladder, leading to decreased contractility. Oxybutynin is an anticholinergic agent indicated for urge incontinence. The use of this agent can be helpful in mixed incontinence. Tamsulosin is helpful in some cases of overflow incontinence and this agent can certainly worsen stress incontinence.

11. **The answer is E (I, II, III)** *[see V.E.1.a; V.F.1.a; V.G.1.a]*.
Bladder retraining and behavioral therapy is helpful for all types of incontinence. The type of bladder retraining depends on the type of incontinence although the concepts are similar between stress and urge incontinence. Overflow incontinence bladder also involves voiding at regular intervals, but they are typically not as frequent as those involved with the other types of incontinence.

12. **The answer is C (I, II)** *[see IV.B.1–5]*.
High-molecular-weight substances are less likely to pass into breast milk because of their size. Drugs that are highly plasma protein bound may reach the breast milk only in small amounts, because a large portion of the drug is bound to the maternal plasma proteins and, therefore, only a small amount is free to diffuse into breast milk. A low molecular weight, moderately lipophilic drug passes easily into breast milk. A drug that has a low degree of plasma protein binding has a significant amount of drug free to diffuse into breast milk. A weakly basic drug may ionize after reaching the breast milk and therefore remain trapped in the milk.

13. **The answer is D (II, III)** *[see III.A.1–3]*.
During first 2 weeks after fertilization, the embryo is impervious to teratogens. Any exposure during this time will have either no effect or the embryo will be destroyed. During the remaining weeks of the pregnancy, teratogens may exert effects on the fetus. Teratogenic effects are not always structural in nature; they can be functional or behavioral. Therefore, exposures during the fetal period can also be problematic.

30 Clinical Laboratory Tests

D. BYRON MAY

I. GENERAL PRINCIPLES

A. **Laboratory tests** are performed for multiple purposes, including to discover a disease, confirm or differentiate a diagnosis, stage or classify a disease, and monitor effectiveness of therapy.

B. **Laboratory tests are classified as screening or diagnostic.** Screening tests are used in patients with no signs or symptoms of a disease (e.g., serum cholesterol for assessing cardiovascular disease risk). Diagnostic tests are done in patients with signs and symptoms of disease or with an abnormal screening test.

C. **Monitoring drug therapy**

1. **Laboratory test results** are used to investigate potential problems with a patient's anatomy or physiology. Pharmacists usually monitor laboratory tests to

a. **Assess the therapeutic and adverse effects of a drug** (e.g., monitoring the serum uric acid level after allopurinol is administered, checking for increased liver function test values after administration of isoniazid)

b. **Determine the proper drug dose** (e.g., assessment of the serum creatinine or creatinine clearance value before use of a renally excreted drug)

c. **Assess the need for additional or alternate drug therapy** (e.g., assessment of white blood cell count after an antibiotic is administered)

d. **Prevent test misinterpretation resulting from drug interference** (e.g., determination of a false-positive result for a urine glucose test after cephalosporin administration)

2. These tests can be **expensive**, and requests for them must be balanced against potential benefits for patients and how the laboratory test will affect your decision regarding therapy. Generally, lab tests should be ordered only if the results will affect the decisions about the management of the patient.

D. **Definition of normal values**

1. **Normal laboratory test results** fall within a predetermined range of values, and **abnormal values** fall outside that range. The normal range of a laboratory test is usually determined by applying statistical methods to results from a representative sample of the general population. Usually, the mean $\pm$ 2 standard deviations is taken as the normal range.

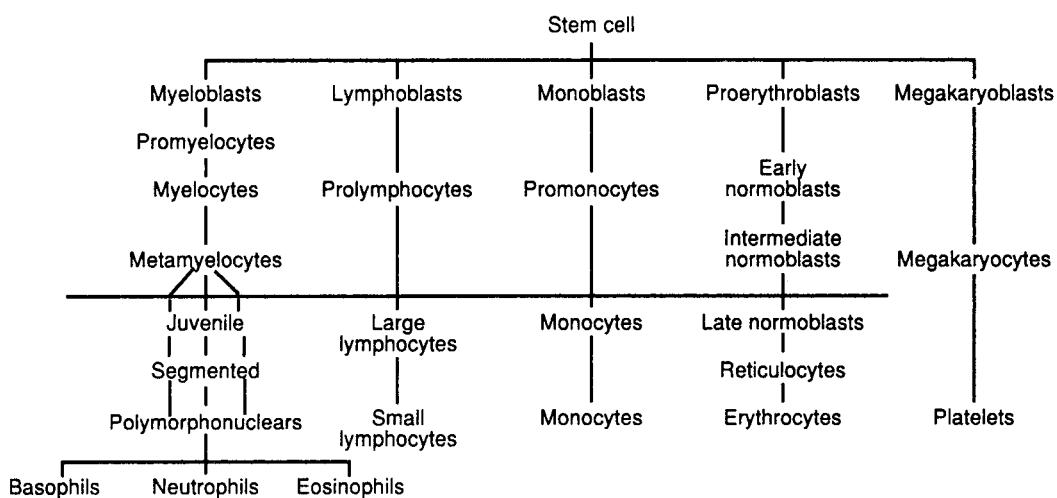
a. **Normal limits may be defined somewhat arbitrarily**; thus, values outside the normal range may not necessarily indicate disease or the need for treatment (e.g., asymptomatic hyperuricemia).

b. Many factors (e.g., age, sex, time since last meal) must be taken into account when evaluating test results.

c. **Normal values also vary among institutions** and may depend on the method used to perform the test.

d. The goal is *not* to make all laboratory values normal; resist urges to do something in a clinically stable patient.

e. Attempts have been made in recent years to standardize the presentation of laboratory data by using the International System of Units (SI units). Controversy surrounds this issue in the United States, and resistance to adopt this system continues. The SI unit of measure is a method of reporting clinical laboratory data in a standard metric format. The basic unit of mass for the SI is the mole. The mole is not influenced by the addition of excess weight of salt or ester formulations. Technically and pharmacologically, the mole is more meaningful than the gram because each physiological reaction occurs on a molecular level.

Efforts to implement the SI system began in the 1970s, resulting in the adoption of full SI-transition policies by a few major medical and pharmaceutical journals in the 1980s. Reluctance to use this system by many clinicians in the United States has forced changes in the policies by some journals to report both conventional and SI units or to report the conversion factor between the two systems. It is still controversial which method should be used to report clinical laboratory values. There are arguments for and against the universal conversion to the SI system. Readers should be aware that some journals report SI and/or conventional units in their text. Particular attention should be paid to the units associated with a reported laboratory value, and access to a conversion table may be necessary to avoid confusion in the interpretation of the data. When appropriate, both conventional and SI units will be reported in this chapter.


2. **Laboratory error** must always be considered when **test results do not correlate with expected results for a given patient**. If necessary, the test should be repeated. Common sources of laboratory error include spoiled specimens, incomplete specimens, specimens taken at the wrong time, faulty reagents, technical errors, incorrect procedures, and failure to take diet or medication into account.

3. During hospital admission or routine physical examination, a **battery of tests** is usually given to augment the history and physical examination. Basic tests may include an electrocardiogram (ECG), a chest x-ray, a sequential multiple analyzer **(SMA) profile**, **electrolyte tests (e.g., Chemistry or Basic Metabolic Panel [BMP])**, **a complete blood count (CBC)**, and **urinalysis**.

E. **Quantitative tests, qualitative tests, and analytical performance**
   1. Tests with normal values reported in ranges (i.e., 3.5 to 5.0 mEq/L) are called **quantitative**.
   2. Tests with **positive (+)** or **negative (−)** outcomes are called **qualitative**.
   3. Those with varying degrees of positivity (e.g., 1+, 2+, 3+ glucose in the urine) are termed **semiquantitative**.
   4. The quality of a quantitative assay is measured in terms of **accuracy** (accuracy is defined as the extent to which the mean measurement is close to the true value). **Precision** refers to the reproducibility of the assay.

II. HEMATOLOGICAL TESTS.
Blood contains three types of formed elements: red blood cells (RBCs), white blood cells (WBCs), and platelets (*Figure 30-1*). A CBC typically includes RBC count, total WBC count, hemoglobin (Hb), hematocrit (Hct), RBC indices (mean cell volume [MCV], mean cell Hb [MCH], mean cell Hb concentration [MCHC]), reticulocyte count, and platelet count.

Figure 30-1. Derivation of blood elements from stem cells. Cells located below the *horizontal* line are found in normal peripheral blood, with the exception of the late normoblasts.

A. **RBCs (erythrocytes)**
1. The **RBC count**, which reports the number of RBCs found in a given volume of blood, provides an indirect estimate of the blood's Hb content. Values are often reported in cells/microliter (μL) or cells/liter and less commonly as cells/cubic millimeter (mm^3). **Normal values** are
   a. 4.3 to 5.9×10^{12} cells/L of blood for men
   b. 3.5 to 5.0×10^{12} cells/L of blood for women
2. The **Hct or packed cell volume (PCV)** measures the percentage by volume of packed RBCs in a whole blood sample after centrifugation. The Hct value is usually three times the Hb value (see II.A.3) and is given as a percent or fraction of 1 (42% to 52% or 0.42 to 0.52 for men; 37% to 47% or 0.37 to 0.47 for women).
   a. **Low Hct** values indicate such conditions as anemia, overhydration, or blood loss.
   b. **High Hct** values indicate such conditions as polycythemia vera or dehydration.
3. The **Hb test** measures the grams of Hb contained in 100 mL (1 dL) or 1 L of whole blood and provides an estimate of the oxygen-carrying capacity of the RBCs. The Hb value depends on the **number of RBCs** and the **amount of Hb in each RBC**.
   a. **Normal values** are 14 to 18 g/dL for men and 12 to 16 g/dL for women.
   b. **Low Hb** values indicate anemia.
4. **RBC indices** provide important information regarding RBC size, Hb concentration, and Hb weight. They are used primarily to categorize anemias, although they may be affected by average cell measurements. A peripheral blood smear can provide most of the information obtained through RBC indices. Observations of a smear may show variation in RBC shape (**poikilocytosis**), as might occur in sickle-cell anemia, or it may show a variation in RBC size (**anisocytosis**), as might occur in a mixed anemia (folic acid and iron deficiency).
   a. **MCV** is the ratio of the Hct to the RBC count. It essentially assesses average RBC size and reflects any anisocytosis.

   $$MCV = \frac{\text{Hct (\%)} \times 10}{\text{RBC (millions)}}$$

   (1) **Low MCV** indicates **microcytic** (undersize) **RBCs**, as occurs in iron deficiency.
   (2) **High MCV** indicates **macrocytic** (oversize) **RBCs**, as occurs in a vitamin B_{12} or folic acid deficiency.
   (3) **Normal range for MCV** is 90 ± 10.
   b. **Mean cell hemoglobin (MCH)** assesses the amount of Hb in an average RBC.
   (1) MCH is defined as:

   $$MCH = \frac{\text{Hb} \times 10}{\text{RBC (millions)}}$$

   (2) **Normal range for MCH** is 30 ± 4.
   c. **Mean cell hemoglobin concentration (MCHC)** represents the average concentration of Hb in an average RBC, defined as:

   $$MCHC = \frac{\text{Hb} \times 100}{\text{Hct}}$$

   (1) **Normal range for MCHC** is 34 ± 3.
   (2) **Low MCHC** indicates **hypochromia** (pale RBCs resulting from decreased Hb content), as occurs in iron deficiency.
   d. **Red blood cell distribution width (RDW)** is a relatively new index of RBCs. Normally, most RBCs are approximately equal in size, so that only one bell-shaped histogram peak is generated. Disease may change the size of some RBCs—for example, the gradual change in size of newly produced RBCs in folic acid or iron deficiency. The difference in size between the abnormal and the less abnormal RBCs produces either more than one histogram peak or a broadening of the normal peak. This value is used primarily with other tests to diagnose iron-deficiency anemia.
   (1) **An increased RDW** is found in factor deficiency anemia (e.g., iron, folate, vitamin B_{12}).
   (2) **A normal RDW** is found in such conditions as anemia or chronic disease.
   (3) The **RDW index** is never decreased.

5. The **reticulocyte count** provides a measure of immature RBCs (reticulocytes), which contain remnants of nuclear material (reticulum). Normal RBCs circulate in the blood for about 1 to 2 days in this form. Hence, this test provides an index of bone marrow production of mature RBCs.
   a. Reticulocytes normally make up 0.1% to 2.4% of the total RBC count.
   b. **Increased reticulocyte count** occurs with such conditions as hemolytic anemia, acute blood loss, and response to the treatment of a factor deficiency (e.g., an iron, vitamin B_{12}, or folate deficiency). **Polychromasia** (the tendency to stain with acidic or basic dyes) noted on a peripheral smear laboratory report usually indicates increased reticulocytes.
   c. **Decreased reticulocyte count** occurs with such conditions as drug-induced aplastic anemia.
6. The **erythrocyte sedimentation rate (ESR)** measures the rate of RBC settling of whole, uncoagulated blood over time, and it primarily reflects plasma composition. Most of the sedimentation effect results from alterations in plasma proteins.
   a. **Normal ESR rates** range from 0 to 20 mm/hr for males and from 0 to 30 mm/hr for females.
   b. **ESR values increase** with acute or chronic infection, tissue necrosis or infarction, well-established malignancy, and rheumatoid collagen diseases.
   c. **ESR values** are used to
      (1) Follow the clinical course of a disease
      (2) Demonstrate the presence of occult organic disease
      (3) Differentiate conditions with similar symptomatology—for example, angina pectoris (no change in ESR value) as opposed to a myocardial infarction (increase in ESR value)

B. **WBCs (leukocytes)**
1. The **WBC count** reports the number of leukocytes in a given volume of whole blood.
   a. **Normal values** range from 4,000 to 11,000 $\times 10^3$ cells/mm^3 (or 10^9 cells/L)
   b. **Increased WBC count (leukocytosis)** usually signals infection; it may also result from leukemia, tissue necrosis, or administration of corticosteroids. It is most often found with **bacterial infection**.
   c. **Decreased WBC count (leukopenia)** indicates bone marrow depression, which may result from metastatic carcinoma, lymphoma, or toxic reactions to substances such as antineoplastic agents.
2. The **WBC differential** evaluates the distribution and morphology of the five major types of WBCs: the **granulocytes** (**neutrophils**, **basophils**, **eosinophils**) and the **nongranulocytes** (**lymphocytes**, **monocytes**). A certain percentage of each type makes up the total WBC count (*Table 30-1*).
   a. **Neutrophils** may be mature or immature. Mature neutrophils are **polymorphonuclear leukocytes** (PMNs), also referred to as polys; segmented neutrophils, or segs; immature neutrophils are referred to as **bands** or stabs.
      (1) **Chemotaxis.** Neutrophils that **phagocytize and degrade many types of particles** serve as the body's first line of defense when tissue is damaged or foreign material gains entry. They congregate at sites in response to a specific stimulus, through a process known as chemotaxis.

Table 30-1	NORMAL PERCENTAGE VALUES FOR WHITE BLOOD CELL (WBC) DIFFERENTIAL

Cell Type	Normal Range of Values (%)
Polymorphonuclear leukocytes	50–70
Bands	3–5
Lymphocytes	20–40
Monocytes	0–7
Eosinophils	0–5
Basophils	0–1

Table 30-2	EXAMPLES OF CHANGES IN TOTAL WHITE BLOOD CELL (WBC) COUNT AND WBC DIFFERENTIAL IN RESPONSE TO BACTERIAL INFECTION

	WBC Count	
Cell Type	Normal	With Bacterial Infection
Total WBCs	8,000 (100%)	15,500 (100%)
Neutrophils		
Polymorphonuclear leukocytes	60%	82%
Bands	3%	6%
Lymphocytes	30%	10%
Monocytes	4%	1%
Eosinophils	2%	1%
Basophils	1%	0%

(2) **Neutrophilic leukocytosis.** This describes a response to an appropriate stimulus in which the total neutrophil count increases, often with an increase in the percentage of immature cells (**a shift to the left**). This may represent a systemic bacterial infection, such as pneumonia (*Table 30-2*).

 (a) **Certain viruses** (e.g., chickenpox, herpes zoster), some **rickettsial diseases** (e.g., Rocky Mountain spotted fever), some **fungi**, and **stress** (e.g., physical exercise, acute hemorrhage or hemolysis, acute emotional stress) may also cause this response.

 (b) Other causes include **inflammatory diseases** (e.g., acute rheumatic fever, rheumatoid arthritis, acute gout), **hypersensitivity reactions to drugs**, **tissue necrosis** (e.g., from myocardial infarction, burns, certain cancers), **metabolic disorders** (e.g., uremia, diabetic ketoacidosis), **myelogenous leukemia**, and **use of certain drugs** (e.g., epinephrine, lithium).

(3) **Neutropenia**, a decreased number of neutrophils, may occur with an **overwhelming infection of any type** (bone marrow is unable to keep up with the demand). It may also occur with **certain viral infections** (e.g., mumps, measles), with **idiosyncratic drug reactions**, and as a result of chemotherapy. Neutropenia is defined as an absolute neutrophil count (ANC) of < 1000 cells/mm^3. Some define absolute neutropenia as an ANC of < 500 cells/mm^3. The ANC is calculated by multiplying the percent of neutrophils by the total WBC count:

$$WBC = 4000/mm^3$$
$$neutrophils = 60\%$$
$$ANC = 4000 \times 0.6 = 2400 \text{ cells/mm}^3$$

b. **Basophils** stain deeply with blue basic dye. Their function in the circulation is not clearly understood; in the tissues, they are referred to as **mast cells**.

 (1) **Basophilia**, an increased number of basophils, may occur with chronic myelogenous leukemia (CML) as well as other conditions.

 (2) A decrease in basophils is generally not apparent because of the small numbers of these cells in the blood.

c. **Eosinophils** stain deep red with acid dye and are classically associated with immune reactions. **Eosinophilia**, an increased number of eosinophils, may occur with such conditions as **acute allergic reactions** (e.g., **asthma**, **hay fever**, **drug allergy**) and **parasitic infestations** (e.g., trichinosis, amebiasis).

d. **Lymphocytes** play a dominant role in immunological activity and appear to produce antibodies. They are classified as B lymphocytes or T lymphocytes; T lymphocytes are further divided into helper-inducer cells (T$_H$4 cells) and suppressor cells (T$_H$8 cells).

 (1) **Lymphocytosis**, an increased number of lymphocytes, usually accompanies a normal or decreased total WBC count and is most commonly caused by **viral infection**.

(2) **Lymphopenia**, a decreased number of lymphocytes, may result from **severe debili-tating illness**, **immunodeficiency**, or from **AIDS**, which has a propensity to attack T_H4 cells.

(3) **Atypical lymphocytes** (i.e., T lymphocytes in a state of immune activation) are classically associated with **infectious mononucleosis**.

e. **Monocytes** are phagocytic cells. **Monocytosis**, an increased number of monocytes, may occur with **tuberculosis (TB)**, **subacute bacterial endocarditis**, and during the recovery phase of some **acute infections**.

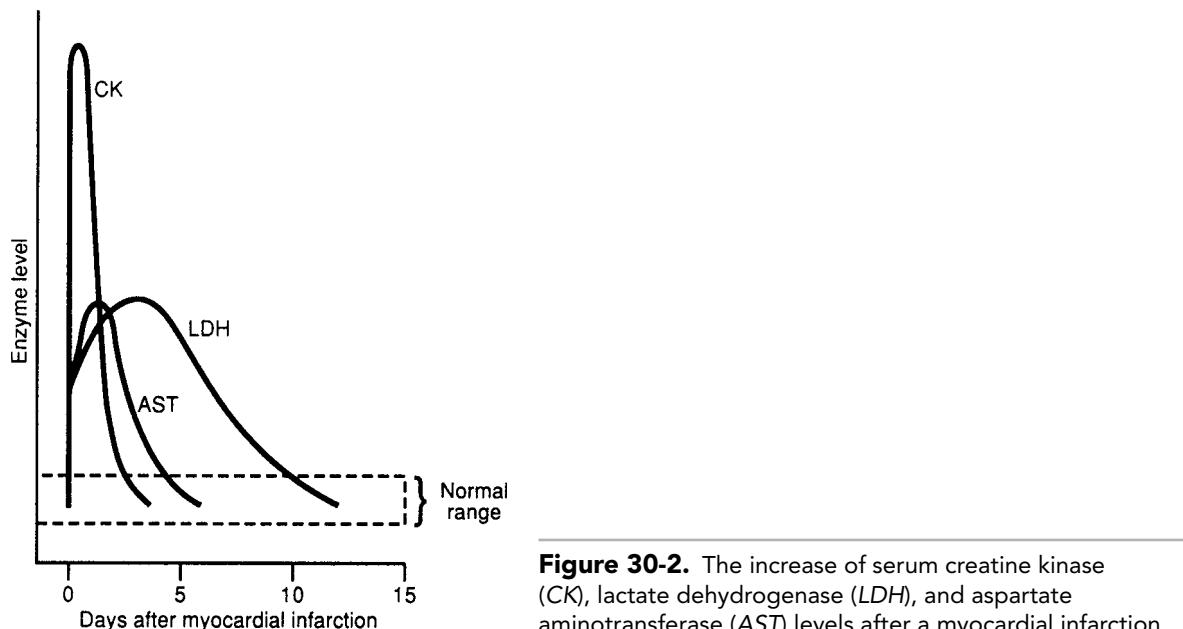
C. **Platelets (thrombocytes).** These are the smallest formed elements in the blood, and they are involved in **blood clotting** and vital to the formation of a hemostatic plug after vascular injury.

1. **Normal values for a platelet count** are 150,000 to 300,000/mm³ (1.5 to 3.0 × 10¹¹/L).

2. **Thrombocytopenia**, a decreased platelet count, can occur with a variety of conditions, such as idiopathic thrombocytopenic purpura or, occasionally, from such drugs as quinidine and sulfonamides.

a. Thrombocytopenia is **moderate** when the platelet count is < 100,000/mm³.

b. Thrombocytopenia is **severe** when the platelet count is < 50,000/mm³.

III. COMMON SERUM ENZYME TESTS.
Small amounts of enzymes (catalysts) circulate in the blood at all times and are released into the blood in larger quantities when tissue damage occurs. Thus, serum enzyme levels can be used to **aid in the diagnosis of certain diseases**.


A. **Creatine kinase (CK)**

1. Creatine kinase—formerly known as creatine phosphokinase (CPK)—is found primarily in heart muscle, skeletal muscle, and brain tissue.

2. CK levels are used primarily to **aid in the diagnosis of acute myocardial** (*Figure 30-2*) **or skeletal muscle damage**. However, vigorous exercise, a fall, or deep intramuscular injections can cause significant increases in CK levels.

3. The **isoenzymes** of CK—**CK-MM**, found in skeletal muscle; **CK-BB**, found in brain tissue; and **CK-MB**, found in heart muscle—can be used to differentiate the source of damage.

a. Normally, serum CK levels are virtually all the **CK-MM isoenzyme**.

b. Increase in **CK-MB** levels provides a sensitive indicator of myocardial necrosis.

B. **Lactate dehydrogenase (LDH)**

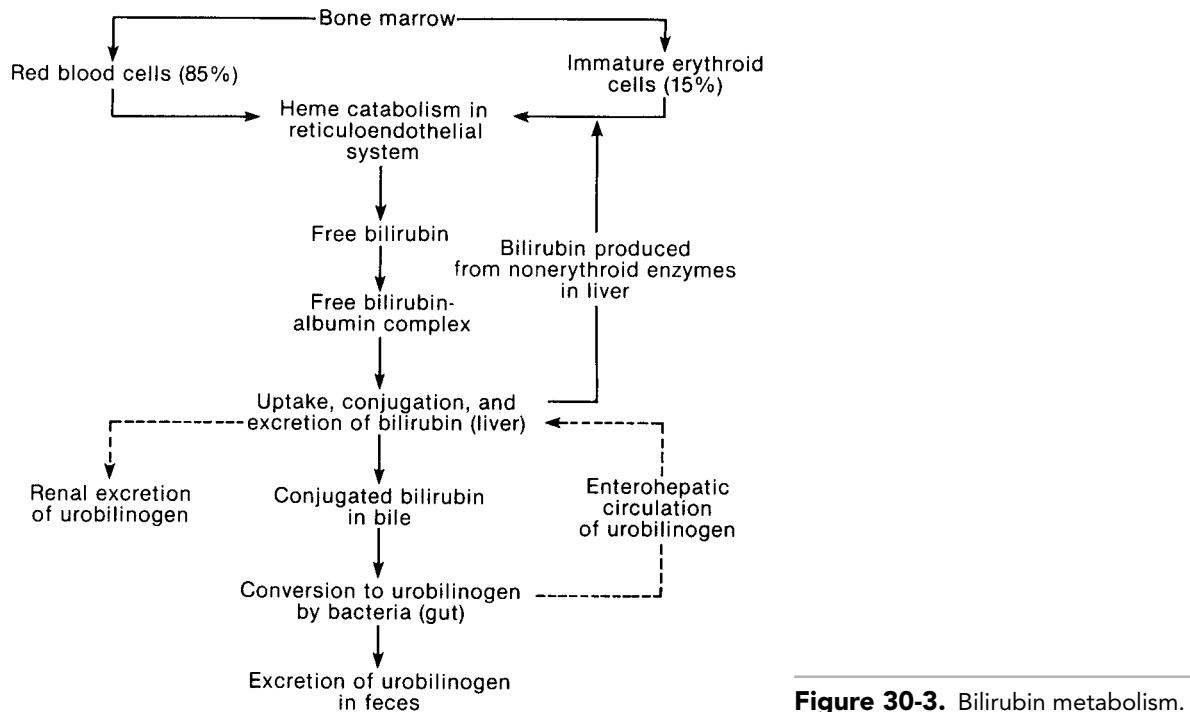
1. LDH catalyzes the interconversion of lactate and pyruvate and represents a group of enzymes present in almost all metabolizing cells.


Figure 30-2. The increase of serum creatine kinase (*CK*), lactate dehydrogenase (*LDH*), and aspartate aminotransferase (*AST*) levels after a myocardial infarction.

2. Five individual **isoenzymes** make up the total LDH serum level.
   a. LDH_1 and LDH_2 appear primarily in the heart.
   b. LDH_3 appears primarily in the lungs.
   c. LDH_4 and LDH_5 appear primarily in the liver and skeletal muscles.
3. The distribution pattern of LDH isoenzymes may aid in diagnosing myocardial infarction, hepatic disease, and lung disease.

C. Alkaline phosphatase (ALP)
   1. ALP is produced primarily in the **liver** and **bones**.
   2. Serum ALP levels are **particularly sensitive to partial or mild biliary obstruction**—either extrahepatic (e.g., caused by a stone in the bile duct) or intrahepatic, both of which cause levels to increase.
   3. **Increased osteoblastic activity**, as occurs in Paget disease, hyperparathyroidism, osteomalacia, and others, also increases serum ALP levels.

D. Aspartate aminotransferase (AST)
   1. Aspartate aminotransferase—formerly known as **serum glutamic-oxaloacetic transaminase (SGOT)**—is found in a number of organs, primarily in heart and liver tissues and, to a lesser extent, in skeletal muscle, kidney tissue, and pancreatic tissue.
   2. **Damage to the heart** (e.g., from **myocardial infarction**) results in increased AST levels about 8 hrs after injury (*Figure 30-2*).
      a. Levels are **increased markedly** with **acute hepatitis**; they are **increased mildly** with **cirrhosis** and a **fatty liver**.
      b. Levels are also **increased** with **passive congestion of the liver**, such as occurs in congestive heart failure (CHF).

E. Alanine aminotransferase (ALT)
   1. Alanine aminotransferase—formerly known as **serum glutamic-pyruvic transaminase (SGPT)**—is found in the liver, with lesser amounts in the heart, skeletal muscles, and kidney.
   2. Although ALT values are **relatively specific for liver cell damage**, ALT is **less sensitive than AST**, and extensive or severe liver damage is necessary before abnormally increased levels are produced.
   3. ALT also **increases less consistently and less markedly than AST after an acute myocardial infarction**.

F. Cardiac troponins (I, T, and C)
   1. Troponins are a relatively new method to identify myocardial cell injury and thus assist in the diagnosis of acute myocardial infarction. These troponins may possess superior specificity in situations in which false-positive elevations of CK-MB are likely.
   2. Troponin T is found in cardiac and skeletal muscle, troponin I is found only in cardiac muscle, and troponin C is present in two isoforms found in skeletal and cardiac muscle. Troponin T has shown prognostic value in unstable angina and in detecting minor myocardial cell injury with greater sensitivity than CK-MB.
   3. The normal value for troponin T is < 0.1 ng/mL and I is < 1.5 ng/mL.

IV. LIVER FUNCTION TESTS

A. Liver enzymes
   1. **Levels of certain enzymes** (e.g., LDH, ALP, AST, ALT) **increase with liver dysfunction** (see III).
   2. These **enzyme tests indicate only that the liver has been damaged**. They do not assess the liver's ability to function. Other tests provide indications of liver dysfunction.

B. Serum bilirubin
   1. Bilirubin, a breakdown product of Hb, is the **predominant pigment in bile**. Effective bilirubin conjugation and excretion depend on **hepatobiliary function** and on the **rate of RBC turnover**.
   2. Serum bilirubin levels are reported as **total bilirubin** (conjugated and unconjugated) and as **direct bilirubin** (conjugated only).
      a. Bilirubin is released by Hb breakdown and is bound to albumin as water-insoluble **indirect bilirubin** (unconjugated bilirubin), which is not filtered by the glomerulus.
      b. **Unconjugated bilirubin** travels to the liver, where it is separated from albumin, conjugated with diglucuronide, and then actively secreted into the bile as **conjugated bilirubin** (direct bilirubin), which is filtered by the glomerulus (*Figure 30-3*).
   3. **Normal values of total serum bilirubin** are 0.1 to 1.0 mg/dL (2 to 18 mmol/L); of **direct bilirubin**, 0.0 to 0.2 mg/dL (0 to 4 mmol/L).

Figure 30-3. Bilirubin metabolism.

4. **An increase in serum bilirubin** results in **jaundice** from bilirubin deposition in the tissues. There are three major causes of increased serum bilirubin.
   a. **Hemolysis** increases total bilirubin; direct bilirubin (conjugated) is usually normal or slightly increased. Urine color is normal, and no bilirubin is found in the urine.
   b. **Biliary obstruction**, which may be intrahepatic (as with a chlorpromazine reaction) or extrahepatic (as with a biliary stone), increases total bilirubin and direct bilirubin; intrahepatic cholestasis (e.g., from chlorpromazine) may increase direct bilirubin as well. Urine color is dark, and bilirubin is present in the urine.
   c. **Liver cell necrosis**, as occurs in viral hepatitis, may cause an increase in both direct bilirubin (because inflammation causes some bile sinusoid blockage) and indirect bilirubin (because the liver's ability to conjugate is altered). Urine color is dark, and bilirubin is present in the urine.

C. **Serum proteins**
   1. **Primary serum proteins** measured are **albumin** and the **globulins** (i.e., α, β, γ).
      a. **Albumin** (4 to 6 g/dL) maintains serum oncotic pressure and serves as a transport agent. Because it is primarily manufactured by the liver, liver disease can decrease albumin levels. Albumin can also be used to assess nutritional status.
      b. **Globulin** (23 to 35 g/L) relates to the total measurement of immunoglobins (antibodies) found in the serum and function as transport agents and play a role in certain immunological mechanisms. A decrease in albumin levels usually results in a compensatory increase in globulin production.
   2. **Normal values** for total serum protein levels are 6 to 8 g/dL (60 to 80 g/L).

V. URINALYSIS.

Composed of chemical and microscopic tests of the urine used to provide basic information regarding renal function, urinary tract disease, and the presence of certain systemic diseases. Components of a standard urinalysis include physical (color, turbidity, odor, specific gravity, and osmolality), chemical (pH, Hb, glucose, protein, glucose, ketone, leukocyte esterase, nitrites, bilirubin) and microscopic examination (RBC, WBC, epithelial cells, casts, bacteria).

A. **Appearance.** Normal urine is **clear** and ranges in color from **pale yellow to deep gold. Changes in color** can result from drugs, diet, or disease.
   1. A **red color** may indicate, among other things, the presence of blood or phenolphthalein (a laxative).

2. A **brownish yellow color** may indicate the presence of conjugated bilirubin.

3. Other shades of red, **orange**, **or brown** may be caused by ingestion of various drugs (e.g., rifampin).

B. pH

1. Normal pH ranges from 4.5 to 9.0 but is typically **acidic** (around 6.0).

2. Alkaline pH may indicate such conditions as alkalosis, a **Proteus** infection, or acetazolamide use. It may also reflect changes caused by leaving the urine sample at room temperature.

C. Specific gravity

1. Normal range for specific gravity is 1.003 to 1.035; it is usually between 1.010 and 1.025.

2. Specific gravity is influenced by the number and nature of solute particles in the urine.

    a. Increased specific gravity may occur with such conditions as diabetes mellitus (excess glucose in the urine) or nephrosis (excess protein in the urine).

    b. Decreased specific gravity may occur with diabetes insipidus, which decreases urine concentration.

    c. Specific gravity, **fixed at 1.010** (the same as plasma), occurs when the kidneys lose their power to concentrate or dilute.

D. Protein

1. Normal values for urine protein are 50 to 80 mg per 24 hr because the glomerular membrane prevents most protein molecules in the blood from entering the urine.

2. Proteinuria occurs with many conditions (e.g., renal disease, bladder infection, venous congestion, fever).

    a. The presence of a **specific protein** can help identify a specific disease state (e.g., Bence Jones protein may indicate multiple myeloma).

    b. Most often, the protein in urine is **albumin**. Albuminuria may indicate abnormal glomerular permeability.

E. Glucose

1. The normal **renal threshold** for glucose is a blood glucose level of about 180 mg/dL; **glucose does not normally appear in urine** as detected by popular testing methods.

2. Glycosuria usually indicates diabetes mellitus (DM). There are certain less common causes (e.g., a lowered renal threshold for glucose).

F. Ketones

1. Ketones **do not normally appear in urine**. They are excreted when the body has used available glucose stores and begins to metabolize fat stores.

2. The **three ketone bodies** are **β-hydroxybutyric acid** (80%), **acetoacetic acid** (about 20%), and acetone (a small percentage). Some commercial tests (e.g., Ames products) measure only acetoacetic acid, but usually all three are excreted in parallel proportions.

3. Ketonuria usually indicates uncontrolled DM, but it may also occur with starvation and with zero- or low-carbohydrate diets.

G. Evaluation. Microscopic examination of centrifuged urine sediment normally reveals 0 to 1 RBC, 0 to 4 WBCs, and only an occasional cast per high-power field (HPF).

1. Hematuria (i.e., the presence of RBCs) may indicate such conditions as trauma, a tumor, or a systemic bleeding disorder. In women, a significant number of **squamous cells** suggests vaginal contamination (menstruation).

2. Casts (i.e., protein conglomerations outlining the shape of the renal tubules in which they were formed) may or may not be significant. Excessive numbers of certain types of casts indicate renal disease.

3. Crystals, which are pH dependent, may occur normally in acid or alkaline urine. **Uric acid crystals** may form in acid urine; **phosphate crystals** may form in alkaline urine.

4. Bacteria do not normally appear in urine. The finding of 50 or more bacteria per HPF may indicate a urinary tract infection (UTI); smaller values may indicate urethral contamination.

VI. COMMON RENAL FUNCTION TESTS

A. Introduction

1. Renal function may be assessed by measuring **blood urea nitrogen (BUN)** and **serum creatinine**. Renal function decreases with age, which must be taken into account when interpreting test values.

    a. These tests primarily evaluate glomerular function by assessing the **glomerular filtration rate (GFR)**.

    b. In many **renal diseases**, urea and creatinine accumulate in the blood because they are not excreted properly.

    c. These tests also aid in determining **drug dosage** for drugs excreted through the kidneys.

  2. Azotemia describes excessive retention of nitrogenous waste products (BUN and creatinine) in the blood. The clinical syndrome resulting from decreased renal function and azotemia is called **uremia**.

    a. Renal azotemia results from renal disease, such as glomerulonephritis and chronic pyelonephritis.

    b. Prerenal azotemia results from such conditions as severe dehydration, hemorrhagic shock, and excessive protein intake.

    c. Postrenal azotemia results from such conditions as ureteral or urethral stones or tumors and prostatic obstructions.

  3. Clearance—a theoretical concept defined as the volume of plasma from which a measured amount of substance can be completely eliminated, or cleared, into the urine per unit time—can be used to estimate glomerular function.

B. BUN

  1. Urea, an end product of protein metabolism, is produced in the liver. From there, it travels through the blood and is excreted by the kidneys. Urea is **filtered at the glomerulus**, where the tubules reabsorb approximately 40%. Thus, under normal conditions, **urea clearance** is about 60% of the true GFR.

  2. Normal values for BUN range from 8 mg/dL to 18 mg/dL (3.0 to 6.5 mmol/L).

    a. Decreased BUN levels occur with **significant liver disease**.

    b. Increased BUN levels may indicate **renal disease**. However, factors other than glomerular function (e.g., protein intake, reduced renal blood flow, blood in the gastrointestinal tract) readily affect BUN levels, sometimes making interpretation of results difficult.

C. Serum creatinine

  1. Creatinine (CR), the metabolic breakdown product of muscle creatine phosphate, has a relatively constant level of daily production. Blood levels vary little in a given individual.

  2. Creatinine is **excreted** by glomerular filtration and tubular secretion. **Creatinine clearance** parallels the GFR within a range of $\pm$ 10% and is a **more sensitive indicator of renal damage than BUN levels** because renal impairment is almost the only cause of an increase in the serum creatinine level.

  3. Normal values for serum creatinine range from 0.6 to 1.2 mg/dL (50 to 110 mmol/L).

    a. Values vary with the **amount of muscle mass**—a value of 1.2 mg/dL in a muscular athlete may represent normal renal function, whereas the same value in a small, sedentary person with little muscle mass may indicate significant renal impairment.

    b. Generally, the **serum creatinine value doubles with each 50% decrease in GFR**. For example, if a patient's normal serum creatinine is 1 mg/dL, 1 mg/dL represents 100% renal function, 2 mg/dL represents 50% function, and 4 mg/dL represents 25% function.

D. Creatinine clearance

  1. Creatinine clearance, which represents the **rate at which creatinine is removed from the blood by the kidneys**, roughly approximates the GFR.

    a. The value is given in units of milliliters per minute, representing the volume of blood cleared of creatinine by the kidney per minute.

    b. Normal values for men range from 75 to 125 mL/min.

  2. Calculation requires knowledge of **urinary creatinine excretion** (usually over 24 hrs) and concurrent **serum creatinine levels**. **Creatinine clearance is calculated** as follows:

$$Cl_{CR} = \frac{C_u V}{C_{CR}}$$

where Cl_{CR} is the creatinine clearance in milliliters per minute, C_U is the concentration of creatinine in the urine, V is the volume of urine (in milliliters per minute of urine formed over the collection period), and C_{CR} is the serum creatinine concentration.

  3. Suppose the serum creatinine concentration is 1 mg/dL, and 1440 mL of urine was collected in 24 hrs (1440 mins) for a urine volume of 1 mL/min. The urine contains 100 mg/dL of creatinine. Creatinine clearance is calculated as:

$$\frac{100\ \text{mg/mL} \times 1\ \text{mL/min}}{1\ \text{mg/dL}} = 100\ \text{mL/min}$$

4. Incomplete bladder emptying and other problems may interfere with obtaining an accurate timed urine specimen. Thus, **estimations of creatinine clearance** may be necessary. These estimations require only a serum creatinine value. One estimation uses the method of **Cockcroft and Gault**, which is based on body weight, age, and gender.

a. This formula provides an **estimated value**, calculated for **males** as:

$$Cl_{CR} = \frac{[140 - \text{age (in years)}] \times \text{body weight (in kg)}}{72 \times C_{CR} \text{ (in mg/dL)}}$$

b. For **females**, use 0.85 of the value calculated for males.

c. **Example:** A 20-year-old man weighing 72 kg has a C_{CR} of 1.0 mg/dL; thus

$$C_{CR} = \frac{(140 - 20 \text{ years}) \times 72 \text{ kg}}{72 \times 1 \text{ mg/dL}} = 120 \text{ mL/min}$$

5. **Determination of GFR.** The modified diet in renal disease (MDRD) equation is considered a more accurate measurement of GFR than other equations used to estimate renal function (e.g., Cockcroft–Gault) in patients with *reduced* GFR and is used in staging renal disease. Patients must have a serum creatinine concentration.

a. The MDRD equation for **males** is as follows:

$$GFR = 186 \, (Pcr)^{-1.154} \times \text{age}^{-0.203}$$

where Pcr is serum creatinine. For **females**, multiply the result by 0.742; for **African Americans**, multiply by 1.210.

b. The MDRD has been validated in Caucasians, patients with diabetic kidney disease, kidney transplant recipients, and African Americans and Asians with nondiabetic kidney disease.

c. The MDRD equation has *not* been validated in patients < 18 years of age, pregnant women, patients > 70 years of age, other ethnic groups, patients with normal kidney function who are at an increased risk for chronic kidney disease, and patients with normal renal function.

d. Many institutions are routinely reporting an MDRD-derived GFR estimation for patients as a routine component of a blood chemistry study. This value should be used to assist the clinician in staging a patient's degree of renal dysfunction and is not a substitute for creatinine clearance as estimated by the Cockcroft and Gault equation, which should be used for drug dosing in renal impairment. The MDRD estimate has not been evaluated for the purpose of drug dosing.

VII. ELECTROLYTES

A. **Sodium (Na)**

1. Sodium is the major cation of the **extracellular** fluid. Sodium, along with chloride (Cl), potassium (K), and water, is important in the regulation of osmotic pressure and water balance between intracellular and extracellular fluids. **Normal values** are 135 to 147 mEq/L or mmol/L.

2. The sodium concentration is defined as the ratio of sodium to water, not the absolute amounts of either. Laboratory tests for sodium are used mainly to detect disturbances in water balance and body osmolality. The kidneys are the major organs of sodium and water balance.

3. An increase in sodium concentration (**hypernatremia**) may indicate impaired sodium excretion or dehydration. A decrease in sodium concentration (hyponatremia) may reflect overhydration, abnormal sodium loss, or decreased sodium intake.

4. Patients with kidney, heart, or pulmonary disease may have difficulty with sodium and water balance. In adults, changes in sodium concentrations most often reflect changes in water balance, not salt imbalances. Therefore, sodium concentration is often used as an indicator of fluid status, rather than salt imbalance.

5. Control of sodium by the body is accomplished mainly through the hormones aldosterone and antidiuretic hormone (ADH).

a. ADH is released from the pituitary gland in response to signals from the hypothalamus. ADH's presence in the distal tubules and collecting ducts of the kidney causes them to become more permeable to the reabsorption of water; therefore, concentrating urine.
    b. Aldosterone affects the distal tubular reabsorption of sodium as opposed to water. Aldosterone is released from the adrenal cortex in response to low sodium, high potassium, low blood volume, and angiotensin II. Aldosterone causes the spilling of potassium from the distal tubules into the urine in exchange for sodium reabsorption.

6. **Hyponatremia** is usually related to total body depletion of sodium—as in mineralocorticoid deficiencies, sodium-wasting renal disease, replacement of fluid loss with nonsaline solutions, gastrointestinal (GI) losses, renal losses, or loss of sodium through the skin—or to dilution of serum sodium—as in cirrhosis, CHF, nephrosis, renal failure, excess water intake, or syndrome of inappropriate antidiuretic hormone (SIADH) secretion.

7. **Hypernatremia** usually results from a loss of free water or hypotonic fluid or through excessive sodium intake. Free water loss is most often associated with diabetes insipidus, but fluid loss can be via the GI tract, renal, skin, or respiratory systems. Excess sodium intake can occur through the administration of hypertonic intravenous (IV) solutions, mineralocorticoid excess, excessive sodium ingestion, or after administration of drugs high in sodium content (e.g., ticarcillin, sodium bicarbonate [HCO^{-3}]).

B. **Potassium (K)**

1. Potassium is the most abundant **intracellular** cation (intracellular fluid potassium averages 141 mEq/L). Approximately 3500 mEq of potassium is contained in the body of a 70-kg adult. Only 10% of the body's potassium is extracellular. Normal values are 3.5 to 5.0 mEq/L or mmol/L.

2. The serum potassium concentration is not an adequate measure of the total body potassium because most of the body's potassium is intracellular. Fortunately, the clinical signs and symptoms of potassium deficiency—malaise, confusion, dizziness, electrocardiogram (ECG) changes, muscle weakness, and pain—correlate well with serum concentrations. The serum potassium concentration is buffered by the body and may be "normal" despite total body potassium loss. Potassium depletion causes a shift of intracellular potassium to the extracellular fluid to maintain potassium concentrations. There is approximately a 100 mEq total body potassium deficit when the serum potassium concentration decreases by 0.3 mEq/L. This may result in misinterpretation of serum potassium concentrations as they relate to total body potassium.

3. The role or function of potassium is in the maintenance of proper electrical conduction in cardiac and skeletal muscles (muscle and nerve excitability); it exerts an influence on the body's water balance (intracellular volume) and plays a role in acid–base equilibrium.

4. Potassium is regulated by
       a. Kidneys (renal function)
       b. Aldosterone
       c. Arterial pH
       d. Insulin
       e. Potassium intake
       f. Sodium delivery to distal tubules

5. **Hypokalemia** can occur. The kidneys are responsible for approximately 90% of the daily potassium loss. Other losses occur mainly through the GI system. Even in states of no potassium intake, the kidneys still excrete up to 20 mEq of potassium daily. Therefore, prolonged periods of potassium deprivation can result in hypokalemia. Hypokalemia can also result from potassium loss through vomiting or diarrhea, nasogastric suction, laxative abuse, and by diuretic use (mannitol, thiazides, or loop diuretics). Excessive mineralocorticoid activity and glucosuria can also result in hypokalemia. Potassium can be shifted into cells with alkalemia and after administration of glucose and insulin.

6. **Hyperkalemia** most commonly results from decreased renal elimination, excessive intake, or from cellular breakdown (tissue damage, hemolysis, burns, infections). Metabolic acidosis may also result in a shift of potassium extracellularly as hydrogen ions move into cells and are exchanged for potassium and sodium ions. As a general guideline, for every 0.1 unit, pH change from 7.4, the potassium concentration will change by about 0.6 mEq/L. If a patient has a pH of 7.1 and a measured potassium of 4.5 mEq/L, the actual potassium concentration would be

$$0.3 \text{ (units less than 7.4)} \times 0.6 = 1.8$$
$$\text{Potassium concentration} = 4.5 - 1.8 = 2.7 \text{ mEq/L}$$

Correction of the acidosis in this situation will result in a dramatic decrease in potassium unless supplementation is instituted.

C. **Chloride (Cl)**

1. Chloride is the major anion of the extracellular fluid and is important in the maintenance of acid–base balance. Alterations in the serum chloride concentration are rarely a primary indicator of major medical problems. Chloride itself is not of primary diagnostic significance. It is usually measured to confirm the serum sodium concentration. The relationship among sodium, chloride, and HCO^{-3} is described by the following:

$$Cl^- + HCO^{-3} + R = Na^+$$

where R is the anion gap. The **normal value** for Cl is 95 to 105 mEq/L or mmol/L.

2. **Hypochloremia** is a decreased chloride concentration, and it is often accompanied by metabolic alkalosis or acidosis caused by organic or other acids. Other causes include chronic renal failure, adrenal insufficiency, fasting, prolonged diarrhea, severe vomiting, and diuretic therapy.

3. **Hyperchloremia** is an increased chloride concentration that may indicate hyperchloremic metabolic acidosis. Hyperchloremia in the absence of metabolic acidosis is unusual because chloride retention is often accompanied by sodium and water retention. Other causes include acute renal failure, dehydration, and excess chloride administration.

D. **Bicarbonate (HCO^{-3})/carbon dioxide (CO_2) content**

1. The carbon dioxide (CO_2) content represents the sum of the bicarbonate (HCO^{-3}) concentration and the concentration of CO_2 dissolved in the serum. The HCO^{-3}/CO_2 system is the most important buffering system to maintain pH within physiological limits. Most disturbances of acid–base balance can be considered in terms of this system. Normal values are 22 to 28 mEq/L or mmol/L.

2. The relationship among this system is defined as follows:

$$HCO^{-3} + H^+ \times H_2CO_3 \times H_2O + CO_2$$

(bicarbonate ions bind hydrogen ions to form carbonic acid). Clinically, the serum HCO^{-3} concentration is measured because acid–base balance can be inferred if the patient has normal pulmonary function.

3. **Hypobicarbonatemia** is usually caused by metabolic acidosis, renal failure, hyperventilation, severe diarrhea, drainage of intestinal fluid, and by drugs such as acetazolamide. Toxicity caused by salicylates, methanol, and ethylene glycol can also decrease the HCO^{-3} level.

4. **Hyperbicarbonatemia** is usually caused by alkalosis, hypoventilation, pulmonary disease, persistent vomiting, excess HCO^{-3} intake with poor renal function, and diuretics.

VIII. MINERALS

A. **Calcium (Ca)**

1. Calcium plays an important role in nerve impulse transmission, muscle contraction, pancreatic insulin release, and hydrogen ion release from the stomach, as a cofactor for some enzyme reactions and blood coagulation and, most important, bone and tooth structural integrity. Normal total calcium values are 8.8 to 10.3 mg/dL or 2.20 to 2.56 mmol/L.

2. The total calcium content of normal adults is 20 to 25 g/kg of fat-free tissue, and about 44% of this calcium is in the body skeleton. Approximately 1% of skeletal calcium is freely exchangeable with that of the extracellular fluid. The reservoir of calcium in bones maintains the concentration of calcium in the plasma constant. About 40% of the calcium in the extracellular fluid is bound to plasma proteins (especially albumin), 5% to 15% is complexed with phosphate and citrate, and 45% to 55% is in the unbound, ionized form. Most laboratories measure the total calcium concentration; however, it is the free, ionized calcium that is important physiologically. Ionized calcium levels may be obtained from the laboratory. Clinically, the most important determinant of ionized calcium is the amount of serum protein (albumin) available for binding. The normal serum calcium range is for a serum albumin of 4.0 g/dL. A good approximation is that for every 1.0 g/dL decrease in albumin, 0.8 g/dL should be added to the calcium laboratory result. Doing this corrects the total plasma concentration to reflect the additional amount of free (active) calcium.

3. **Hypocalcemia** usually implies a deficiency in either the production or response to parathyroid hormone (PTH) or vitamin D. PTH abnormalities include hypoparathyroidism, pseudohypoparathyroidism, or hypomagnesemia. Vitamin D abnormalities can be caused by decreased

nutritional intake, decreased absorption of vitamin D, a decrease in production, or an increase in metabolism. Administration of loop diuretics causing diuresis can also decrease serum calcium.

4. **Hypercalcemia** is an increased calcium concentration, and it is usually associated with malignancy or metastatic diseases. Other causes include hyperparathyroidism, Paget disease, milk-alkali syndrome, granulomatous disorders, thiazide diuretics, excessive calcium intake, or vitamin D intoxication.

B. **Phosphate (PO_4)**

1. Phosphate is a major intracellular anion and is the source of phosphate for adenosine triphosphate (ATP) and phospholipid synthesis. Serum calcium and PO_4 are influenced by many of the same factors. It is useful to consider calcium and PO_4 together when interpreting lab results. Normal PO_4 values are 2.5 to 5.0 mg/dL or 0.80 to 1.60 mmol/L.

2. **Hyperphosphatemia** and **hypophosphatemia** can occur. The extracellular fluid concentration of phosphate is influenced by PTH, intestinal absorption, renal function, nutrition, and bone metabolism. Hyperphosphatemia is usually caused by renal insufficiency, although increased vitamin D or phosphate intake, hypoparathyroidism, and hyperthyroidism are also causes. Hypophosphatemia can occur in malnutrition, especially when anabolism is induced, after administration of aluminum-containing antacids or calcium acetate, in chronic alcoholics, and in septic patients. Hyperparathyroidism and insufficient vitamin D intake can also induce hypophosphatemia.

C. **Magnesium (Mg)**

1. Magnesium is the second most abundant intracellular and extracellular cation. It is an activator of numerous enzyme systems that control carbohydrate, fat and electrolyte metabolism, protein synthesis, nerve conduction, muscular contractility, as well as membrane transport and integrity. Normal values are 1.6 to 2.4 mEq/L or 0.80 to 1.20 mmol/L.

2. **Hypomagnesemia** and **hypermagnesemia** can occur. **Hypomagnesemia** is found more often than hypermagnesemia. Depletion of magnesium usually results from excessive loss from the GI tract or the kidneys. Depletion can occur from either poor intestinal absorption or excessive GI fluid loss. Signs and symptoms include weakness, muscle fasciculations with tremor, tetany, and increased reflexes. Decreased intracardiac magnesium may manifest as an increased QT interval with an increased risk of arrhythmia. **Hypermagnesemia** is most commonly caused by increased magnesium intake in the setting of renal insufficiency. Other causes include excess magnesium intake, hepatitis, and Addison disease. Signs and symptoms of hypermagnesemia include bradycardia, flushing, sweating, nausea and vomiting, decreased calcium level, decreased deep-tendon reflexes, flaccid paralysis, increased pulse rate and QRS intervals, respiratory distress, and asystole.

Study Questions

Directions for questions 1–16: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Hematological testing of a patient with AIDS is most likely to show which of the following abnormalities?

   (A) basophilia
   (B) eosinophilia
   (C) lymphopenia
   (D) reticulocytosis
   (E) agranulocytosis

2. Hematological studies are most likely to show a low reticulocyte count in a patient who has which of the following abnormalities?

   (A) aplastic anemia secondary to cancer chemotherapy
   (B) acute hemolytic anemia secondary to quinidine treatment
   (C) severe bleeding secondary to an automobile accident
   (D) iron-deficiency anemia 1 week after treatment with ferrous sulfate
   (E) megaloblastic anemia owing to folate deficiency 1 week after treatment with folic acid

3. All of the following findings on a routine urinalysis would be considered normal *except* which one?

   (A) pH: 6.5
   (B) glucose: negative
   (C) ketones: negative
   (D) white blood cells (WBCs): 3 per high-power field (HPF), no casts
   (E) red blood cells (RBCs): 5 per HPF

4. A 12-year-old boy is treated for otitis media with cefaclor (Ceclor). On the seventh day of therapy, he spikes a fever and develops an urticarial rash on his trunk. Which of the following laboratory tests could best confirm the physician's suspicion of a hypersensitivity (allergic) reaction?

   (A) complete blood count (CBC) and differential
   (B) serum hemoglobin (Hb) and reticulocyte count
   (C) liver function test profile
   (D) lactate dehydrogenase (LDH) isoenzyme profile
   (E) red blood cell (RBC) count and serum bilirubin

5. An increased hematocrit (Hct) is a likely finding in all of the following individuals *except* which one?

   (A) a man who has just returned from a 3-week skiing trip in the Colorado Rockies
   (B) a woman who has polycythemia vera
   (C) a hospitalized patient who mistakenly received 5 L of intravenous (IV) dextrose 5% in water (D_5W) over the last 24 hrs
   (D) a man who has been rescued from the Arizona desert after spending 4 days without water
   (E) a woman who has chronic obstructive pulmonary disease

6. A 29-year-old white man is seen in the emergency room. His white blood cell (WBC) count is 14,200 with 80% polys. All of the following conditions could normally produce these laboratory findings *except* which one?

   (A) a localized bacterial infection on the tip of the index finger
   (B) acute bacterial pneumonia caused by *Streptococcus pneumoniae*
   (C) a heart attack
   (D) a gunshot wound to the abdomen with a loss of 2 pints of blood
   (E) an attack of gout

7. A 52-year-old male construction worker who drinks "fairly heavily" when he gets off work is seen in the emergency room with, among other abnormal laboratory results, an increased creatine kinase (CK) level. All of the following circumstances could explain this increase *except* which one?

   (A) He fell against the bumper of his car in a drunken stupor and bruised his right side.
   (B) He is showing evidence of some liver damage owing to the heavy alcohol intake.
   (C) He has experienced a heart attack.
   (D) He received an intramuscular (IM) injection a few hours before the blood sample was drawn.
   (E) He pulled a muscle that day when lifting a heavy concrete slab.

8. A 45-year-old man with jaundice has spillage of bilirubin into his urine. All of the following statements could apply to this patient *except* which one?

   (A) His total bilirubin is increased.
   (B) His direct bilirubin is increased.
   (C) He may have viral hepatitis.
   (D) He may have hemolytic anemia.
   (E) He may have cholestatic hepatitis.

For questions 9–11: A 70-year-old black man weighing 154 lbs complains of chronic fatigue. Several laboratory tests were performed with the following results:

> **blood urea nitrogen (BUN)** 15 mg/dL
> **aspartate aminotransferase (AST)** within normal limits
> **white blood cell (WBC) count** 7500/mm^3
> **red blood cell (RBC) count** 4 million/mm^3
> **hematocrit (Hct)** 29%
> **hemoglobin (Hb)** 9 g/dL

9. This patient's mean cell hemoglobin concentration (MCHC) is

   (A) 27.5.
   (B) 28.9.
   (C) 31.0.
   (D) 33.5.
   (E) 35.4.

10. His mean cell volume (MCV) is

   (A) 61.3.
   (B) 72.5.
   (C) 77.5.
   (D) 90.2.
   (E) 93.5.

11. From the data provided and from the calculations in questions 9 and 10, this patient is best described as

    (A) normal except for a slightly increased blood urea nitrogen (BUN).

    (B) having normochromic, microcytic anemia.

    (C) having sickle-cell anemia.

    (D) having hypochromic, normocytic anemia.

    (E) having folic acid deficiency.

12. All of the following statements about sodium (Na) are true *except* which one?

    (A) The normal range for sodium is 135 to 147 mEq/L.

    (B) Sodium is the major cation of the extracellular fluid, and the laboratory test is used mainly to detect disturbances in water balance.

    (C) Hyponatremia usually results from the total body depletion of sodium or through a dilutional effect.

    (D) Control of the sodium concentration is mainly through regulation of arterial pH.

13. A 53-year-old woman with diabetes mellitus is seen in the emergency room. Her blood glucose is 673 mg/dL and ketones are present in her blood. A diagnosis of diabetic ketoacidosis (DKA) is made. Other important laboratory values are potassium of 4.8 mEq/L, 4+ glucose in urine, and an arterial pH of 7.1. All of the following statements apply to this patient *except* which one?

    (A) Her potassium value is normal; therefore, no potassium supplementation is likely to be necessary.

    (B) Her potassium value should be corrected owing to her acidosis; a corrected potassium would be 3.0 mEq/L.

    (C) Potassium supplementation should be instituted because her total body potassium is depleted.

    (D) Factors affecting potassium in this patient include glycosuria and arterial pH.

14. A 50-year-old man presents with bicarbonate of 18 mEq/L. All of the following could be a cause of his low bicarbonate level *except*

    (A) metabolic acidosis.

    (B) salicylate toxicity.

    (C) diuretic therapy.

    (D) diarrhea.

15. All of the following statements about calcium (Ca) and phosphorus (PO_4) are true *except* which one?

    (A) An alcoholic with a serum albumin of 2.0 g/dL and a serum total calcium of 8.0 mg/dL has a corrected total calcium of 9.6 mg/dL.

    (B) Calcium and PO_4 levels should be interpreted together because many of the same factors influence both minerals.

    (C) Metastatic cancer often induces a decrease in serum calcium levels.

    (D) A patient with renal failure may present with hypocalcemia and hyperphosphatemia.

16. All of the following are important functions of magnesium (Mg) *except*

    (A) nerve conduction.

    (B) phospholipid synthesis.

    (C) muscle contractility.

    (D) carbohydrate, fat, and electrolyte metabolism.

Directions for questions 17–19: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

    A   if **I only** is correct

    B   if **III only** is correct

    C   if **I and II** are correct

    D   if **II and III** are correct

    E   if **I, II**, **and III** are correct

17. Factors likely to cause an increase in the blood urea nitrogen (BUN) level include

    I. intramuscular (IM) injection of diazepam (Valium).

    II. severe liver disease.

    III. chronic kidney disease.

18. A patient who undergoes serum enzyme testing is found to have an increased aspartate aminotransferase (AST) level. Possible underlying causes of this abnormality include

    I. methyldopa-induced hepatitis.

    II. congestive heart failure (CHF).

    III. pneumonia.

19. Serum enzyme tests that may aid in the diagnosis of myocardial infarction include

    I. alkaline phosphatase.

    II. creatine kinase (CK).

    III. lactate dehydrogenase (LDH).

Answers and Explanations

1. **The answer is C** *[see II.B.2.d.(2)]*.
Valuable diagnostic information can be obtained through quantitative and qualitative testing of the cells of the blood. A finding of lymphopenia (i.e., decreased number of lymphocytes) suggests an attack on the immune system or some underlying immunodeficiency. AIDS attacks the T_H4 population of lymphocytes and thus may result in lymphopenia.

2. **The answer is A** *[see II.A.5]*.
The reticulocyte count measures the amount of circulating immature RBCs, which provides information about bone marrow function. A low reticulocyte count is a likely finding in a patient with aplastic anemia—a disorder characterized by a deficiency of all cellular elements of the blood owing to a lack of hematopoietic stem cells in bone marrow. A variety of drugs (e.g., those used in anticancer therapy) and other agents produce marrow aplasia. A high reticulocyte count would likely be found in a patient with hemolytic anemia or acute blood loss or in a patient who has been treated for an iron, vitamin B_{12}, or folate deficiency.

3. **The answer is E** *[see V.B; V.E–G]*.
Microscopic examination of the urine sediment normally shows < 1 RBC and from 0 to 4 WBCs per HPF. Other normal findings on urinalysis include an acid pH (i.e., around 6) and an absence of glucose and ketones.

4. **The answer is A** *[see II.B.2.c]*.
An allergic drug reaction will usually produce an increase in the eosinophil count (eosinophilia). This could be determined by ordering a WBC differential.

5. **The answer is C** *[see II.A.2]*.
Overhydration with an excess infusion of D_5W produces a low Hct. The other situations described in the question result in increases of the Hct.

6. **The answer is A** *[see II.B.2.a]*.
The patient has leukocytosis with an increased neutrophil count (neutrophilia). A localized infection does not normally result in an increase in the total leukocyte count or neutrophil count. The other situations given in the question can produce a neutrophilic leukocytosis.

7. **The answer is B** *[see III.A]*.
Because CK is not present in the liver, alcoholic liver damage would not result in an increase in the level of this enzyme. CK is present primarily in cardiac and skeletal muscle. The other situations described in the question could all result in the release of increased amounts of CK into the bloodstream.

8. **The answer is D** *[see IV.B]*.
The patient with jaundice (deposition of bilirubin in the skin) usually has an increase in the total bilirubin serum level. Spillage of bilirubin into the urine requires an increased level of direct bilirubin, which is likely with viral hepatitis or cholestatic hepatitis. In hemolytic anemia, direct bilirubin is not usually increased, and therefore, there would be no spillage of bilirubin into the urine.

9. **The answer is C** *[see II.A.4.c]*.

10. **The answer is B** *[see II.A.4.a]*.

11. **The answer is B** *[see II.A.4; VI.B.2]*.
The MCHC is calculated as follows:

$$\text{MCHC} = \frac{\text{Hb} \times 100}{\text{Hct}} = \frac{9 \times 100}{29} = 31.0$$

The mean cell volume (MCV) is calculated as follows:

$$\text{MCV} = \frac{\text{Hct (\%)} \times 10}{\text{RBC (millions)}} = \frac{29 \times 10}{4} = 72.5$$

The patient described in the question is anemic because his Hb is 9 (normal: 14 to 18). The anemia is normochromic because the patient's MCHC of 31 is normal (normal range: 31 to 37), but the anemia is microcytic because the patient's MCV is 72.5 (normal: 80 to 100). The patient's BUN, 15 mg/dL, is within the normal range of 10 to 20 mg/dL.

12. **The answer is D** *[see VII.A.1; VII.A.5–7]*.
Sodium, the major extracellular cation, is measured mainly to assist in the determination of fluid status and water balance. Regulation of sodium is mainly through the kidneys via ADH and aldosterone.

13. **The answer is A** *[see VII.B.2; VII.B.4; VII.B.6]*.
A "normal" potassium level in the setting of metabolic acidosis, especially in a patient with DKA, should be treated appropriately. If the serum potassium level is corrected for the patient's acidosis, the corrected level is 3.0 mEq/L. This corresponds to depletion in total body potassium stores. Once the acidosis and hyperglycemia begin to correct with appropriate treatment, potassium levels will decrease precipitously unless supplementation is begun. It is important to recognize that a laboratory value in the "normal" range may not actually be normal, especially when potassium is involved.

14. **The answer is C** *[see VII.D.3–4]*.
Low HCO^{-3} is usually found in patients with acidosis or renal failure and after hyperventilation or severe diarrhea. In general, disturbances in acid–base balance cause alteration in the serum HCO^{-3} or CO_2 content. Diuretic therapy can cause an alkalosis and an increase in HCO^{-3}.

15. **The answer is C** *[see VIII.A.2–4; VII.B.2].*
    Malignancy or other metastatic diseases are most often associated with hypercalcemia, not hypocalcemia. Ionized calcium is the free active form, and this level is increased in the setting of a low albumin. Therefore, the total calcium level must be adjusted to account for increased ionized calcium in this setting. Both minerals are influenced by many of the same factors and thus are often interpreted together. Renal function is one such factor whereby a decrease in renal function (i.e., renal failure) can result in a low level of calcium and a high level of PO_4.

16. **The answer is B** *[see VIII.C.1].*
    Magnesium is the second most abundant intracellular and extracellular cation. It is an activator of numerous enzyme systems that control carbohydrate, fat, and electrolyte metabolism; protein synthesis; nerve conduction; muscular contractility; and membrane transport and integrity. PO_4, on the other hand, is important for ATP and phospholipid synthesis.

17. **The answer is B (III)** *[see VI.B.2].*
    Chronic kidney disease can cause an increase in the BUN level; a heavy protein diet and bleeding into the GI tract are other factors that can produce this finding. Severe liver disease can prevent the formation of urea and, therefore, is likely to cause a decrease in the BUN level. Although an IM injection of diazepam (Valium) may cause an increase in the serum CK or AST level, it would have no effect on the BUN.

18. **The answer is C (I, II)** *[see III.D].*
