    A lung infection, such as pneumonia, normally would not cause an increase in the release of AST, an enzyme primarily found in the liver and heart. In acute hepatitis, a marked increase of AST is a likely finding. AST levels also can be increased with passive congestion of the liver, as occurs in CHF.

19. **The answer is D (II, III)** *[see III.A–C].*
    Usually, the CK, ALT, AST, and LDH enzyme levels are increased after a myocardial infarction. Alkaline phosphatase is not present in cardiac tissue and, therefore, would not be useful in the diagnosis of a myocardial infarction.

Coronary Artery Disease

ALAN H. MUTNICK

I. INTRODUCTION

A. Definition. **Coronary artery disease (CAD)** is a general term that refers to several diseases other than atherosclerosis, which causes a narrowing of the major epicardial coronary arteries. **Ischemic heart disease (IHD)** is a form of heart disease with primary manifestations that result from myocardial ischemia owing to atherosclerotic CAD. This term encompasses a spectrum of conditions, ranging from the asymptomatic preclinical phase to acute myocardial infarction and sudden cardiac death and is used throughout this chapter.

B. Incidence

1. IHD continues to be the most common chronic life-threatening illness in the United States (231.1 to 297.9 deaths per 100,000); cancer is the second leading cause of death (159.1 to 228.1 deaths per 100,000). It currently affects 11 million citizens in the United States, and it has been estimated that if all forms of major CAD were eliminated, life expectancy would increase by almost 7 years to our current population.

2. Each year, more than 5 million patients present to emergency rooms with chest discomfort and related symptoms, and approximately 1.5 million are hospitalized for acute coronary syndromes. Each year in the United States, more than 1 million patients suffer an acute myocardial infarction (MI).

C. Economics. Based on models evaluating the costs associated with the treatment of Medicare patients with common IHD-related diagnosis, it has been estimated that the direct costs of hospitalization are > \$15 billion yearly, with an additional \$4.5 billion yearly in diagnostic procedures.

D. Clinical guidelines. Owing to the clinical, humanistic, and economic effect that IHD has in the United States, evidence-based practice guidelines have evolved based on the differences in the diagnosis and management of IHD. The author has relied heavily on the use of those guidelines to ensure the most up-to-date recommendations based on the clinical literature. ***However, the author has chosen to limit the treatment options to those within a class I benefit; (Benefit >>> Risk) with the associated level of evidence rather than providing each recommendation for all four classes (I, IIa, IIb, III).*** Guidelines that are pertinent to daily pharmacy practice include the following:

1. Fraker TD Jr, Fihn SD, 2002 Chronic Stable Angina Writing Committee, et al. 2007 chronic angina focused update of the ACC/AHA 2002 guidelines for the management of patients with chronic stable angina: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines Writing Group to develop the focused update of the 2002 guidelines for the management of patients with chronic stable angina. *J Am Coll Cardiol*. 2007;50(23): 2264–2274. http://content.onlinejacc.org/cgi/reprint/50/23/2264.pdf

E. Manifestations

1. **Angina pectoris**, an episodic, reversible oxygen insufficiency, is the most common form of IHD (see II).

2. The term **acute ischemic (coronary) syndromes** describes a group of clinical symptoms representing acute myocardial ischemia. The clinical symptoms include acute myocardial infarction, which includes either ST-segment elevation (STEMI) or non–ST-segment elevation (NSTEMI), and unstable angina (UA) (see III).

F. Etiology. The processes, singly or in combination, that produce IHD include decreased blood flow to the myocardium, increased oxygen demand, and decreased oxygenation of the blood. Generally, significant IHD is defined via angiography as a stenosis that is $\geq$ 70% of the diameter of at least one major coronary artery segment or 50% of the diameter of the left main coronary artery.

1. **Decreased blood flow** (*Figure 31-1*)

    a. **Atherosclerosis**, with or without coronary thrombosis, is the most common cause of IHD. In this condition, the coronary arteries are progressively narrowed by smooth muscle cell proliferation and the accumulation of lipid deposits (plaque) along the inner lining (intima) of the arteries.

    b. **Coronary artery spasm**, a sustained contraction of one or more coronary arteries, can occur spontaneously or be induced by irritation (e.g., by coronary catheter or intimal hemorrhage), exposure to the cold, and ergot-derivative drugs. One long-term study demonstrated that coronary spasm was most often associated with an atypical chest pain syndrome and cigarette smoking. These spasms can cause Prinzmetal angina and even MI. Variant angina (Prinzmetal angina) is a form of unstable angina that usually occurs spontaneously, is characterized by transient ST-segment elevation, and most commonly resolves without progression to MI.

Figure 31-1. Oxygen and other nutrients are borne to the myocardium through the two major coronary arteries (the left and right) and their tributaries. The hemodynamic consequences of ischemic heart disease depend on which of the coronary vessels are involved and what part of the myocardium those vessels supply.

    c. Traumatic injury, whether blunt or penetrating, can interfere with myocardial blood supply (e.g., the impact of a steering wheel on the chest causing a myocardial contusion in which the capillaries hemorrhage).

    d. Embolic events, even in otherwise normal coronary vessels, can abruptly restrict the oxygen supply to the myocardium.

  2. Increased oxygen demand usually in the presence of a fixed restricted oxygen supply can occur with exertion (e.g., exercise, shoveling snow) and emotional stress as well as under circumstances external to the coronary arterial bed, which increases sympathetic stimulation and heart rate. Some factors affecting cardiac workload and therefore myocardial oxygen supply and demand are listed in *Table 31-1*.

    a. Diastole. Under normal circumstances, almost all of the oxygen is removed (during diastole) from the arterial blood as it passes through the heart. Thus, little remains to be extracted if oxygen demand increases. To increase the coronary oxygen supply, blood flow has to increase. The normal response mechanism is for the blood vessels, particularly the coronary arteries, to dilate, thereby increasing blood flow.

    b. Systole. The two phases of systole—contraction and ejection—strongly influence oxygen demand.

      (1) The **contractile (inotropic) state of the heart** influences the amount of oxygen it requires to perform.

Table 31-1   FACTORS AFFECTING CARDIAC PARAMETERS THAT CONTROL MYOCARDIAL OXYGEN DEMAND

Factor	Heart Rate	Blood Pressure	Ejection Time	Ventricular Volume	Inotropic Effect
Exercise	Increase	Increase	Decrease	Increase or decrease	Increase
Cold	Increase	Increase	—	—	—
Smoking	Increase	Increase	Increase	—	Increase
Nitroglycerin	Increase	Decrease	Decrease	Decrease	Increase
β-Blockers	Decrease	Decrease	Increase	Increase	Decrease

(2) Increases in systolic wall tension, influenced by left ventricular volume and systolic pressure, increase oxygen demand.

(3) Lengthening of ejection time (i.e., the duration of systolic wall tension per cardiac cycle) also increases oxygen demand.

(4) Changes in heart rate influence oxygen consumption by changing the ejection time.

3. Reduced blood oxygenation. The oxygen-carrying capacity of the blood may be reduced, as occurs in various forms of anemia or hypoxemia.

G. Risk factors for IHD and goals for secondary prevention have been updated with the recently released Guidelines for the Management of Patients with ST-Elevation Myocardial Infarction and are provided in *Table 31-2*.

H. Therapeutic considerations. Because most IHD occurs secondary to atherosclerosis, which is a long-term, cumulative process, medical efforts focus on reducing risk factors through individual patient education and media campaigns. Once manifestations occur, treatment addresses their specific variables.

II. ANGINA PECTORIS

A. Definition. The term **angina pectoris** is applied to varying forms of transient chest discomfort that are attributable to insufficient myocardial oxygen.

1. Angina is a clinical syndrome characterized by discomfort in the chest, jaw, shoulder, back, and arms, which is usually aggravated by exertion or stress and relieved by nitroglycerin.

2. Angina can occur in patients with valvular heart disease, uncontrolled hypertension, as well as in noncardiac organ systems such as the chest wall, esophagus, or lungs.

B. Common causes. Atherosclerotic lesions that produce a narrowing of the coronary arteries are the major cause of angina. However, tachycardia, anemia, hyperthyroidism, hypotension, and arterial hypoxemia can all cause an oxygen imbalance.

C. Types

1. Stable (classic) angina

a. In this most common form, has a more predictable pattern, which is brought on by exertion, emotional stress, or a heavy meal, which is usually relieved by rest, nitroglycerin, or both.

b. Five components are usually considered: quality, location, and duration of pain; factors provoking pain; and factors that relieve pain.

c. Pain has been referred to as "squeezing," "grip-like," "pressure-like," "suffocating," and "heavy" and is usually referred to as a discomfort rather than "pain."

d. The anginal episode typically lasts for "minutes" and is usually substernal but has a tendency to radiate to the neck, jaw, epigastrium, or arms.

e. Characteristically, the discomfort builds to a peak, radiating to the jaw, neck, shoulder, and arms, and then subsides without residual sensation. Angina is normally related to physical exertion, and the discomfort usually subsides quickly (i.e., in 3 to 5 mins) with rest; if precipitated by emotional stress, the episode tends to last longer (i.e., about 10 mins).

f. Stable angina is characteristically the result of a fixed obstruction in a coronary artery.

2. Unstable angina. (See also III.)

a. In many patients who experience unstable angina, symptoms will be caused by significant coronary artery disease. Angina is considered unstable and requires further evaluation if patients experience

(1) Rest angina, which usually is prolonged > 20 mins occurring within a week of presentation

(2) Severe new-onset angina refers to angina of at least Canadian Cardiovascular Society Classification (CCSC) to class III severity, with onset within 2 months of initial presentation

(3) Increasing angina refers to previously diagnosed angina that is distinctly more frequent, longer in duration, or lower in threshold

(4) Decreased response to rest or nitroglycerin

b. Unstable angina predicts a higher short-term risk, represents a progressive clinical entity, may signal incipient MI, is referred to as an acute coronary syndrome, and should be reported promptly to a physician.

Table 31-2   RISK FACTORS FOR ISCHEMIC HEART DISEASE AND GUIDELINES FOR THEIR MODIFICATION, WHEN APPLICABLE

I. Risk factors: Not necessarily modifiable

Family history of ischemic heart disease

Age and gender (i.e., prevalence is higher among men than among premenopausal women and increases for both genders with age)

Chronic stress or type A personality (i.e., aggressive, ambitious, chronically impatient, competitive)

Gout

II. Secondary preventive goals: As recommended in the 2007 smoking-complete cessation, no exposure to environmental tobacco smoke. *Class 1 recommendation

Status of tobacco use should be asked about at every visit.

Every tobacco user and family members who smoke should be advised to quit at every visit.

The tobacco user's willingness to quit should be assessed.

The tobacco user should be assisted by counseling and developing a plan for quitting.

Follow-up, referral to special programs, or pharmacotherapy (including nicotine replacement and pharmacological treatment) should be arranged.

Exposure to environmental tobacco smoke at work and home should be avoided.

Blood pressure control: Blood pressure should be reduced to less than 140/90 mm Hg or less than 130/90 mm Hg if chronic kidney disease or diabetes mellitus. *Class 1 recommendation

Initiate or maintain lifestyle modification (weight control, increased physical activity, alcohol moderation, decreased sodium intake, and increased emphasis on consumption of fresh fruits, vegetables, and low-fat dairy products).

Add blood pressure medication, as tolerated, treating initially with β-adrenoreceptor blockers and/or ACE inhibitors.

The addition of other blood pressure lowering drugs such as thiazides as needed to achieve the goal blood pressure.

Blood lipid management: Low density lipoprotein-cholesterol (LDL-C) levels should be less than 100 mg/dL. (If triglycerides are greater than or equal to 200 mg/dL, total cholesterol minus high density lipoprotein cholesterol (HDL-C) should be less than 130 mg/dL.) *Class I recommendation

Initiate dietary therapy in all patients; which includes reducing intake of saturated fats (< 7% of total calories), trans fatty acids, and cholesterol (< 200 mg/day).

The addition of plant stanol/sterols (2 g/day) and/or viscous fiber (> 10 g/day) to further lower LDL-C.

Promotion of daily physical activity and weight management.

It may be reasonable to encourage the increase in the consumption of omega-3 fatty acids in the form of fish or in capsule form (1 g/d) for risk reduction.

A fasting lipid profile should be assessed in all patients and within 24 hrs of hospitalization for those with an acute cardiovascular or coronary event.

Physical activity: Participate in 30 mins of physical activity 7 days a week. *Class 1 recommendation

It is recommended that all patients have a risk assessment with a physical activity history and/or an exercise test to guide prescription.

All patients should be encouraged to participate in 30 to 60 mins of moderate-intensity aerobic activity, (i.e., brisk walking) on most, preferably all, days of the week, supplemented by an increase in daily lifestyle activities (e.g., walking breaks at work, gardening, household work).

Advise medically supervised programs for high-risk patients (e.g., recent acute coronary syndrome or revascularization, heart failure).

Weight management: Body mass index (BMI) of 18.5 to 24.9 kg/m² with waist circumference of less than 35 inches (women) and less than 40 inches (men). *Class 1 recommendation

Assessment of body mass index and/or waist circumference on each visit and consistently.

Encourage weight maintenance/reduction through an appropriate balance of physical activity, caloric intake, and formal behavioral programs when indicated to maintain/achieve a body mass index between 18.5 and 24.9 kg/m².

The initial goal of weight loss therapy should be to reduce body weight by approximately 10% from baseline.

With success, further weight loss can be attempted if indicated.

If waist circumference is greater than or equal to 35 inches in women and greater than or equal to 40 inches in men, it is useful to initiate lifestyle changes and consider treatment strategies for metabolic syndrome as indicated.

Table 31-2	Continued.

Diabetes management: Achieve a glycosylated hemoglobin (HbA1c) level of less than 7% *Class 1 recommendation

It is recommended to initiate lifestyle and pharmacotherapy to achieve near-normal levels of HbA1c.

Aggressive modification of other risk factors such as physical activity, weight management, blood pressure control, and cholesterol management, as recommended above is beneficial.

Coordination of diabetic care with patient's primary care physician or endocrinologist is beneficial.

*Class I recommendation: The benefits of the intervention/treatment are much greater than the risk, and the procedure/treatment should be performed.
ACE, angiotensin-converting enzyme.

3. **Angina decubitus (nocturnal angina)**
   a. This angina occurs in the recumbent position and is not specifically related to either rest or exertion.
   b. Gravitational forces shift fluids within the body with a resultant increase in ventricular volume, which increases oxygen needs and produces angina decubitus, and which may indicate cardiac decompensation.
   c. Diuretics alone or in combination effectively reduce left ventricular volume and may aid the patient.
   d. Nitrates such as nitroglycerin may relieve the paroxysmal nocturnal dyspnea (PND) associated with angina decubitus by reducing preload, owing to venous pooling, and improving left ventricular dysfunction.
   e. PND refers to a condition where fluid accumulation in the lungs, normally due to gravitational forces when one is in the recumbent position, makes it very difficult for a patient to breath. Some have referred to this as "cardiac asthma," as the patient is unable to breath and it gets progressively worse. Sleeping with several additional pillows might allow gravity to work on the added fluid in the lungs, with a resultant decrease in symptoms. However, the underlying cause needs to be corrected or the PND will remain.

4. **Prinzmetal angina (vasospastic or variant angina)**
   a. Coronary artery spasm that reduces blood flow precipitates this angina. The spasm may be superimposed on a coronary artery that already has a fixed obstruction owing to thrombi or plaque formation.
   b. It usually occurs at rest (i.e., pain may disrupt sleep) rather than with exertion or emotional stress, and usually resolves without progression to an acute MI. However, if the attack is prolonged, MI, life-threatening ventricular arrhythmias, and sudden cardiac death can occur.
   c. Characteristically, an electrocardiogram (EKG/ECG) taken during an attack reveals a transient ST-segment elevation, which returns toward normal after the acute attack. The gold standard for identifying Prinzmetal angina is the use of coronary angiography with the administration of agents capable of inducing vasospasm, such as ergot alkaloids.
   d. Calcium-channel blockers, rather than β-blockers, are most effective for this form of angina. Nitroglycerin may not provide relief, depending on the cause of vasospasm.

D. **Physical examination** is usually not revealing, especially between attacks. However, the patient's history, risk factors, and full description of attacks—precipitation pattern, intensity, duration, relieving factors—usually prove diagnostic.

E. **Diagnostic test results**
   1. The **EKG/ECG** is normal in 50% or more of patients with stable angina pectoris, and a normal resting EKG/ECG does not exclude severe IHD. However, an EKG/ECG with evidence of left ventricular hypertrophy or ST-T-wave changes consistent with myocardial ischemia favors the diagnosis of angina pectoris. The presence of Q waves from a previous MI makes the diagnosis of IHD very likely. An EKG/ECG obtained during chest pain is abnormal in 50% of patients with angina who have a normal resting EKG/ECG. The ST segment can be either elevated or depressed.
   2. **Stress testing (exercise EKG/ECG)** is a well-established procedure, which aids the diagnosis in patients who have normal resting EKGs/ECGs. The most commonly used definition for a positive test is a ≥ 1-mm ST-segment depression or elevation for ≥ 60 to 80 msec either during or after

exercise. Exercise stress testing is preferable to other variations of the stress test (pharmacological) in patients who are able to exercise.

3. **Pharmacological stress testing** is performed in suspected IHD patients when they are not able to perform more than moderate exercise due to various reasons (i.e., severe arthritis, prior injury, reduced exercise tolerance as a result of debilitating illnesses, etc.), or in patients who are unable to increase the heart rate.

   a. Intravenous dipyridamole (Persantine®; coronary vasodilation), adenosine (Adenocard®; coronary vasodilation) by inhibiting cellular uptake and degradation of adenosine increase coronary blood flow, and high-dose dobutamine (Dobutrex®; 20 to 40 mcg/kg/min) increase oxygen demand through increased heart rate, systolic blood pressure, and myocardial contractility causing an increase in myocardial blood flow are all able to induce detectable cardiac ischemia in conjunction with EKG/ECG testing.

   b. Side effects occur for each of the agents and include **dipyridamole** (angina, 18% to 42%; arrhythmias, 2%; headache, 5% to 23%; dizziness, 5% to 21%; nausea, 8% to 12%; and flushing, 3%), **adenosine** (chest pain, 57%; headache, 35%; flushing, 25%; shortness of breath, 15%; and first-degree atrioventricular [AV] heart block, 18%), **dobutamine** (premature ventricular beats, 15%; premature atrial beats, 8%; supraventricular tachycardia and nonsustained ventricular tachycardia, 3% to 4%; nausea, 8%; anxiety, 6%; headache, 4%; and tremor, 4%).

4. **Stress perfusion imaging** with thallium-201 or more recently, technetium-99m (^{99m}Tc) (sestamibi [Cardiolite®] or tetrafosmin [Myoview®]), can diagnose multivessel disease, localized ischemia, and may be able to determine myocardial viability. Coronary arteriography and cardiac catheterization are very specific and sensitive but are also invasive, expensive, and risky (the mortality rate is 1% to 2%); therefore, they must be used judiciously when trying to confirm suspected angina and to differentiate its origin.

5. Various drugs can have an effect on the EKG/ECG and should be considered before, during, and after an exercise test is carried out. Examples include

   a. Digoxin (Lanoxin®) produces abnormal exercise-induced ST depression in 25% to 40% of apparently healthy, normal subjects without ischemia.

   b. β-Adrenergic blockers may delay the development of an abnormal EKG/ECG if patients receive them before or during a stress test. If possible, therapy should be slowly withheld from the patient at least four to five half-lives before the exercise testing. If it is not possible to withdraw therapy, the clinician needs to recognize that the test might be less reliable.

   c. Antihypertensives such as vasodilators can alter the stress test by altering the normal hemodynamic response of blood pressure. In addition, short-term use of nitrates can attenuate angina and ST-segment changes associated with myocardial ischemia.

F. **Treatment goals**

1. To prevent MI and death, thereby increasing a patient's quality of life

2. To reduce symptoms of angina and occurrence of ischemia, which should improve a patient's quality of life

3. To remove or reduce **risk factors**

4. The management of angina pectoris includes therapies aimed at reversing cardiac risk factors.

   a. **Hyperlipidemia**, if present, should be treated. Reducing cholesterol and low-density lipoprotein (LDL) is associated with a reduced risk of cardiovascular disease and incidence of ischemic cardiac events, as demonstrated by several recent studies using β-hydroxy-β-methylglutaryl-coenzyme A (HMG-CoA) reductase inhibitors. The NCEP has published guidelines for treatment of high blood cholesterol (Adult Treatment Panel III), and a fourth set of guidelines is currently being developed with a publication date in 2012.

      (1) Total cholesterol is no longer the primary target of treatment; LDL cholesterol is now the primary target.

      (2) Current recommendations include the completion of a lipoprotein profile—total cholesterol, LDL cholesterol, high-density lipoprotein (HDL) cholesterol, and triglycerides—as the preferred initial test, rather than screening for total cholesterol and HDL alone. Additionally, the ATP-3 guidelines identify LDL cholesterol < 100 mg/dL as optimal and raises categorical low HDL cholesterol from < 35 mg/dL to < 40 mg/dL because the latter is a better measure of a depressed HDL.

Finally, the ATP-3 lowered the triglyceride classification cutpoints to give more attention to moderate elevations.

(3) Persons are categorized into one of four levels of risk to identify group-specific treatment modalities: (1) *high-risk*, established IHD or IHD risk equivalents (diabetes, noncoronary forms of atherosclerotic disease); (2) *moderately high-risk*, multiple (more than two) risk factors and a calculated 10-year risk of 10% to 20%; (3) *moderate risk*, multiple (more than two) risk factors and a calculated 10-year risk of 10%; and (4) *lower risk*, zero to one risk factor.

(4) All individuals with IHD or IHD risk equivalents have been called "high risk," and the treatment goals is to have LDL-cholesterol (LDL-C) levels < 100 mg/dL. Other recommendations are as follows:

(a) If baseline LDL-C is < 100 mg/dL (goal of treatment), patients with IHD should be given instructions on diet and exercise and have levels monitored annually; although the guidelines suggest an optional goal of obtaining an LDL-C of < 70 mg/dL.

(b) If baseline LDL-C is ≥ 100 mg/dL, an LDL-lowering drug should be started along with therapeutic lifestyle changes (TLCs). Lifestyle-related risk factors include things such as obesity, physical inactivity, elevated triglyceride, low-HDL-C, or metabolic syndrome.

(c) Adult Treatment Panel III did not mandate LDL-lowering drugs for patients with baseline LDL-C levels between 100 and 129 mg/dL, but suggested intensifying lifestyle and the optional use of drug therapies to lower LDL to < 100 mg/dL. However, if the patient had elevated triglycerides or low high-density lipoprotein cholesterol (HDL-C), a drug should be started that targets these abnormalities—for example, nicotinic acid or fibric acid if the patient has elevated triglycerides (> 200 mg/dL) or low HDL levels (< 40 mg/dL). If triglycerides are ≥ 500 mg/dL, consider fibrate or niacin before LDL-lowering therapy.

(5) For moderately high-risk patients, the recommended LDL-C goal is < 130 mg/dL, but a goal of < 100 mg/dL is an optional goal, based on recent clinical trial evidence. In addition, a recommendation to initiate TLCs when the patient has an LDL-C ≥ 130 mg/dL.

(6) For moderate risk patients, the recommended LDL-C goal is < 130 mg/dL. In addition, a recommendation to initiate TLC when the patient has an LDL-C ≥ 160 mg/dL.

(7) For lower risk patients, the recommended LDL-C goal is < 160 mg/dL, but again, a recommendation to initiate TLC for those patients with an LDL ≥ 190 mg/dL.

(8) The **metabolic syndrome** is closely linked to insulin resistance, when the normal actions of insulin are impaired. Excess body fat and physical inactivity promote the development of the syndrome; however, some individuals may be predisposed genetically. Patients with three or more of the following characteristics are referred to as having the metabolic syndrome and should be treated accordingly: abdominal obesity, triglycerides > 150 mg/dL, HDL levels of < 40 mg/dL for men and < 50 mg/dL for women, blood pressure readings ≥ 130/85 mm Hg, and a fasting serum glucose level ≥ 110 mg/dL.

(9) **Increased interest in triglycerides** due to a long-standing association between elevated triglyceride levels and cardiovascular disease. The continuing rise since 1976 of triglyceride levels in concert with the growing incidence of obesity, type 2 diabetes mellitus, and insulin resistance has occurred at a time when LDL-C levels have continued to decrease. This ongoing concern has resulted in a recent scientific statement from the American Heart Association with the intent to update clinicians on the continued role that triglycerides play in cardiovascular disease. (Available through the Internet at: **http://circ.ahajournals .org/cgi/reprint/123/20/2292?maxtoshow=&hits=10&RESULTFORMAT=&fulltext =triglycerides&searchid=1&FIRSTINDEX=0&volume=123&issue=20&resource type=HWCIT)**

G. Individual drug classes

1. Bile acid-binding resins

a. Mechanism of action. These insoluble, nonabsorbable, anion-exchange resins bind bile acids within the intestines and prevent them from being reabsorbed. Bile acids are synthesized from cholesterol.

    b. Indications. These agents have been shown to be safe and effective in lowering LDL-C, especially in patients with modestly elevated levels, in primary prevention, in young adult men, and in postmenopausal women. They are effective in combination with other agents.

    c. Currently available agents include the following:

      (1) Cholestyramine (Questran®): 4 to 24 g by mouth in two daily doses

      (2) Colestipol (Colestid®): 2 to 16 g by mouth in one to four daily doses

      (3) Colesevelam (Welchol®): six to seven tablets (625 mg/tablet) by mouth in one daily dose

    d. Precautions and monitoring effects

      (1) These resins are taken just before meals and present palatability problems in patients.

      (2) Gastrointestinal (GI) intolerance, especially constipation, flatulence, and dyspepsia are frequent.

      (3) Absorption of many other drugs can be affected. Other drugs should be taken 1 hr before or 4 to 6 hrs after resins.

  2. Statins or HMG-CoA reductase inhibitors

    a. Mechanism of action. These agents inhibit the enzyme HMG-CoA, resulting in a reduction in cholesterol production.

    b. Indications. These agents are effective in lowering LDL levels while increasing HDL levels and lowering triglyceride levels. They are primarily used to lower LDL cholesterol levels and are generally considered to be the most effective of the lipid lowering agents.

    c. Currently available agents include the following:

      (1) Atorvastatin (Lipitor®): 10 to 80 mg by mouth daily

      (2) Fluvastatin (Lescol®): 20 to 80 mg by mouth in one to two doses

      (3) Lovastatin (Mevacor®, various): 10 to 80 mg by mouth in the evening

      (4) Pitavastatin (Livalo®): 1 to 4 mg by mouth daily

      (5) Pravastatin (Pravachol®): 10 to 80 mg by mouth daily

      (6) Rosuvastatin (Crestor®): 5 to 40 mg by mouth daily

      (7) Simvastatin (Zocor®, various): 5 to 80 mg by mouth in the evening

        (a) Recent FDA alert on dosing limitations for products containing simvastatin: Simvastatin 80 mg is limited to patients that have been taking this dose for > 12 consecutive months without evidence of myopathy and are not currently taking or beginning to take a simvastatin dose-limiting or contraindicated interacting medication.

    d. Precautions and monitoring effects

      (1) GI adverse effects are less frequently seen than with other classes of agents. Headache and dyspepsia frequently occur and should be evaluated, then followed up in 6 to 8 weeks, and then at each follow-up visit thereafter.

      (2) These agents can elevate liver function tests—alanine aminotransferase (ALT) and aspartate aminotransferase (AST), which requires initial evaluation, then after approximately 12 weeks of therapy, then annually thereafter.

      (3) Although the incidence of myopathy is believed to be low (0.08%) for lovastatin and simvastatin, elevations of creatine kinase (CK) > 10 times the upper limit of normal have been reported with pravastatin, with similar potential for the other members of the group. Cerivastatin (Baycol) was voluntarily removed from the market owing to the reported deaths of 31 patients from rhabdomyolysis while receiving the drug alone or in combination with gemfibrozil (Lopid). Consequently, routine monitoring is necessary in all patients as follows:

        (a) Evaluate muscle symptoms and check CK before starting therapy, evaluate in 6 to 12 weeks after starting therapy, and then at each follow-up visit.

        (b) Patients presenting with muscle soreness, tenderness, or pain should have a CK measurement on presentation to minimize the development of myopathies.

        (c) Concurrent therapy with other agents, including cyclosporine, macrolide antibiotics, azole antifungals, niacin, fibrates, or nefazodone, may increase the risk.

  3. Fibric acid derivatives

    a. Mechanism of action. These agents are presumed to inhibit cholesterol synthesis and lower LDL-C and bile acids. They are most effective in lowering triglyceride levels by reducing the concentration of very-low-density lipoproteins (VLDL). In some patients, they modestly lower LDL-C and raise HDL-C.

      b. Precautions and monitoring effects
         (1) GI effects are the most commonly experienced adverse effect.
         (2) These agents can elevate liver function tests; routine monitoring should be carried out.
         (3) Use with statins can lead to elevated CK, and monitoring is necessary to identify myopathies or rhabdomyolysis.
      c. Currently available agents include the following:
         (1) Fenofibrate (Tricor®, various): 145 to 160 mg by mouth daily
         (2) Gemfibrozil (Lopid®, various): 600 mg by mouth twice daily
   4. Niacin
      a. Mechanism of action. Numerous studies have demonstrated the role of niacin in the lowering of LDL-C and triglycerides through various mechanisms such as participation in tissue respiration oxidation–reduction reactions, which decreases hepatic LDL and VLDL production; inhibition of adipose tissue lipolysis; decreased hepatic triglyceride esterification; and increases in lipoprotein lipase activity. *Table 31-3* presents several agents and their effects on lipoproteins.
      b. Indications. Niacin is valuable in treating patients with elevated total cholesterol and low LDL-C levels. It works primarily by reducing the production of VLDL in the liver and has been shown to lower LDL-C and triglycerides while also increasing HDL-C. It is used in combination therapy.
      c. Currently available agents include the following:
         (1) Niacin controlled-release (Niaspan®): 1000 to 2000 mg by mouth at bedtime
         (2) Niacin controlled-release (Slo-Niacin®): 1 to 2 g by mouth at bedtime
         (3) Niacin immediate-release (Niacor®, Various): 1500 to 3000 mg by mouth two to three times daily
      d. Precautions
         (1) Adverse GI effects are experienced with the use of niacin.
         (2) Patients may experience flushing and itchy skin, which may be reduced with the administration of 325 mg aspirin about 30 mins before the dose.
         (3) Cases of severe liver toxicity have been reported. Liver function tests should be performed in patients receiving this drug.

Table 31-3   SELECTED AGENTS AND THEIR EFFECTS ON LIPOPROTEINS

Class/Agent	Lipid/Lipoprotein Effects	Daily Dose	Adverse Drug Effects
HMG-CoA reductase inhibitors (statins)	LDL: 18%–55% reduction HDL: 5%–15% increase TG: 7%–30% reduction	Lovastatin: 10–80 mg Pravastatin: 20–40 mg Simvastatin: 5–80 mg Fluvastatin: 20–80 mg Atorvastatin: 10–80 mg Rosuvastatin: 5–40 mg	Myopathy, increased liver enzymes
Bile acid sequestrants	LDL: 15%–30% reduction HDL: 3%–5% increase TG: No change or increase	Cholestyramine: 4–16 g Colestipol: 5–20 g Colesevelam: 2.6–3.8 g	GI distress, constipation, decreased absorption of other drugs
Nicotinic acid	LDL: 5%–25% reduction HDL: 15%–35% increase TG: 20%–50% reduction	Immediate-release: 1.5–3.0 g Extended-release: 1–2 g Sustained-release: 1–2 g	Flushing, hyperglycemia, hyperuricemia (or gout), upper GI distress, hepatotoxicity
Fibric acids	LDL: 5%–20% reduction HDL: 10%–20% increase TG: 20%–50% reduction	Gemfibrozil: 600 mg twice daily Fenofibrate: 145–160 mg Clofibrate: 1000 mg twice daily	Dyspepsia, gallstones, myopathy, unexplained non-CHD deaths in WHO study

CHD, coronary heart disease; *GI*, gastrointestinal; *HDL*, high-density lipoprotein; *HMG-CoA*, β-hydroxy-β-methylglutaryl-coenzyme A; *LDL*, low-density lipoprotein; *TG*, triglycerides; *WHO*, World Health Organization. Adapted from Grundy SM, Becher D, Clark LT, et al. Third Report of the National Cholesterol Education Program (NCEP): detection, evaluation, and treatment of high blood cholesterol in adults (Adult Treatment Panel III) [NIH Publication No. 01-3670]. Washington, DC: U.S. Department of Health and Human Services; May 2001. Available at http://www.nhlbi.nih.gov/guidelines/cholesterol/atp3xsum.pdf.

5. **Ezetimibe (Zetia®)**
    a. **Mechanism of action.** Works by selectively inhibiting the intestinal absorption of cholesterol and related phytosterols, with a resultant decrease in intestinal cholesterol delivered to the liver, decreased hepatic cholesterol stores, and an increase in the clearance of cholesterol from the blood. Ezetimibe has demonstrated the ability to reduce total cholesterol, LDL-C, apolipoprotein B, and triglyceride levels while increasing HDL levels in patients with hypercholesterolemia.
    b. **Indications.** Ezetimibe as adjunctive therapy along with dietary measures, alone in patients with primary heterozygous familial and nonfamilial hypercholesterolemia, or in combination with the HMG-CoA reductase inhibitors in homozygous familial hypercholesterolemia.
    c. **Dose.** Normal dosing recommendations are a 10-mg dose given once daily.
    d. **Precautions.** As monotherapy, studies to date have not revealed significant side effects above those seen with placebo administration. However, when used in combination with HMG-CoA reductase inhibitors, reports have described an increased incidence (approximately 1.4%) in the elevation of liver transaminase levels (three times the upper limit of normal) as compared to the incidence of 0.4% with HMG-CoA agents used alone.
6. **Combination products**
    a. Ezetimibe/simvastatin (Vytorin®) uses the individual class properties of the HMG-CoA reductase inhibitors (simvastatin) to reduce cholesterol production with the absorption-inhibiting properties of ezetimibe to target cholesterol with two differing mechanisms, which might aid in improving patient compliance.
        (1) Available product is supplied as 10/10, 10/20, 10/40, 10/80 combinations of ezetimibe and simvastatin, respectively, and the daily recommended dose is one tablet by mouth every evening.
        (2) Side effects reflect the additive side effect properties of ezetimibe and simvastatin and warrant consideration when occurring during therapy. **Recent FDA alert on dosing limitations for products containing simvastatin:** Simvastatin 80 mg is limited to patients that have been taking this dose for > 12 consecutive months without evidence of myopathy and are not currently taking or beginning to take a simvastatin dose-limiting or contraindicated interacting medication.
    b. Lovastatin/niacin (Advicor®) is a product that incorporates the actions of the HMG-CoA reductase inhibitor lovastatin with an extended-release niacin component into a single product, using differing mechanisms, which might aid in improving patient compliance.
        (1) Available product is supplied as 20/500, 20/750, 20/1000, 40/1000 immediate-release tablet combinations of lovastatin and niacin, respectively. The recommended daily dose is one to two tablets by mouth at bedtime.
        (2) Side effects reflect the additive side effect properties for both lovastatin and niacin and warrant consideration during therapy.
    c. Amlodipine/atorvastatin (Caduet®) is a combination product that incorporates the actions of the dihydropyridine calcium-channel blocker amlodipine with the lipid-lowering properties of the HMG-CoA reductase inhibitor atorvastatin. The calcium-channel blocker offers no benefit for lipid lowering but represents a potentially beneficial product for a patient with coexisting disease states, such as IHD and hypertension, for which the use of a calcium-channel blocker would be warranted.
        (1) Available product is supplied as 2.5/10, 2.5/20, 2.5/40, 5/10, 5/20, 5/40, 5/80, 10/10, 10/20, /10/40, and 10/80; which consist of amlodipine and atorvastatin, respectively, in an immediate-release dosage form. The recommended daily dose is one to two tablets by mouth at bedtime.
        (2) Side effects reflect the additive side effect properties for both amlodipine and atorvastatin and warrant consideration during therapy.
    d. Simvastatin/niacin (Simcor®) is a product that incorporates the actions of the HMG-CoA reductase inhibitor simvastatin with an extended-release niacin component into a single product, using differing mechanisms, which might aid in improving patient compliance.
        (1) Available product is supplied as 500/20, 500/40, 750/20, 1000/20, 1000/40 which consist of extended-release niacin and simvastatin, respectively, in an immediate-release dosage form. The recommended daily dose is one to two tablets by mouth at bedtime.

(2) Side effects reflect the additive side effect properties for both niacin and simvastatin and warrant consideration during therapy. **Recent FDA alert on dosing limitations for products containing simvastatin:** Simvastatin 80 mg is limited to patients that have been taking this dose for > 12 consecutive months without evidence of myopathy and are not currently taking or beginning to take a simvastatin dose-limiting or contraindicated interacting medication.

e. Omega-3-acid ethyl esters (Lovaza®) is the first FDA-approved omega-3 fatty acid, which is indicated for patients with elevated levels of triglycerides (> 500 mg/dL).

(1) Mechanism of action. Although not entirely worked out yet, may work by one of several mechanisms, including an increased hepatic beta-oxidation, a reduction in the hepatic synthesis of triglycerides, or an increase in plasma lipoprotein lipase activity.

(2) Available product is supplied as a 1-g capsule; the recommended daily dose is four capsules by mouth daily in one to two doses.

(3) Side effects that have been reported include burping, infection, flu-like symptoms, upset stomach, change in one's sense of taste, back pain, and rash.

f. Hypertension. Treatment of hypertension according to the Joint National Conference VII guidelines has received a class I recommendation based on data from multiple randomized clinical trials with large numbers of patients (A, high) and should be controlled. Class I recommendations are based on evidence or general agreement that a given procedure or treatment is useful and effective (see Chapter 33).

g. Smoking should be stopped if at all possible and has received a class I recommendation based on data derived from a limited number of randomized trials with small numbers of patients (B, intermediate).

(1) Transdermal use of nicotine-containing patches has become one strategy for aiding the cessation of smoking. Products such as Nicotrol®, NicoDerm®, and others are available in varying strengths both as prescription and over-the-counter treatments, in order to wean patients off the use of cigarettes over an 8- to 12-week period, using descending doses.

(2) Nicotine gum (oral nicotine polacrilex chewing pieces) is available in 2- or 4-mg pieces as an over-the-counter product. Nicorette® is usually used for 3 months to aid in cessation of smoking.

(3) Bupropion is a prescription antidepressant, which is also marketed under the brand name of Zyban® as an aid to smoking cessation.

(4) Varenicline (Chantix®) is an approved product, which works as a partial neuronal α_4-β_2 nicotinic receptor agonist in the brain to reduce the craving for nicotine. Therapy is started with a dose of 0.5 mg by mouth daily for 3 days, followed by 0.5 mg tablets twice daily for 4 days, then 1 mg twice daily thereafter for 12 weeks, which can be given for an additional 12 weeks if successful.

h. Obesity should be reduced through diet and an appropriate exercise program in patients with hypertension, hyperlipidemia, or diabetes mellitus and has received a class I recommendation based on expert consensus as the primary basis (C, low).

H. Therapeutic agents

1. Recent evidence-based guidelines have provided recommendations for the treatment of patients with chronic stable angina. (See I.D.1; Fraker et al.). Recommendations use the following levels of rankings:

Ranking Based on Size of Treatment Effect	Assessment of Benefit Versus Risk	Recommended Action
Class I	Benefit >>> risk	Treatment should be used
Class IIa	Benefit >> risk	Reasonable to use treatment
Class IIb	Benefit ≥ risk	Treatment may be considered
Class III	No benefit; potentially harmful	No proven benefit; even harmful

Estimate of Certainty for Treatment Effect	Extent of Populations Studied	Types of Trials Used
Level A	Multiple populations evaluated	Data derived from multiple trials/ meta-analyses
Level B	Limited populations evaluated	Data derived from a single trial or nonrandomized study
Level C	Very limited populations evaluated	Consensus opinion of experts or case reports

  2. **Nitrates (e.g., nitroglycerin)**
    a. **Mechanism of action**
      (1) The primary value of nitrates is venous dilation, which reduces left ventricular volume (preload) and myocardial wall tension, decreasing oxygen requirements (demand).
      (2) Nitrates may also reduce arteriolar resistance, helping reduce afterload, which decreases myocardial oxygen demand.
      (3) By reducing pressure in cardiac tissues, nitrates also facilitate collateral circulation, which increases blood distribution to ischemic areas.
      (4) Pharmacological effects have been shown to improve exercise tolerance, prolong the time to onset of angina, and the appearance of ST-segment depression during exercise testing.
    b. **Indications**
      (1) Acute attacks of angina pectoris can be managed with sublingual, transmucosal (Nitrolingual® spray or Nitrostat® sublingual tablets), or intravenous delivery.
      (2) Indications include the prevention of anticipated attacks, using tablets (oral or buccal) or transdermal paste or patches. Sublingual nitrates (Nitrostat®) can be used before eating, sexual activity, or a known stressful event.
      (3) Nitrates are used in treatment of stable angina. They may not be effective as a single agent for treatment of Prinzmetal angina, although some studies have shown nitrates to prevent or reverse vasospasm at varying doses. Intravenous nitroglycerin is used in the immediate treatment of unstable angina and is used for long-term therapeutic relief.
      (4) Nitrates used in combination with β-adrenergic blockers have been shown to be more effective than nitrates or β-adrenergic blockers used alone.
    c. **Choice of preparation** should be based on onset of action, duration of action, and patient compliance and preference because all nitrates have the same mechanism of action.
    d. **Precautions and monitoring effects**
      (1) To maximize the therapeutic effect, patients should thoroughly understand the use of their specific dosage forms (e.g., sublingual tablets, transdermal patches or pastes, tablets, capsules).
      (2) Blood pressure and heart rate should be monitored because all nitrates can increase heart rate while lowering blood pressure.
      (3) Preload reduction can be assessed through reduction of pulmonary symptoms such as shortness of breath, paroxysmal nocturnal dyspnea, or dyspnea.
      (4) Nitrate-induced headaches are the most common side effect.
        (a) Patients should be warned of the nature, suddenness, and potential strength of these headaches to minimize the anxiety that might otherwise occur.
        (b) Compliance can be enhanced if the patient understands that the effect is transient and that the headaches usually disappear with continued therapy.
        (c) Acetaminophen ingested 15 to 30 mins before nitrate administration may prevent the headache.
    e. **Effective therapy** should result in fewer anginal attacks without inducing significant adverse effects (e.g., postural hypotension, hypoxia). If maximal doses are reached and the patient still experiences attacks, additional agents should be administered.
    f. **Nitrate tolerance** is a major problem with the long-term use of nitroglycerin and long-acting nitrates. Several agents such as ACE inhibitors (sulfhydryl-containing drugs), acetylcysteine, and diuretics have been shown to reverse nitrate tolerance by increasing the availability of

sulfhydryl radicals. However, practical considerations suggest that less frequent administration (8 to 12 hrs of nitrate-free intervals) is effective without introducing additional agents.

3. β-Adrenergic blockers. Based on the 2007 Focused Guidelines for Patients With Chronic Stable Angina, a class 1a recommendation states that it is beneficial to start and continue β-blocker therapy indefinitely in all patients who have had MI, acute coronary syndrome, or left ventricular dysfunction with or without heart failure symptoms, unless contraindicated.

   a. Mechanism of action. β-Blockers reduce oxygen demand, both at rest and during exertion, by decreasing the heart rate and myocardial contractility, which also decreases arterial blood pressure.

   b. Indications

   (1) These agents reduce the frequency and severity of exertional angina that is not controlled by nitrates.

   (2) Nitrates have been combined with calcium antagonists, when slow-release dihydropyridines (e.g., felodipine [Plendil®], amlodipine [Norvasc®]) are preferred over diltiazem (Cardizem®) or verapamil (Calan®). If patients need to receive a β-adrenergic blocker along with verapamil or diltiazem owing to the added effects, they have the potential to induce bradycardia, AV heart block, and fatigue.

   c. Precautions and monitoring effects

   (1) Doses should be increased until the anginal episodes have been reduced or until unacceptable side effects occur.

   (2) β-Blockers should be avoided in Prinzmetal angina (caused by coronary vasospasm) because they increase coronary resistance and may induce vasospasm.

   (3) Asthma is a relative contraindication because all β-blockers increase airway resistance and have the potential to induce bronchospasm in susceptible patients.

   (4) Patients with diabetes and others predisposed to hypoglycemia should be warned that β-blockers mask tachycardia, which is a key sign of developing hypoglycemia.

   (5) Patients should be monitored for excessive negative inotropic effects. Findings such as fatigue, shortness of breath, edema, and paroxysmal nocturnal dyspnea may signal developing cardiac decompensation, which also increases the metabolic demands of the heart.

   (6) Sudden cessation of β-blocker therapy may trigger a withdrawal syndrome that can exacerbate anginal attacks (especially in patients with IHD) or cause MI.

   d. Choice of preparations. All β-blockers are likely to be equally effective for stable (exertional) angina. For further review of β-adrenergic blockers, see Chapter 33-Hypertension. For a list of β-adrenergic blockers, see Table 33-4, and for complete descriptions for each β-adrenergic blocker, see Chapter 33: III.B.3.a.

4. Calcium-channel blockers

   a. Mechanism of action. Two actions are most pertinent in the treatment of angina.

   (1) These agents prevent and reverse coronary spasm by inhibiting calcium influx into vascular smooth muscle and myocardial muscle. This results in increased blood flow, which enhances myocardial oxygen supply.

   (2) Calcium-channel blockers decrease coronary vascular resistance and increase coronary blood flow, resulting in increased oxygen supply.

   (3) Calcium-channel blockers decrease systemic vascular resistance and arterial pressure; in addition, they decrease inotropic effects, resulting in decreased myocardial oxygen demand.

   b. Indications

   (1) Calcium-channel blockers are used in stable (exertional) angina that is not controlled by nitrates and β-blockers and in patients for whom β-blocker therapy is inadvisable. Combination therapy—with nitrates, β-blockers, or both—may be most effective.

   (2) These agents, alone or with a nitrate, are particularly valuable in the treatment of Prinzmetal angina. They are considered the drug of choice in treatment of angina at rest.

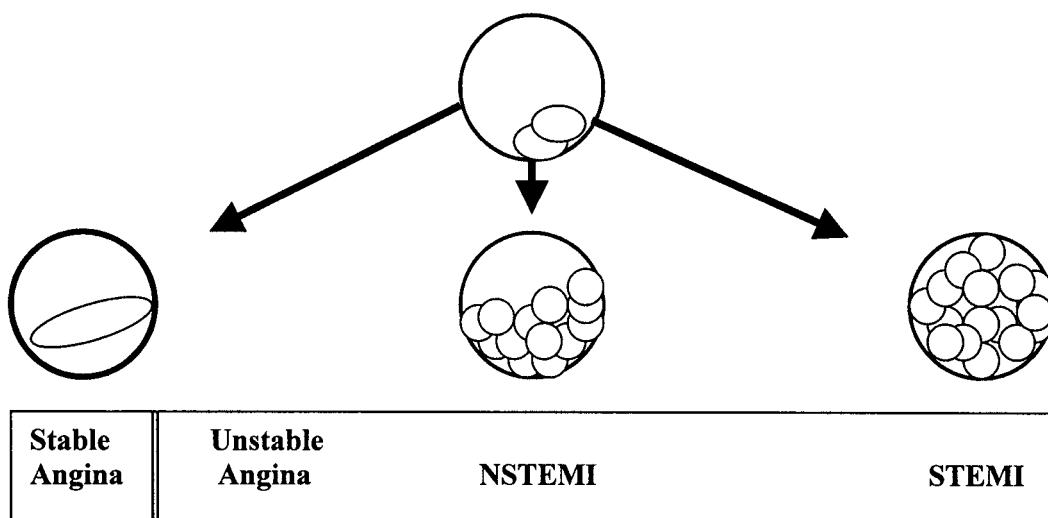
   c. Individual agents

   (1) Diltiazem (Cardizem®) and verapamil (Calan®)

   (a) These drugs produce negative inotropic effects, and patients must be monitored closely for signs of developing cardiac decompensation (i.e., fatigue, shortness of breath, edema, paroxysmal nocturnal dyspnea). When coadministered with β-blockers or other agents that produce negative inotropic effects (e.g., disopyramide [Norpace®], quinidine Various, procainamide [Pronestyl®], flecainide [Tambocor®]), the negative effects are additive.

Table 31-4 SELECTED AGENTS AND THEIR DOSES IN THE TREATMENT OF CORONARY ARTERY DISEASE

Class/Agent	Dose/Dosage Schedule	Comments
Nitrates		
Nitroglycerin sublingual tablets (Nitrostat®)	0.3–0.6 mg up to 1.5 mg	Short-term effects: 1–7 mins
Nitroglycerin spray (Nitrolingual®)	0.4 mg as needed	Similar to sublingual tablets
Nitroglycerin transdermal (Nitro-Dur®)	0.2–0.8 mg/hr every 12 hrs	Remove patch for 8–12 hrs to reduce tolerance
Nitroglycerin intravenous infusion (Various)	5–200 mcg/min	Short acting requiring continuous infusion and monitoring
Isosorbide mononitrate (Imdur®, Monoket®)	10–40 mg daily in two doses	Also available as extended-release product for single daily dosing
Isosorbide dinitrate SL	2.5–10 mg SL every 2–3 hrs	For acute angina attacks
Isosorbide dinitrate oral tablets (Various)	5–80 mg, two to three times daily	Longer acting up to 8 hrs
Isosorbide dinitrate slow-release tablets (Dilatrate-SR®)	40 mg once or twice daily	Duration of activity up to 8 hrs
β-Adrenergic blockers		
Propranolol (Inderal®)	20–80 mg twice daily	Possesses both β_1- and β_2-blocker effects
Metoprolol (Lopressor®)	50–200 mg twice daily	Possesses β_1-blocker effects
Atenolol (Tenormin®)	50–200 mg/day	Possesses β_1-blocker effects
Nadolol (Corgard®)	40–80 mg/day	Possesses both β_1- and β_2-blocker effects
Timolol	10 mg twice daily	Possesses both β_1- and β_2-blocker effects
Acebutolol (Sectral®)	200–600 mg twice daily	Possesses β_1-blocker effects
Betaxolol (Kerlone®)	10–20 mg/day	Possesses β_1-blocker effects
Bisoprolol (Zebeta®)	10 mg/day	Possesses β_1-blocker effects
Esmolol (intravenous) (Brevibloc®)	50–300 mcg/kg/min	Possesses β_1-blocker effects
Labetalol (Trandate®, Various)	200–600 mg twice daily	Possesses both α_1-, β_1-, and β_2-blocker effects
Pindolol (Various)	2.5–7.5 mg three times daily	Possesses both β_1- and β_2-blocker effects
Carvedilol (Coreg®)	25 mg twice daily	Possesses both α_1- β_1-, and β_2-blocker effects
Penbutolol (Levatol®)		Possesses both β_1- and β_2-blocker effects
Calcium-channel blockers		
Dihydropyridine derivatives		
Nifedipine (Procardia®)	Immediate-release; 30–90 mg daily	Short duration of action of 4–6 hrs
Amlodipine (Norvasc®, Various)	5–10 mg once daily	Long duration of action
Felodipine (Plendil®)	5–10 mg once daily	Long duration of action
Isradipine (Dynacirc®)	2.5–10 mg twice daily	Intermediate duration of action
Nicardipine (Cardene®)	20–40 mg three times daily	Short duration of action
Nisoldipine (Sular®)	20–40 mg once daily	Short duration of action

Table 31-4   Continued.


Class/Agent	Dose/Dosage Schedule	Comments
	Miscellaneous	
Diltiazem (Cardizem®)	Immediate-release: 30–80 mg four times daily	Short duration of action; important consideration necessary owing to hypotension, bradycardia, and edema
	Slow-release: 120–320 mg once daily	Long duration of action; important consideration necessary owing to hypotension, bradycardia, and edema
Verapamil (Calan®)	Immediate-release: 80–160 mg three times daily	Short duration of action; important consideration necessary owing to hypotension, bradycardia, edema, myocardial depression, and heart failure
	Slow-release: 120–480 mg once daily	Long duration of action; important consideration necessary owing to hypotension, bradycardia, edema, myocardial depression, and heart failure

(b) Patients should be monitored for signs of developing bradyarrhythmias and heart block because these agents have negative chronotropic effects.

(c) Verapamil (Calan®) frequently causes constipation that must be treated as needed to prevent straining at stool, which could cause an increased oxygen demand (Valsalva maneuver). Verapamil is not recommended in patients with sick sinus syndromes, AV nodal disease, or heart failure (HF).

(2) **Nifedipine (Procardia®)**

(a) This calcium-channel blocker is believed to possess the greatest degree of negative inotropic effects compared to the newer second-generation members of this group, amlodipine (Norvasc®) and felodipine (Plendil®). Nifedipine 10 mg (chewed or swallowed) has been used to treat Prinzmetal angina or refractory spasm in patients who are not hypotensive. Controversy still exists about the use of short-acting, rapid-release agents such as nifedipine in patients with IHD.

(b) Because nifedipine increases the heart rate somewhat, it can produce tachycardia, which would increase oxygen demand. Coadministration of a β-blocker should prevent reflex tachycardia.

(c) Its potent peripheral dilatory effects can decrease coronary perfusion and produce excessive hypotension, which can aggravate myocardial ischemia.

(d) Dizziness, light-headedness, and lower extremity edema are the most common adverse effects, but these tend to disappear with time or dose adjustment.

(3) **Amlodipine (Norvasc®), clevidipine (Cleviprex®), felodipine (Plendil®), isradipine (Dynacirc®), nicardipine (Cardene®), and nisoldipine (Sular®)** are second-generation dihydropyridine derivative, calcium-channel blockers. They have been used effectively as once- or twice-a-day agents owing to their long activity. Because of the potent negative inotropic effects of these agents, they are not recommended in patients with HF (amlodipine has been shown to have less negative potential in HF than other members of the class). Clevidipine is available in the injectable form only and is administered as a continuous slow IV infusion.

5. **Antiplatelet agents**

a. **Aspirin.** Based on the 2007 Focused Guidelines for Patients With Chronic Stable Angina, a class Ia recommendation states that aspirin should be started at 75 to 162 mg/day and continued indefinitely in all patients unless contraindicated.

b. **Ticlopidine (Ticlid®)** is a thienopyridine derivative that inhibits platelet aggregation induced by adenosine diphosphate. However, unlike aspirin, it has not been shown to decrease adverse

cardiovascular events in patients with stable angina and has been associated with thrombotic thrombocytopenic purpura on an infrequent basis.

   c. Clopidogrel (Plavix®) is also a thienopyridine derivative related to ticlopidine, but it possesses antithrombotic effects that are greater than those of ticlopidine. Clopidogrel is a therapeutic option in those angina patients who cannot take aspirin because of contraindications. Doses of 75 mg daily are recommended to prevent the development of acute coronary syndromes.

      (1) Recently there has been added concern regarding the interaction which takes place when patients receiving clopidogrel are also given one of the proton pump inhibitors (PPIs), such as omeprazole (Nexium®). The American College of Cardiology Foundation, in conjunction with the American College of Gastroenterology and the American Heart Association, has issued a consensus document regarding the concomitant use of PPIs and thienopyridines, specifically clopidogrel. The following highlighted recommendations are discussed within the consensus statement as they relate to the combinations of clopidogrel and PPIs:

         (a) PPIs are appropriate in patients with multiple risk factors for GI bleeding who are also receiving antiplatelet therapy (e.g., clopidogrel).

         (b) Although pharmacokinetic and pharmacodynamic studies have demonstrated varying effects of PPIs on the extent of clopidogrel metabolic conversion to the active metabolite, no evidence has established clinically meaningful differences in outcomes.

         (c) A clinically significant interaction cannot be excluded in subgroups who are poor metabolizers of clopidogrel.

         (d) Until solid evidence exists to support staggering PPIs with clopidogrel, the dosing of PPIs should not be altered.

   d. Based on the 2007 Focused Guidelines for Patients With Chronic Stable Angina, a class Ib recommendation states that the use of warfarin in conjunction with aspirin and/or clopidogrel is associated with an increased risk of bleeding and should be monitored closely.

  6. ACE inhibitors. Based on the 2007 Focused Guidelines for Patients With Chronic Stable Angina, the following recommendations have been made for ACE inhibitors.

   a. Class 1a recommendation states that ACE inhibitors should be started and continued indefinitely in all patients with left ventricular ejection fraction $\leq 40\%$ and in those with hypertension, diabetes, or chronic kidney disease unless contraindicated.

   b. Class Ib recommendation that ACE inhibitors should be started and continued indefinitely in patients who are not lower risk (lower risk defined as those with normal left ventricular ejection fraction in whom cardiovascular risk factors are well controlled and revascularization has been performed), unless contraindicated.

   c. Class IIa recommendation that it is reasonable to use ACE inhibitors among lower risk patients with mildly reduced or normal left ventricular ejection fraction in whom cardiovascular risk factors are well controlled and revascularization has been performed.

   d. Current guidelines do not suggest which agent to use, and it is anticipated that ongoing trials with additional agents will provide additional information regarding dosing regimens and potential differences that might exist among the class of drugs.

  7. Angiotensin receptor blockers (ARBs). Based on the 2007 Focused Guidelines for Patients With Chronic Stable Angina, three new recommendations have been made for the use of ARBs in patients with chronic stable angina.

   a. Class Ia recommendation that ARBs are recommended for patients who have hypertension, have indications for but are intolerant of ACE inhibitors, have heart failure, or have had a myocardial infarction with left ventricular ejection fraction $\leq 40\%$.

   b. Class IIb recommendation that ARBs may be considered in combination with ACE inhibitors for heart failure due to left ventricular systolic dysfunction.

   c. Class Ia recommendation that aldosterone blockade is recommended for use in post-MI patients without significant renal dysfunction or hyperkalemia who are already receiving therapeutic doses of an ACE inhibitor and a β-blocker, have a left ventricular ejection fraction $\leq 40\%$, and have either diabetes or heart failure.

  8. Chelation therapy. Based on the 2007 Focused Guidelines for Patients With Chronic Stable Angina, a class IIIc recommendation stated that chelation therapy (intravenous infusions of ethylenediaminetetraacetic acid or EDTA) is not recommended for the treatment of chronic angina or arteriosclerotic cardiovascular disease and may be harmful because of its potential to cause hypocalcemia.

III. ACUTE CORONARY SYNDROME (ACS)

A. **Definition.** ACS is a relatively new term that has been introduced into the medical literature to describe any pattern of clinical symptoms that reflects the development of acute MI (*Figure 31-2*). This category includes the symptoms related to STEMI, NSTEMI, and unstable angina.

B. **Incidence.** It has been estimated that nearly 8 million patients seen in emergency departments each year in the United States are seen for chest pain, and that up to 5 million of these patients are admitted to the hospital. More than 1.5 million of the patients admitted to the hospital are admitted with an ACS (330,000 with STEMI, and 1.24 million with UA and NSTEMI).

C. Classification of patients presenting with presumed ACS is critical to the appropriate determination of prognosis as well as clinical interventions. In ACS owing to STEMI and NSTEMI, a portion of the cardiac muscle suffers a severe and prolonged restriction of oxygenated coronary blood. In most patients, the cause is an occlusive or near-occlusive thrombus overlying or adjacent to a ruptured atherosclerotic plaque. This results in cellular ischemia, tissue injury, and tissue necrosis. About 1.5 million people suffer an acute myocardial infarction (AMI) each year. UA is believed to indicate an impending AMI, and the goal of treatment is to prevent the development of the AMI.

  1. **STEMI.** A condition that requires immediate reperfusion therapy, if possible, through either thrombolysis or percutaneous coronary intervention (PCI).
     a. The introduction of thrombolysis or PCI for the management of STEMI has demonstrated ability to remove the offending thrombus from the affected coronary artery.
     b. Damage to the myocardial tissue is not routinely reversible, as in the case of angina pectoris, owing to potential death of myocardial tissue if reperfusion does not take place early enough.

  2. **UA and NSTEMI.** Similar conditions for which there is no evidence showing the benefit to patients of reperfusion therapy. Specific guidelines have been developed for the diagnosis and management of these conditions. Up to 25% of patients who have both NSTEMI and elevated cardiac enzymes eventually develop Q-wave MI; the remaining patients develop non–Q-wave MI. Patients with UA carry a 10% to 20% risk of progression to an MI if untreated; treatment has been shown to reduce the risk to 5% to 7%.

D. **Diagnosis.** The EKG/ECG is at the center of the decision pathway for the evaluation and management of patients with ACS and is confirmed with serial cardiac markers in > 90% of patients presenting with significant ST-segment elevation. Patients who present without ST-segment elevation

Stable Angina	Unstable Angina	NSTEMI	STEMI

Figure 31-2. Evolutionary progression of ACSs. As atherosclerosis (most common cause of ischemic heart disease) advances, the reduction in myocardial perfusion results in the development of the ACS owing to unstable angina, NSTEMI, or STEMI. The thrombi, which form in unstable angina, NSTEMI, and STEMI, are rich in both fibrin and platelets. Adapted from Vanscoy G. Integrating new fibrinolytic findings into AMI reperfusion and combination therapy: 2002 and beyond. Paper presented at the meeting of the Delaware Valley Chapter of the Pennsylvania Society of Health-Systems Pharmacists; March 7, 2002. *STEMI*, ST-segment elevation; *NSTEMI*, non–ST-segment elevation.

are considered to have either UA or NSTEMI; the final diagnosis is made later, after the presence or absence of serial cardiac markers is determined.

1. **Diagnostic test results.** The development of an ACS is a life-threatening emergency; diagnosis is presumed—and treatment is instituted—based on the patient's complaints and the results of an immediate 12-lead EKG/ECG. Laboratory tests and further diagnostic tests can rule out or provide confirmation and help identify the locale and extent of myocardial damage.

2. **Serial 12-lead EKG.** Abnormalities may be absent or inconclusive during the first few hours after presentation of the ACS and may not aid the diagnosis in about 15% of the cases. When present, characteristic findings show progressive changes.

   a. First, ST-segment elevation (injury current) appears in the leads, reflecting the injured area. Peaked upright or inverted T waves usually indicate acute myocardial injury, the early stages of a transmural Q-wave MI. Persistent ST depression may also indicate a non–Q-wave MI.

   b. Q waves developing (indicating necrosis) is generally diagnostic of an MI but can be seen in other conditions.

   c. Unequivocal diagnosis can be made only in the presence of all three abnormalities. However, the manifestations depend on the area of injury. For example, in non–Q-wave infarction, only ST-segment depression may appear.

   d. The most serious arrhythmic complication of an AMI is ventricular fibrillation, which may occur without warning.

   e. Ventricular premature beats (VPBs) are the most commonly encountered arrhythmias and may require treatment.

3. **Cardiac enzymes**

   a. **Creatine kinase–heart muscle** (CK-MB) is first elevated 3 to 12 hrs after the onset of pain, peaks in 24 hrs, and returns to baseline in 48 to 72 hrs. Other conditions elevate the CK-MB enzyme but do not demonstrate the typical pattern of rise and fall as seen in an MI. Until recently, CK-MB had been the principal serum cardiac marker used in the evaluation of ACS.

   b. **Cardiac troponin I** (cTnI) and **cardiac troponin T** (cTnT) are even more sensitive than CK-MB. They represent a powerful tool for risk stratification and have greater sensitivity and specificity than CK-MB. However, they do provide a low sensitivity in the early phases of an MI (< 6 hrs after symptom onset) and require repeat measurements at 12 to 16 hrs, if negative. Levels increase 3 to 12 hrs after the onset of pain, peak at 24 to 48 hrs, and return to baseline over 5 to 14 days.

   c. **Lactate dehydrogenase** (LDH) is followed for its characteristic patterns of rise and fall. The ratio of $LDH_1:LDH_2$ is helpful in diagnosing an MI. LDH assays are being replaced by cTnT assays.

4. **Cardiac imaging.** As cardiac enzyme assays improve, the use of noninvasive cardiac imaging techniques are not indicated for initial diagnosis of an MI. Tests include ^{99m}Tc-pyrophosphate scintigraphy, myocardial perfusion imaging, radionucleotide ventriculography, two-dimensional echocardiography, and coronary angiography.

E. **Signs and symptoms**

1. Recent evidence-based clinical guidelines indicate a class I recommendation for patients with suspected ACS with chest discomfort at rest for longer than 20 mins; hemodynamic instability or recent syncope or presyncope should be strongly considered for immediate referral to an emergency department or specialized chest pain unit. The foremost characteristic of ACS is persistent, severe chest pain or pressure, commonly described as crushing, squeezing, or heavy (likened to having an elephant sitting on the chest). The pain generally begins in the chest and, like angina, may radiate to the left arm, the abdomen, back, neck, jaw, or teeth. The onset of pain generally occurs at rest or with normal daily activities; it is not commonly associated with exertion.

2. Other common complaints include a sense of impending doom, sweating, nausea, vomiting, and difficulty breathing. In some patients, fainting and sudden death may be the initial presentation of ACS.

3. Observable findings include extreme anxiety, restless, agitated behavior, and ashen pallor.

4. Some patients, particularly those with diabetes or the elderly, may experience only mild or indigestion-like pain or a clinically silent MI, which may only manifest in worsening heart failure, loss of consciousness, acute confusion, dyspnea, a sudden drop in blood pressure, or a lethal arrhythmia.

F.   Overall treatment goals in ACS

  1. To relieve chest pain and anxiety

  2. To reduce cardiac workload and stabilize cardiac rhythm

  3. To prevent/reduce myocardial damage by limiting the area affected and preserving pump function

  4. To prevent or arrest complications, such as lethal arrhythmias, AMI, HF, or sudden death

  5. To reopen (or reperfuse) closed coronary vessels with thrombolytic drugs and/or PCI

G.   Treatment of UA and NSTEMI

  1. Anti-ischemic therapy

   a. Current evidence-based clinical guidelines indicate class I recommendations for the following therapeutic interventions in patients with UA or NSTEMI:

   (1) Bed rest with continuous EKG/ECG monitoring for ischemia and arrhythmia detection in patients with ongoing rest pain.

   (2) Patients with UA/NSTEMI with ongoing ischemic discomfort should receive SL nitroglycerin (NTG) 0.4 mg every 5 min $\times$ 3 doses, after which time reassess for potential need for intravenous nitroglycerin. Intravenous NTG is indicated in the first 48 hrs in patients with UA/NSTEMI for treatment of persistent ischemia, heart failure, or hypertension.

   (3) Supplemental oxygen for patients with cyanosis or respiratory distress and continued need for supplemental oxygen in the presence of hypoxemia.

   (4) Aspirin in doses of 162 to 325 mg (chewable) should be given to patients with UA/NSTEMI as soon as possible, if the patient has not already taken.

   (5) An oral β-adrenergic blocker should be administered within the first 24 hrs to all patients without contraindications. Intravenous β-adrenergic blockers should only be used for specific indications and not as routine therapy.

   (6) In patients with continuing or frequently recurring ischemia when β-adrenergic blockers are contraindicated, a nondihydropyridine calcium antagonist (i.e., diltiazem or verapamil) is recommended as initial therapy in the absence of severe left ventricular dysfunction or other contraindications. In patients presenting with left ventricular dysfunction, current evidence shows that these agents might worsen the clinical status.

   (7) An ACE inhibitor should be administered orally within the first 24 hrs to patients with pulmonary congestion or left ventricular ejection fraction ≤ 40% in the absence of hypotension (systolic blood pressure less than 100 mm Hg or less than 30 mm Hg below baseline) or known contraindications. An ARB may be used for ACE inhibitor–intolerant patients.

  2. **Therapeutic agents.** *Table 31-4* lists selected agents and dosing regimens.

   a. **Nitrates (e.g., nitroglycerin).** (See II.H.)

   b. **Morphine.** Guidelines for UA/NSTEMI and STEMI from 2007 have stated that morphine is considered a class I recommendation in patients with STEMI; however, in UA/NSTEMI patients, it might increase the rate of adverse events and has been downgraded from a class I recommendation to a class IIa. In the absence of contraindications, morphine sulfate can be administered to patients if there is uncontrolled ischemic pain despite the use of NTG provided additional therapy to treat the underlying ischemia.

   (1) **Mechanism of action.** Morphine causes venous pooling and reduces preload, cardiac workload, and oxygen consumption. Morphine should be administered intravenously, starting with 2 mg and titrating at 5- to 15-min intervals until the pain is relieved or toxicity becomes evident.

   (2) **Indications.** Morphine sulfate is a reasonable choice for myocardial pain and anxiety in doses of 1 to 5 mg IV every 5 to 30 mins as needed, based on level of patient pain and blood pressure.

   (3) **Precautions and monitoring effects**

    (a) Because morphine increases peripheral vasodilation and decreases peripheral resistance, it can produce orthostatic hypotension and fainting.

    (b) Patients should be monitored for hypotension and signs of respiratory depression.

    (c) Morphine has a vagomimetic effect that can produce bradyarrhythmias. If EKG/ECG monitoring reveals excess bradycardia, it should be reversed by administering atropine (0.5 to 1.0 mg).

    (d) Nausea and vomiting may occur (about 20% incidence), especially with initial doses, and patients must be protected against aspiration of stomach contents.

(e) Severe constipation is a potential problem with ongoing morphine administration. The patient may need to use a Valsalva maneuver while straining at the stool, which can produce bradycardia or can overload the cardiac system and trigger cardiac arrest. Docusate (100 mg twice daily) is a useful prophylactic.

c. **Oxygen** is considered a class I recommendation for anti-ischemic therapy, and should be administered to patients with an arterial saturation less than 90%, respiratory distress, or other high-risk features for hypoxemia. The use of pulse oximetry is useful for the continuous measurements of oxygen saturation. Mild hypoxemia is common in AMI patients. Increasing the oxygen content of the blood, thus improving oxygenation of the myocardium, is a top priority as continuing hypoxia rapidly increases myocardial damage.

d. **Thrombolytic agents (fibrinolytics)** have not demonstrated beneficial clinical outcomes in the absence of STEMI. Studies carried out to date have failed to show benefit with using thrombolytics in UA versus standard therapy to prevent MI. In addition, thrombolytic agents actually increased the risk of MI in such patients. Therefore, based on current evidence-based guidelines, thrombolytic agents are not recommended in the management of ACS without ST-segment elevation.

3. **Antiplatelet and anticoagulation therapy.** *Table 31-5* lists selected agents and dosing regimens.

   a. Current evidence-based clinical guidelines indicate class I recommendations for the following therapeutic interventions in patients with UA or NSTEMI:

      (1) Antiplatelet therapy should be initiated promptly. Aspirin should be administered as soon as possible after presentation and continued indefinitely.

      (2) Clopidogrel (Plavix®) (loading dose, 300 to 600 mg; followed by maintenance dose, 75 mg by mouth daily) should be administered to hospitalized patients who are unable to take aspirin because of hypersensitivity or major GI intolerance.

      (3) In hospitalized patients for whom an early noninterventional approach is planned, clopidogrel should be added to aspirin and anticoagulants as soon as possible on admission and administered for at least 1 month and ideally up to 1 year.

      (4) The usefulness of glycoprotein IIb/IIIa receptor antagonists as part of a preparatory strategy for patients with STEMI before their arrival in the cardiac catheterization laboratory for PCI is uncertain, and received a class IIb, level b recommendation.

      (5) In patients for whom a PCI is planned, an additional antiplatelet agent should be added to aspirin as follows prior to the planned PCI: i) clopidogrel should be given in a dose of 300 to 600 mg, or prasugrel (Effient®), 60 mg OR; ii) an intravenous glycoprotein IIb/IIIa inhibitor (GP IIb/IIIa) preferably tirofiban or eptifibatide should be added to the previous aspirin therapy. Abciximab (ReoPro®) is indicated only if there is no appreciable delay to angiography, and PCI is likely to be performed; otherwise, IV eptifibatide or tirofiban is the preferred choice of GP IIb/IIIa inhibitor. Patients should continue receiving clopidogrel in doses of 75 mg daily or prasugrel, 10 mg daily for 12 months after the PCI.

      (6) In patients taking clopidogrel or prasugrel in whom elective coronary artery bypass grafting (CABG) is planned, the drugs should be withheld for 5 and 7 days, respectively.

      (7) Anticoagulant therapy should be added to antiplatelet therapy in UA/NSTEMI patients as soon as possible after presentation. For patients in whom an invasive strategy is selected, regimens with established efficacy with a high level of evidence include enoxaparin and heparin. The most recent focused guidelines add that for patients in whom a conservative strategy is selected, regimens using either enoxaparin (Lovenox®) or heparin or fondaparinux (Arixtra®) can be used. In patients in whom a conservative strategy is selected and who have an increased risk of bleeding, fondaparinux is preferable.

      (8) A platelet glycoprotein IIb/IIIa antagonist or clopidogrel should be administered, in addition to aspirin and heparin, to patients for whom catheterization and PCI are planned. The agent may also be administered just before PCI.

H. **STEMI**

1. Of the more than 1.68 million patients admitted to hospitals with ACS each year, more than 500,000 of them will be diagnosed with STEMI. Approximately 90% of those diagnosed with STEMI will have complete occlusion of the infarct-related artery by a thrombus.

Table 31-5 SELECT ANTIPLATELET/ANTICOAGULANT AGENTS USED IN THE TREATMENT OF STEMI PATIENTS

Class/Agent	Dosing Regimen	Level of Evidence (Guidelines)
	Oral antiplatelets/anticoagulants	
Aspirin*	**For acute STEMI patients:**	
	162 mg should be chewed by patients who have not taken aspirin before presentation with STEMI.	Class I
	For all post-PCI STEMI stented patients:	
	1. 162–325 mg daily for at least 1 month after bare-metal stent implantation, 3 months after sirolimus-eluting stent, and 6 months after paclitaxel-eluting stent, and then indefinitely at doses of 75–162 mg daily.	Class IIa
	2. In patients where there is concern of bleeding, 75–162 mg (lower dose) aspirin is reasonable during the initial period after stent implantation.	Class IIa
Clopidogrel (Plavix)	1. 75 mg orally daily added to ASA in STEMI patients.	Class I-Post-STEMI patients
	2. Treatment should be at least 14 days.	Class I-Post-STEMI patients
	3. Loading dose of 300 mg orally (patients < 75 years who receive fibrinolytic therapy or who do not receive reperfusion therapy)	Class IIa-Post-STEMI patients
	4. 75 mg orally per day, long-term maintenance therapy (e.g., 1 year) (regardless of whether they undergo reperfusion with fibrinolytic therapy).	Class IIa-Post-STEMI patients
	For all post-PCI STEMI stented patients:	
	5. Receive a drug-eluting stent (DES), clopidogrel 75 mg daily should be given for at least 12 months if patients are not at high risk of bleeding.	Class I
	6. Receive a bare metal stent (BMS), clopidogrel should be given for a minimum of 1 month and ideally up to 12 months (unless the patient is at increased risk of bleeding; then it should be given for a minimum of 2 weeks).	Class I
	7. For patients taking clopidogrel for whom CABG is planned, if possible, the drug should be withheld for at least 5 days, and preferably for 7, unless the urgency for revascularization outweighs the risks of bleeding.	Class I
Warfarin	1. Managing warfarin to INR = 2.0 to 3.0 in post-STEMI patients. Use of warfarin in conjunction with aspirin and/or clopidogrel is associated with increased risk of bleeding and should be monitored closely.	Class I-Post-STEMI patients
	2. In patients requiring warfarin, clopidogrel, and aspirin therapy, an INR of 2.0 to 2.5 is recommended with low-dose aspirin (75–81 mg) and a 75 mg dose of clopidogrel.	
	Parenteral antiplatelets/anticoagulants	
Heparin (UFH)	1. Bolus of 60 U/kg, maximum 4000 U IV followed by an initial infusion 12 U/kg/hr, (maximum of 1000 U/hr) in patient at high risk for systemic emboli (large or anterior MI, atrial fibrillation, previous embolus, known LV thrombus, or cardiogenic shock.	Class I-Post-STEMI
	2. IV or SQ UFH or with subcutaneous LMWH for at least 48 hrs. In patients whose clinical condition necessitates prolonged bed rest and/or minimized activities, it is reasonable that treatment be continued until the patient is ambulatory.	Class IIa-Post-STEMI and not undergoing reperfusion, and no contraindications.

(Continued on next page)

Table 31-5   Continued.

Class/Agent	Dosing Regimen	Level of Evidence (Guidelines)
	3. SQ UFH, 7,500 units–12,500 units twice daily for prophylaxis for deep venous thrombosis (DVT) until completely ambulatory, may be useful, but the effectiveness of such a strategy is not well established in the contemporary era of routine aspirin use and early mobilization.	Class IIb
	For STEMI patients receiving PCI:	
	4. Bolus of 70–100 U/kg, and maintenance to target 1.5–2.0 times aPTT, if no GP IIb/IIIa previously given. However, if a GP IIb/ IIIa has been given previously, 50–70 U/kg bolus, and maintenance to target, as above.	Class I
Enoxaparin (Lovenox)	**Patients undergoing reperfusion with fibrinolytics:**	
	For patients younger than 75 years of age:	
	1. 30 mg intravenous bolus, followed in 15 mins by 1.0 mg/kg SQ every 12 hrs (serum creatinine < 2.5 mg/dL in men and 2.0 mg/dL in women).	Class I-Post-STEMI
	For patients ≥ 75 years of age,	
	2. 0.75 mg/kg SQ every 12 hrs. (No loading dose). Maintenance doses with enoxaparin should continue for the duration of the index hospitalization, up to 8 days. Regardless of age, if the creatinine clearance (using the Cockcroft-Gault formula) during the course of treatment is estimated to be less than 30 mL/min, the subcutaneous regimen is 1.0 mg/kg every 24 hrs.	Class I-Post-STEMI
Fondaparinux (Arixtra)	**Patients undergoing reperfusion with fibrinolytics:**	
	1. 2.5 mg IV, followed by 2.5 mg SQ once daily. (serum creatinine is less than 3.0 mg/dL)	Class I-Post-STEMI
	2. Maintenance doses with fondaparinux should be continued for the duration of the index hospitalization, up to 8 days.	Class I-Post-STEMI
Bivalirudin (Angiomax)	**Patients undergoing PCI:**	
	1. Initial IV bolus dose of 0.75 mg/kg, followed by 1.75 mg/kg/hr infusion for the duration of the procedure.	Class I-Post-STEMI
Abciximab (ReoPro)	0.25 mg/kg IV bolus followed by infusion of 0.125 mcg/kg/min for 12–24 hrs	Class IIa, for use in addition to aspirin and heparin in STEMI patients for whom catheterization and PCI are planned just before PCI. Class III, in STEMI patients for whom PCI is not planned.
Eptifibatide (Integrilin)	180 mcg/kg IV bolus followed by infusion of 2.0 mcg/kg/min for 72–96 hrs.	Class I, for use in addition to aspirin and heparin in STEMI patients for whom catheterization and PCI are planned, and in patients just before PCI.
Tirofiban (Aggrestat)	0.4 mcg/kg/min for 30 mins followed by infusion of 0.1 mcg/kg/min for 48–96 hrs.	Class IIa, in addition to aspirin and a LMWH or UFH in STEMI patients without continuing ischemia who have no other high-risk features and for whom PCI is not planned. Class IIb, in addition to aspirin and a LMWH or UFH in STEMI patients without continuing ischemia who have no other high-risk features and for whom PCI is not planned.

*Assuming no aspirin resistance, allergy, or increased risk of bleeding.
aPTT, activated partial thromboplastin time; CABG, coronary artery bypass graft; GP, glycoprotein; INR, international normalized ratio; IV, intravenous; LMWH, low-molecular-weight-heparin; PCI, percutaneous coronary intervention; SQ, subcutaneously. STEMI, ST-segment elevation; UFH, unfractionated heparin

2. When the lesion ruptures, it triggers the release of adenosine diphosphate (ADP), serotonins, and thromboxane A_2, which leads to platelet aggregation and the formation of the primary clot. Thromboplastin, released from the injured vessel initiates the clotting cascade, and the resulting fibrin traps red blood cells (RBCs), platelets, and plasma protein to form an intraluminal thrombus. The subsequent clot dissolution is caused by the conversion of plasminogen to plasmin, which is mediated by plasminogen activators.

3. According to updated management guidelines (see I.D.6.), all patients with STEMI should receive either primary PCI within 90 mins of first medical contact (class Ia recommendation) or fibrinolytic therapy within 30 mins of hospital presentation if they cannot be transferred to a PCI center and undergo PCI within 90 mins of first medical contact, unless fibrinolytic therapy is contraindicated (class Ib recommendation).

4. It is beyond the realm of this text to expand on the clinical implications for primary PCI, facilitated PCI, and rescue PCI, as described in the 2009 Focused Updates: ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction (Updating the 2004 Guideline and 2007 Focused Update) and ACC/AHA/SCAI Guidelines on Percutaneous Coronary Intervention (Updating the 2005 Guideline and 2007 Focused Update). Consequently, the review will focus strictly on the pharmacologic agents recommended for use in the STEMI patient population, which include fibrinolytics, analgesics, anticoagulants, thienopyridines, antiplatelets, ACE inhibitors, ARBs, and β-adrenergic receptor blockers as either primary treatment or secondary preventive and long-term management, as discussed in the guidelines.

   a. Fibrinolytics. Administration of thrombolytic agents causes the thrombus clot to be lysed when administered early after symptom onset ($<$ 6 to 12 hrs) and to restore blood flow. The conversion of plasminogen to plasmin promotes fibrinolysis and breakdown of the clot.

   (1) Indications

   (a) Thrombolytic agents were used in patients with STEMI with chest pain $<$ 6 to 12 hrs. Successful early reperfusion has been shown to reduce infarct size, improve ventricular function, and improve mortality. However, benefits may be seen in patients using thrombolytic therapy as late as 12 hrs after pain starts. Therapy of choice when PCI is not available.

   (b) Intravenous administration of a recombinant tissue-plasminogen activator (t-PA) such as alteplase (Activase®), a recombinant plasminogen activator (r-PA) such as reteplase (Retavase®), or tenecteplase (Tnkase®), may restore blood flow in an occluded artery if administered within 12 hrs of an AMI, although $<$ 6 hrs is optimal. The goal of treatment of STEMI patients is to initiate thrombolytic therapy within 30 to 60 mins of arrival in an emergency room.

   (i) t-PA is relatively fibrin specific and is able to lyse clots without depleting fibrinogen, and Tnkase has a greater fibrin specificity.

   (ii) Most studies have shown that each agent, when used early, can reopen (reperfuse) occluded coronary arteries and reduce mortality by up to 30% from STEMI. However, considerations such as ease of use, market availability, onset of action, incidence of bleed, and cost are important factors in determining which agent to use for a given hospital and patient.

   (2) Individual agents

   (a) Alteplase (Activase®)

   (i) **Absolute contraindications** to t-PA include active internal bleeding; recent cerebrovascular accident (CVA); intracranial neoplasm; aneurysm; pregnancy; arteriovenous malformations; recent (within 2 months) intracranial surgery, spinal surgery, or trauma; and severe uncontrolled hypertension, bleeding diathesis, or hemorrhagic ophthalmic conditions.

   (ii) A **front-loaded regimen**—an accelerated infusion that consists of a total dose of 100 mg or less that is given over 1.5 hr—may be more beneficial. The initial dose of 15 mg is given as an IV bolus, 1 to 2 mins, while an infusion is begun to

   (a) Infuse t-PA at the rate of 0.75 mg/kg over 30 mins (not to exceed 50 mg)

   (b) Followed by t-PA infused at 0.5 mg/kg over 60 mins (not to exceed 35 mg)

   (iii) An alternate dosing regimen is based on the patient's weight.

   (a) **Dosage for patients $>$ 65 kg.** A total of 100 mg of t-PA is generally administered to all patients who weigh $>$ 65 kg over a 3-hr period. Although many

regimens have been used, generally speaking, 6 to 10 mg of t-PA is given as an IV bolus over 1 to 2 mins, followed by the remaining infusion rates over the next 3 hrs: a 54- to 60-mg IV infusion over the first hour, a 20-mg IV infusion over the second hour, and a 20-mg IV infusion over the third hour.

  (b) **Dosage for patients < 65 kg.** A dose of 1.25 mg/kg is given over a 3-hr period, with 10% of the total dose given initially as a bolus dose over 1 to 2 mins.

(b) **Reteplase (Retavase®)**

  (i) **Absolute contraindications** to reteplase are similar to those for t-PA, although additional cautionary statements are given for patients with severely impaired renal function or liver function.

  (ii) **Dosing** is initiated with the intravenous administration of 10 units over a 2-min period, and then repeated after 30 mins, if there are no complications.

(c) **Tenecteplase (Tnkase®)**

  (i) **Absolute contraindications** to tenecteplase are similar to those for t-PA and r-PA with the following addition: use with caution in patients recently receiving a glycoprotein IIb/IIIa agent, pregnant patients, elderly patients, patients with endocarditis, and patients with severe liver disease.

  (ii) Tenecteplase is approved for use in acute treatment of STEMI at doses of 30 to 50 mg (based on the patient's weight) as a single IV bolus over 10 to 15 secs. Rapid rate of administration, fibrin specificity, fewer bleeding complications compared to t-PA, and superiority over t-PA in late-treated patients make tenecteplase a likely candidate to replace t-PA as the agent of choice in STEMI.

(3) **Adjunctive fibrinolysis therapy.** The 2007 Focused Guidelines for ST-segment elevated MI discuss the use of analgesia, β-adrenergic receptor blockers, anticoagulants, and thienopyridines in STEMI patients based on the quality of available literature for their use.

  (a) Analgesia

   (i) Morphine sulfate in doses of 2 to 4 mg IV in increments of 2 to 8 mg IV, repeated in 5- to 15-min intervals, is the analgesic of choice for the management of pain due to STEMI (class Ic).

   (ii) Patients taking NSAIDs with the exception of aspirin, before being treated for STEMI should stop taking them due to increased risk of mortality, reinfarction, hypertension, heart failure, and myocardial rupture associated with their use (class Ic).

  (b) **Aspirin** administered (160 to 325 mg) during acute thrombolytic therapy has been shown to affect thrombolysis positively by preventing platelet aggregation and has reduced postinfarct mortality. Doses of aspirin, 75 to 162 mg daily have been recommended for long-term use at hospital discharge. Other agents include ticlopidine (Ticlid®) and clopidogrel (Plavix®) for those unable to take aspirin.

  (c) **β-Adrenergic blockers**

   (i) It is recommended to initiate and/or continue β-blocker therapy indefinitely in all MI, acute coronary, or left ventricular dysfunction patients with or without signs of heart failure, unless contraindicated.

   (ii) Patients who may initially present with contraindications to receiving β-blockers during the initial 24 hrs of their STEMI should be reevaluated for receiving such therapy as a secondary preventive measure (class Ic).

   (iii) Patients with moderate or severe left ventricular failure should receive β-blocker therapy as a secondary preventive measure but with a gradual dose escalation titration (class Ib).

   (iv) It is reasonable to administer an IV β-blocker to a STEMI patient at the time of presentation if they have hypertension and do not have any of the aforementioned contraindications to receiving them (class IIa).

  (d) **Anticoagulants**

   (i) Patients who undergo reperfusion with fibrinolytics should receive anticoagulant therapy for at least 48 hrs and ideally throughout the hospitalization, up to 8 days (class Ic).

(ii) Patients who receive anticoagulants for more than 48 hrs should receive an agent other than unfractionated heparin (UFH) due to the increased risk of heparin-induced thrombocytopenia with its prolonged use (class Ia).

(iii) Anticoagulant regimens with established efficacy in STEMI include:

— **UFH.** Initial IV bolus of 60 units/kg (maximum 4000 units) followed by an IV infusion of 12 units/kg/hr (maximum of 1000 units/hr) initially. The dose should be adjusted to maintain an activated partial thromboplastin time (aPTT) of 1.5 to 2 times control (class Ic).

— **Enoxaparin (Lovenox®).** An initial 30 mg IV bolus, followed in 15 mins by a subcutaneous injection of 1 mg/kg every 12 hrs (assuming serum creatinine is less than 2.5 mg/dL in men, 2.0 mg/dL in women in patients younger than 75 years of age). For patients 75 years of age and older, the IV bolus dose is eliminated, and the patient is given a subcutaneous dose of 0.75 mg/kg every 12 hrs. CAUTION: In all patients, if the creatinine clearance is estimated to be less than 30 mL/min, the dosing regimen should be changed to 1 mg/kg every 24 hrs. The current guidelines recommend the use of maintenance dosing of enoxaparin for the duration of hospitalization, up to a maximum of 8 days (class Ia).

— **Fondaparinux (Arixtra®).** An initial dose of 2.5 mg intravenously and subsequent subcutaneous injections of 2.5 mg given once daily (assuming serum creatinine is less than 3.0 mg/dL). The current guidelines, as in the case of enoxaparin, recommend the use of maintenance dosing of fondaparinux for the duration of hospitalization, up to a maximum of 8 days (class Ib).

(iv) Anticoagulants have also been shown to be effective in STEMI patients prior to undergoing PCI, with the following dosing recommendations:

— **UFH.** For prior treatment, administer additional boluses of UFH as needed to support the procedure, but take into account whether other agents such as GP IIb/IIIa receptor antagonists (class Ic). Bivalirudin (Angiomax®) can also be used in patients previously treated with UFH (class Ic).

— **Enoxaparin (Lovenox®).** For prior treatment, if the last subcutaneous dose of enoxaparin was given within the previous 8 hrs, no additional drug is needed; however, if the last dose was administered 8 to 12 hrs earlier, an intravenous dose of 0.3 mg/kg should be given (class Ib).

— **Bivalirudin (Angiomax®).** With the most recent national guidelines updated for STEMI/PCI, bivalirudin received a class I, level b recommendation as useful supportive measure for primary PCI with or without prior treatment with UFH. Bivalirudin has also received a class IIa, level b recommendation in STEMI patients undergoing PCI who are at a high risk of bleeding due to its relatively low risk of bleeding compared to other anticoagulants.

(v) Anticoagulants (non-UFH regimens) have also been recommended for patients with STEMI who do not undergo reperfusion therapy for the duration of the initial hospitalization (class IIa). Dosing regimens that can be used include enoxaparin or fondaparinux in the same dosing regimens as in those patients receiving fibrinolytic (see iv previously).

(e) Thienopyridines

(i) Clopidogrel (Plavix®) should be added to aspirin in STEMI patients regardless of whether they undergo reperfusion with fibrinolytics or do not receive reperfusion (class Ib). Doses of 75 mg by mouth daily should be administered. Treatment should continue for at least 14 days (class Ib).

(ii) Prasugrel (Effient®) 60 mg should be given as soon as possible prior to PCI, if clopidogrel is not being used (class Ib). Prasugrel should be given in those patients not receiving clopidogrel within 1 hr of PCI (class Ib).

(iii) Patients receiving clopidogrel (Plavix®) or prasugrel (Effient®) who are planning on undergoing CABG should discontinue therapy 5 to 7 days prior to the surgery, respectively, unless the urgency of the procedure outweighs the risks of excess bleeding (class Ic).

(iv) For patients younger than 75 years receiving fibrinolytic therapy or not receiving reperfusion therapy, it is reasonable to administer an oral clopidogrel loading dose of 300 mg. (No data are available to guide decision making regarding an oral loading dose in patients ≥ 75 years of age.) (class IIa).

(v) Long-term maintenance therapy (e.g., 1 year) with clopidogrel (75 mg/day orally) can be useful in STEMI patients regardless of whether they undergo reperfusion with fibrinolytic therapy or do not receive reperfusion therapy (class IIa).

(vi) Patients who have received a stent, i.e., bare-metal or drug eluting during PCI for ACS, should continue to receive maintenance therapy of clopidogrel (Plavix®) or prasugrel (Effient®), 75 mg or 10 mg, respectively, by mouth daily for at least 12 months (class Ib).

(4) Secondary prevention and long-term management: *Table 31-2* provides a combination of risk factors as well as disease-based recommendations, which have been incorporated into the 2007 Focused Guidelines for STEMI patients. Additionally, the guidelines include recommendations made for select pharmacologic agents that include aspirin, clopidogrel, warfarin, ACE inhibitors, angiotensin receptor blockers, aldosterone blockade, and β-blockers, and influenza vaccination.

(a) **Aspirin**

(i) All post-PCI STEMI patients receiving a stent (bare-metal, sirolimus, paclitaxel) without contraindications to aspirin should receive aspirin 162 to 325 mg daily for 1 to 6 months depending on the type of stent used. After the initial 1 to 6 months, a maintenance dose of aspirin should be continued at a dose of 75 to 162 mg daily, indefinitely (class Ib).

(ii) In those patients where there is concern for a high risk of bleeding, doses of aspirin 75 mg to 162 mg daily are reasonable during the initial period and after stent implantation (class IIa).

(b) **Warfarin (Coumadin®)**

(i) Managing warfarin to an INR = 2.0 to 3.0 in post-STEMI patients when clinically indicated (e.g., atrial fibrillation, left ventricular thrombus, and paroxysmal or chronic atrial fibrillation or flutter) is recommended (class Ia).

(ii) Use of warfarin in conjunction with aspirin and/or clopidogrel is associated with increased risk of bleeding and should be monitored closely (class Ib).

(iii) For patients requiring warfarin, clopidogrel, and aspirin therapy, an INR of 2 to 2.5 is recommended with low-dose aspirin (75 to 81 mg) and a 75 mg dose of clopidogrel (class Ic).

(c) **ACE inhibitors (see Hypertension Chapter; *Table 33-4* for listing of available agents)**

(i) ACE inhibitors should be started and continued indefinitely in all patients recovering from STEMI with LVEF ≤ 40% and in those patients with hypertension, diabetes, or chronic kidney disease, unless contraindicated (class Ia).

(ii) ACE inhibitors should be started and continued indefinitely in patients recovering from STEMI who are not lower risk (lower risk defined as those with normal LVEF in whom cardiovascular risk factors are well controlled and revascularization has been performed), unless contraindicated (class Ib).

(d) **ARBs (see Hypertension Chapter; *Table 33-4* for listing of available agents)**

(i) ARBs are recommended in patients who are intolerant of ACE inhibitors and have had an STEMI with LVEF ≤ 40% or have heart failure (class Ia).

(ii) ARB therapy is beneficial in other patients who are ACE inhibitor–intolerant and have hypertension (class Ib).

(e) **Aldosterone-blocking agents (Spironolactone [Aldactone®], Eplerenone [Inspra®])**

(i) Use of aldosterone blockade in post-STEMI patients without significant renal dysfunction or hyperkalemia is recommended in patients who are already

receiving therapeutic doses of an ACE inhibitor and β-blocker, have an LVEF of ≤ 40% and have either diabetes or heart failure (class Ia).

    (f) β-Adrenergic blockers

        (i) It is beneficial to start and continue β-blocker therapy indefinitely in all patients who have had an STEMI, ACS, or left ventricular dysfunction with or without heart failure symptoms, unless contraindicated (class Ia).

    (g) Influenza vaccine (Fluvirin®, FluMist®)

        (i) Patients with cardiovascular disease should have an annual influenza vaccination (class Ib).

I. Complications. MI potentiates many complications; the most common of these include the following:

    1. Lethal arrhythmias. See Chapter 32-Arrhythmias for a detailed discussion.

    2. Heart failure. See Chapter 34-Heart Failure for a detailed discussion.

        a. Left ventricular failure causes pulmonary congestion. Diuretics, especially furosemide (Lasix®), help reduce the congestion.

        b. ACE inhibitors, β-adrenergic blockers, angiotensin receptor blockers, and direct-acting aldosterone antagonists play a key role in the treatment of heart failure.

    3. Cardiogenic shock

        a. In this life-threatening complication, cardiac output is decreased, and pulmonary artery and pulmonary capillary wedge pressures are increased. This typically occurs when the area of infarction exceeds 40% of muscle mass and compensatory mechanisms only strain the already compromised myocardium.

        b. Vasopressors: for example, norepinephrine (Levophed®), epinephrine (Adrenalin®), dopamine (Various) in high doses, and vasopressin (Pitressin®) enhance blood pressure through β-adrenergic stimulation and V1 receptors within smooth muscle (vasopressin) and may be indicated, as per Advanced Cardiac Life Support (ACLS) protocol.

        c. Inotropic drugs—for example, epinephrine, dopamine (middle doses), dobutamine (Dobutrex®), isoproterenol (Isuprel®), and digoxin (Lanoxin®)—are rapidly acting agents used to increase myocardial contractility and improve cardiac output.

        d. Vasodilators—for example, nitroprusside (Nipride®)—reduce preload, lower pulmonary capillary wedge pressure by dilating veins, and reduce afterload by decreasing resistance to left ventricular ejection.

        e. Additional treatment may include invasive procedures such as intra-aortic balloon pumping.

Study Questions

Directions for questions 1–16: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Exertion-induced angina, which is relieved by rest, nitroglycerin, or both, is referred to as

    (A) Prinzmetal angina.
    (B) unstable angina.
    (C) stable angina.
    (D) variant angina.
    (E) preinfarction angina.

2. Myocardial oxygen demand is increased by all of the following factors *except*

    (A) exercise.
    (B) smoking.
    (C) cold temperatures.
    (D) isoproterenol.
    (E) metoprolol.

3. Which of the following agents used in Prinzmetal angina has spasmolytic actions, which increase coronary blood supply?

   (A) nitroglycerin
   (B) diltiazem
   (C) timolol
   (D) isosorbide mononitrate
   (E) propranolol

4. The development of ischemic pain occurs when the demand for oxygen exceeds the supply. Determinants of oxygen demand include all of the following choices *except* which one?

   (A) contractile state of the heart
   (B) myocardial ejection time
   (C) left ventricular volume
   (D) right atrial pressure
   (E) systolic pressure

5. Myopathy is an adverse effect of all the following agents *except*

   (A) lovastatin.
   (B) simvastatin.
   (C) pravastatin.
   (D) gemfibrozil.
   (E) colestipol.

Directions for question 6 : The question can be correctly answered by one or more of the suggested answers. Choose the answer, **A–E.**

   (A) if **I only** is correct
   (B) if **III only** is correct
   (C) if **I and II** are correct
   (D) if **II and III** are correct
   (E) if **I, II, and III** are correct

6. Which of the following is considered a component of acute coronary syndrome (ACS)?

   I. unstable angina
   II. non–ST-segment elevated myocardial infarction (NSTEMI)
   III. ST-segment elevated myocardial infarction (STEMI)

Directions for questions 7–11: Each of the following descriptions is most closely related to one of the following drugs. The descriptions may be used more than once or not at all. Choose the **best** answer, **A–E.**

   (A) Inhibition of intestinal absorption of cholesterol
   (B) Lowering of low-density lipoproteins (LDLs), triglycerides, and increased high-density lipoprotein (HDL) along with potential anti-inflammatory effects
   (C) Recommendations for this agent have been substantially expanded beyond an alternative for aspirin-intolerant patients due to recent trials demonstrating its benefit in select ACS patients.
   (D) Recommended for ACS patients who cannot tolerate aspirin
   (E) Recommended over unfractionated heparin (UFH) as an anticoagulant in patients with unstable angina (UA) or NSTEMI

7. tirofiban (Aggrastat®)

8. enoxaparin (Lovenox®)

9. simvastatin (Various)

10. clopidogrel (Plavix®)

11. ezetimibe (Zetia®)

Answers and Explanations

1. **The answer is C** *[see II.C.1.a–f].*
   Classic, or stable, angina refers to the syndrome in which physical activity or emotional excess causes chest discomfort, which may spread to the arms, legs, neck, and so forth. This type of angina is relieved promptly (within 1 to 10 mins) with rest, nitroglycerin, or both.

2. **The answer is E** *[see II.H.3.a; Table 31-1].*
   Owing to the β-adrenergic blocking effects of metoprolol (e.g., decreased heart rate, decreased blood pressure, decreased inotropic effect), there is a net decrease in myocardial oxygen demand. This is the direct opposite of the effects seen with the β-agonist isoproterenol. Exercise, cigarette smoking, and exposure to cold temperatures have all been shown to increase myocardial oxygen demand.

3. **The answer is B** *[see II.4.d and II.H.4.c].*
   Calcium-channel blocking agents such as diltiazem have been shown to be capable of reversing spasm and, therefore, increasing coronary blood flow in Prinzmetal angina. The calcium-channel blockers have proven benefit in the treatment of Prinzmetal angina, a syndrome believed due more to a spastic event than to a fixed coronary occlusion. β-adrenergic blockers such as timolol and propranolol (Inderal®) are not indicated in the treatment of Prinzmetal angina, and nitrates such as nitroglycerin and isosorbide mononitrate are not the primary agents indicated and in many cases do not have any effect.

4. **The answer is D** *[see I.F.2.B.(1)–(4)]*.
As with most muscles in the body, the contractile force of the heart dictates the amount of oxygen that the heart needs to perform efficiently. Consequently, as contractility decreases, the oxygen needs of the heart increase. As contractility continues to decrease, the volume of fluid in the left ventricle increases owing to poor muscle performance and increasing tension within the ventricle, resulting in additional oxygen requirements. As the amount of tension within the ventricle increases per cardiac cycle, there is again an added requirement for oxygen by the heart muscle.

5. **The answer is E** *[see II.G.2.d.(3); II.G.3.c.(2)]*.
Myopathy is an adverse effect of all the HMG-CoA reductase inhibitors (lovastatin, simvastatin, pravastatin, atorvastatin, fluvastatin, and rosuvastatin), and the combination of the fibric acid derivatives (gemfibrozil, fenofibrate, and clofibrate) has been shown to increase the creatine kinase levels and predispose patients to myopathies and rhabdomyolysis.

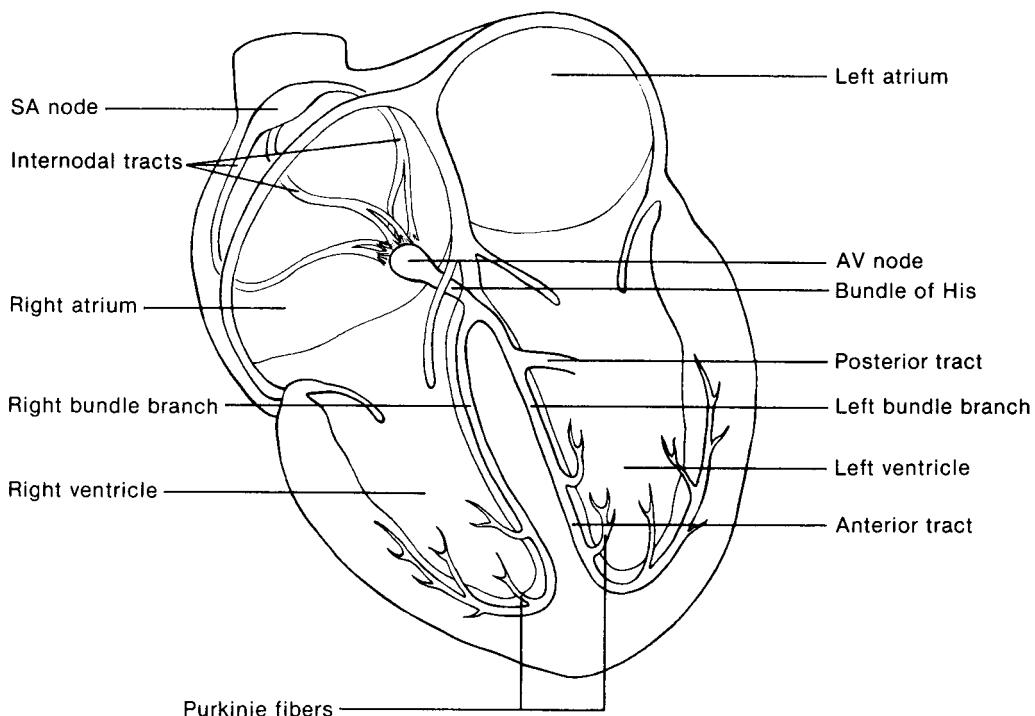
6. **The answer is E (I, II, III)** *[see I.E.2]*.
During recent years, there has been an attempt to link the various clinical symptoms of IHD into key categories, based on the presentation and symptoms at the time of evaluation. ACS refers to those situations that reflect an acute ischemic event and includes UA, NSTEMI, and STEMI. Clinical guidelines have incorporated treatment modalities based on these three presentations. UA and NSTEMI have similar recommended therapies, and STEMI has different treatment guidelines. Stable angina is not considered one of the ACS but represents the starting point for the progression of atherosclerosis, resulting in IHD.

7. **The answer is C** *[see III.G.3.a.(5)]*.
Tirofiban is an antiplatelet that is referred to as a glycoprotein IIb/III, a receptor antagonist. This class of drugs works to prevent platelet aggregation by inhibiting the interaction between the primary binding site of platelets and has been shown to be effective in the prevention of thrombosis.

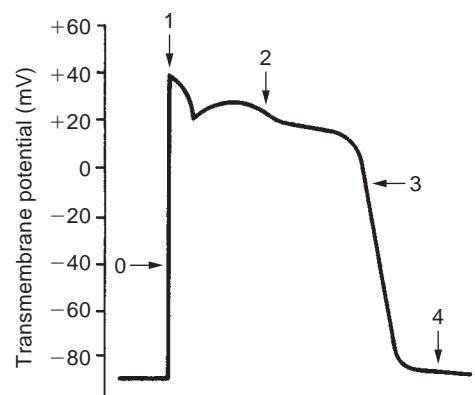
8. **The answer is E** *[see III.G.3.a.(7) and III.H.4.a.(3).(d).(iii); Table 31-5]*.
Enoxaparin is an example of a low-molecular-weight heparin (LMWH). As a group, the major advantage of these drugs over the more traditional heparin is that they exhibit a more predictable anticoagulant response. Owing to their lower molecular weight and decreased binding to plasma proteins, they have better bioavailability than heparin. In addition, their decrease in plasma protein binding and binding to the endothelium results in half-lives that are two to four times longer than that of heparin. Current clinical practice guidelines recommend enoxaparin over heparin in patients with UA or NSTEMI, unless CABG is planned within 24 hrs.

9. **The answer is B** *[see II.G.2.c.(7)]*.
Simvastatin is one of the currently available HMG-CoA reductase inhibitors that have been shown to significantly reduce LDL levels and nonfatal MI or CHD (30% to 40% reduction). Recent studies have demonstrated that inflammation may be an important mechanism involved in ACS and that statins might exert an important anti-inflammatory effect within coronary arteries (independent of their cholesterol-lowering effects).

10. **The answer is D** *[see II.H.5.c]*.
The most recently introduced guidelines for the treatment of ACS has incorporated recent trials, which have shown the value of clopidogrel in various patient populations with ACS. Besides being used in those who are unable to take or tolerate aspirin, it is included as "add-on" therapy for patients receiving aspirin who suffer from ACS.

11. **The answer is A** *[see II.G.5.a]*.
Ezetimibe reduces cholesterol levels via a different mechanism of action than previous agents. By selectively blocking the intestinal absorption of cholesterol, it is able to stop one of the major pathways responsible for increasing available cholesterol within the body. Ezetimibe has demonstrated the ability to reduce total cholesterol, LDL, apolipoprotein B, and triglyceride levels while increasing HDL levels in patients with hypercholesterolemia. Simvastatin has recently been incorporated into a combination product with ezetimibe (Vytorin), which uses the individual class properties of the HMG-CoA reductase inhibitors (simvastatin) to reduce cholesterol production with the absorption-inhibiting properties of ezetimibe to target cholesterol with two different mechanisms, which might also aid in improving patient compliance with taking the medication.


32 Cardiac Arrhythmias

ALAN H. MUTNICK


I. INTRODUCTION.

Sudden death from cardiac causes in the United States has been estimated to occur in the range of 300,000 to 350,000 cases annually. Depending on the definition, sudden cardiac death could be classified as low as 13% of all natural deaths up to approximately 50% of all deaths from cardiovascular causes occurring shortly after onset (instantaneous to 1 hr), with the majority of sudden deaths being caused by acute ventricular tachyarrhythmias. These incidence reports might appear to create greater need for the knowledge necessary to appropriately use antiarrhythmics for this high-risk patient population. However, previously conducted studies have cast doubt on the true place of antiarrhythmics in the treatment and prevention of cardiac arrhythmias. Studies such as the Cardiac Arrhythmia Suppression Trial (CAST) have demonstrated that certain classes of antiarrhythmics increased mortality in patients treated with antiarrhythmics as compared to placebo. Since the release of the data from the CAST trial, subsequent studies have confirmed the finding that certain antiarrhythmics do possess "proarrhythmic" effects when used injudiciously. Consequently, the use of trial and error to determine antiarrhythmic therapy has given way to an era of outcome-based antiarrhythmic drug decision making. By understanding the causes of arrhythmias and being aware of drug–drug and drug–target interactions, we are more likely to understand the key considerations to maximize therapeutic strategies while minimizing drug-induced toxicities.

A. **Definition.** Cardiac arrhythmias are deviations from the normal heartbeat pattern. They include **abnormalities of impulse formation**, such as heart rate, rhythm, or site of impulse origin and **conduction disturbances**, which disrupt the normal sequence of atrial and ventricular activation.

B. **Electrophysiology**

1. **Conduction system**

   a. **Two electrical sequences** that cause the heart chambers to fill with blood and contract are initiated by the conduction system of the heart.

      (1) **Impulse formation**, the first sequence, takes place when an electrical impulse is generated automatically.

      (2) **Impulse transmission**, the second sequence, occurs once the impulse has been generated, signaling the heart to contract.

   b. **Four main structures** composed of tissue that can generate or conduct electrical impulses make up the conduction system of the heart.

      (1) The **sinoatrial (SA) node** in the wall of the right atrium contains cells that spontaneously initiate an action potential. Serving as the main pacemaker of the heart, the SA node initiates 60 to 100 beats/min.

         (a) Impulses generated by the SA node trigger atrial contraction.

         (b) Impulses travel through internodal tracts—the anterior tract, middle tract, posterior tract, and anterior interatrial tract (*Figure 32-1*).

      (2) At the **atrioventricular (AV) node** situated in the lower interatrial septum, the impulses are delayed briefly to permit completion of atrial contraction before ventricular contraction begins.

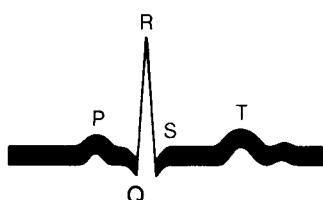
      (3) At the **bundle of His**—muscle fibers arising from the AV junction—impulses travel along the left and right bundle branches, located on either side of the intraventricular septum.


Figure 32-1. Electrical pathways of the heart. *AV*, atrioventricular; *SA*, sinoatrial.

    (4) The impulses reach the **Purkinje fibers**, a diffuse network extending from the bundle branches and ending in the ventricular endocardial surfaces. Ventricular contraction then occurs.

  c. **Latent pacemakers.** The AV junction, bundle of His, and Purkinje fibers are latent pacemakers; they contain cells capable of generating impulses. However, these regions have a slower firing rate than the SA node. Consequently, the SA node predominates except when it is depressed or injured, which is known as **overdrive suppression**.

2. **Myocardial action potential.** Before cardiac contraction can take place, cardiac cells must depolarize and repolarize.

  a. **Depolarization** and **repolarization** result from changes in the electrical potential across the cell membrane, caused by the exchange of sodium and potassium ions.

  b. **Action potential**, which reflects this electrical activity, has five phases (*Figure 32-2*).

    (1) **Phase 0 (rapid depolarization)** takes place as sodium ions enter the cell through fast channels; the cell membrane's electrical charge changes from negative to positive.

    (2) **Phase 1 (early rapid repolarization).** As fast sodium channels close and potassium ions leave the cell, the cell rapidly repolarizes (i.e., returns to resting potential).

Figure 32-2. Myocardial action potential curve. This curve represents ventricular depolarization–repolarization. Phases: *0*, rapid depolarization; *1*, early rapid repolarization; *2*, plateau; *3*, final rapid repolarization; *4*, slow depolarization.

(3) **Phase 2 (plateau).** Calcium ions enter the cell through slow channels while potassium ions exit. As the cell membrane's electrical activity temporarily stabilizes, the action potential reaches a plateau (represented by the notch at the beginning of this phase in *Figure 32-2*).

(4) **Phase 3 (final rapid repolarization).** Potassium ions are pumped out of the cell as the cell rapidly completes repolarization and resumes its initial negativity.

(5) **Phase 4 (slow depolarization).** The cell returns to its resting state with potassium ions inside the cell and sodium and calcium ions outside.

c. During both depolarization and repolarization, a cell's ability to initiate an action potential varies.

(1) The cell cannot respond to any stimulus during the **absolute refractory period** (beginning during phase 1 and ending at the start of phase 3).

(2) A cell's ability to respond to stimuli increases as repolarization continues. During the **relative refractory period**, which occurs during phase 3, the cell can respond to a strong stimulus.

(3) When the cell has been completely repolarized, it can again respond fully to stimuli.

d. Cells in different cardiac regions depolarize at different speeds, depending on whether fast or slow channels predominate.

(1) Sodium flows through fast channels; calcium flows through slow channels.

(2) Where fast channels dominate (e.g., in cardiac muscle cells), depolarization occurs quickly. Where slow channels dominate (e.g., in the electrical cells of the SA node and AV junction), depolarization occurs slowly.

3. **Electrocardiography.** The electrical activity occurring during depolarization–repolarization can be transmitted through electrodes attached to the body and transformed by an **electrocardiograph (EKG/ECG) machine** into a series of waveforms (EKG/ECG waveform). *Figure 32-3* shows a normal EKG/ECG waveform.

a. The **P wave** reflects atrial depolarization.

b. The **PR interval** represents the spread of the impulse from the atria through the Purkinje fibers.

c. The **QRS complex** reflects ventricular depolarization (phase 0).

d. The **ST segment** represents phase 2 of the action potential—the absolute refractory period (part of ventricular repolarization).

e. The **T wave** shows phase 3 of the action potential—ventricular repolarization.

C. **Classification.** Arrhythmias generally are classified by origin (i.e., supraventricular or ventricular).

1. **Supraventricular arrhythmias** stem from enhanced automaticity of the SA node (or another pacemaker region, above the bundle of His or ventricular tissue) or from reentry conduction.

2. **Ventricular arrhythmias** occur below the bundle of His, when an ectopic (abnormal) pacemaker triggers a ventricular contraction before the SA node fires (e.g., from a conduction disturbance or ventricular irritability).

3. **Special note**

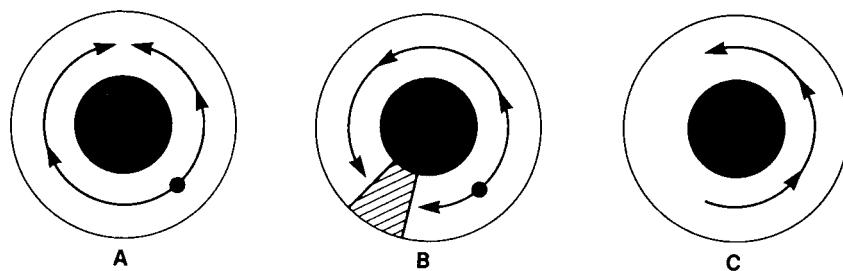
a. **Torsades de pointes (TdP; French for "twisting of the points")** has received increased attention during recent years as a major proarrhythmic event, which has been reported with antiarrhythmic drug therapy. It is defined as a polymorphic ventricular tachycardia with a twisting QRS complex morphology, which sometimes occurs with drugs that prolong ventricular repolarization (QT interval widening). Although initial reports of TdP centered around antiarrhythmic drugs (quinidine), today, more than 50 drugs, both antiarrhythmic agents and other


Figure 32-3. Normal EKG/ECG waveform.

classes of drugs, such as antibiotics, have been shown to affect the duration of the QT interval and have been associated with this arrhythmia.

b. A Web site devoted to providing education and research on drug-induced arrhythmias, especially those due to prolongation of the QT interval on the electrocardiogram (EKG/ECG), is available. The site, http://www.torsades.org/medical-pros/drug-lists/drug-lists.htm, is currently maintained by Dr. Raymond Woosley.

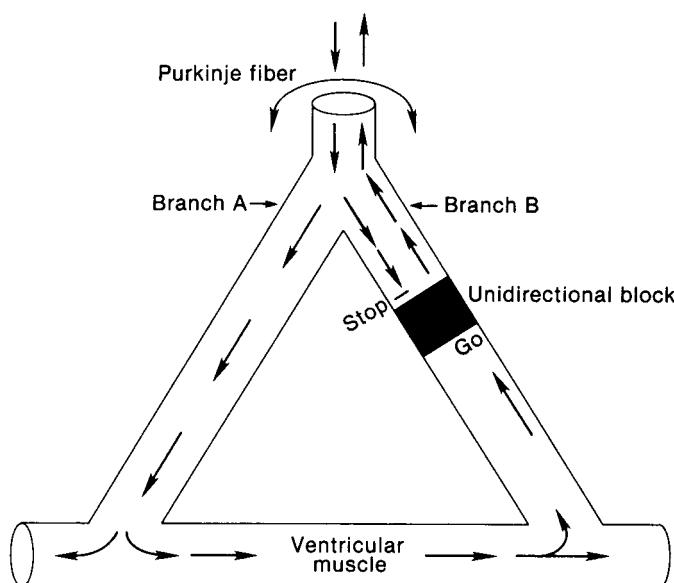
c. Dr. Woosley and colleagues have established the International Registry for Drug-Induced Arrhythmias, to which one can submit a suspected "drug-induced arrhythmia event." The registry also provides a list of drugs reported to prolong the QT interval or cause TdP (http://www.Torsades.org). Four drug lists have been created based on the relative risk of inducing TdP or a prolonged QT interval.

d. It is beyond the intention of this chapter to provide a comprehensive listing, as done on Dr. Woosley's Web site. However, the four categories of drug lists include the following with select examples:

(1) List 1: Drugs that are generally accepted by authorities to carry a risk of causing TdP; that is, amiodarone (Cordarone®), chlorpromazine (Thorazine®), clarithromycin (Biaxin®), disopyramide (Norpace®), dofetilide (Tikosyn®), erythromycin (Erythrocin®), haloperidol (Haldol®), ibutilide (Corvert®), methadone (Dolophine®), moxifloxacin (Avelox®), pentamidine (NebuPent®), pimozide (Orap®), procainamide (Various), quinidine (Quinaglute®), sotalol (Betapace®), and thioridazine (Mellaril®).

(2) List 2: Drugs that in some reports have been associated with TdP and/or QT prolongation but at this time lack substantial evidence for causing TdP; that is, amantadine (Symmetrel®), azithromycin (Zithromax®), clozapine (Clozaril®), dolasetron (Anzemet®), dronedarone (Multaq®), escitalopram (Lexapro®), felbamate (Felbatol®), flecainide (Tambocor®), foscarnet (Foscavir®), fosphenytoin (Cerebyx®), granisetron (Kytril®), isradipine (DynaCirc®), levofloxacin (Levaquin®), nicardipine (Cardene®), ondansetron (Zofran®), quetiapine (Seroquel®), risperidone (Risperdal®), sunitinib (Sutent®), tacrolimus (Prograf®), venlafaxine (Effexor®), voriconazole (Vfend®), and ziprasidone (Geodon®).

(3) List 3: Drugs with a conditional risk of TdP—drugs that carry a risk of TdP and/or QT prolongation under certain conditions, such as patients with long QT syndrome, drug overdose, or coadministration of interacting drugs; that is, amitriptyline (Elavil®), ciprofloxacin (Cipro®), citalopram (Celexa®), clomipramine (Anafranil®), desipramine (Norpramin®), diphenhydramine (Benadryl®), doxepin (Silenor®), fluconazole (Diflucan®), fluoxetine (Prozac®), galantamine (Razadyne®), imipramine (Tofranil®), itraconazole (Sporanox®), ketoconazole (Nizoral®), nortriptyline (Pamelor®), paroxetine (Paxil®), ritonavir (Norvir®), sertraline (Zoloft®), solifenacin (VESIcare®), trazodone (Desyrel®), trimethoprim-sulfamethoxazole (Bactrim), trimipramine (Surmontil).

(4) List 4: Drugs to be avoided for use in patients with diagnoses or suspected congenital long QT syndrome. (Drugs on Lists 1, 2, and 3 would also be included here.) That is, albuterol (Ventolin®), amphetamine (Adderall®), dobutamine (Dobutrex®), dopamine (Intropin®), isoproterenol (Isuprel®), lapatinib (Tykerb®), levalbuterol (Xopenex®), and vardenafil (Levitra®).


D. Causes

1. Precipitating causes. Arrhythmias result from various conditions, including

a. Heart disease—infection, coronary artery disease (CAD), valvular heart disease, rheumatic heart disease, ischemic heart disease

b. Myocardial infarction (MI)

c. Systemic hypertension

d. Hyperkalemia/hypokalemia

e. Chronic obstructive pulmonary disease (COPD)—emphysema, bronchitis

f. Thyroid disorders

g. Drug therapy (both antiarrhythmic and nonantiarrhythmic drugs)

h. Toxic doses of cardioactive drugs (e.g., digitalis preparations)

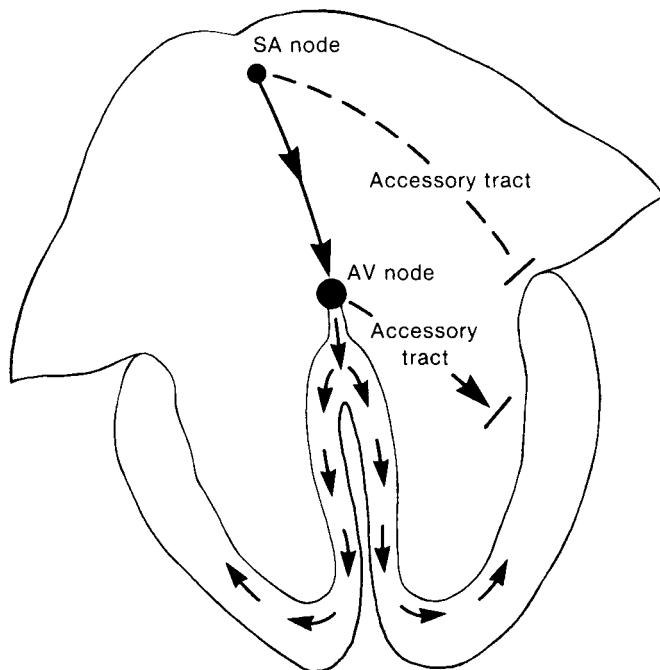
i. Increased sympathetic tone


Figure 32-4. Reentry arrhythmias. **A.** Two waves of excitation going in opposite directions. **B.** A unidirectional wave of excitation. **C.** Reexcitation of tissue in a slow conduction area.

  j. Decreased parasympathetic tone
  k. Vagal stimulation (e.g., straining at stool)
  l. Increased oxygen demand (e.g., from stress, exercise, fever)
  m. Metabolic disturbances
  n. Cor pulmonale
 2. Mechanisms of arrhythmias. Abnormal impulse formation, abnormal impulse conduction, or a combination of both may give rise to arrhythmias.
  a. Abnormal impulse formation may stem from
   (1) Depressed automaticity, as in escape beats and bradycardia
   (2) Increased automaticity, as in premature beats, tachycardia, and extrasystole
   (3) Depolarization and triggered activity, leading to sustained ectopic firing
  b. Abnormal impulse conduction results from
   (1) A conduction block or delay
   (2) Reentry occurs when an impulse is rerouted through certain regions in which it has already traveled. Thus, the impulse depolarizes the same tissue more than once, producing an additional impulse (*Figures 32-4* and *32-5*). Reentry sites include the SA and AV nodes as well as various accessory pathways in the atria and ventricles (*Figure 32-6*). For reentry to occur, the following conditions must exist:
   (a) Markedly shortened refractoriness or a slow conduction area that allows an adequate delay so that depolarization recurs.
   (b) Unidirectional conduction

Figure 32-5. Ventricular reentry: a branched Purkinje fiber joining ventricular muscle. The *dark area* represents the site of a unidirectional block. In this depolarization region, the impulse heading toward the atrioventricular node continues upward, whereas the impulse traveling toward the muscle is blocked. Because retrograde conduction in *branch B* is slow, cells in *branch A* have time to recover and respond to the reentrant impulse.

Figure 32-6. Reentry sites. *AV*, atrioventricular; *SA*, sinoatrial.

E. Pathophysiology. Arrhythmias may decrease cardiac output, reduce blood pressure, and disrupt perfusion of vital organs. Specific pathophysiological consequences depend on the arrhythmia present.

F. Clinical evaluation

   1. Physical findings. Although some arrhythmias are silent, most produce signs and symptoms. Only an EKG/ECG can definitively identify an arrhythmia. However, physical findings may suggest which arrhythmia is present; they also yield information about the patient's clinical status and may help identify associated complications. **Signs and symptoms** that typically accompany arrhythmias include

      a. Chest pain

      b. Anxiety and confusion (reduced brain perfusion)

      c. Dyspnea

      d. Skin pallor or cyanosis

      e. Abnormal pulse rate, rhythm, or amplitude

      f. Reduce blood pressure

      g. Palpitations

      h. Syncope

      i. Weakness

      j. Convulsions

      k. Hypotension

      l. Decreased urinary output

   2. Diagnostic test results

      a. An **EKG/ECG** can identify a specific arrhythmia; usually, a 12-lead EKG/ECG is used.

      b. Electrophysiological (EP) testing. This intracardiac procedure determines the location of ectopic foci and bypass tracts and may help assess therapeutic response to antiarrhythmic drug therapy. It also can determine the need for a pacemaker or surgical intervention.

      c. His bundle study, a type of EP testing, can locate the origin of a heart block or reentry pattern.

      d. Laboratory findings. Some arrhythmias result from electrolyte abnormalities—most commonly, hyperkalemia and hypocalcemia.

         (1) A serum potassium level > 5 mEq/L reflects hyperkalemia, a serum calcium level < 4.5 mEq/L signifies hypocalcemia, and serum magnesium levels < 2.5 mEq/L signify hypomagnesemia.

         (2) An EKG/ECG tracing may suggest an electrolyte abnormality. For example, prolonged QRS complexes, tented T waves, and lengthened PR intervals may signal hyperkalemia; prolonged QT intervals and flattened or inverted T waves suggest hypocalcemia.

G. **Treatment objectives**
  1. **Terminate** or **suppress the arrhythmia** if it causes hemodynamic compromise or disturbing symptoms.
  2. **Maintain adequate cardiac output and tissue perfusion.**
  3. **Correct or maintain fluid balance** (some arrhythmias cause hypervolemia).
H. **National guidelines.** During recent years, several prominent national organizations have formalized a structure, which encourages the dissemination of "clinical practice guidelines," which focus on "evidence-based practice." The American College of Cardiology, in collaboration with the American Heart Association and European Society of Cardiology, has established a routine standard for the evaluation, development, approval, and subsequent distribution of such practice guidelines for a wide array of cardiac situations. We have used guidelines published in the following text to serve as primary reference for this chapter:
  - Fuster V, Rydén LE, Cannom DS, et al. ACC/AHA/ESC 2006 guidelines for the management of patients with atrial fibrillation-executive summary: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines and the European Society of Cardiology Committee for Practice Guidelines (Writing Committee to revise the 2001 guidelines for the management of patients with atrial fibrillation). *Eur Heart J.* 2006;27(16):1979–2030.
  - Fuster V, Rydén LE, Cannom DS, et al. 2011 ACCF/AHA/HRS focused updates incorporated into the ACC/AHA/ESC 2006 guidelines for the management of patients with atrial fibrillation: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines developed in partnership with the European Society of Cardiology and in collaboration with the European Heart Rhythm Association and the Heart Rhythm Society. *J Am Coll Cardiol.* 2011;57(11):e101–e198.
  - Zipes DP, Camm AJ, Borggrefe M, et al. ACC/AHA/ESC 2006 guidelines for management of patients with ventricular arrhythmias and the prevention of sudden cardiac death—executive summary: a report of the American College of Cardiology/American Heart Association Task Force and the European Society of Cardiology Committee for Practice Guidelines (Writing Committee to develop guidelines for management of patients with ventricular arrhythmias and the prevention of sudden cardiac death). Developed in collaboration with the European Heart Rhythm Association and the Heart Rhythm Society. *Eur Heart J.* 2006;27(17):2099–2140.
  - Wann LS, Curtis AB, January CT, et al. 2011 ACCF/AHA/HRS focused update on the management of patients with atrial fibrillation (updating the 2006 guideline): a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines. *Circulation.* 2011;123(1):104–123.

  1. **Ranking Recommendations**

Ranking Based on Size of Treatment Effect	Assessment of Benefit Versus Risk	Recommended Action
Class I	Benefit >>> Risk	Treatment should be used
Class IIa	Benefit >> Risk	Reasonable to use treatment
Class IIb	Benefit ≥ Risk	Treatment may be considered
Class III	No benefit; potentially harmful	No proven benefit; even harmful

Estimate of Certainty for Treatment Effect	Extent of Populations Studied	Types of Trials Used
Level A	Multiple populations evaluated	Data derived from multiple trials/meta-analyses
Level B	Limited populations evaluated	Data derived from a single trial or nonrandomized study
Level C	Very limited populations evaluated	Consensus opinion of experts or case reports

2. Each recommendation is given two scores: one referring to the relationship between benefit of effect/treatment and one being the level of evidence, based on populations studied. Best ranking would be a class I recommendation with level A evidence versus the lowest ranking, which would be a class III recommendation with level C evidence, where it would be more risky then beneficial and perhaps even harmful to use a treatment, which has been studied in very limited populations and only supported by opinions or case reports.

II. THERAPY. Antiarrhythmic agents, directly or indirectly, alter the duration of the myocardial action potential. Most antiarrhythmics fall into one of four classes, depending on their specific effects on the heart's electrical activity (*Table 32-1*) and on what portion of the action potential they directly affect.

A. Class I antiarrhythmics interfere with the sodium ion channel
  1. **Indications**
     a. Class Ia drugs-Agents in this class include quinidine, procainamide, and disopyramide.
        (1) **Quinidine (Various)** is used to conversion and prevention of relapse into atrial fibrillation and/or flutter and the suppression of ventricular arrhythmia. Due to a substantial number of concerns with its administration, its use today has been reduced due to other therapeutic options currently available. Quinidine poses added concern when used intravenously because of increased cardiovascular effects (i.e., hypotension, syncope, myocardial depression).

        The latest set of guidelines provides a class IIb recommendation with a "C" level of evidence for its use in conversion of atrial fibrillation.

Table 32-1 WILLIAMS'S CLASSIFICATION OF ANTIARRHYTHMIC DRUGS CURRENTLY AVAILABLE IN THE UNITED STATES

Class	Action	Drugs
Ia (fast-channel blockers)	Moderate depression of conduction, prolongation of repolarization, which results in an increase in the QRS interval and an increase in the QT interval	Disopyramide (Norpace®), procainamide (Various), quinidine (Various)
Ib	Modest depression of conduction, shortening of repolarization, which results in a decrease in the QT interval	Lidocaine (Xylocaine®), mexiletine (Various), phenytoin (Dilantin®)
Ic	Strong depression of conduction, with mild or no effect on repolarization, which results in a very large increase in the QRS interval	Flecainide (Tambocor®), propafenone (Rythmol®)
II (β-blockers)	β-Adrenergic blockers slow sinus, as well as AV nodal conduction, which results in a decrease in heart rate and a prolongation in the PR interval (atrial depolarization)	Propranolol (Inderal®), esmolol (Brevibloc®), acebutolol (Sectral®)[a]
III	Prolongation of repolarization, which results in prolongation of the QT interval	Amiodarone (Cordarone®), sotalol[b] (Betapace®), ibutilide (Corvert®), dofetilide (Tikosyn®)
IV (slow-channel blockers)	Calcium-channel blockade in calcium-dependent channels, which results in reduced heart rate and an increase in the PR interval	Verapamil (Calan®), diltiazem (Cardizem®)
Other		Adenosine (Adenocard®), atropine (Various), digoxin (Lanoxin®), magnesium (Various), dronedarone (Multaq®)

[a]Singh BN, Vaughan Williams EM. Classification of antiarrhythmic drugs. In: Sandoe E, Flensted-Jensen E, Olesen KH, eds. *Symposium on Cardiac Arrhythmias.* Sodertalige, Sweden: AB Astra; 1970.
[b]Sotalol is a β-adrenergic blocker that prolongs the action potential of phase 3 and is classified as type III.

(2) **Procainamide (Various)** is used for the same arrhythmias for which quinidine is given. It is used more frequently than quinidine because it can be administered intravenously and in sustained-release oral preparations. The most recent guidelines give procainamide a class IIa recommendation for patients where cardioversion from atrial fibrillation is not necessary with a "C" level of evidence. It is also rated as class IIb for patients in atrial fibrillation involving conduction over an accessory pathway, and similar to quinidine, has been given a class IIb ranking for conversion from atrial fibrillation with a "C" level of evidence.

(3) **Disopyramide (Norpace®)** may be used for the suppression and prevention of atrial and premature ventricular complexes. Also effective in the conversion of atrial fibrillation, atrial flutter, and paroxysmal atrial tachycardia to normal sinus rhythm and prevention of their recurrences. Similar to procainamide, disopyramide is rated as class IIb for patients in atrial fibrillation involving conduction over an accessory pathway with a "B" level of evidence, and similar to quinidine and procainamide, has been given a class IIb ranking for conversion from atrial fibrillation with a "C" level of evidence.

b. Class Ib drugs-Agents in this class include lidocaine, phenytoin, and flecainide, although phenytoin has begun to be removed from the antiarrhythmic categories.

(1) **Lidocaine (Xylocaine®)** is used therapeutically for ventricular arrhythmias (especially premature ventricular contractions [PVCs] and ventricular tachycardia) that result from acute MI and open-heart surgery. Controversy still exists as to the benefits of lidocaine when used prophylactically in patients with acute MI to prevent ventricular fibrillation. A recent analysis showed an increase in the number of deaths in patients receiving lidocaine during an acute MI as compared to placebo. Many feel that its current use prophylactically post-MI is no longer justified. Lidocaine has been given a rating of class IIb in the initial treatment of patients with MI or myocardial ischemia with a "C" level of evidence. It has also been given a class IIb rating in patients with ventricular tachycardia with MI or myocardial ischemia and in patients presenting with long QT syndrome and TdP.

(2) **Phenytoin (Dilantin®)** in the past has been primarily indicated in the treatment of digitalis-induced ventricular arrhythmias and heart block. However, most recent guidelines provide it with a class III recommendation and a "C" level of evidence. It will no longer be included in this chapter until updated guidelines reintroduce it as an antiarrhythmic.

(3) **Mexiletine (Various)** is closely related to lidocaine structurally, with modifications that reduce first-pass liver metabolism, making oral therapy possible. It is most commonly used to treat patients in with serious ventricular arrhythmias or PVCs. Similar to lidocaine, mexiletine is rated as a class IIb in patients who have a long QT syndrome and TdP.

c. Class Ic drugs-Agents in this class include flecainide and propafenone.

(1) **Flecainide (Tambocor®)** is indicated in the prevention and treatment of life-threatening ventricular arrhythmias, such as sustained ventricular tachycardia, controlling symptomatic, and disabling supraventricular tachycardias, in patients without structural heart disease when other agents fail. Flecainide is reserved for patients with refractory life-threatening ventricular arrhythmias who do not have CAD. Flecainide has received a class Ia recommendation in the conversion from atrial fibrillation with an "A" class of evidence.

(2) **Propafenone (Rythmol®)** is indicated in the treatment of life-threatening ventricular arrhythmias and in the maintenance of normal sinus rhythm in patients with symptomatic atrial fibrillation. Similar to flecainide, propafenone has also received a class Ia recommendation in the conversion from atrial fibrillation with an "A" class of evidence.

2. **Mechanism of action.** As a class, all of the agents work by blocking the rapid inward sodium current and thereby slow down the rate of rise of the cardiac tissue's action potential. However, differences in EP effects has led to a subclassification of the class I agents into three subsets (Ia, Ib, and Ic), based on these EP effects.

a. **Class Ia drugs** moderately reduce the depolarization rate and prolong repolarization (refractory period).

b. **Class Ib drugs** shorten repolarization (refractory period); they also weakly affect the repolarization rate.

c. **Class Ic drugs** strongly depress depolarization but have a negligible effect on the duration of repolarization or refractoriness.

3. **Administration and dosage**
    a. **Quinidine (Various)** is administered orally, usually in three to four daily doses of 200 to 400 mg as a rapid-release sulfate salt (83% quinidine). However, sustained-release products in the form of a gluconate (62% quinidine) salt in doses of 324 to 648 mg, which corresponds to 300 to 600 mg of the sulfate salt, may be given every 12 hrs. (In special circumstances, it has been given intravenously or intramuscularly with caution.) To achieve an effective plasma concentration rapidly, a loading dose of 600 to 1000 mg may be administered in doses of 200 mg every 2 hrs to a maximum of 1000 mg, or a 5 to 8 mg/kg intravenous infusion can be given at a rate of 0.3 mg/kg/min.
    b. **Procainamide (Various)** is available for intravenous or intramuscular use.
        (1) For **acute therapy**, intravenous administration is preferred.
            (a) Intermittent intravenous administration calls for the administration of an intravenous dose of 3 to 6 mg/kg infusion (up to 100 mg) over 2 to 4 mins, repeated every 5 to 10 mins until the arrhythmia is abolished, side effects occur, or 1 g has been given. The usual effective dose is 500 to 1000 mg.
            (b) Rapid intravenous administration calls for infusion of 1.0 to 1.5 g at a rate of 20 to 50 mg/min.
            (c) Once the arrhythmia is terminated, 1.5 to 5.0 mg/min is given as a continuous infusion.
        (2) For **long-term therapy**, oral administration with procainamide is no longer available in the United States.
    c. **Disopyramide (Norpace®, Norpace CR®)** is available in oral form.
        (1) Usually, 300 to 400 mg is given as a loading dose to attain an effective plasma level rapidly.
        (2) For maintenance therapy, doses of 400 to 800 mg/day are given in four doses every 6 hrs (nonsustained-release capsule) or in two doses every 12 hrs (sustained-release capsule).
    d. **Lidocaine (Xylocaine®)** may be administered intravenously or intramuscularly.
        (1) An intravenous loading dose rapidly achieves a therapeutic plasma level.
            (a) Initially, 1 to 1.5 mg/kg (100 mg) is administered.
            (b) A second injection of half the initial dose may be required 5 mins later, up to a maximum of 300 mg.
        (2) Continuous intravenous infusion of 2 to 4 mg/min produces an effective plasma level in 7 to 10 hrs.
        (3) In an emergency, an intramuscular injection rapidly achieves an effective plasma level. The usual dosage is 300 to 400 mg injected into the deltoid muscle.
    e. **Mexiletine (Various)** is administered orally and should be initiated in the hospital setting.
        (1) A loading dose of 400 mg followed by maintenance dosage in 8 hrs.
        (2) If this fails to control the arrhythmia, the dosage may be increased to 400 mg every 8 hrs. (Alternatively, doses may be given every 12 hrs.)
        (3) Normal maintenance doses are 200 to 300 mg every 8 hrs.
    f. **Flecainide (Tambocor®)** is administered orally and should be initiated in the hospital setting.
        (1) Initial dosage is 50 mg every 12 hrs, and the dosage may be increased in twice-daily increments of 50 mg every 4 days to a maximum of 300 mg/day.
        (2) The usual maintenance dose is 100 mg every 12 hrs.
    g. **Propafenone (Rythmol®, Rythmol SR®)** is administered orally and should be initiated in the hospital setting.
        (1) Initial dosage is 150 mg every 8 hrs and can be increased every 3 to 4 days to the desired therapeutic effect or side effects.
        (2) The usual maintenance dose is 150 to 200 mg every 8 hrs (Rythmol®) or every 12 hrs (Rythmol SR®) up to a maximum of 900 mg/day.
4. **Precautions and monitoring effects. Note:** Proarrhythmia (the ability to cause an arrhythmia) is the most important risk associated with the use of antiarrhythmic drug therapy. Bradyarrhythmias and ventricular tachyarrhythmias, such as TdP, can occur. These often take place during the initiation of antiarrhythmic drug treatment and should be considered

when decision makers choose between outpatient and inpatient initiation of antiarrhythmic therapy.

a. Quinidine (Various)

   (1) This drug is contraindicated in patients with

      (a) Complete AV block unless a ventricular pacemaker is in place.

      (b) Marked prolongation of the QT interval or prolonged QT syndrome because ventricular tachyarrhythmia (TdP) may arise, resulting in quinidine syncope (i.e., syncope or sudden death).

   (2) An increase of 50% or more in the duration of the QRS complex necessitates dosage reduction.

   (3) Quinidine has a narrow therapeutic index. Therapeutic serum levels are in the range of 2 to 6 μg/mL, depending on the specificity of the assay. Toxicity may cause acute cardiac effects, such as pronounced slowing of conduction in all heart regions; this, in turn, may lead to SA block or arrest, ventricular tachycardia, or asystole.

   (4) The EKG/ECG should be monitored during quinidine therapy to detect signs of cardiotoxicity. To counteract quinidine-induced ventricular tachyarrhythmias, catecholamines, glucagon, or sodium lactate may be given.

   (5) In patients receiving quinidine for atrial tachyarrhythmias, vagolytic effects may increase impulse conduction at the AV node, resulting in an accelerated ventricular response. To prevent this, agents that slow AV nodal conduction (e.g., verapamil, digoxin) may be administered.

   (6) The dosage should be reduced in elderly patients ($>$ 60 years old) and in patients with hepatic dysfunction or congestive heart failure (CHF).

   (7) Embolism may occur on restoration of normal sinus rhythm after prolonged atrial fibrillation. To prevent or minimize this complication, anticoagulants may be administered before quinidine therapy begins.

   (8) Quinidine may cause cinchonism at high serum concentrations, manifested by tinnitus, hearing loss, blurred vision, and gastrointestinal (GI) disturbances. In severe cases, nausea, vomiting, diarrhea, headache, confusion, delirium, photophobia, diplopia, and psychosis may occur.

   (9) GI reactions are the most common adverse reactions to quinidine. About 30% of patients experience diarrhea; nausea and vomiting may also occur. Arising almost immediately after the first dose, these symptoms sometimes warrant discontinuing the drug. However, aluminum hydroxide or use of the polygalacturonate salt may reverse this.

   (10) Hypersensitivity reactions include anaphylaxis, thrombocytopenia, respiratory distress, and vascular collapse.

b. **Procainamide (Various)**

   (1) This drug is contraindicated in patients with hypersensitivity to procaine and related drugs, myasthenia gravis, second- or third-degree AV block with no pacemaker, a history of procainamide-induced systemic lupus erythematosus (SLE), prolonged QT syndrome, or TdP.

   (2) An increase of 50% or more in the duration of the QRS complex necessitates dosage reduction.

   (3) Procainamide has a narrow therapeutic index. Therapeutic serum levels are reported in the range of 4 to 10 μg/mL. N-acetyl procainamide (NAPA) levels of 15 to 25 μg/mL are considered therapeutic. The active metabolite, NAPA, possesses differing pharmacological cardiovascular effects, and serum levels need to be evaluated independently of procainamide. Toxicity may cause acute cardiac effects (e.g., pronounced slowing of conduction in all heart regions), which, in turn, may lead to SA block or arrest, ventricular tachycardia, or asystole.

   (4) High serum procainamide levels may induce ventricular arrhythmias (e.g., PVCs, ventricular tachycardia, or fibrillation). The EKG/ECG should be monitored continuously to detect these problems. Catecholamines, glucagon, or sodium lactate may be administered to counteract these arrhythmias.

(5) Hypotension may occur with rapid intravenous administration.

(6) GI effects are less common than with quinidine therapy.

(7) Hypersensitivity reactions are the most severe adverse effects of procainamide. These reactions include drug fever, agranulocytosis, and an SLE-like syndrome.

    (a) An SLE-like syndrome is manifested by fatigue, arthralgia, myalgia, and low-grade fever.

    (b) Antinuclear antibody titer is positive in 50% to 80% of patients receiving procainamide. However, only 20% to 30% of these patients develop symptoms of the SLE-like syndrome.

    (c) Drug discontinuation usually is necessary when symptomatic SLE-like syndrome occurs.

(8) The dosage should be reduced and given over 6 hrs to patients with renal or hepatic impairment, as the drug half-life is increased in these patients.

(9) Lower doses may be needed in patients with CHF to adjust for the lower volume of distribution.

(10) Embolism may occur on restoration of normal sinus rhythm after prolonged atrial fibrillation. An anticoagulant is frequently administered before procainamide therapy begins to prevent this complication.

c. Disopyramide (Norpace®)

(1) This drug may cause marked hemodynamic compromise and ventricular dysfunction. It is contraindicated in patients with cardiogenic shock or second- or third-degree AV block with no pacemaker.

(2) Disopyramide should be avoided or used with extreme caution in patients with heart failure (HF). It should also be used cautiously in patients with urinary tract disorders, myasthenia gravis, and renal or hepatic dysfunction.

(3) In patients receiving this drug for atrial tachyarrhythmias, vagolytic effects may increase impulse conduction at the AV node, resulting in an accelerated ventricular response. To prevent this, agents that slow AV nodal conduction (e.g., verapamil, digoxin) may be given.

(4) Anticholinergic effects of this drug include dry mouth, constipation, urinary hesitancy or retention, and blurred vision.

(5) Therapeutic plasma levels range from 2 to 4 μg/mL.

d. Lidocaine (Xylocaine®)

(1) This drug may cause hemodynamic compromise in patients with severe cardiac dysfunction. Generally, however, it has few untoward cardiovascular effects.

(2) Lidocaine should be used cautiously and in reduced dosage in patients with CHF or renal or hepatic impairment.

(3) Central nervous system (CNS) reactions are the most pronounced adverse effects of lidocaine. These reactions may range from lightheadedness and restlessness to confusion, tremors, stupor, and convulsions.

(4) Tinnitus, blurred vision, and anaphylaxis have been reported.

(5) Plasma lidocaine levels of 1.5 to 6.5 μg/mL are therapeutic.

(6) Lidocaine's metabolites—glycinexylidide and monoethylglycinexylidide—may have neurotoxic as well as antiarrhythmic effects.

e. Mexiletine (Various)

(1) This drug is contraindicated in patients with cardiogenic shock or second- or third-degree AV block with no pacemaker.

(2) Tremor is an early sign of mexiletine toxicity. Dizziness, ataxia, and nystagmus indicate an increasing plasma drug concentration.

(3) Hypotension, bradycardia, and widened QRS complexes may develop during mexiletine therapy.

(4) Adverse GI effects include nausea and vomiting.

(5) Therapeutic serum levels range from 0.50 to 2.0 μg/mL.

f. Flecainide (Tambocor®)

(1) This drug is contraindicated in patients with cardiogenic shock or second- or third-degree AV block with no pacemaker.

(2) The EKG/ECG should be monitored during flecainide therapy because this drug may exacerbate existing arrhythmias or precipitate new ones. Flecainide was shown in the CAST study to increase mortality in patients with asymptomatic ventricular arrhythmias and, therefore, should be reserved for patients with life-threatening ventricular arrhythmias that are refractory to other drugs.

(3) This drug has a significant negative inotropic effect and may bring on or worsen CHF and cardiomyopathy.

(4) Adverse CNS effects (e.g., dizziness, headache, tremor) and GI effects (e.g., nausea, abdominal pain) may occur.

(5) Blurred vision and dyspnea have been reported.

(6) Therapeutic serum levels recommended for flecainide are between 0.2 and 1.0 μg/mL.

g. Propafenone (Rythmol®)

(1) This drug, such as other antiarrhythmic agents, may cause new or worsened arrhythmias. Such proarrhythmic properties range from an increased frequency of PVCs to the development of severe ventricular tachycardia, ventricular fibrillation, and TdP. This proarrhythmic effect has been under discussion for the class Ic agents; thus, when used, these agents should be monitored closely. The findings from the CAST study must be weighed against the benefits of using these agents for treating significant ventricular arrhythmias.

(2) Dizziness is a side effect that has been reported in as many as 10% to 15% of patients taking the drug.

(3) Other associated side effects include vomiting, a metallic bitter taste in the mouth, constipation, headache, and new or worsening CHF and asthma.

(4) Therapeutic serum levels recommended for propafenone are between 0.06 and 1.0 μg/mL.

5. Significant interactions

a. Quinidine

(1) Quinidine may increase serum levels of **digoxin** and increase the effects of **digitalis** on the heart, with a resultant increase in toxicity.

(2) Severe orthostatic hypotension may occur with concomitant administration of **vasodilators** (e.g., **nitroglycerin**).

(3) **Phenytoin**, **rifampin (Rifadin®)**, and **barbiturates** may antagonize quinidine activity and reduce its therapeutic efficacy.

(4) **Nifedipine (Procardia®)** may reduce plasma quinidine levels.

(5) **Antacids**, **sodium bicarbonate**, and **sodium acetazolamide (Diamox®)** may increase plasma quinidine levels, possibly resulting in toxicity.

(6) Quinidine may produce additive hypoprothrombinemic effects with **coumarin** anticoagulants.

b. Amiodarone (Cordarone®) and **cimetidine (Tagamet®)** may increase plasma procainamide levels, possibly leading to drug toxicity.

c. Phenytoin accelerates disopyramide metabolism, possibly reducing its therapeutic efficacy.

d. Lidocaine

(1) **Phenytoin** may increase the cardiodepressant effects of lidocaine.

(2) **β-Blockers** (class II antiarrhythmics) may reduce lidocaine metabolism, possibly leading to drug toxicity.

e. Mexiletine (Various). Phenobarbital, **rifampin (Rifadin®)**, and **phenytoin (Dilantin®)** reduce plasma mexiletine levels and may decrease therapeutic efficacy.

B. Class II antiarrhythmics

1. Indications. These drugs—**β-adrenergic blockers**—among the drugs in this class indicated for the treatment of select arrhythmias are propranolol (Inderal®), esmolol (Brevibloc®), and acebutolol (Sectral®) are approved for antiarrhythmic use.

a. Propranolol (Inderal®) may be given to

(1) Control supraventricular arrhythmias (e.g., atrial fibrillation or flutter, paroxysmal supraventricular tachycardia [PSVTs])

(2) Treat tachyarrhythmias caused by catecholamine stimulation (e.g., in hyperthyroidism, during anesthesia)

(3) Suppress severe ventricular arrhythmias in **prolonged QT syndrome**

(4) Treat digitalis-induced ventricular arrhythmias

       (5) Terminate certain ventricular arrhythmias (e.g., PVCs in patients without structural heart disease)

       (6) In the most recently completed guidelines, the intravenous administration of β-adrenergic blockers was given a class I recommendation with a "B" level of evidence to slow the ventricular response to atrial fibrillation in acute setting, with cautious considerations to those with hypotension or HF.

    b. **Esmolol (Brevibloc®)** is used to treat supraventricular tachycardias; it possesses a very short (9 mins) half-life, and has been used to control the ventricular response to atrial fibrillation or flutter during or after surgery.

    c. **Acebutolol (Sectral®)** has been used in the management of ventricular arrhythmias; although not specifically listed within the recent guidelines, like esmolol and propranolol, the β-adrenergic blockers were given a class I ranking for ventricular control in patients with atrial fibrillation.

2. **Mechanism of action.** Class II antiarrhythmics reduce sympathetic stimulation of the heart, decreasing impulse conduction through the AV node and lengthening the refractory period. Additionally, this class of antiarrhythmics slows the sinus rhythm without significantly changing the QT or QRS intervals, resulting in a reduced heart rate and a decrease in myocardial oxygen demand.

3. **Administration and dosage**

    a. **Propranolol (Inderal®)** may be given intravenously or orally when used as an antiarrhythmic.

       (1) Emergency therapy calls for slow intravenous administration of 1 to 3 mg diluted in 50 mL dextrose 5% in water or normal saline solution. This dose is infused slowly (no faster than 1 mg/min). A second dose of 1 to 3 mg may be given 2 mins later.

       (2) For oral therapy, 10 to 80 mg/day is given in three to four doses. (However, 1000 mg or more may be required for resistant ventricular arrhythmias.)

    b. **Esmolol (Brevibloc®)** is given intravenously. A loading dose of 500 mcg/kg/min is infused over 1 min, followed by a 4-min maintenance infusion of 50 mcg/kg/min. If a satisfactory response is not achieved within 5 mins, the loading dose is repeated and followed by a maintenance infusion of 100 mcg/kg/min.

    c. **Acebutolol (Sectral®)** is given orally. An oral dose of 400 mg is given by mouth daily up to a maximum of 1200 mg/day for the treatment of ventricular arrhythmias.

4. **Precautions and monitoring effects**

    a. **Propranolol (Inderal®)**

       (1) This drug is contraindicated in patients with sinus bradycardia, second- or third-degree AV block, cardiogenic shock, severe HF, or asthma.

       (2) The β-blocking effects of this drug may lead to marked hypotension, exacerbation of HF and left ventricular failure, or cardiac arrest.

       (3) Blood pressure, heart rate, and the EKG/ECG should be monitored during intravenous infusion.

       (4) Embolism may occur upon restoration of normal sinus rhythm after sustained atrial fibrillation. An anticoagulant may be given before propranolol therapy begins to prevent this complication.

       (5) Propranolol may depress AV node conduction and ventricular pacemaker activity, resulting in AV block or asystole.

       (6) This drug may mask the signs and symptoms of hypoglycemia. It also may mask signs of shock.

       (7) Fatigue, lethargy, increased airway resistance, and skin rash have been reported.

       (8) Nausea, vomiting, and diarrhea may occur.

       (9) Sudden withdrawal of propranolol may lead to acute MI, arrhythmias, or angina in cardiac patients. Drug therapy is discontinued by tapering the dose over 4 to 7 days.

    b. **Esmolol (Brevibloc®)**

       (1) This drug is contraindicated in patients with severe CHF or sinus bradycardia.

       (2) Hypotension occurs in approximately 30% of patients receiving esmolol. This effect can be reversed by reducing the dosage or stopping the infusion.

       (3) This drug is for short-term use only and should be replaced by a long-acting antiarrhythmic once the patient's heart stabilizes.

       (4) Dizziness, headache, fatigue, and agitation may occur.

       (5) Other adverse effects include nausea, vomiting, and bronchospasm.

    c. Acebutolol (Sectral®)
- **(1)** Similar contraindications as other β-blockers; heart block, uncompensated HF, sick sinus syndrome.
- **(2)** Major monitoring parameters for patients include serum creatinine level, heart rate, and blood pressure.
- **(3)** Therapy should not be rapidly discontinued but rather gradually over 10 to 14 days. Abrupt discontinuation in cardiac patients may exacerbate an angina attack or a more significant acute coronary syndrome.

5. Significant interactions

    a. Propranolol (Inderal®)
- **(1)** Severe vasoconstriction may occur with concomitant **epinephrine** administration.
- **(2)** **Digitalis** preparations can cause excessive bradycardia.
- **(3)** **Calcium-channel blockers**—for example, **diltiazem (Cardizem®)** and **verapamil (Calan®)**—and other negative **inotropic** and **chronotropic drugs**—such as **disopyramide (Norpace®)** and **quinidine**—add to the myocardial depressant effects of propranolol.

    b. Esmolol (Brevibloc®). Morphine (MS Contin®) may raise plasma esmolol levels.

C. Class III antiarrhythmics

1. Indications

    a. Amiodarone (Cordarone®) is given to control malignant ventricular arrhythmias and is recommended within the advance cardiac life support (ACLS) guidelines, has been given a class I recommendation for victims with ventricular tachyarrhythmia during a cardiac arrest, for attempting a stable rhythm after further defibrillations. A "B" level of evidence has been documented. Unlike most other antiarrhythmics, with the exception of the β-adrenergic blockers, amiodarone has been shown to reduce arrhythmic deaths in patients after an MI. Additionally, amiodarone received a class IIa recommendation for patients with sustained ventricular tachycardia that is hemodynamically unstable and refractory to conversion with countershock or procainamide or other agents. Amiodarone has also received a class I rating for intravenous administration to control the heart rate in atrial fibrillation and HF patients who do not have an accessory pathway.

    b. Sotalol (Betapace®) is used to treat supraventricular and ventricular tachyarrhythmias. Sotalol antagonizes both β_1- and β_2-adrenergic receptors but also prolongs the phase 3 action potential. It is this property that distinguishes it from other β-adrenergic blockers and is the reason why it is classified as a class III antiarrhythmic agent rather than a class II agent (β-adrenergic blocker).

    c. Ibutilide (Corvert®) is used in the conversion of atrial fibrillation and flutter of recent onset (duration < 30 days). In the most recent guidelines provided for the treatment of atrial fibrillation, ibutilide received along with dofetilide, a class I recommendation with "A" level of evidence for its use in the pharmacologic cardioversion of atrial fibrillation.

    d. Dofetilide (Tikosyn®) is available in the United States under restricted access in the treatment of atrial fibrillation/flutter. As mentioned earlier, within the most recent guidelines provided for the treatment of atrial fibrillation, dofetilide received, along with ibutilide, a class I recommendation with "A" level of evidence for its use in the pharmacological cardioversion of atrial fibrillation.

2. Mechanism of action. Class III antiarrhythmic drugs primarily work on the potassium channels of the action potential and prolong the refractory period and action potential; they have no effect on myocardial contractility or conduction time.

3. Administration and dosage

    a. Amiodarone (Cordarone®). Available for both oral and intravenous use and should only be initiated in the hospital setting. Amiodarone has been incorporated into the ACLS guidelines and recommended by the expert panel members as the first-choice antiarrhythmic for shock-refractory ventricular fibrillation/ventricular tachycardia.
- **(1)** It is available for oral use; 800 to 1600 mg every 12 hrs is given for 7 to 14 days, then 200 to 400 mg daily thereafter.
- **(2)** Oral treatment is used to suppress ventricular and supraventricular arrhythmias but can take days or weeks to take effect. Oral doses of 100 to 600 mg/day (usually 300 to 400 mg/day) for maintenance therapy in ventricular tachycardia and 100 to 200 mg/day for maintenance therapy for supraventricular tachycardias are given.

    (3) Intravenous formulation is available for treatment and prophylaxis of recurrent ventricular fibrillation or hemodynamically unstable ventricular tachycardia in refractory patients.

    (4) The intravenous form is rapidly distributed throughout the body. Recommended doses include a rapid loading infusion of 150 mg over 10 mins, followed by a slow infusion of 1.0 mg/min for 6 hrs (360 mg), and then a maintenance infusion of 0.5 mg/min for the remainder of the 24-hr period. Patients usually receive 2 to 4 days of infusions before conversion to oral form. However, a maintenance infusion can be continued for 2 to 3 weeks.

b. Sotalol (Betapace®) is available commercially as an oral tablet, and therapy should be initiated within the hospital setting. Normal dosing of 80 mg twice daily initially and increasing doses at 2- to 3-day intervals to a maximum dose of 640 mg/day, given in two to three doses throughout the day.

c. Ibutilide (Corvert®) is available only for injection in a 0.1-mg/mL, 10-mL vial. Normal doses for the conversion of recent-onset atrial fibrillation to normal sinus rhythm is a dose of 1 mg (0.01 mg/kg for those < 60 kg) over 10 mins, with a repeat dose in 10 mins if the arrhythmia does not end.

d. Dofetilide (Tikosyn®) is available only for oral administration in 0.125-, 0.25-, and 0.5-mg capsules under the trade name of Tikosyn and should only be initiated in a hospital setting with trained personnel and the equipment necessary to provide continuous cardiac monitoring during initiation of therapy.

    (1) A normal dose for the conversion of recent-onset atrial fibrillation to normal sinus rhythm is 0.5 mg twice daily for patients with creatinine clearance values > 60 mL/min; doses are reduced 50% (0.25 mg) for those with creatinine clearance values of 40 to 60 mL/min, and doses are reduced an additional 50% (0.125 mg) for those with creatinine clearance values of 20 to 40 mL/min.

    (2) Maintenance therapy is based on the EKG/ECG, with doses being reduced with QTc prolongation exceeding 15% of the baseline value. Any patient developing a QTc interval exceeding 500 msec should have therapy discontinued immediately.

    (3) Dofetilide should not be given to those with creatinine clearance values < 20 mL/min.

4. Precautions and monitoring effects

  a. Amiodarone (Cordarone®)

    (1) Life-threatening pulmonary toxicity may occur during amiodarone therapy, especially in patients receiving > 400 mg/day. Baseline as well as routine pulmonary function tests reveal relevant pulmonary changes.

    (2) Most patients develop corneal microdeposits 1 to 4 months after amiodarone therapy begins. However, this reaction rarely causes visual disturbance, but the patient should be monitored with routine ophthalmological examinations.

    (3) Blood pressure and heart rate and rhythm should be monitored for hypotension and bradyarrhythmias.

    (4) Patients should be monitored routinely for the possible development of hepatic dysfunction, thyroid disorders (e.g., hyperthyroidism, hypothyroidism), and photosensitivity.

    (5) CNS reactions include fatigue, malaise, peripheral neuropathy, and extrapyramidal effects.

    (6) Nausea and vomiting have been reported.

    (7) This drug has an extremely long half-life (up to 60 days). Therapeutic response may be delayed for weeks after oral therapy begins; adverse reactions may persist up to 4 months after therapy ends.

  b. Sotalol (Betapace®)

    (1) Side effects of this drug are directly related to β-blockade and prolongation of repolarization.

    (2) Transient hypotension, bradycardia, myocardial depression (negative inotropic effect), and bronchospasm have all been associated with this drug.

    (3) This drug carries all the contraindications associated with other β-blockers along with those owing to its electrophysiologic properties.

  c. Ibutilide (Corvert®)

    (1) Infusion should be discontinued as soon as the atrial arrhythmia is terminated or if sustained or nonsustained ventricular arrhythmia or marked QT prolongation is documented.

    (2) Continuous EKG/ECG monitoring is required for at least 4 hrs after discontinuing the infusion or until the QT interval returns to baseline.

    d. Dofetilide (Tikosyn®)

       (1) Patients need to be monitored closely for the subsequent development of ventricular arrhythmias with increasing doses of dofetilide or with declining renal status. In clinical trials, ventricular tachycardias, including TdP, are the most frequently occurring arrhythmias due to dofetilide.

       (2) Hypokalemia and those situations that might cause hypotension will predispose a patient to prolongation of the QT interval, which could put a dofetilide patient at risk for toxic arrhythmias.

  5. Significant interactions

    a. Amiodarone (Cordarone®)

       (1) Amiodarone may increase the plasma levels of **quinidine**, **procainamide**, **diltiazem**, **digitalis**, and **flecainide**.

       (2) It may increase the pharmacological effect of **β-blockers**, **calcium-channel blockers**, and **warfarin**.

       (3) Special note: Amiodarone has been reported to have numerous drug–drug interactions among all categories of drugs. To avoid the development of a significant drug–drug interaction, a thorough patient medication profile should be carried out for each patient having amiodarone therapy initiated, as well as each time a patient currently receiving amiodarone is given an additional drug.

    b. Sotalol (Betapace®)

       (1) Sotalol must be used cautiously in those patients receiving agents with cardiac-depressant properties.

       (2) Agents such as sotalol that prolong the QT interval may induce malignant arrhythmias when used in combination with other class Ia antiarrhythmics, especially in the presence of low potassium levels.

    c. Ibutilide (Corvert®) should be avoided with other agents that prolong repolarization or within 4 hrs of administration.

    d. Dofetilide (Tikosyn®) should be avoided in patients who have hypokalemia or preexisting QT prolongation.

D. Class IV antiarrhythmics

  1. Indications

    a. Calcium-channel blockers (e.g., verapamil [Calan®]; diltiazem [Cardizem®]) are used mainly to treat and prevent supraventricular arrhythmias.

       (1) They are first-line agents for the suppression of PSVTs stemming from AV nodal reentry.

       (2) They can rapidly control the ventricular response to atrial flutter and fibrillation.

    b. Other calcium-channel blockers available include amlodipine (Norvasc®), clevidipine (Cleviprex®), felodipine (Plendil®), isradipine (DynaCirc®), nicardipine (Cardene®), nifedipine (Procardia®), nimodipine (Nimotop®), and nisoldipine (Sular®), but these agents have primarily been used in the treatment of angina pectoris and hypertension and will not be discussed further in this section.

  2. Mechanism of action. Class IV antiarrhythmics are calcium-channel blockers. They decrease conduction through those areas of the heart dependent on slow calcium channels, which include the SA and AV nodes.

  3. Administration and dosage

    a. To control atrial arrhythmias, verapamil usually is administered intravenously. A dose of 2.5 to 10 mg is given over at least 2 mins and may be repeated in 30 mins, if necessary. A 5 to 10 mg/hr continuous intravenous infusion has also been used in treating arrhythmias.

    b. To prevent PSVTs, verapamil may be given orally in four daily doses of 80 to 120 mg each.

    c. To control atrial arrhythmias, diltiazem usually is administered intravenously. A dose of 20 mg (0.25 mg/kg) is given over 2 mins. If an adequate response is not obtained, a second dose of 25 mg (0.35 mg/kg) is administered after 15 mins. A 5 to 15 mg/hr intravenous continuous infusion has also been used in treating arrhythmias.

  4. Precautions and monitoring effects

    a. Verapamil and diltiazem are contraindicated in patients with AV block; left ventricular dysfunction; severe hypotension; concomitant, intravenous β-blockers; and atrial fibrillation with an accessory AV pathway.

    b. These drugs must be used cautiously in patients with CHF, sick sinus syndrome, MI, and hepatic or renal impairment.

    c. Because of the negative chronotropic effect, verapamil and diltiazem must be used cautiously in patients who have slow heart rates or who are receiving digitalis glycosides.

    d. The EKG/ECG (especially the respiratory rate (RR) interval) should be monitored during therapy.

    e. Patients > 60 years old should receive reduced dosages and slower injection rates.

    f. Constipation and nausea have been reported with verapamil.

5. Significant interactions

    a. Concomitant administration of **β-blockers** or **disopyramide** may precipitate HF.

    b. **Quinidine** may increase the risk of calcium-channel blocker–induced hypotension.

    c. Verapamil may increase serum **digoxin** concentrations, and diltiazem may do the same to a lesser extent.

    d. **Rifampin** may enhance the metabolism of calcium-channel blockers, with a resultant decrease in pharmacological effect.

    e. Verapamil and diltiazem may inhibit **theophylline** metabolism and may require reductions in theophylline dosage.

    f. Diltiazem and verapamil inhibit the metabolism of **cyclosporine (Gengraf®)** and may require reductions in cyclosporine dosages.

E. Unclassified antiarrhythmics

1. Atropine (Various)

    a. Indications. Atropine is therapeutic for symptomatic sinus bradycardia and junctional rhythm.

    b. Mechanism of action. An anticholinergic, atropine blocks vagal effects on the SA node, promoting conduction through the AV node and increasing the heart rate.

    c. Administration and dosage. For antiarrhythmic use, atropine is administered in a dose of 0.4 to 1.0 mg by intravenous push; the dose is given every 5 mins to a maximum of 2.0 mg.

    d. Precautions and monitoring effects

        (1) Thirst and dry mouth are the most common adverse effects of atropine.

        (2) CNS reactions (e.g., restlessness, headache, disorientation, dizziness) may occur with doses over 5 mg.

        (3) Tachycardia and ophthalmic disturbances (e.g., mydriasis, blurred vision, photophobia) may occur with doses of 1 mg or more.

        (4) Initial doses may induce a reflex bradycardia owing to incomplete suppression of vagal impulses.

2. Adenosine (Adenocard®)

    a. Indications. Adenosine is indicated for the conversion of acute supraventricular tachycardia (SVT) to normal sinus rhythm.

    b. Mechanism of action. Adenosine is a naturally occurring nucleoside, which is normally present in all cells of the body. It has been shown to

        (1) slow conduction through the AV node,

        (2) interrupt reentry pathways through the AV node, and

        (3) restore normal sinus rhythm in patients with PSVTs.

    c. Administration and dosage. For antiarrhythmic effects, adenosine is given as a rapid bolus intravenous injection in a 6-mg dose over 1 to 2 secs. If the first dose does not eliminate the arrhythmia within 1 to 2 mins, the dose should be increased to 12 mg and again given as a rapid intravenous dose. An additional 12-mg dose may be repeated if necessary.

    d. Precautions and monitoring effects

        (1) The effects of adenosine are antagonized by methylxanthines, such as caffeine and theophylline. Theophylline has been successfully used for treating adenosine-induced side effects, such as hypotension, sweating, and palpitations. If side effects are encountered, aggressive therapy is not required because of the ultrashort half-life of the drug (10 secs or less).

        (2) The main side effect associated with adenosine use in up to 18% of patients is facial flushing, but this effect is normally very short-lived.

        (3) Other side effects associated with adenosine use include shortness of breath, chest pressure, nausea, headache, and a metallic taste.

e. **Additional use.** Adenosine has been used as an adjunctive agent in patients undergoing various types of pharmacological stress testing (e.g., thallium). In this situation, adenosine is given as a continuous infusion over a period of 4 to 6 mins and is able to provide a form of exercise tolerance test in patients not able to exert themselves owing to age, fatigue, and various other physical handicaps.

3. **Magnesium sulfate (Various)**
   a. **Indications.** Previous national guidelines have recommended magnesium for the treatment of drug-induced long QT syndrome. In the most recent ACLS guidelines, published in 2010, magnesium received a class IIb rating with a "class B" level of evidence, for its use *strictly* in patients presenting with TdP associated with a long QT interval. Additionally, magnesium has been used in the treatment of arrhythmias (ventricular tachycardia/fibrillation, due to hypomagnesemia).
   b. **Mechanism of action.** Acts on the myocardium by slowing the rate of impulse formation at the SA node and therefore slows down conduction. Magnesium is also necessary in the exchange of calcium, sodium, and potassium in and out of cells, which in the case of TdP might lower the amplitude of the early after depolarizations.
   c. **Administration and dosage.** For the treatment of TdP, 1 to 6 g over several minutes, occasionally followed by approximately 3 to 20 mg/min by IV infusion for 5 to 48 hrs, depending on response and serum magnesium concentrations.
      (1) Alternatively, for TdP associated with cardiac (pulseless) arrest, 1 to 2 g in 10 mL 5% dextrose injection over 5 to 20 mins.
      (2) Alternatively, for TdP in a patient with pulses, give a loading dose of 1 to 2 g (8 to 16 mEq) in 50 to 100 mL 5% dextrose injection over 5 to 60 mins.
      (3) **Intraosseous** TdP associated with cardiac (pulseless) arrest, 1 to 2 g in 10 mL 5% dextrose injection over 5 to 20 mins.
   d. **Precautions and monitoring effects**
      (1) Routine monitoring of magnesium levels, in order to prevent hypermagnesemia, while also monitoring calcium levels and phosphorus levels, which can be reduced when administering IV magnesium.

4. **Digoxin (Lanoxin®)**
   a. **Indications.** Recent guidelines recommend that digoxin is effective in stable, narrow-complex regular tachycardias if rhythm remains uncontrolled or unconverted by adenosine or vagal maneuvers or if SVT is recurrent. Additionally, digoxin has been shown effective to control the ventricular rate in patients with atrial fibrillation or atrial flutter.
   b. **Mechanism of action.** As a cardiac glycoside, digoxin has positive inotropic effects; however, for rhythm control digoxin relies on its "parasympathomimetic properties," which slow conduction through the AV node and decrease impulses going through to the ventricles.
   c. **Administration and dosage.** Digoxin can be given as 8 to 12 mcg/kg with half of that being given over 5 mins, and the remaining 50% given in two doses at 4 and 8 hrs later.
   d. **Precautions and monitoring effects**
      (1) The onset of action is slow and depending on the circumstances might not be acceptable for acute arrhythmias.
      (2) Long-term use of digoxin will expose the patient to numerous monitoring requirements, including renal function, drug–drug interactions, and fluid and electrolyte monitoring, in order to minimize likelihood of adverse drug reactions.

5. **Dronedarone (Multaq®)**
   a. The newest antiarrhythmic, which was a major focal point for recently updated guidelines for the treatment of atrial fibrillation, and which has not yet been formally added into the current Vaughan Williams classification.
   b. Within the updated guidelines, dronedarone (Multaq®) received a class IIa rating with a "class B" level of evidence, to decrease the need for hospitalization for cardiovascular events in patients with paroxysmal atrial fibrillation or after conversion of persistent atrial fibrillation. Additionally, it was felt that dronedarone could be initiated during outpatient therapy. However, within the same guidelines, dronedarone was also given a class III for use in class IV HF or patients who have had an episode of decompensated HF in the past 4 weeks, especially with depressed left ventricular function (ejection fraction $< 35\%$).

    c. Dronedarone (Multaq®) is available and is doses as 400 mg by mouth twice daily in the prevention of atrial fibrillation and/or flutter.

    d. Dronedarone (Multaq®), similar to amiodarone, there are numerous drug–drug interactions with dronedarone; consequently, each newly added therapy should be evaluated in order to identify the potential impact when starting, as well as when ending each therapy.

Study Questions

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Strong anticholinergic effects limit the antiarrhythmic use of

    (A) quinidine (Various).
    (B) procainamide (Various).
    (C) mexiletine (Various).
    (D) flecainide (Tambocor®).
    (E) disopyramide (Norpace®).

2. A pronounced slowing of phase 0 of the myocardial action potential results in a prolongation of either atrial depolarization, causing a prolonged P wave on the electrocardiogram (EKG/ECG), or ventricular depolarization, causing a prolonged QRS complex characterized by which class of antiarrhythmics?

    (A) Class I
    (B) Class II
    (C) Class III
    (D) Class IV
    (E) Class V

3. Which of the following class III antiarrhythmics has been reported as "carrying a risk for" causing torsades de pointes?

    (A) lidocaine (Xylocaine®)
    (B) amiodarone (Cordarone®)
    (C) quinidine (Various)
    (D) flecainide (Tambocor®)
    (E) diltiazem (Cardizem®)

4. A patient receiving a class I antiarrhythmic agent complains of GI symptoms, including nausea, vomiting, and occasional diarrhea after taking a dose. The patient is most likely receiving

    (A) lidocaine (Xylocaine®).
    (B) procainamide (Various).
    (C) quinidine (Various).
    (D) flecainide (Tambocor®).
    (E) propranolol (Inderal®).

5. Class III antiarrhythmics have which of the following effects to the cardiac cell's action potential?

    (A) Slow the rate of rise for phase 0 of depolarization.
    (B) Delay the fast-channel conductance of sodium ions.
    (C) Prolong phases 2 and 3 of repolarization.
    (D) Inhibit the slow-channel conductance of calcium ions.
    (E) Prolong the refractory period of the action potential.

6. Which of the following drugs is a class IV antiarrhythmic that is primarily indicated for the treatment of supraventricular tachyarrhythmias?

    (A) ibutilide (Corvert®)
    (B) mexiletine (Various)
    (C) diltiazem (Cardizem®)
    (D) procainamide (Various)
    (E) propranolol (Inderal®)

7. Relatively new antiarrhythmic agent, which has not yet been formally added into the Vaughan Williams classification table but received a class IIa rating with a class B level of evidence to decrease the need for hospitalization in patients with paroxysmal atrial fibrillation or after conversion of persistent atrial fibrillation. Which of the following agents is best described by the above statements?

    (A) aliskiren (Tekturna®)
    (B) inamrinone (Various)
    (C) dronedarone (Multaq®)
    (D) amiodarone (Cordarone®)
    (E) dofetilide (Tikosyn®)

8. Which of the following drugs is a class III antiarrhythmic agent that is effective in the acute management of atrial fibrillation or atrial flutter of recent onset?

    (A) propranolol (Inderal®)
    (B) ibutilide (Corvert®)
    (C) metoprolol (Lopressor®)
    (D) disopyramide (Norpace®)
    (E) diltiazem (Cardizem®)

9. All of the following problems represent concerns when patients are started on amiodarone *except*

(A) extremely long $t_{\frac{1}{2}}$.
(B) need for multiple daily doses.
(C) development of hyperthyroidism or hypothyroidism.
(D) development of liver toxicity.
(E) interactions with numerous other drugs.

10. Based on the criteria used for recent national guidelines used within the cardiology arena, which of the following recommendations would most likely result in the use of a selected antiarrhythmic therapy for a patient with atrial fibrillation?

(A) Class I; level C
(B) Class I; level A
(C) Class IIa; level B
(D) Class III; level A
(E) Class IIb; level A

Answers and Explanations

1. The answer is E *[see II.A.4.c.(4)]*.
Disopyramide has anticholinergic actions about one-tenth the potency of atropine. Effects include dry mouth, constipation, urinary retention, and blurred vision. Therefore, it cannot be used in patients with glaucoma or with conditions causing urinary retention. Moreover, disopyramide has a negative inotropic effect and must, therefore, be used with great caution, if at all, in patients with preexisting ventricular failure.

2. The answer is A *[see I.B.2 and II.A]*.
The class I antiarrhythmics (fast-channel blockers) slow impulse conduction by depressing the flow of sodium ions into cells during phase 0 of the action potential.

3. The answer is B *[see I.C.3.d; Table 32-1]*.
Torsades de pointes is a form of ventricular tachyarrhythmia characterized by electrocardiographic changes, which include a markedly prolonged QT interval. This potentially fatal reaction has now been reported for both antiarrhythmics and nonantiarrhythmics. Antiarrhythmics, which have been reported to cause torsades de pointes, include amiodarone, disopyramide, dofetilide, flecainide, ibutilide, procainamide, quinidine, and sotalol. Of the agents listed, only amiodarone is a class III antiarrhythmic.

4. The answer is C *[see II.A.4.a]*.
The patient's complaints are typical of many patients receiving quinidine as an antiarrhythmic. GI side effects are the major ones associated with quinidine administration, with diarrhea being reported in up to 30% of patients receiving the drug. These GI side effects are different from those associated with high serum concentrations of quinidine, where tinnitus, hearing loss, and blurred vision are added to the GI symptoms in a syndrome referred to as cinchonism.

5. The answer is E *[see II.C.2]*.
Class III antiarrhythmic agents work primarily on the potassium channels of the action potential and prolong the refractory period and action potential. Class Ia agents slow the rate of rise for phase 0 depolarization, as well as slowing fast-channel conduction of sodium and phases 2 and 3 of repolarization. Class IV agents (verapamil, diltiazem) inhibit the slow-channel conductance of calcium ions.

6. The answer is C *[see II.D.2]*.
Of the agents listed, diltiazem is a calcium-channel blocker and represents the class IV antiarrhythmics. Diltiazem has been used for its direct-acting effects on impulse conduction throughout the heart. Diltiazem is used to treat and prevent supraventricular arrhythmias. Ibutilide is a class III agent, procainamide is a class Ia drug, mexiletine is a class Ib agent, and propranolol, a β-adrenergic blocker, is class II. Mexiletine, quinidine, and propranolol are all also effective for supraventricular arrhythmias, and ibutilide is indicated for the treatment of atrial fibrillation/flutter of recent onset.

7. The answer is C *[see II.E.5.a–d]*.
Dronedarone (Multaq®) is the newest of the currently available antiarrhythmic agents and has yet to be included within the Vaughan Williams antiarrhythmic classification table. It also was the primary subject for a recently focused guidelines update for the treatment of patients with atrial tachyarrhythmias. Aliskiren (Tekturna®) is a relatively new agent referred to as a direct renin antagonist, which is available for the treatment of hypertension. Inamrinone (Various) is referred to as a phosphodiesterase inhibitor, which has been used for its positive inotropic actions in the treatment of heart failure. Amiodarone (Cordarone®) and dofetilide (Tikosyn®) are both considered class III Vaughan Williams antiarrhythmic agents.

8. **The answer is B** *[see II.C.1.d]*.
Dofetilide, ibutilide, amiodarone, and sotalol are class III antiarrhythmic agents. Class III agents prolong the refractory period and myocardial action potential and are used to treat ventricular arrhythmias. However, dofetilide and ibutilide are approved as class III agents indicated for the conversion from atrial fibrillation and flutter of recent onset to normal sinus rhythm. Propranolol, along with other β-blockers, is a class II antiarrhythmic; metoprolol is not routinely used in the treatment of arrhythmias; and disopyramide and diltiazem are class Ia and class IV antiarrhythmics, respectively.

9. **The answer is B** *[see II.C.3.a; II.C.4.a; II.C.5.a]*.
Amiodarone is a class III antiarrhythmic agent and acts by prolonging repolarization of cardiac cells. Amiodarone can be given either orally or parenterally and is often dosed as a once-a-day or twice-a-day maintenance dosage. Due to an extremely long elimination half-life, therapeutic response may be delayed for weeks. Therefore, an initial loading phase is often advisable. This requires hospitalization with close monitoring for desired effects, untoward reactions, and adjustments in dosage. Amiodarone has numerous drug–drug interactions with both other antiarrhythmic agents, as well as other nonarrhythmic agents. During therapy with amiodarone, patients may develop hypothyroidism or hyperthyroidism, pulmonary disorders (black box warning), hepatic dysfunction (black box warning), and various other unwanted effects.

10. **The answer is B** *[see I.H.1–2]*.
Recent national guidelines within the cardiology societies have used a scoring system, which includes two elements: one provides a recommendation based on benefit to risk where a class I recommendation has the greatest benefit compared to risk, as compared to class III where the risk may be equal to or worse than the risk; and a second element evaluates the degree of populations studied, where level A has been studied in numerous populations with well-controlled clinical trials, as compared to level C with very limited populations studied and reliance on opinion and case reports. A class I level A recommendation would be the best one would find, to help justify the use of a specific treatment or intervention, based on the cardiology guidelines criteria.

33 Hypertension

ALAN H. MUTNICK

I. GENERAL CONSIDERATIONS

A. Definition. Hypertension is blood pressure elevated enough to perfuse tissues and organs. Elevated systemic blood pressure is usually defined as a systolic reading $\geq$ 140 mm Hg and a diastolic reading $\geq$ 90 mm Hg ($\geq$ 140/90 mm Hg). The "Seventh Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure" (JNC-7) added a "prehypertension" category that includes individuals with systolic blood pressure readings of 120 to 139 mm Hg or diastolic blood pressure readings of 80 to 89 mm Hg; this category is now included in contemporary management strategies.

   1. It has been 7 years since the most recent set of national guidelines referred to as JNC-7; however, currently the National Heart, Lung, and Blood Institute is leading the development of an integrated set of cardiovascular risk reduction guidelines for adults using state-of-the-art methodology.
   2. The integrated approach will include updates for Cholesterol Guideline Update (ATP IV), Hypertension Guideline Update (JNC-8), and Obesity Guideline Update (Obesity-2) Integrated Cardiovascular Risk Reduction Guideline. The current timeline calls for the release of JNC-8 for public review and comment during the fall of 2011 and the release of the final update during the spring of 2012.
   3. The majority of this chapter will focus on the current guidelines, as described within the JNC-7 guidelines. However, the recently released 2011 Consensus document on the treatment of hypertension in the elderly has been added and can be viewed in their entirety with the following citation:
      a. Aronow WS, Fleg JL, Pepine CJ, et al. ACCF/AHA 2011 expert consensus document on hypertension in the elderly: a report of the American College of Cardiology Foundation Task Force on Clinical Expert Consensus Documents. *Circulation*. 2011;123(21):2434–2506.

B. Classification of hypertension is shown in *Table 33-1*. The table reflects the recommendations of the JNC-7.

C. The **relationship between elevated blood pressure and cardiovascular disease** was addressed in the JNC-7, which formalizes the fact that the higher the blood pressure, the greater the chance of a myocardial infarction (MI), heart failure (HF), stroke, or kidney disease. *Table 33-2* provides cardiovascular risk factors and/or lifestyle factors that affect the prognosis and treatment of hypertension and the various types of target-organ damage associated with hypertension.

D. Incidence. Hypertension is the most common cardiovascular disorder. Approximately 43 million Americans have blood pressure measurements > 140/90 mm Hg. This number translates to almost 25% of the adult population. The incidence increases with age—that is, 60% to 71% of people > 60 years of age have hypertension, according to data obtained from the Third National Health and Nutrition Examination Survey (NHANES III).

   1. **Primary (or essential) hypertension**, in which no specific cause can be identified, constitutes > 90% of all cases of systemic hypertension. The average age of onset is about 35 years.
   2. **Secondary hypertension**, resulting from an identifiable cause, such as renal disease or adrenal hyperfunction, accounts for the remaining 2% to 5% of cases of systemic hypertension. This type usually develops between the ages of 30 and 50.

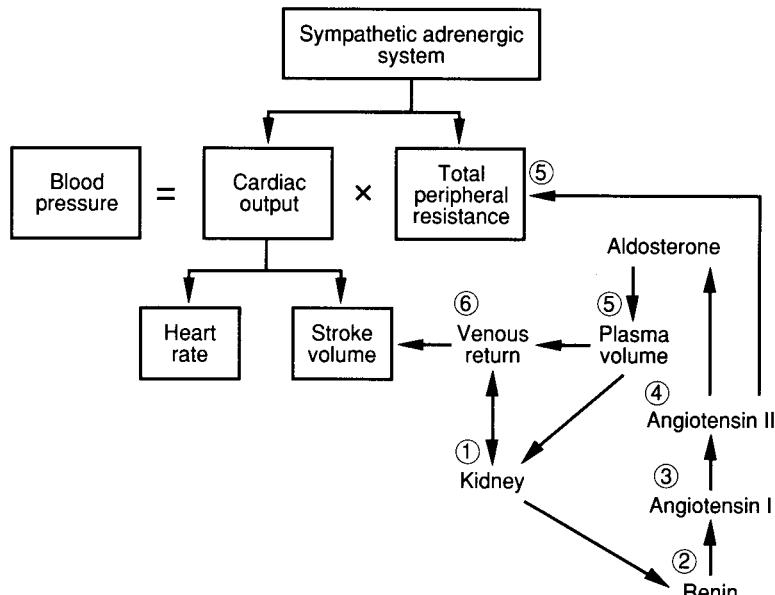
Table 33-1   CLASSIFICATION OF HYPERTENSION FOR ADULTS ≥18 YEARS OF AGE

					Management		
						Initial Drug Therapy	
Classification	Systolic (mm Hg)[a]		Diastolic (mm Hg)[a]	Lifestyle Modification	Without Compelling Indication	With Compelling Indications
Normal	< 120	and	< 80	Encourage		
Prehypertension	120–139	or	80–89	Yes	No antihypertensive drug indicated, unless presence of a compelling indication[b] requiring use of drug therapy	Drug(s) for compelling indications
Stage 1 hypertension	140–159	or	90–99	Yes	Thiazide-type diuretics for most; may consider ACE inhibitor, ARB, β-blocker, CCB, or combination	Drug(s) for compelling indications; other antihypertensive drugs (diuretics, ACE inhibitor, ARB, β-blocker, CCB) as needed
Stage 2 hypertension	≥ 160	or	≥ 100	Yes	Two-drug combination for most (usually thiazide-type diuretic and ACE inhibitor, ARB, β-blocker, or CCB)	Drug(s) for compelling indications; other antihypertensive drugs (diuretics, ACE inhibitor, ARB, β-blocker, CCB) as needed

[a]Treatment is determined by the patient's highest blood pressure category.
[b]Selected drug therapies have been identified from clinical trials to possess positive clinical outcomes for specific clinical situations and represent compelling indication for their use. Compelling indications (and drug therapies): heart failure (diuretics, β-blockers, ACE inhibitors, ARB, aldosterone antagonists), postmyocardial infarction (β-blockers, ACE inhibitors, and aldosterone antagonists), high coronary disease risk (diuretic, β-blocker, ACE inhibitors, CCB), diabetes (diuretic, β-blockers, ACE inhibitors, ARB, CCB), chronic kidney disease (ACE inhibitors, ARB), and recurrent stroke prevention (diuretic, ACE inhibitors).
Based on Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure. The seventh report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure: the JNC-7 report.
ACE, angiotensin-converting enzyme; ARB, angiotensin–receptor blocker; CCB, calcium-channel blocker.

Table 33-2	CARDIOVASCULAR AND/OR LIFESTYLE RISK FACTORS FOR CONSIDERATION IN THE MANAGEMENT OF HYPERTENSION

Hypertension
Cigarette smoking
Obesity (BMI ≥ 30)
Physical inactivity
Dyslipidemia (as a component of the metabolic syndrome)
Diabetes mellitus (as a component of the metabolic syndrome)
Microalbuminuria or estimated glomerular filtration rate < 60 mL/min
Age (> 55 years for men; > 65 years for women)
Family history of premature cardiovascular disease (men < 55 years; women < 65 years)

BMI, body mass index (calculated as weight in kilograms divided by the square of height in meters).
Based on Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure. The seventh report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure: the JNC-7 report.


E. Physiology

Blood pressure = (stroke volume × heart rate) × total peripheral vascular resistance (TPR)

Altering any of the factors on the right side of the blood pressure equation results in a change in blood pressure, as shown in *Figure 33-1*.

1. **Sympathetic nervous system. Baroreceptors** (pressure receptors) in the carotids and aortic arch respond to changes in blood pressure and influence arteriolar dilation and arteriolar constriction. When stimulated to constrict, the contractile force strengthens, increasing the heart rate and augmenting peripheral resistance, thus increasing cardiac output. If pressure remains elevated, the baroreceptors reset at the higher levels and sustains the hypertension. Little evidence to date suggests that epinephrine and norepinephrine, two major neurotransmitters of the sympathetic nervous system, have a clear role in the cause of hypertension. However, many of the drugs used to treat hypertension lower blood pressure by blocking the sympathetic nervous system.

2. **Renin–angiotensin–aldosterone system.** Sympathetic stimulation, renal artery hypotension, and decreased sodium delivery to the distal tubules stimulate the release of renin by the kidney (juxtaglomerular apparatus of the kidney). Renin (an enzyme) reacts with a circulating substrate, angiotensinogen, to produce angiotensin I (a weak vasoconstrictor). Within the pulmonary

Figure 33-1. Blood pressure regulation: the determinants of blood pressure as they relate to cardiac output and total peripheral resistance. Angiotensin II, a potent vasopressor, not only increases total peripheral resistance but also, by stimulating aldosterone release, leads to an increase in plasma volume, venous return, stroke volume, and ultimately an increase in cardiac output.

endothelium is another enzyme, referred to as angiotensin-converting enzyme (ACE), which is able to hydrolyze the decapeptide angiotensin I to form the octapeptide angiotensin II (a potent natural vasoconstrictor). Angiotensin II has several important functions in the regulation of fluid volume.

    a. It stimulates the release of aldosterone from the adrenal gland (zona glomerulosa), which results in increased sodium reabsorption, fluid volume, and blood pressure.

    b. It constricts resistance vessels, which increases peripheral vascular resistance and arterial pressure.

    c. It stimulates the release of vasopressin or antidiuretic hormone (ADH) from the posterior pituitary gland, which acts within the kidneys to increase fluid retention.

    d. It stimulates cardiac hypertrophy and vascular hypertrophy.

    e. It facilitates norepinephrine release from sympathetic nerve endings and inhibits norepinephrine reuptake by nerve endings, which enhances sympathetic function.

  3. **Mosaic theory** centers around the fact that multiple factors, rather than one factor alone, are responsible for sustaining hypertension. The interactions among the sympathetic nervous system, renin–angiotensin–aldosterone system, and potential defects in sodium transport within and outside the cell may all play a role in long-term hypertension. Additional factors contributing to the development include genetics, endothelial dysfunction, and neurovascular anomalies. Other vasoactive substances that are involved in the maintenance of normal blood pressure have also been identified; these include nitric oxide (vasodilating factor), endothelin (vasoconstrictor peptide), bradykinin (potent vasodilator inactivated by ACE), and atrial natriuretic peptide (naturally occurring diuretic).

  4. **Fluid volume regulation**. **Increased fluid volume** increases venous system distention and venous return, affecting cardiac output and tissue perfusion. These changes **alter vascular resistance**, increasing the blood pressure.

F. **Complications.** Untreated systemic hypertension, regardless of cause, results in inflammation and necrosis of the arterioles, narrowing of the blood vessels, and restriction of the blood flow to major body organs (*Table 33-3*). When blood flow is severely compromised, target-organ damage ensues.

  1. **Cardiac effects**

    a. Left ventricular hypertrophy (cardiac remodeling) compensates for the increased cardiac workload. Signs and symptoms of heart failure occur, and the increased oxygen requirements of the enlarged heart may produce angina pectoris.

    b. Hypertension can be caused by accelerated atherosclerosis. Atheromatous lesions in the coronary arteries lead to decreased blood flow, resulting in angina pectoris. MI and sudden death may ensue.

  2. **Renal effects**

    a. Decreased blood flow leads to an increase in renin–aldosterone secretion, which heightens the reabsorption of sodium and water and increases blood volume.

    b. Accelerated atherosclerosis decreases the oxygen supply, leading to renal parenchymal damage with decreased filtration capability and to azotemia. The atherosclerosis also decreases blood flow to the renal arterioles, leading to nephrosclerosis and, ultimately, renal failure (acute as well as chronic).

  3. **Cerebral effects.** Decreased blood flow, decreased oxygen supply, and weakened blood vessel walls lead to transient ischemic attacks, cerebral thromboses, and the development of aneurysms with hemorrhage. There are alterations in mobility, weakness and paralysis, and memory deficits.

  4. **Retinal effects.** Decreased blood flow with retinal vascular sclerosis and increased arteriolar pressure with the appearance of exudates and hemorrhage result in visual defects (e.g., blurred vision, spots, blindness).

II. SECONDARY HYPERTENSION

A. **Clinical evaluation.** Because most patients presenting with high blood pressure have primary rather than secondary hypertension, extensive screening is unwarranted. A thorough history and physical examination followed by an evaluation of common laboratory tests should rule out most causes of secondary hypertension. Patient age (primary hypertension is normally seen between 30 and 55 years of age), sudden onset of worsening of hypertension, and blood pressure elevations not responding to

Table 33-3   TARGET-ORGAN DAMAGE ASSOCIATED WITH HYPERTENSION

Organ/System and Findings	Basis of Findings
Cardiovascular	
Blood pressure persistently ≥ 140 mm Hg systolic and/or ≥ 90 mm Hg diastolic	Constricted arterioles, causing abnormal resistance to blood flow
Angina pain	Insufficient blood flow to coronary vasculature
Left ventricular hypertrophy/dyspnea on exertion	Heart failure
Edema of extremities	Decrease in blood supply
Neurological	
Severe occipital headaches with nausea and vomiting, drowsiness, anxiety, and mental impairment	Vessel damage within brain characteristic of dizziness, severe mental impairment, hypertension, resulting in transient ischemic attacks or strokes
Renal	
Polyuria, nocturia, and diminished ability to concentrate urine; protein and red blood cells in urine; elevated serum creatinine	Arteriolar nephrosclerosis (hardening of arterioles within kidney)
Ocular	
Retinal hemorrhage and exudates	Damage to arterioles that supply retina
Peripheral vascular	Absence of pulses in extremities with or without intermittent claudication; development of aneurysm

Based on Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure. The seventh report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure: the JNC-7 report.

treatment are findings consistent with secondary hypertension. If a secondary cause is not found, the patient is considered to have essential (primary) hypertension.

1. A patient's **history** and **other physical findings** suggest an underlying cause of hypertension. These include the following:
   a. Weight gain, moon face, truncal obesity, osteoporosis, purple striae, hirsutism, hypokalemia, diabetes, and increased plasma cortisol may signal Cushing syndrome.
   b. Weight loss, episodic flushing, diaphoresis, increased urinary catecholamines, headaches, intermittent hypertension, tremors, and palpitations suggest pheochromocytoma.
   c. Steroid or estrogen intake, including oral contraceptives, nonsteroidal anti-inflammatory drugs (NSAIDs), nasal decongestants, tricyclic antidepressants, appetite suppressants, cyclosporine, erythropoietin, and monoamine oxidase (MAO) inhibitors suggests drug-induced hypertension.
   d. Repeated urinary tract infections, elevated serum creatinine levels, nocturia, hematuria, and pain on urinating may signify renal involvement (e.g., chronic kidney disease).
   e. Abdominal bruits, recent onset, and accelerated hypertension indicate renal artery stenosis (e.g., renovascular disease).
   f. Muscle cramps, weakness, excess urination, and isolated hypokalemia may suggest primary aldosteronism.
   g. Sleep apnea, coarctation of the aorta, thyroid disease, and parathyroid disease have been included by the JNC-7 as additional secondary causes of hypertension.

2. **Laboratory findings**
   a. Blood urea nitrogen (BUN) and creatinine elevations suggest renal disease.
   b. Increased urinary excretion of catecholamine or its metabolites (e.g., vanillylmandelic acid, metanephrine) confirms pheochromocytoma.
   c. Serum potassium evaluation revealing hypokalemia suggests primary aldosteronism or Cushing syndrome.

3. **Diagnostic tests**
   a. Renal arteriography, ultrasound, or renal venography may show evidence of renal artery stenosis.
   b. Electrocardiography (ECG) may reveal left ventricular hypertrophy or ischemia.

B. **Cause**
   1. **Primary aldosteronism.** Hypersecretion of aldosterone by the adrenal cortex increases distal tubular sodium retention, expanding the blood volume, which increases total peripheral resistance.
   2. **Pheochromocytoma.** A tumor of the adrenal medulla stimulates hypersecretion of epinephrine and norepinephrine, which results in increased total peripheral resistance.
   3. **Renal artery stenosis.** Decreased renal tissue perfusion activates the renin–angiotensin–aldosterone system (see I.E.2).

C. **Treatment.** Secondary hypertension requires treatment of the underlying cause (e.g., surgical intervention accompanied by supplementary control of hypertensive effects; see III.B).

III. ESSENTIAL (PRIMARY) HYPERTENSION

A. **Clinical evaluation** requires a thorough history and physical examination followed by a careful-analysis of common laboratory test results.
   1. **Objectives**
      a. To rule out uncommon secondary causes of hypertension
      b. To determine the presence and extent of target-organ damage
      c. To determine the presence of other cardiovascular risk factors in addition to high blood pressure
      d. To reduce morbidity and mortality through multiple strategies that reduce blood pressure through lifestyle modifications with or without pharmacological treatment with minimal side effects

   2. **Predisposing factors**
      a. **Family history** of essential hypertension, stroke, and premature cardiac disease.
      b. **Patient history** of intermittent elevations in blood pressure.
      c. **Racial predisposition.** Hypertension is more common among African Americans than Whites.
      d. **Obesity.** Weight reduction has been shown to reduce blood pressure in a large proportion of hypertensive patients who are > 10% above ideal body weight.
      e. **Smoking**, resulting in vasoconstriction and activation of the sympathetic nervous system, is a major risk factor for cardiovascular disease.
      f. Stress
      g. High dietary intake of saturated fats or sodium
      h. Sedentary lifestyle
      i. Diabetes mellitus
      j. Hyperlipidemia
      k. Major risk factors according to the JNC-7 include smoking, diabetes mellitus, age (> 55 for men; > 65 for women), family history of cardiovascular disease, and dyslipidemia.
      l. Target-organ damage/clinical cardiovascular disease according to the JNC-7 includes heart disease (e.g., left ventricular hypertrophy, angina, prior MI, heart failure), stroke or transient ischemic attacks, nephropathy, peripheral artery disease, and retinopathy.

   3. **Physical findings**
      a. Serial blood pressure readings ≥ 140/90 mm Hg should be obtained on at least two occasions before specific therapy is begun, unless the initial blood pressure levels are markedly elevated (i.e., > 210 mm Hg systolic; > 120 mm Hg diastolic, or both) or are associated with target-organ damage. A single elevated reading is an insufficient basis for a diagnosis.

    b. Essential hypertension usually does not become clinically evident—other than through serial blood pressure elevations—until vascular changes affect the heart, brain, kidneys, or ocular fundi.

    c. Examination of the ocular fundi is valuable; their condition can indicate the duration and severity of the hypertension.

        (1) **Early stages.** Hard, shiny deposits; tiny hemorrhages; and elevated arterial blood pressure occur.

        (2) **Late stages.** Cotton-wool patches, exudates, retinal edema, papilledema caused by ischemia and capillary insufficiency, hemorrhages, and microaneurysms become evident.

  4. Untreated hypertension increases the likelihood of the development of numerous organ problems, which include left ventricular failure, MI, renal failure, cerebral hemorrhage or infarction, and severe changes in the retina of the eye.

B. Treatment (*Tables 33-4* and *33-5*, *Figure 33-2*)

  1. **General principles.** Treatment primarily aims to lower blood pressure toward "normal" with minimal side effects and to prevent or reverse organ damage. Currently, there is no cure for primary hypertension. Treating systolic and diastolic blood pressures to targets that are < 140/90 mm Hg is associated with a decrease in cardiovascular complications. For patients with hypertension who have diabetes or renal disease, the blood pressure goal recommended by the JNC-7 is 130/80 mm Hg.

    a. **Candidates for treatment**

        (1) All patients with a diastolic pressure of > 90 mm Hg, a systolic pressure of > 140 mm Hg, or a combination of both should receive antihypertensive drug therapy.

        (2) For those patients with a diastolic pressure of 80 to 89 mm Hg or a systolic pressure of 120 to 139 mm Hg (prehypertension), no drug treatment is indicated unless the patient has a compelling indication. However, lifestyle modifications, such as weight reduction, dietary sodium reduction, increased physical activity, and moderation of alcohol consumption, should be initiated.

    b. **Nonspecific measures.** Before initiating antihypertensive drug therapy, patients are encouraged to eliminate or minimize controllable risk factors (see III.A.2).

    c. **Pharmacological treatment.** The recommendations of the JNC-7 suggest that recent clinical trials have demonstrated that most hypertensive patients will require two or more antihypertensive drugs.

        (1) Thiazide diuretics should be the initial choice of therapy because they have demonstrated a reduction in morbidity and mortality when used as initial monotherapy. They have been shown to lower morbidity and mortality rates, have shown adequate long-term safety data, and have demonstrated patient tolerability.

        (2) Thiazide diuretics should be considered initial agents for treatment unless there are compelling indications for other medications.

        (3) Agents such as ACE inhibitors, angiotensin-receptor blockers, β-blockers, and calcium-channel blockers have all been recommended for patients who cannot receive a thiazide diuretic or in combination with a thiazide diuretic for adequate control of blood pressure. This may include the use of ACE inhibitors in hypertensive patients having systolic dysfunction after a MI, a diabetic nephropathy patient who might benefit from an ACE inhibitor in combination with a diuretic, or a patient with HF.

    d. **Monitoring guidelines.** Specific monitoring guidelines for the various drug categories are outlined in III.B.2–7.

        (1) Blood pressure should be monitored routinely to determine the therapeutic response and to encourage patient compliance.

        (2) Clinicians must be alert to indications of adverse drug effects. Many patients do not link side effects to drug therapy or are embarrassed to discuss them, especially effects related to sexual function or effects that appear late in therapy.

    e. **Patient compliance**

        (1) Because hypertension is usually a symptomless disease, how the patient "feels" does not reflect the blood pressure level. In fact, the patient may actually report "feeling normal" with an elevated blood pressure and "abnormal" during a hypotensive episode because of the light-headedness associated with a sudden drop in blood pressure. Because essential hypertension requires a lifelong drug regimen, it is extremely difficult but necessary to impress on patients the need for compliance with their therapeutic regimen.

Table 33-4	COMMON ANTIHYPERTENSIVE DRUGS

I. Diuretics
- **A.** Thiazide diuretics
  - Chlorothiazide (Diuril®)
  - Chlorthalidone (Various)
  - Hydrochlorothiazide (Microzide®)
  - Indapamide (Various)
  - Methyclothiazide (Various)
  - Metolazone (Zaroxolyn®)
- **B.** Loop diuretics
  - Bumetanide (Various)
  - Ethacrynic acid (Edecrin®)
  - Furosemide (Lasix®)
  - Torsemide (Demadex®)
- **C.** Potassium-sparing diuretics
  - Amiloride (Various)
  - Eplerenone (Inspra®)
  - Spironolactone (Aldactone®)
  - Triamterene (Dyrenium®)

II. Vasodilators (direct acting)
- Hydralazine (Various)
- Minoxidil (Various)
- Nitroprusside (Nitropress®)

III. Angiotensin-converting enzyme (ACE) inhibitors
- Benazepril (Lotensin®)
- Captopril (Capoten®)
- Enalapril (Vasotec®)
- Enalaprilat (IV) (Various)
- Fosinopril (Various)
- Lisinopril (Prinivil®, Zestril®)
- Moexipril (Univasc®)
- Perindopril (Aceon®)
- Quinapril (Accupril®)
- Ramipril (Altace®)
- Trandolapril (Mavik®)

IV. Angiotensin II receptor antagonists
- Azilsartan (Edarbi®)
- Candesartan cilexetil (Atacand®)
- Eprosartan (Teveten®)
- Irbesartan (Avapro®)
- Losartan (Cozaar®)
- Olmesartan (Benicar®)
- Telmisartan (Micardis®)
- Valsartan (Diovan®)

V. Renin inhibitors
- Aliskiren (Tekturna®)

VI. Sympatholytics
- **A.** β-Adrenergic blocking agents
  - Acebutolol (Sectral®)
  - Atenolol (Tenormin®)
  - Betaxolol (Kerlone®)
  - Bisoprolol (Zebeta®)
  - Carvedilol (Coreg®)
  - Esmolol (Various - IV)
  - Labetalol (Trandate®)
  - Metoprolol (Lopressor®, Toprol XL®)
  - Nadolol (Corgard®)
  - Nebivolol (Bystolic®)
  - Penbutolol (Levatol®)
  - Pindolol (Various)
  - Propranolol (Inderal®)
  - Timolol (Various)
- **B.** Centrally acting α-agonists
  - Clonidine (Catapres®)
  - Guanabenz (Various)
  - Guanfacine (Tenex®)
  - Methyldopa (Various)
- **C.** Postganglionic adrenergic neuron blockers
  - Reserpine (Various)
- **D.** α-Adrenergic blocking agents
  - Doxazosin (Cardura®)
  - Prazosin (Minipress®)
  - Terazosin (Hytrin®)
- **E.** Calcium-channel blockers
  - 1. Benzodiazepine derivatives
    - Diltiazem (Cardizem®)
  - 2. Diphenylalkylamine derivatives
    - Verapamil (Calan®)
  - 3. Dihydropyridines
    - Amlodipine (Norvasc®)
    - Clevidipine (Cleviprex®)
    - Felodipine (Plendil®)
    - Isradipine (DynaCirc CR®)
    - Nicardipine (Cardene®)
    - Nifedipine (Procardia XL, Adalat CC®)
    - Nisoldipine (Sular®)

Table 33-5   COMMON COMBINATION PRODUCTS FOR HYPERTENSION

I. **Diuretics**

   Hydrochlorothiazide—spironolactone (Aldactazide®)
   Hydrochlorothiazide—triamterene (Dyazide®)
   Hydrochlorothiazide—amiloride (Various)

II. **Diuretics—β-adrenergic blockers**

   Bendroflumethiazide—nadolol (Corzide®)
   Chlorthalidone—atenolol (Tenoretic®)
   Hydrochlorothiazide—propranolol (Inderide®)
   Hydrochlorothiazide—metoprolol (Lopressor HCT®)
   Hydrochlorothiazide—bisoprolol (Ziac®)

III. **Diuretics—angiotensin-converting enzyme (ACE) inhibitors**

   Hydrochlorothiazide—captopril (Capozide®)
   Hydrochlorothiazide—benazepril (Lotensin HCT®)
   Hydrochlorothiazide—lisinopril (Prinzide®, Zestoretic®)
   Hydrochlorothiazide—enalapril (Vaseretic®)
   Hydrochlorothiazide—fosinopril (Various)
   Hydrochlorothiazide—moexipril (Uniretic®)
   Hydrochlorothiazide—quinapril (Accuretic®)

IV. **Diuretics—angiotensin II receptor antagonists**

   Hydrochlorothiazide—losartan (Hyzaar®)
   Hydrochlorothiazide—irbesartan (Avalide®)
   Hydrochlorothiazide—valsartan (Diovan HCT®)
   Hydrochlorothiazide—telmisartan (Micardis HCT®)
   Hydrochlorothiazide—candesartan (Atacand HCT®)
   Hydrochlorothiazide—eprosartan (Teveten HCT®)
   Hydrochlorothiazide—olmesartan (Benicar HCT®)

V. **Angiotensin-converting enzyme (ACE) inhibitors—calcium-channel blockers**

   Enalapril—felodipine (Lexxel®)
   Trandolapril—verapamil (Tarka®)
   Benazepril—amlodipine (Lotrel®)

VI. **Angiotensin II receptor antagonists—calcium-channel blockers**
   Olmesartan—amlodipine (Azor®)
   Valsartan—amlodipine (Exforge®)
   Telmisartan—amlodipine (Twynsta®)

VII. **Triple products**

   Amlodipine/Valsartan/Hydrochlorothiazide (Exforge HCT®)
   Amlodipine/Olmesartan/Hydrochlorothiazide (Tribenzor®)
   Aliskiren/Amlodipine/Hydrochlorothiazide (Amturnide®)

VIII. **Other**

   Hydrochlorothiazide—hydralazine (Hydra-zide®)
   Hydrochlorothiazide—methyldopa (Various)
   Amlodipine—atorvastatin (Caduet®)
   Clonidine—chlorthalidone (Clorpres®)
   Hydralazine—isosorbide dinitrate (BiDil®)
   Aliskiren—valsartan (Valturna®)
   Aliskiren—amlodipine (Tekamlo®)
   Aliskiren—hydrochlorothiazide (Tekturna HCT®)

Figure 33-2. Algorithm for the treatment of hypertension. *ACE*, angiotensin-converting enzyme; *ARB*, angiotensin-receptor blocker; *BP*, blood pressure; *CCB*, calcium-channel blocker. [Based on the recommendations from the Seventh Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure (JNC-7).]

    (2) Recognizing the seriousness of the consequences of noncompliance is key. Patients should be told that prolonged, untreated hypertension, known as the "silent killer," can affect the heart, brain, kidneys, and ocular fundi.

2. Diuretics

    a. Thiazide diuretics and their derivatives are currently recommended as initial therapy for hypertension. JNC-7 recommends initiating therapy with a low dose (12.5 mg of hydrochlorothiazide [Microzide®]), increasing the dose if necessary, and not exceeding a dose of 50 mg of hydrochlorothiazide or its equivalent.

      (1) Actions. Antihypertensive effects are produced by directly dilating the arterioles and reducing the total fluid volume. Thiazide diuretics increase the following:

        (a) Urinary excretion of sodium and water by inhibiting sodium and chloride reabsorption in the distal convoluted (renal) tubules

        (b) Urinary excretion of potassium and, to a lesser extent, bicarbonate

        (c) The effectiveness of other antihypertensive agents by preventing reexpansion of extracellular and plasma volumes

      (2) Significant interactions. NSAIDs, such as the now common over-the-counter forms of ibuprofen (Advil®, Motrin®), interact to diminish the antihypertensive effects of the thiazide diuretics.

(3) Precautions and monitoring effects

    (a) Potassium ion (K^+) depletion may require supplementation, increased dietary intake, or the use of a potassium-sparing diuretic, such as spironolactone (Aldactone®).

    (b) Uric acid retention may occur; this is potentially significant in patients who are predisposed to gout and related disorders.

    (c) Blood glucose levels may increase, which may be significant in patients with diabetes.

    (d) Calcium levels may increase because of the potential for retaining calcium ions.

    (e) Patients with known allergies to sulfa-type drugs should be questioned to determine the significance of the allergy.

    (f) Other common effects include fatigue, headache, palpitations, rash, vertigo, and transitory impotence.

    (g) Hyperlipidemia, including **hypertriglyceridemia**, hypercholesterolemia, increased low-density lipoprotein (LDL) cholesterol, and decreased high-density lipoprotein (HDL) cholesterol, must be evaluated routinely to prevent an added risk for coronary artery disease.

    (h) Fluid losses must be evaluated and monitored to prevent dehydration, postural hypotension, and even hypovolemic shock.

        (i) Alterations in fluids and electrolytes (e.g., hypokalemia, hypomagnesemia, hypercalcemia) may predispose patients to cardiac irritability, with a resultant increase in cardiac arrhythmias. ECG is performed routinely to detect and prevent the development of life-threatening arrhythmias.

(4) Usual effective doses

    (a) **Chlorothiazide (Diuril®):** 250 to 500 mg daily or twice daily

    (b) **Chlorthalidone (Various®):** 12.5 to 25 mg daily

    (c) **Hydrochlorothiazide (HydroDIURIL®):** 12.5 to 50 mg daily

    (d) **Indapamide (Various):** 1.25 to 5.0 mg daily

    (e) **Methyclothiazide (Various):** 2.5 to 5.0 mg daily

    (f) **Metolazone (Zaroxolyn®):** 2.5 to 5.0 mg daily

b. Loop (high-ceiling) diuretics

    (1) Indications. These agents are indicated when patients are unable to tolerate thiazides, experience a loss of thiazide effectiveness, or have impaired renal function (clearance < 30 mL/min).

    (2) Actions. Furosemide (Lasix®), ethacrynic acid (Edecrin®), bumetanide (Various), and torsemide (Demadex®) act primarily in the ascending loop of Henle; hence, they are called "loop" diuretics. By acting within the loop of Henle, they decrease sodium reabsorption. Their action is more intense but of shorter duration (1 to 4 hrs) than that of the thiazides; loss of patent exclusivity has resulted in an increase in the availability of generic products, which had reduced the coasts associated with their usage.

    (3) Significant interactions. As with the thiazides, the antihypertensive effect of loop diuretics may be diminished by **NSAIDs**.

    (4) Precautions and monitoring effects. Loop diuretics have the same effects as thiazides (see III.B.2.a), in addition to the following:

        (a) Loop diuretics have a complex influence on renal hemodynamics; thus, patients must be monitored closely for signs of hypovolemia.

        (b) Because these agents should be used cautiously in patients with episodic or chronic renal impairment, BUN and serum creatinine levels should be checked routinely.

        (c) Transient deafness has been reported. If the patient is taking a potentially ototoxic drug (e.g., an aminoglycoside antibiotic), another class of diuretic (e.g., a thiazide diuretic) should be substituted.

    (5) Usual effective doses

        (a) **Bumetanide (Various):** 0.5 to 2.0 mg daily

        (b) **Ethacrynic acid (Edecrin®):** 25 to 100 mg daily

        (c) **Furosemide (Lasix®):** 20 to 80 mg daily

        (d) **Torsemide (Demadex®):** 2.5 to 10 mg daily

c. **Potassium-sparing diuretics**
   (1) **Indications.** The diuretics in this group—spironolactone (Aldactone®), amiloride (Various), and triamterene (Dyrenium®)—are indicated for patients in whom potassium loss is significant and supplementation is not feasible. These agents are often used in combination with a thiazide diuretic because they potentiate the effects of the thiazide while minimizing potassium loss. **Spironolactone (Aldactone®)** is particularly useful in patients with hyperaldosteronism, as it has direct antagonistic effects on aldosterone (aldosterone-receptor blocker). **Eplerenone** (Inspra®), is another aldosterone-receptor blocker recently approved by the U.S. Food and Drug Administration (FDA) that, similar to spironolactone, blocks aldosterone binding at the mineralocorticoid receptor. Both of these agents have been used in hypertension and have an increased level of use in the treatment of HF (see Chapter 34).
   (2) **Actions.** Potassium-sparing diuretics achieve their diuretic effects differently and less potently than the thiazides and loop diuretics. Their most pertinent shared feature is that they promote potassium retention.
   (3) **Significant interactions.** Coadministration with **ACE inhibitors** or **potassium supplements** significantly increases the risk of hyperkalemia.
   (4) **Precautions and monitoring effects**
      (a) Potassium-sparing diuretics should be avoided in patients with acute renal failure and used with caution in patients with impaired renal function (monitor serum creatinine) because they can retain potassium.
      (b) **Triamterene (Dyrenium®)** should not be used in patients with a history of kidney stones or hepatic disease.
      (c) **Hyperkalemia** is a major risk, requiring routine monitoring of serum electrolytes. BUN and serum creatinine levels should be checked routinely to signal incipient excess potassium retention and impaired renal function.
   (5) **Usual effective doses**
      (a) **Amiloride (Various):** 5 to 10 mg daily
      (b) **Spironolactone (Aldactone®):** 25 to 100 mg daily and 400 mg daily to treat hyperaldosteronism
      (c) **Triamterene (Dyrenium®):** 50 to 100 mg daily
      (d) **Eplerenone (Inspra®):** 50 to 100 mg daily
d. **Combination products.** A growing number of products are available as combination products and can be found within *Table 33-5*.
3. **Sympatholytics**
   a. **β-Adrenergic blockers**
      (1) **Indications.** β-Blockers are particularly effective in patients with rapid resting heart rates (i.e., atrial fibrillation, paroxysmal supraventricular tachycardia) or for those compelling indications, such as heart failure, post-MI, high coronary disease risk, and diabetes mellitus, as described within the JNC-7 report.
      (2) **Actions.** Proposed mechanisms of action include the following:
         (a) Stimulation of renin secretion is blocked.
         (b) Cardiac contractility is decreased, thus diminishing cardiac output.
         (c) Sympathetic output is decreased centrally.
         (d) Reduction in heart rate decreases cardiac output.
         (e) β-Blocker action may combine all of the above mechanisms.
      (3) **Epidemiology.** Young (< 45 years) whites with high cardiac output, high heart rate, and normal vascular resistance respond best to β-blocker therapy.
      (4) **Precautions and monitoring effects**
         (a) Patients must be monitored for signs and symptoms of **cardiac decompensation** (i.e., reduction in cardiac output) owing to the fact that decreased myocardial contractility can trigger compensatory mechanisms, leading to HF (see Chapter 34).
         (b) ECGs should be monitored routinely because all β-blockers can decrease electrical conduction within the heart and cause bradyarrhythmias.
         (c) Relative cardioselectivity is dose dependent and is lost as dosages are increased. **No β-blocker is totally safe in patients with bronchospastic disease**—that is asthma and chronic obstructive pulmonary disease (COPD).

   (d) Abrupt stoppage of a β-blocker in cardiac patients puts the patient at risk for a **withdrawal syndrome** that may produce
      (i) exacerbated anginal attacks,
      (ii) myocardial infarction, and
      (iii) a life-threatening rebound of blood pressure to levels exceeding pretreatment readings.
   (e) β-Blocker therapy should be used with caution in patients with the following conditions:
      (i) Diabetes mellitus. β-Blockers can mask hypoglycemic symptoms, such as tachycardia.
      (ii) Raynaud phenomenon or peripheral vascular disease. Vasoconstriction can occur and, in predisposed patients, might result in a clinically significant problem.
      (iii) Neurological disorders. Several β-blockers enter the central nervous system (CNS), potentiating related side effects (e.g., fatigue, lethargy, poor memory, weakness, or mental depression).
   (f) Impotence and decreased libido may result in reduced patient compliance.
(5) Significant interactions. β-Adrenergic blockers interact with numerous agents, requiring cautious selection, administration, and monitoring.
(6) β-Blocker terms
   (a) Relative cardioselective activity. Relative to propranolol (Inderal®), β-blockers have a greater tendency to occupy the β_1-receptor in the heart, rather than the β_2-receptors in the lungs.
   (b) Intrinsic sympathomimetic activity. These agents have the ability to release catecholamines and to maintain a satisfactory heart rate. Intrinsic sympathomimetic activity may also prevent bronchoconstriction and other direct β-blocking actions.
(7) Specific agents
   (a) Propranolol (Inderal®) was the first β-adrenergic blocking agent shown to block both β_1- and β_2-receptors. The **usual daily dose range** is 40 to 160 mg. It is available both as a rapid-acting product and a long-acting product (Inderal-LA®); the usual daily dose range is 60 to 180 mg.
   (b) Metoprolol (Lopressor®) was the first β-adrenergic blocking agent to show relative cardioselective blocking activity, with relatively less blockade of the β_2-receptors in the lung when compared to propranolol. The **usual daily dose** is 50 to 100 mg. A sustained-release form of the drug is now available, as the succinate salt (Toprol XL®), which requires less frequent dosing (daily vs. once or twice daily for immediate-release metoprolol).
   (c) Nadolol (Corgard®) was the first β-adrenergic blocking agent that allowed once-daily dosing. It blocks both β_1- and β_2-receptors, similar to propranolol. The **usual daily dose** is 40 to 120 mg.
   (d) Atenolol (Tenormin®) was the first β-adrenergic blocking agent to combine once-daily dosing (nadolol) with relative cardioselective blocking activity (metoprolol). The **usual daily dose** is 25 to 100 mg.
   (e) Timolol (Various) was the first β-adrenergic blocking agent shown to be effective after an acute MI to prevent sudden death. It blocks both β_1- and β_2-receptors. The **usual daily dose** is 20 to 40 mg.
   (f) Pindolol (Various) was the first β-adrenergic blocking agent shown to have high intrinsic sympathomimetic activity. The **usual daily dose** is 10 to 40 mg.
   (g) Labetalol (Trandate®) was the first β-adrenergic blocking agent shown to possess both α- and β-adrenergic blocking activity. The **usual daily dose** is 200 to 800 mg. Labetalol is also effective for treating hypertensive crisis (*Table 33-6*).
   (h) Acebutolol (Sectral®) was the first β-adrenergic blocking agent that combined efficacy with once-daily dosing (nadolol), possessing intrinsic sympathomimetic activity (pindolol) and having relative cardioselective blocking activity (metoprolol). The **usual daily dose** is 200 to 800 mg.
   (i) Esmolol (Brevibloc®) was the first β-adrenergic blocking agent to have an ultrashort duration of action. This agent is not used routinely in treating hypertension owing to its duration of action and the need for intravenous administration. However, it has

Table 33-6	RAPID-ACTING PARENTERAL ANTIHYPERTENSIVE AGENTS FOR HYPERTENSIVE CRISIS

Drug	Dose/Route	Onset of Action	Duration of Action	Comments
Vasodilators				
Sodium nitroprusside (Nitropress®)	0.3–10 mg/kg/min as IV infusion	0.5–1 mins	1–2 mins	Immediate effect, very short duration; nausea, vomiting, muscle twitching, sweating, thiocyanate and cyanide intoxication
Nicardipine hydrochloride (Various)	5–15 mg/hr IV	< 5–15 mins	1–4 hrs	Intermediate onset and duration; tachycardia may occur, headache, flushing, local phlebitis
Fenoldopam mesylate (Corlopam®)	0.1–0.3 mcg/kg/min as IV infusion	< 5 mins	30 mins	Intermediate onset and duration; action on dopamine D_1-receptors (dilation of renal/mesenteric vessels might be preferred over nitroprusside for long-term or with renal dysfunction; tachycardia, headache, nausea, flushing
Nitroglycerin (Various)	5–200 mcg/min (0.3–6.0 mg/hr) as IV infusion	2–5 mins	3–5 mins	Useful in coronary artery disease; headache, vomiting, methemoglobinemia, tolerance with prolonged use
Enalaprilat (Various)	0.625–1.25 mg every 6 hrs IV	15–30 mins	4–6 hrs	Useful in HF, but avoid in renal impairment; precipitous fall in blood pressure in high-renin states
Hydralazine (Various)	10–20 mg IV/IM	10–20 mins	3–8 hrs	Afterload reduction through arteriole dilation resulting in increased cardiac output; tachycardia, flushing headache, vomiting, aggravation of preexisting angina
Clevidipine (Cleviprex®)	1–21 mg/hr	2–4 mins	5–15 mins	A fit nausea, fever caution with lipid disorder
Adrenergic inhibitors				
Labetalol hydrochloride (Various)	40–80 mg IV bolus every 10 mins, or 0.5–2.0 mg/min IV infusion	5–10 mins	3–6 hrs	Contraindicated in HF, bronchospastic patients, or bradycardia; predictable hypotensive effect; vomiting, scalp tingling, burning in throat, heart block, orthostatic hypotension
Esmolol (Brevibloc®)	250–500 mcg/kg/min for 2 mins, then 50–100 mcg/kg/min for 4 mins; may repeat if needed	1–2 mins	10–20 mins	β-Adrenergic blocker with ultra-short duration of effect; primary use in perioperative situation owing to short duration and quick onset; hypotension, nausea
Phentolamine (OraVerse®)	5–15 mg IV	1–2 mins	3–10 mins	α-Adrenergic blocker causing peripheral dilation; tachycardia, flushing, headache

HF, heart failure; *IM*, intramuscular; *IV*, intravenous.

been used for hypertension and or tachycardia during and after surgical procedures. The **usual dose** is 150 to 300 mcg/kg/min up to 300 mcg/kg/min intravenously.

(j) **Betaxolol (Kerlone®)** is a β-adrenergic blocker that possesses relative cardioselective blocking activity similar to metoprolol but has a half-life that allows for once-daily dosing. The **usual daily dose** is 5 to 20 mg.

(k) **Penbutolol (Levatol®)** is a β-adrenergic blocking agent that has weak intrinsic sympathomimetic activity like pindolol and allows for once-daily dosing. The **usual daily dose** is 10 to 20 mg.

(l) **Bisoprolol (Zebeta®)** is a β-adrenergic blocking agent that is cardioselective and has no intrinsic sympathomimetic activity. It allows for once-daily dosing, and the **usual daily dose** is 2.5 to 10 mg.

(m) **Carvedilol (Coreg®)** is a β-adrenergic blocking agent that has β-blocking properties as well as α-blocking properties, with a resultant vasodilation. The drug is administered twice daily with a starting dose of 6.25 mg titrated at 7- to 14-day intervals to a dose of 25 mg twice daily. **Usual daily doses** are 12.5 to 50 mg daily.

(n) **Nebivolol (Bystolic®)** is a β-adrenergic blocking agent that has cardioselective β_1 blocking tendencies, similar to several other agents in the class. Initial reports also suggest that nebivolol has vasodilatory properties through its release of nitric oxide. Nebivolol is administered in a single daily dose of 5 mg with dose titration required based on therapeutic response.

b. **Peripheral α_1-adrenergic blockers**—for example, prazosin (Minipress®), terazosin (Hytrin®), and doxazosin (Cardura®)

(1) **Indications.** This group of drugs is available for hypertensive patients who have not responded to initial antihypertensive therapy.

(2) **Actions.** The α_1-blockers (indirect vasodilators) block the peripheral postsynaptic α_1-adrenergic receptor, causing vasodilation of both arteries and veins. Also, the incidence of reflex tachycardia is lower with these agents than with the vasodilator hydralazine (Various). These hemodynamic changes reverse the abnormalities in hypertension and preserve organ perfusion. Recent studies have also shown that these agents have no adverse effect on serum lipids and other cardiac risk factors.

(3) **Precautions and monitoring effects**

(a) **First-dose phenomenon.** A syncopal episode may occur within 30 to 90 mins of the first dose; similarly associated are postural hypotension, nausea, dizziness, headache, palpitations, and sweating. To minimize these effects, the first dose should be limited to a small dose (1 mg) and administered just before bedtime.

(b) Additional adverse effects include diarrhea, weight gain, peripheral edema, dry mouth, urinary urgency, constipation, and priapism. Doxazosin (Cardura®) in doses of 2 to 8 mg/day was one of the treatment arms in the recent Antihypertensive and Lipid-Lowering Treatment to Prevent Heart Attack Trial (ALLHAT), and the treatment was discontinued prematurely owing to an apparent 25% increase in the incidence of combined cardiovascular disease outcomes than patients in the control group receiving the diuretic chlorthalidone. The added risk for HF, stroke, and coronary heart disease were the major outcomes affected in the doxazosin arm.

(4) **The average daily doses are**

(a) **Prazosin (Minipress®):** 2 to 20 mg

(b) **Terazosin (Hytrin®):** 1 to 20 mg

(c) **Doxazosin (Cardura®):** 1 to 16 mg

c. **Centrally active α-agonists** have been used in the past as alternatives to initial antihypertensives, but their use in mild-to-moderate hypertension has been reduced primarily owing to other available agents. They act primarily within the CNS on α_2-receptors to decrease sympathetic outflow to the cardiovascular system.

(1) **Methyldopa (Various)**

(a) **Actions.** Methyldopa decreases total peripheral resistance through the aforementioned mechanism while having little effect on cardiac output or heart rate (except in older patients).

- (b) **Precautions and monitoring effects**
    - (i) Common untoward effects include orthostatic hypotension, fluid accumulation (in the absence of a diuretic), and rebound hypertension on abrupt withdrawal. Sedation is a common finding upon initiating therapy and when increasing doses; however, the sedative effect usually decreases with continued therapy.
    - (ii) Fever and other flu-like symptoms occasionally occur and may represent hepatic dysfunction, which should be monitored by liver function tests.
    - (iii) A positive Coombs test develops in 25% of patients with chronic use (> 6 months). Less than 1% of these patients develop a hemolytic anemia. (Red blood cells, hemoglobin, and blood count indices should be checked.) The anemia is reversible by discontinuing the drug.
    - (iv) Other effects include dry mouth, subtly decreased mental activity, sleep disturbances, depression, impotence, and lactation in either gender.
- (c) The **usual daily dose** is 250 mg to 1 g
- **(2) Clonidine (Catapres®)**
    - (a) **Indications.** Clonidine is effective in patients with renal impairment, although they may require a reduced dose or a longer dosing interval.
    - (b) **Actions.** Clonidine stimulates α_2-receptors centrally, decreasing vasomotor tone and heart rate.
    - (c) **Precautions and monitoring effects**
        - (i) Intravenous administration causes an initial paradoxical increase in pressure (diastolic and systolic) that is followed by a prolonged drop. As with methyldopa, abrupt withdrawal can cause rebound hypertension.
        - (ii) Sedation and dry mouth are common but usually disappear with continued therapy.
        - (iii) Clonidine has a tendency to cause or worsen depression, and it heightens the depressant effects of alcohol and other sedating substances.
    - (d) The **usual daily dose** is 0.1 to 0.8 mg divided in two doses.
    - (e) Patient compliance is a major issue for most hypertensive patients. The recently released once-weekly patch (Catapres-TTS®), which provides 0.1 to 0.3 mg per 24 hrs, may improve compliance.
- **(3) Guanabenz (Various)** and **guanfacine (Tenex®)**
    - (a) **Indications.** These agents are recommended as adjunctive therapy with other antihypertensives for additive effects when initial therapy has failed.
    - (b) **Actions.** Guanabenz and guanfacine are centrally active α_2-agonists that have actions similar to clonidine.
    - (c) **Precautions and monitoring effects.** These agents should be used cautiously with other sedating medications and in patients with severe coronary insufficiency, recent MI, cerebrovascular accident (CVA), and hepatic or renal disease. Side effects include sedation, dry mouth, dizziness, and reduced heart rate.
    - (d) The **usual daily doses** are 4 to 8 mg in two doses for guanabenz and 1 to 3 mg in one dose for guanfacine.
- d. **Postganglionic adrenergic neuron blockers.** This class of antihypertensive drugs is best avoided unless it is necessary to treat severe refractory hypertension that is unresponsive to all other medications because agents in this class are poorly tolerated by most patients.
    - **(1) Reserpine (Various)**
        - (a) **General considerations.** Because of the high incidence of adverse effects, other agents are usually chosen first. When used, reserpine is given in low doses and in conjunction with other antihypertensive agents. Reserpine in very low doses (0.05 mg) combined with a diuretic, such as chlorothiazide (50 to 100 mg), may be an alternative to traditional doses of 0.05 to 0.25 mg/day.
        - (b) **Actions.** Reserpine acts centrally, as well as peripherally, by depleting catecholamine stores in the brain and in the peripheral adrenergic system.

(c) **Precautions and monitoring effects**

    (i) A history of depression is a contraindication for reserpine. Even low doses, such as 0.25 mg/day, can trigger a range of psychic responses, from nightmares to suicide attempts. Drug-induced depression may linger for months after the last dose.

    (ii) Peptic ulcer is also a contraindication for using reserpine. Even a single dose tends to increase gastric acid secretion.

    (iii) Common adverse effects include drowsiness, dizziness, weakness, lethargy, memory impairment, sleep disturbances, and weight gain. Nasal congestion is also common but may decrease with continued therapy.

(d) The **usual daily dose** of **reserpine** is 0.1 to 0.25 mg.

  4. ACE inhibitors

    a. General considerations. The ACE inhibitors—benazepril (Lotensin®), captopril (Capoten®), enalapril (Vasotec®), enalaprilat (Various-IV), fosinopril (Various), lisinopril (Zestril®), moexipril (Univasc®), perindopril (Aceon®), quinapril (Accupril®), ramipril (Altace®), and trandolapril (Mavik®)—are a rapidly growing group of drugs.

    b. Indications. Previous guidelines used ACE inhibitors as first-line alternatives for treating hypertension in patients unable to tolerate thiazides or β-blockers. However, JNC-7 recommendations have identified specific patient populations that have compelling indications—such as diabetes mellitus, post-MI, high coronary disease risk, chronic kidney disease, and recurrent stroke prevention—for which the ACE inhibitors are indicated in the treatment of hypertension or prehypertension. This has been primarily because of studies documenting their clinical efficacy, as well as minimal effect on patients' abilities to maintain normal function.

    c. Actions

      (1) These agents inhibit the conversion of angiotensin I (a weak vasoconstrictor) to angiotensin II (a potent vasoconstrictor), which decreases the availability of angiotensin II.

      (2) ACE inhibitors indirectly inhibit fluid volume increases when interfering with angiotensin II by inhibiting angiotensin II–stimulated release of aldosterone, which promotes sodium and water retention. The net effect appears to be a decrease in fluid volume, along with peripheral vasodilation.

    d. Significant interactions

      (1) The antihypertensive effect of ACE inhibitors may be diminished by **NSAIDs** (e.g., over-the-counter forms of ibuprofen).

      (2) Potassium-sparing diuretics increase serum potassium levels when used with ACE inhibitors, and potassium levels need to be closely monitored in these patients.

    e. Precautions and monitoring effects

      (1) Neutropenia is rare but serious; there is an increased incidence in patients with renal insufficiency or autoimmune disease.

      (2) Proteinuria occurs, particularly in patients with a history of renal disease. Urinary proteins should be monitored regularly.

      (3) Serum potassium levels should be monitored regularly for hyperkalemia. The mechanism of action tends to increase potassium levels somewhat. Patients with renal impairment are at increased risk.

      (4) Renal insufficiency can occur in patients with predisposing factors, such as renal stenosis, and when ACE inhibitors are administered with thiazide diuretics. Renal function should be monitored (e.g., through monitoring levels of serum creatinine and BUN).

      (5) A dry cough may occur but disappears within a few days after the ACE inhibitor is discontinued. All ACE inhibitors have the potential to cause this side effect, but switching to an alternative agent may improve the symptoms.

      (6) Other untoward effects include rashes, an altered sense of taste (dysgeusia), vertigo, headache, fatigue, first-dose hypotension, and minor gastrointestinal disturbances.

    f. Specific agents

      (1) **Captopril (Capoten®).** The original ACE inhibitor is given initially as a 12.5 to 25 mg dose three times daily and is increased to a **usual daily dose** of 25 to 100 mg in two or three doses. Initial dose is usually lower if patient is on diuretics to avoid initial hypotensive response.

(2) Enalapril (Vasotec®) is a prodrug, which is rapidly converted to its active metabolite, enalaprilat. Initial doses are 5 mg daily, with a **usual daily dose** of 5 to 40 mg in one to two doses. In addition, the enalaprilat form (Various) of the drug has been used effectively for treating acute hypertensive crisis (*Table 33-6*).

(3) Lisinopril (Zestril®) is a long-acting analog of enalapril, given initially as a 5 to 10 mg daily dose and adjusted to a **usual daily dose** of 10 to 40 mg in one dose.

(4) Benazepril (Lotensin), fosinopril (Various), moexipril (Univasc), perindopril (Aceon), quinapril (Accupril), ramipril (Altace), and trandolapril (Mavik) have as their major benefit a longer duration of action, which in many patients may result in once-daily dosing and improved compliance. **Average daily doses** for these agents are

    (a) Benazepril (Lotensin®): 10 to 40 mg in one to two doses

    (b) Fosinopril (Various): 10 to 40 mg in one dose

    (c) Moexipril (Univasc®): 7.5 to 30 mg in one dose

    (d) Perindopril (Aceon®): 4 to 8 mg in one to two doses

    (e) Quinapril (Accupril®): 10 to 80 mg in one dose

    (f) Ramipril (Altace®): 2.5 to 20 mg in one dose

    (g) Trandolapril (Mavik®): 1 to 4 mg in one dose

(5) Further study of these agents continues, and their use in other cardiovascular, as well as noncardiovascular diseases continues to expand.

5. Angiotensin II type I receptor antagonists

  a. Indications. This class of drugs has been one of the fastest growing groups of drugs for the treatment of hypertension. Currently, eight agents are available: azilsartan (Edarbi®), candesartan cilexetil (Atacand®), eprosartan (Teveten®), irbesartan (Avapro®), losartan (Cozaar®), olmesartan (Benicar®), telmisartan (Micardis®), and valsartan (Diovan®).

  b. Actions. This class of drugs works by blocking the binding of angiotensin II to the angiotensin II receptors. By blocking the receptor site, these agents inhibit the vasoconstrictor effects of angiotensin II while also preventing the release of aldosterone from the adrenal glands. These two properties of angiotensin II have been shown to be important causes for developing hypertension. Clinically, angiotensin receptor blockers appear to be equally effective for the treatment of hypertension as ACE inhibitors.

  c. Precautions and monitoring effects

    (1) Similar to ACE inhibitors, increases in serum potassium levels can occur, especially in patients receiving potassium-sparing diuretics. When used alone, hyperkalemia has not been reported to be severe enough to require stopping its use. However, as in patients receiving ACE inhibitors, potassium levels need to be monitored closely in those with compromised renal function.

    (2) Renal function is an important consideration for patients receiving angiotensin receptor blockers (ARBs). Similar to ACE inhibitors, declining renal function or acute renal failure will result in elevated serum potassium levels, owing to the kidneys inability to excrete potassium. BUN and serum creatinine levels should be monitored to prevent the development of hyperkalemia.

  d. Dosage guidelines for the available agents are as follows:

    (1) Candesartan cilexetil (Atacand): 8 to 32 mg in one to two doses

    (2) Eprosartan (Teveten): 400 to 800 mg in one to two doses

    (3) Irbesartan (Avapro): 150 to 300 mg in one dose

    (4) Losartan (Cozaar): 25 to 100 mg in one to two doses

    (5) Olmesartan (Benicar): 20 to 40 mg in one dose

    (6) Telmisartan (Micardis): 20 to 80 mg in one dose

    (7) Valsartan (Diovan): 80 to 320 mg in one to two doses

    (8) Azilsartan (Edarbi): 80 mg daily in one dose

  e. Current status

    (1) Many authorities believe that in the treatment of hypertension, there do not appear to be significant differences between ACE inhibitors and ARBs.

    (2) Familiarity and cost might well provide the basis of the selection of one agent over another at this time.

(3) ARBs have found use in special hypertensive populations with compelling indications, such as diabetes mellitus, HF, and chronic kidney disease, especially in patients who cannot tolerate an ACE inhibitor.

6. Calcium-channel blockers

a. Indications. The calcium-channel blockers are considered alternative drugs for the initial treatment of hypertension in select patient populations that are unable to take β-adrenergic receptor blockers, such as patients with a high coronary disease risk or diabetes mellitus who also have bronchospastic disease or Raynaud disease. Currently, nine agents—amlodipine (Norvasc®), clevidipine (Cleviprex®), diltiazem (Cardizem®), felodipine (Plendil®), isradipine (DynaCirc CR®), nicardipine (Cardene SR®), nifedipine (Procardia XL®), nisoldipine (Sular®), and verapamil (Calan®)—are available.

b. Actions

(1) Calcium-channel blockers inhibit the influx of calcium through slow channels in vascular smooth muscle and cause relaxation. Low-renin hypertensive, black, and elderly patients respond well to these agents.

(2) Although the calcium-channel blockers share a similar mechanism of action, each agent produces different degrees of systemic and coronary arterial vasodilation, sino-atrial (SA) and atrioventricular (AV) nodal depression, and a decrease in myocardial contractility.

c. Significant interactions. β-**Adrenergic blockers**, when used with calcium-channel blockers, may have an additive effect on inducing HF and bradycardia. Electrical conduction to the AV node may be further depressed when patients are given agents such as verapamil (Calan®) or diltiazem (Cardizem®) along with β-blockers.

d. Precautions and monitoring effects

(1) Diltiazem (Cardizem®) and verapamil (Calan®) must be used with extreme caution or not at all in patients with conductive disturbances involving the SA or AV node, such as second- or third-degree AV block, sick sinus syndrome, and digitalis toxicity.

(2) Nifedipine (Procardia®) use has been associated with flushing, headache, and peripheral edema; the patient may find these troublesome and thus may become noncompliant. Using the sustained-release product, Procardia® once daily has been shown to effectively reduce these effects.

(3) Verapamil use has been associated with a significant degree of constipation, which must be treated to prevent stool straining and noncompliance.

e. Specific agents

(1) Diltiazem (Cardizem®). Availability of extended-release products (Cardizem CD®, Cardizem-LA®, Dilacor XR®, Tiazac®) has reduced the frequency of daily doses in the treatment of hypertension. A single daily dose of 120 to 540 mg is effective for treating mild-to-moderate hypertension. Diltiazem already has proven efficacy as an antiarrhythmic and an antianginal agent.

(2) Nifedipine (Procardia®). The release of once-daily sustained-release preparations (Procardia XL®, Adalat CC®) has made this agent effective as a once-daily therapy for long-term treatment of hypertension. A previously reported long list of side effects has been reduced with the sustained-release product at a single daily dose of 30 to 90 mg. Immediate-release nifedipine has been reported to cause ischemic events, and the current recommendation is to avoid its use if at all possible.

(3) Verapamil (Calan®). This drug is similar to diltiazem in its actions (though with more potent effects on electrical conduction depression). Sustained-release products (Calan SR®, Isoptin SR®, Covera-HS®, Verelan PM®) at doses of 120 to 480 mg daily have been shown to be efficacious for long-term management of mild-to-moderate hypertension, whereas side effects such as dizziness, constipation, and hypotension are reduced.

(4) Amlodipine (Norvasc®), clevidipine (Cleviprex®), isradipine (DynaCirc®), felodipine (Plendil®), nicardipine (Cardene SR®), and nisoldipine (Sular®) are second-generation calcium-channel blockers. These agents have been developed to produce more selective effects on specific target tissues than the first-generation agents: diltiazem, nifedipine,

and verapamil. These agents are chemically similar to nifedipine and are referred to as dihydropyridine derivatives. The daily dose ranges are

   (a) **Amlodipine (Norvasc®):** 2.5 to 10 mg in one dose

   (b) **Isradipine (DynaCirc®):** 2.5 to 10 mg in one to two doses

   (c) **Felodipine (Plendil®):** 2.5 to 20 mg in one dose

   (d) **Nicardipine (Cardene SR®):** 60 to 120 mg as an extended-release product twice daily

   (e) **Nisoldipine (Sular®):** 10 to 40 mg in one dose

   (f) **Clevidipine (Cleviprex®):** Intravenous administration only; as 1 to 2 mg/hr, doubled at 90-second intervals up to target blood pressure goal.

7. Vasodilators. These drugs are used as second-line agents in patient's refractory to initial therapy with diuretics, β-blockers, ACE inhibitors, ARBs, or calcium-channel blockers. Vasodilators directly relax peripheral vascular smooth muscle—arterial, venous, or both. The direct vasodilators should not be used alone owing to increases in plasma renin activity, cardiac output, and heart rate.

  a. Hydralazine (Various)

    (1) Actions. Hydralazine directly relaxes arterioles, decreasing systemic vascular resistance. It is also used intravenously or intramuscularly in managing hypertensive crisis.

    (2) Precautions and monitoring effects

      (a) Because hydralazine triggers compensatory reactions that counteract its antihypertensive effects, it is most useful when combined with a β-blocker, central α-agonist, or diuretic as a latter-step agent.

      (b) Reflex tachycardia is common and should be considered before initiating therapy.

      (c) Hydralazine may induce angina, especially in patients with coronary artery disease and those not receiving a β-blocker.

      (d) Drug-induced systemic lupus erythematosus (SLE) may occur.

        (i) Baseline and serial complete blood counts (CBCs) with antinuclear antibody titers should be followed routinely to detect SLE.

        (ii) Slow acetylators of this drug have an increased incidence of SLE. Their risk may be reduced by administering doses of < 200 mg/day.

        (iii) Fatigue, malaise, low-grade fever, and joint aches may signal SLE.

      (e) Other adverse effects may include headache, peripheral neuropathy, nausea, vomiting, fluid retention, and postural hypotension.

    (3) The **usual daily dose** is 25 to 100 mg.

  b. Minoxidil (Various)

    (1) Actions. A more potent vasodilator than hydralazine, minoxidil relaxes arteriolar smooth muscle directly, decreasing peripheral resistance. It also decreases renal vascular resistance while preserving renal blood flow. Effective in most patients, minoxidil is commonly used to treat patients with severe hypertension that has been refractory to conventional drug regimens.

    (2) Precautions and monitoring effects

      (a) Peripheral dilation results in a reflex activation of the sympathetic nervous system and an increase in heart rate, cardiac output, and renin secretion.

      (b) Because this agent promotes sodium and water retention, particularly in the presence of renal impairment, patients should be monitored for fluid accumulation and signs of cardiac decompensation. Administering minoxidil along with a sympatholytic agent and a potent diuretic (e.g., furosemide) minimizes increased sympathetic stimulation and fluid retention.

      (c) Hypertrichosis (i.e., excessive hair growth) is a common side effect, particularly if the drug is continued for > 4 weeks.

    (3) The **usual daily dose** is 2.5 to 80 mg.

  c. Nitroprusside (Nitropress)

    (1) Actions. A direct-acting peripheral dilator, this agent has potent effects on both the arterial and venous systems. It is usually used only in short-term emergency treatment of acute hypertensive crisis, when a rapid effect is required. Onset of action is almost instantaneous and is maximal in 1 to 2 mins. Nitroprusside is administered intravenously with continuous blood pressure monitoring.

       (2) Precautions and monitoring effects. To prevent acute hypotensive episodes, initial doses should be very low, followed by slow titration upward until the desired effect is achieved.

        (a) Once the solution is prepared, it should be protected from light. Color changes are a signal that replacement is needed.

        (b) Thiocyanate toxicity may develop with long-term treatment—particularly in patients with reduced renal activity—but can be treated with hemodialysis. Symptoms may include fatigue, anorexia, disorientation, nausea, psychotic behavior, or muscle spasms.

        (c) Cyanide toxicity can occur (rarely) with long-term, high-dose administration. It may present as altered consciousness, convulsions, tachypnea, or even coma.

       (3) The **usual dose** is 0.3 to 10 mcg/kg/min as a continuous intravenous infusion.

   8. Renin Inhibitors

     a. Indications. Aliskiren (Tekturna®) is the first of this new class of drugs recently approved by the FDA for the treatment of hypertension.

     b. Actions. Unlike ACE inhibitors and ARBs, which act during the later stages of the renin-angiotensin system to reduce angiotensin II (see I.E.2-*Figure 33-1*), aliskiren works directly on the enzyme renin, to reduce the eventual production of angiotensin II.

     c. Aliskiren (Tekturna®) is available in 150 and 300 mg tablets. The usual starting dose is 150 mg daily, and for those who do not respond the dose can be increased to 300 mg daily. Doses greater than 300 mg have not been shown to offer additional blood pressure lowering effects.

     d. Aliskiren has already been incorporated into four combination products for the treatment of hypertension, once a patient has been stabilized on a therapeutic regimen.

       (1) Aliskiren/valsartan (Valturna®) 150/160 and 300/320, respectively

       (2) Aliskiren/amlodipine (Tekamlo®) 150/5, 150/10; and 300/5, 300/10, respectively

       (3) Aliskiren/hydrochlorothiazide (Tekturna HCT®) 150/12.5, 150/25; and 300/12.5, 300/25, respectively

       (4) Aliskiren/amlodipine/hydrochlorothiazide (Amturnide®)

        Aliskiren 150 mg, amlodipine 5 mg, and hydrochlorothiazide 12.5 mg

        Aliskiren 300 mg, amlodipine 5 mg, and hydrochlorothiazide 12.5 mg

        Aliskiren 300 mg, amlodipine 5 mg, and hydrochlorothiazide 25 mg

        Aliskiren 300 mg, amlodipine 10 mg, and hydrochlorothiazide 12.5 mg

        Aliskiren 300 mg, amlodipine 10 mg, and hydrochlorothiazide 25 mg

     e. Significant interactions. Furosemide serum levels have been reported to be reduced significantly when administered in patients receiving aliskiren. This might result in a diminished pharmacologic effect from furosemide.

     f. Precautions and monitoring effects

     Unlike the ACE inhibitors and ARBs, which have the potential to increase serum potassium levels, patients receiving aliskiren have not shown significant increases in potassium as compared to patients studies receiving placebo. However, in a population of diabetic patients receiving both ACE inhibitors or ARBs in combination with aliskiren, close monitoring of serum electrolytes and renal function is required due to an increased frequency of elevated serum potassium levels.

IV. HYPERTENSIVE EMERGENCIES

   A. Definition. A hypertensive emergency is a severe elevation of blood pressure (i.e., > 180 mm Hg systolic or > 110 mm Hg diastolic) that demands reduction—either immediate (within minutes) or prompt (within hours) to prevent or limit target-organ damage.

     1. Conditions requiring immediate reduction include hypertensive encephalopathy, acute left ventricular failure with pulmonary edema, eclampsia, dissecting aortic aneurysm, acute MI, stroke, and intracranial hemorrhage.

     2. Conditions requiring prompt reduction include malignant or accelerated hypertension.

B. **Treatment**
1. The **reduction in blood pressure must be gradual** (e.g., a 20% to 25% decrease in mean arterial pressure over the first hour) rather than precipitous to avoid compromising perfusion of critical organs, particularly cerebral perfusion.
2. **Specific agents** used in hypertensive crisis are shown in *Table 33-6*.

V. PRINCIPLES OF HYPERTENSION TREATMENT IN THE ELDERLY. Drug therapy for the elderly has been recommended in the past but with a greater degree of concern due to alterations in end organ functions, changes in drug distribution and elimination, and impact which declining blood pressure has in this patient population. A recent expert consensus document supported by the American College of Cardiology Foundation Task Force on Clinical Expert Consensus Documents was completed in April of 2011, and forms the basis for the brief overview to conclude this chapter. (See I.A.3.a.)

A. **General principles for drug therapy in the elderly**
1. Initial therapy should be started with a low dose and gradually increased, if needed to the maximal tolerated dose. If the drug is not tolerated as doses are increased toward target, a second drug from a different class should be substituted for the initial drug.
2. If the initial therapy does not achieve the targeted goal, a second agent from a different class should be added and the initial agent should be continued provided the initial drug was well tolerated.
3. If the target blood pressure goal is not achieved after reaching the full dose for the second agent, a third agent from yet another class should be added.
4. For the initiation of therapy, if the blood pressure is greater than 20/10 mm Hg above the targeted goal, therapy should be initiated with two antihypertensive agents.

B. **Selection of special drug classes in the elderly**
1. Thiazide diuretics
    a. Thiazide diuretics, hydrochlorothiazide (Microzide®) and chlorthalidone (Various), have been recommended for initiating therapy in the elderly.
    b. Despite the various age-related changes, which can be exacerbated with diuretic usage, the consensus of experts felt that the initial reductions in intravascular volume, peripheral vascular resistance, and blood pressure offset them and are usually well tolerated in the elderly.
    c. Therapeutic drug monitoring, routine monitoring of fluid and electrolyte status in order to prevent the development of orthostatic hypotension (depletion of sodium and water), arrhythmias (hypokalemia, hypomagnesemia, and hyponatremia), hyperuricemia, glucose intolerance, and dyslipidemia, which can all be exacerbated by thiazide diuretics.
2. Nonthiazide diuretics
    a. Indapamide (Various) is a sulfonamide diuretic used in the treatment of hypertension, which does not increase uric acid levels but has been associated with increases in blood glucose levels, as well as potassium-independent prolongation of the QT interval. It also needs to be used carefully in patients also receiving lithium.
    b. Loop diuretics described by the consensus group included furosemide (Lasix®), bumetanide (Various), and torsemide (Demadex®) have shown value in treating hypertension in patients with HF or chronic kidney disease. Fluid and electrolytes must be monitored for increases in glucose, as well as hypokalemia and hyponatremia.
    c. Potassium-retaining diuretics have also been included in the consensus document and include the mineralocorticoid antagonists spironolactone (Aldactone®) and eplerenone (Inspra®), as well as the sodium transport channel antagonists, amiloride (Various) and triamterene (Dyrenium®). These agents are generally used in combination with other agents.
3. β-adrenergic blockers
    a. Have not demonstrated convincing value in elderly being treated for hypertension. Although many feel they have a role, especially when added to a diuretic.
    b. The consensus group recommended their use in elderly hypertensive patients with coronary artery disease, HF, select arrhythmias, migraine headaches, and senile tremor.

4. Calcium-channel blockers
   a. A wide array of effects on heart muscle, SA and AV nodal function, peripheral arteries, and coronary circulation provide them with a positive recommendation by the consensus group.
   b. Clinical trials have shown the group of agents to be safe and efficacious in the elderly with hypertension.
   c. Due to the numerous clinical applications for the calcium-channel blockers, the consensus group recommended their use in elderly hypertensive patients with the comorbid conditions that include angina and supraventricular arrhythmias.
   d. The group added concern for the primary adverse effects of the largest group of calcium-channel blockers, the dihydropyridines as being due to peripheral dilation, which include edema, headache, postural hypotension, which could result in added risks of falls in the elderly.
   e. Final review from the consensus document results in the conclusions that the short-acting rapid-release dihydropyridines, that is, nifedipine (Procardia®), must be avoided, as should verapamil (Calan®) and diltiazem (Cardizem®) in those patients predisposed to heart block, and the need to avoid the first generation calcium-channel blockers, verapamil (Calan®), diltiazem (Cardizem®), and nifedipine (Procardia®) in patients with left ventricular dysfunction. This leaves the second generation dihydropyridine derivatives, as described earlier in this chapter.

5. Angiotensin-converting enzyme inhibitors (ACEIs) and ARBs
   a. ACEIs are considered first-line therapy in the elderly hypertensive patient with HF due to their ability to reduce morbidity and mortality in patients with HF. They have also been shown to retard the progression of diabetic renal disease and hypertensive nephrosclerosis.
   b. Main adverse effects associated with ACEIs include hypotension, chronic dry cough, and, rarely, angioedema or rash. Renal failure can develop in those with renal artery stenosis, and hyperkalemia can occur in patients taking potassium supplements, as well as those with renal insufficiency. Rarely, neutropenia or agranulocytosis can occur; close monitoring is suggested during the first months of therapy.
   c. Serum creatinine and potassium levels should be monitored for both classes of drugs in order to prevent the development of hyperkalemia due to the potential for increased potassium retention as well as reduced renal function.
   d. The consensus experts recommended the use of ARBs as first-line therapy in elderly hypertensive patients with diabetes mellitus and an alternative in elderly hypertensives with heart failure who cannot tolerate the ACEIs.

6. Direct acting renin inhibitors
   a. Aliskiren (Tekturna®) is the first of the direct acting renin inhibitors, and the consensus experts felt that it has similar effectiveness to ARBs and ACEIs for lowering blood pressure, without the dose-related increase in adverse events in the elderly.
   b. Combination therapy with hydrochlorothiazide (Microzide®), ramipril (Altace®), or amlodipine (Norvasc®) causes a greater reduction in blood pressure than when either agent is used alone. Data in combination with β-blockers is lacking, only a very limited amount of data are available in black hypertensive patients, and there is no data on the use of aliskiren (Tekturna®) in patients with glomerular filtration rates less than 30 mL/min/1.73 m^2.
   c. Aliskiren appears to be well tolerated in patients older than 75 years of age, including those with renal disease.

7. Miscellaneous agents
   a. Vasodilator agents such as hydralazine (Various) and minoxidil (Various) have demonstrated unfavorable side effects (i.e., tachycardia, fluid accumulation, atrial arrhythmias) and are therefore not included as initial therapy for the elderly. They have been suggested only as part of a combination regimen.
   b. Centrally acting agents such as clonidine (Catapres®) are less than ideal in the elderly due to their sedative properties and ability to induce bradycardias. Additionally, the sudden abruption in usage leads to increased blood pressure and heart rate, which could pose added dangers in the elderly population.
   c. Combination therapy provides an opportunity to maximize efficacy while reducing adverse events, enhanced convenience, and patient compliance.

Study Questions

Directions for questions 1–6: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following agents represents an angiotensin II receptor antagonist (ARB)?

   (A) trandolapril (Mavik®)
   (B) carvedilol (Coreg®)
   (C) irbesartan (Avapro®)
   (D) moexipril (Univasc®)
   (E) nimodipine (Various)

2. Reflex tachycardia, headache, and postural hypotension are adverse effects that limit the use of which of the following antihypertensive agents?

   (A) prazosin (Minipress®)
   (B) captopril (Capoten®)
   (C) methyldopa (Various)
   (D) guanabenz (Various)
   (E) hydralazine (Various)

3. A 65-year-old man presents with stage I hypertension. He has diabetes mellitus and chronic kidney disease and is intolerant to lisinopril. Which of the following agents would be an appropriate selection for initial treatment in this patient based on the guidelines from the "Seventh Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure" (JNC-7)?

   (A) chlorothiazide (Various)
   (B) propranolol (Inderal®)
   (C) nitroprusside (Nitropress®)
   (D) candesartan (Atacand®)
   (E) clonidine (Catapres®)

4. A patient with stage I hypertension who has bronchospastic airway disease and who is noncompliant would be best treated with which of the following β-blocking agents?

   (A) timolol (Various)
   (B) penbutolol (Levatol®)
   (C) esmolol (Brevibloc®)
   (D) acebutolol (Sectral®)
   (E) propranolol (Inderal®)

5. Long-standing hypertension leads to tissue damage in all of the following organs *except* the

   (A) heart.
   (B) lungs.
   (C) kidneys.
   (D) brain.
   (E) eyes.

6. According to the "Seventh Report of the Joint National Committee on Detection, Evaluation, and Treatment of High Blood Pressure" (JNC-7), which of the following agents is suitable as initial therapy for treating stage I hypertension (assuming no compelling indications for another type of drug)?

   (A) chlorothiazide (Various)
   (B) labetalol (Trandate®)
   (C) atenolol (Tenormin®)
   (D) propranolol (Inderal®)
   (E) bisoprolol (Zebeta®)

Directions for questions 7–9: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

   A   if **I only** is correct
   B   if **III only** is correct
   C   if **I and II** are correct
   D   if **II and III** are correct
   E   if **I, II, and III** are correct

7. A patient treated with a spironolactone (Aldactone®) should be monitored regularly for altered plasma levels of

   I. potassium.
   II. serum creatinine.
   III. blood urea nitrogen (BUN).

8. Before antihypertensive therapy begins, secondary causes of hypertension should be ruled out. Laboratory findings that suggest an underlying cause of hypertension include

   I. a decreased serum potassium level.
   II. an increased urinary catecholamine level.
   III. an increased blood cortisol level.

9. In an otherwise healthy adult with stage I hypertension, appropriate initial antihypertensive therapy would be

   I. chlorthalidone (Various)
   II. metoprolol (Lopressor®)
   III. bisoprolol (Zebeta®)

Directions for questions 10–14: Each list of adverse effects in this section is most closely associated with **one** of the following antihypertensive agents. The agents may be used more than once or not at all. Choose the **best** answer, **A–E**.

- (A) clonidine (Catapres®)
- (B) olmesartan (Benicar®)
- (C) nitroprusside (Nitropress®)
- (D) prazosin (Minipress®)
- (E) propranolol (Inderal®)

10. Thiocyanate intoxication, hypotension, and convulsions

11. Bradycardia, bronchospasm, and cardiac decompensation

12. Angioedema, cough, and hyperkalemia

13. Rebound hypertension, dry mouth, and drowsiness

14. First-dose syncope, postural hypotension, and palpitations

Directions for questions 15–19: Each description listed in this section is most closely associated with **one** of the following β-adrenergic blocking agents. The agents may be used more than once or not at all. Choose the **best** answer, **A–E**.

- (A) esmolol (Brevibloc®)
- (B) labetalol (Trandate®)
- (C) bisoprolol (Zebeta®)
- (D) nadolol (Corgard®)
- (E) pindolol (Visken®)

15. A β-blocker with intrinsic sympathomimetic activity

16. A β-blocker that also blocks α-adrenergic receptors

17. A β-blocker with an ultrashort duration of action

18. A β-blocker with a long duration of action and nonselective blocking activity

19. A β-blocker with relative cardioselective blocking activity

Answers and Explanations

1. **The answer is C** *[see III.B.5.a]*.
   Irbesartan is one of the relatively new classes of drugs used in the treatment of hypertension referred to as an angiotensin II receptor antagonist, which blocks the production of angiotensin II and consequently its effects as a powerful vasoconstrictor and stimulant for aldosterone release. Trandolapril and moexipril are ACE inhibitors; carvedilol is a β-adrenergic blocking agent; and nimodipine is a calcium-channel blocker used in the treatment of subarachnoid hemorrhage.

2. **The answer is E** *[see III.B.7.a]*.
   Hydralazine is a vasodilator that works by directly relaxing arterioles, thereby reducing peripheral vascular resistance. Its effectiveness as an antihypertensive agent is compromised; however, by the compensatory reactions it triggers (e.g., reflex tachycardia) and by its other adverse effects (e.g., headache, postural hypotension, nausea, palpitations). Fortunately, the unwanted effects of hydralazine are minimized when it is used in combination with a diuretic agent and a β-blocker. Hydralazine is most effective as a supplemental antihypertensive drug in combination with first-line therapy.

3. **The answer is D** *[see III.B.5.e.(3)]*.
   Candesartan, an angiotensin II receptor blocker, which acts by blocking the binding of angiotensin II to the angiotensin II receptors. By blocking the receptor site, this class of drugs inhibits the vasoconstrictor effects of angiotensin II and prevents the release of aldosterone owing to angiotensin II from the adrenal glands. JNC-7 guidelines call for the use of diuretics in the initial treatment of hypertension, unless the patient has compelling indications that have been shown to benefit from the use of specific classes of drugs. This patient has diabetes and chronic kidney disease and is unable to tolerate the ACE inhibitor lisinopril; therefore, an ARB would be an acceptable alternative for this patient rather than a β-blocker (propranolol) or diuretic (chlorothiazide). Nitroprusside is normally used in the treatment of hypertensive emergencies as an intravenous infusion, and clonidine is not considered initial treatment for hypertension.

4. The answer is D *[see III.B.3.a.(7).(a)–(n)]*.
The β-adrenergic blocking agents continue to demonstrate effectiveness in the treatment of hypertension. A major feature of some of these agents is their relative selectivity for β$_1$-receptors (in the heart) rather than for β$_2$-receptors (in the lung), which provides advantages in the treatment of certain patients (e.g., those with bronchospastic airway or COPD). Of the β-blockers listed, acebutolol is less likely than the rest to block β$_2$-receptors because of its relative cardioselective-blocking activity. Acebutolol also has a long duration of action, which could be helpful in the noncompliant patient by requiring fewer doses per day. Penbutolol has weak intrinsic sympathomimetic activity like pindolol but lacks relative cardioselectivity, despite its long duration of action. Esmolol by nature of its continuous intravenous infusion would not lend itself to chronic ambulatory therapy. Timolol is a long-acting β-blocker and lacks the relative cardioselective properties that acebutolol possesses.

5. The answer is B *[see I.F; Table 33-3]*.
Left untreated, hypertension can be lethal because of its progressively destructive effects on major organs, such as the heart, kidneys, and brain. The eyes also suffer damage; the lungs, however, do not. End-organ damage caused by hypertension includes left ventricular hypertrophy, heart failure, angina pectoris, myocardial infarction, renal insufficiency caused by atherosclerotic lesions, nephrosclerosis, cerebral aneurysm and hemorrhage, retinal hemorrhage, and papilledema.

6. The answer is A *[see III.B.2.a]*.
Thiazide diuretics are considered the first-line treatment choice for hypertension and should be used alone or in combination with other antihypertensives, if necessary. β-Blockers such as labetalol, atenolol, bisoprolol, and propranolol are no longer considered initial agents for treating hypertension unless there is a compelling reason for their use. β-Blockers have shown positive clinical outcomes in patients with heart failure, post-MI, high coronary disease risk, and diabetes (compelling indications) and would be acceptable options for patients presenting with prehypertension or hypertension with a compelling indication.

7. The answer is E (I, II, III) *[see III.B.2.c.(4)]*.
Spironolactone is a direct-acting aldosterone-receptor blocker and decreases its effects on sodium and water retention. However, a benefit of spironolactone is its potassium-sparing effect, through the exchange of sodium for potassium in the kidney. Patients with reduced renal function and acute renal failure (evidenced by elevations in serum creatinine) lose their ability to excrete potassium, and this needs to be monitored when patients are started on spironolactone. BUN and creatinine are good indirect indicators of renal function.

8. The answer is E (I, II, III) *[see II.A.2]*.
Low serum potassium levels in a hypertensive patient suggest primary aldosteronism. Elevated urinary catecholamines suggest a pheochromocytoma; other signs and symptoms of this tumor include weight loss, episodic flushing, and sweating. Elevated serum cortisol levels suggest Cushing syndrome; the patient is also likely to have a round (moon) face and truncal obesity. Secondary hypertension requires treatment of the underlying cause; supplementary antihypertensive drug therapy may also be needed.

9. The answer is A (I) *[see III.B.2.a]*.
Thiazide diuretics such as chlorthalidone are now considered, based on the JNC-7, first-line therapy for hypertension, barring any compelling indications, such as heart failure, diabetes, chronic kidney disease, or post-MI, when other antihypertensive agents would be indicated. β-Adrenergic blockers, such as metoprolol and bisoprolol, are no longer indicated as initial antihypertensive agents for treating hypertension.

10. The answer is C *[see III.B.7.c.(2)]*.

11. The answer is E *[see III.B.3.a.(4)]*.

12. The answer is B *[see III.B.5.c.(2)]*.

13. The answer is A *[see III.B.3.c.(2).(c)]*.

14. The answer is D *[see III.B.3.b.(3).(a)]*.
The goal of treatment in hypertension is to lower blood pressure toward normal with minimal side effects. All antihypertensive drugs can cause adverse effects. The primary purpose of the JNC-7 guidelines is to acknowledge the long-term benefits of diuretics in the treatment of hypertension.

15. The answer is E *[see III.B.3.a.(7).(f)]*.

16. The answer is B *[see III.B.3.a.(7).(g)]*.

17. The answer is A *[see III.B.3.a.(7).(i)]*.

18. The answer is D *[see III.B.3.a.(7).(c)]*.

19. The answer is C *[see III.B.3.a.(7).(l)]*.
The β-adrenergic blocking agents are valuable for managing hypertension and are used as initial antihypertensives. The β-blockers are sympathetic antagonists. They act by blocking various receptors of the sympathetic nervous system. They differ in their selectivity for these sympathetic receptors. For example, β$_1$-blockers have relative cardioselective activity—that is, they block β$_1$-receptors (in the heart) rather than β$_2$-receptors (in bronchial smooth muscle) and, therefore, are highly useful antihypertensive agents. Intrinsic sympathomimetic activity also appears to reduce the problem of bronchoconstriction; moreover, drugs with this property can also maintain a satisfactory heart rate.

34 Heart Failure

ALAN H. MUTNICK

I. INTRODUCTION

A. **Definition.** **Heart failure** (HF) is a complex clinical syndrome that can result from any cardiac disorder that impairs the ability of the ventricle to deliver adequate quantities of blood to the metabolizing tissues during normal activity or at rest. The condition in the past has been referred to as "congestive heart failure," owing to the **edematous state** commonly produced by the fluid backup resulting in shortness of breath, fatigue, limitation of exercise tolerance, and fluid retention. Fluid retention may lead to pulmonary and peripheral edema. More recently, because all patients do not necessarily present with fluid overload at the initial or follow-up evaluations, the term "heart failure" is used to more adequately reflect the clinical syndrome.

B. **Mortality rate.** Approximately 300,000 patients die as a result of the direct or indirect consequences of HF each year, and the number of deaths owing to HF (primary or secondary causes) has increased steadily, despite treatment advances. The risk of death is 5% to 10% annually in patients with mild symptoms and is as high as 30% to 40% in patients with advanced disease manifestations.

C. **Incidence of HF.** HF is a common medical condition that affects almost 5 million people in the United States, with more than 500,000 new cases diagnosed each year. Between 1.5% and 2.0% of the population has HF, and the incidence increases to 6% to 10% in patients older than age 65. HF makes up 20% of all hospitalizations in patients older than 65 years of age. HF is the only major cardiovascular disorder that is increasing in incidence and prevalence. During the last 10 years, there has been a dramatic increase in the number of hospitalizations, primarily owing to HF (810,000 in 1990 to more than 1 million, currently). The reasons for the increased numbers of hospital admissions include the aging of the population in the United States and improved treatment results obtained for myocardial infarction, coronary artery bypass surgery, and stenting.

D. **Cost of HF.** The total costs (direct and indirect) for the treatment of HF in the United States during 2005 were approximately $27.9 billion. Currently in the United States, more than $2.9 billion is spent annually on drugs used in the treatment of HF.

E. **Causes**

1. Although the disease occurs most commonly among the elderly (80% of patients hospitalized with HF are older than 65 years of age), it may appear at any age as a consequence of underlying cardiovascular disease.

2. There currently is no single diagnostic test for HF, and the clinical diagnosis is normally based on patient history and physical examination.

3. HF should not be considered an independent diagnosis because it is superimposed on an underlying cause.

   a. Coronary artery disease (CAD) is the cause of HF in about two-thirds of patients with left ventricular systolic dysfunction.

   b. The remaining third of patients have a nonischemic cause of systolic dysfunction owing to other causes of myocardial stress, which include trauma, disease, or other abnormal states (e.g., pulmonary embolism, infection, anemia, pregnancy, drug use or abuse, fluid overload, arrhythmia, valvular heart disease, cardiomyopathies, congenital heart disease).

4. The New York Heart Association (NYHA) developed a classification system still used today to quantify the functional limitations of HF patients. The NYHA classes are as follows:

   a. Class I. Degree of effort necessary to elicit HF symptoms equals those that would **limit normal individuals**.

      b. Class II. Degree of effort necessary to elicit HF symptoms occurs with **ordinary exertion**.

      c. Class III. Degree of effort necessary to elicit HF symptoms occurs with **less-than-ordinary exertion**.

      d. Class IV. Degree of effort necessary to elicit HF symptoms occurs while **at rest**.

   5. A criticism of the NYHA classification is its dependence on subjective assessments by the clinical practitioner, which changes frequently and might not accurately reflect different treatment options based on the degree of symptoms. Consequently, more recently, the "American College of Cardiology/American Heart Association (ACC/AHA) Guidelines for the Evaluation and Management of Chronic Heart Failure" offered new classification scheme that depicts HF as an evolving clinical entity and details a progression based on risk factors and structural changes, which may be asymptomatic or symptomatic. Within this classification, specific treatments can be targeted at each stage to affect morbidity and mortality (*Table 34-1*). The introduction of the four stages of HF are not intended to replace the NYHA classification but rather to complement it.

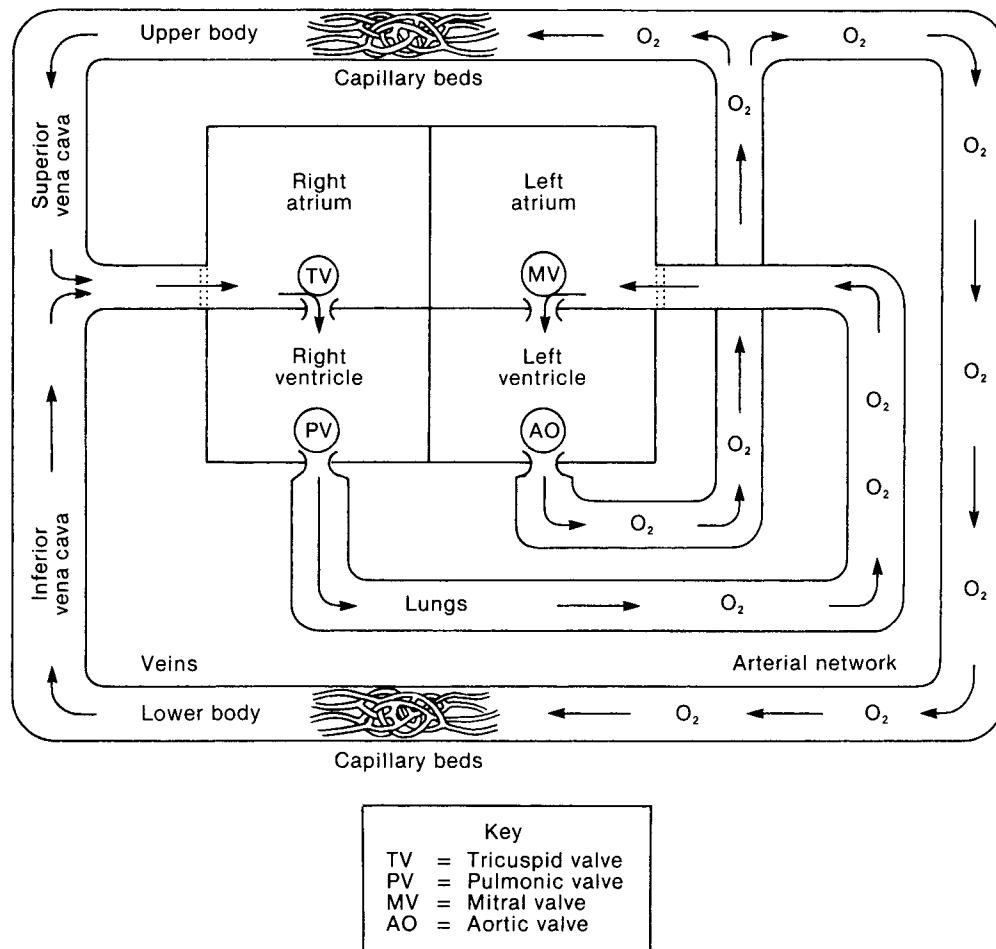
F. **Forms of HF.** As mentioned, HF is a complex syndrome and has been described in various ways. The cardinal manifestations of HF are dyspnea and fatigue, which may limit exercise tolerance, result in fluid retention, and lead to pulmonary congestion and peripheral edema. However, the following sections provide several ways that have been used to describe the pathophysiology and the symptomatology involved in the condition. Although the terms *low output* versus *high output* and *left sided* versus *right sided* are not routinely used in the clinical setting, their use here is to help convey important educational aspects of HF and are presented only for the purpose of simplifying the discussion of the pathophysiology and symptomatology.

   1. **Low-output versus high-output failure**

      a. If metabolic demands are within normal limits but the heart is unable to meet them, the failure is designated **low output** (the most common type).

      b. If metabolic demands increase (e.g., hyperthyroidism, anemia) and the heart is unable to meet them, the failure is designated **high output**. Compared to low-output failure, correction of the underlying cause of high-output failure is paramount as the initial treatment modality.

Table 34-1   STAGES OF HEART FAILURE (HF) BASED ON EVOLUTION AND PROGRESSION OF CLINICAL FINDINGS

Stage	Description	Examples
A	Patients at high risk of developing HF because of the presence of conditions that are strongly associated with the condition; such patients have no identified structural or functional abnormalities of the pericardium, myocardium, or cardiac valves and have never shown signs or symptoms of HF	Hypertension, atherosclerotic disease, diabetes mellitus, obesity, metabolic syndrome, history of cardiotoxic drug therapy or alcohol abuse, personal history of rheumatic fever, family history of cardiomyopathy
B	Patients who have developed structural heart disease that is strongly associated with the development of HF but who have never shown signs or symptoms condition	Left ventricular remodeling, including left ventricular hypertrophy or low ejection fraction; asymptomatic valvular disease of the previous myocardial infarction
C	Patients who have current or prior symptoms of HF associated with underlying structural heart disease	Known structural heart disease, dyspnea, or fatigue; reduced exercise tolerance
D	Patients with refractory HF who require specialized interventions	Patients with marked symptoms at rest despite maximal medical therapy (are frequently hospitalized for HF and cannot be safely discharged from the hospital, patients in the hospital awaiting heart transplantation, patients at home receiving continuous intravenous support for symptom relief or being supported with a mechanical circulatory assist device, patients in a hospice setting for the management of HF)


Adapted from Hunt SA, Abraham WT, Chin MH, et al. 2009 focused update incorporated into the ACC/AHA 2005 guidelines for the diagnosis and management of heart failure in adults: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines. *J Am Coll Cardiol.* 2009;53:e1– e90.

2. **Left-sided versus right-sided failure**
   a. **General symptomatology.** The signs and symptoms of HF usually result from the effects of blood backing up behind the failing ventricle (except in HF owing to increased body demands).
   b. Left-sided and right-sided HF do not routinely exist as separate entities; however, the use of separate terms best illustrates the systemic consequences.
   c. This progression occurs because the cardiovascular system is a closed system (*Figure 34-1*); thus, over time, right-sided failure causes left-sided failure and vice versa.
   d. **Left-sided failure.** If blood cannot be adequately pumped from the left ventricle to the peripheral circulation and it accumulates within the left ventricle, the patient is likely to exhibit signs of **left-sided HF.** As the fluid portion of the blood backs up into the pulmonary alveoli, the result is the development of pulmonary edema that can present as shortness of breath, dyspnea on exertion, and a third heart sound.
   e. **Right-sided failure.** When blood is not pumped from the right ventricle, the fluid portion of the blood backs up throughout the body (e.g., in the veins, liver, legs, bowels), producing systemic edema. Such signs would include evidence of elevated pressures in the venous system (e.g., peripheral edema, jugular venous distention [JVD]).

3. **Diastolic versus systolic dysfunction**
   a. Diastolic dysfunction refers to an inability for the ventricles to fill with blood during diastole, or ventricular relaxation. Under normal circumstances, blood returns to the right side of the heart from either the upper and lower body (superior vena cava and inferior vena cava, respectively) or left side of the heart from the lungs (via the pulmonary vein, left atria, and

Figure 34-1. An overview of blood flow through the cardiovascular system.

mitral valve). An inability for the respective ventricle(s) to accommodate the blood that is returning to it will result in a back up of blood in those areas where it originated from.

b. The inability of the ventricle(s) to accommodate the blood being presented to it is referred to as *noncompliance* and occurs due to stiffness occurring within the ventricular walls. Stiffness can result from clinical situations, such as hypertension, aortic stenosis, diabetes, myocardial infarction, and cardiac ischemia.

c. Keys to the diagnosis of diastolic HF are three conditions: (1) presence of signs or symptoms of heart failure, (2) presence of normal or slightly reduced left ventricular ejection fraction (LVEF) (EF > 50%), and (3) the presence of increased diastolic filling pressure.

d. Systolic dysfunction refers to an impaired degree of ventricular contraction resulting in a decrease in cardiac inotropy (contractility) and cardiac stroke volume (see II. Pathophysiology). This sets in motion a series of compensatory mechanisms with the purpose being to increase the ability of the heart to deliver blood to the body (increase stroke volume) but which have a negative effect by increasing plasma volume (preload) and pulmonary capillary wedge pressure. Patients with systolic dysfunction, unlike those with diastolic dysfunction, have lower than normal cardiac ejection fractions (EF < 40%) due to stroke volume reductions along with increases in end diastolic volumes.

e. Although the development of HF might occur in patients from various underlying causes (pericardium, epicardium, myocardium, great vessels, etc.), the majority of patients present with symptoms due to left ventricular dysfunction. Patients may present with HF and a normal-sized ventricle and normal ejection fraction to those with a severely dilated ventricle and low ejection fraction. Alhough these patients may present with different symptoms that might necessitate various therapeutic strategies, this approach is also at the present time controversial. CAD, hypertension, and dilated cardiomyopathy represent the primary causes of HF within the Western world.

f. Inotropic agents, preload reducing and afterload reducing agents, and diuretics are used to reverse the consequences of systolic dysfunction; that is, reduced cardiac output due to decreased myocardial contractility. However, angiotensin-converting enzyme (ACE) inhibitors, angiontensin II receptor blockers (ARBs), and β-adrenergic blockers have also been included in recent therapeutic guidelines for use in patients with systolic dysfunction.

g. ACE inhibitors, ARBs, and β-adrenergic blockers represent the backbone of current treatment options recommended for patients with diastolic dysfunction. However, patients identified with signs and symptoms suggestive of fluid accumulation and reduced cardiac ejection fractions have shown benefit from the use of diuretics to decrease fluid retention and inotropic agents, such as digoxin, to reduce hospitalizations.

4. Progressive nature of HF

a. Injury to the myocardium or stress placed on it is generally required before the development of left ventricular dysfunction.

b. The primary presentation for the associated signs and symptoms of HF is a change in the shape and structure of the left ventricle where it dilates and/or hypertrophies into more of a spherical shape, referred to as cardiac remodeling. Such changes in the shape of the heart result in altered stresses on the cardiac walls owing to size as well as structural changes, which also lend themselves to altered blood flow through the various heart chambers.

G. Treatment goals. HF requires a two-pronged therapeutic approach, the overall goals of which are the following:

1. To remove or mitigate the underlying causes or risk factors—for example, by eliminating ingestion of certain drugs or other substances that can produce or exacerbate HF or by correcting an anemic syndrome, which can increase cardiac demands (*Table 34-2*). In addition, modify risk factors that can cause cardiac injury by treating hypertension and diabetes; managing atherosclerotic disease; and controlling smoking, alcohol, and illicit drug use.

2. To relieve the symptoms and improve pump function by

a. reducing metabolic demands through rest, relaxation, and pharmaceutical controls;

b. reducing fluid volume excess through dietary and pharmaceutical controls;

c. administering a combination of diuretics, angiotensin-converting enzyme inhibitors (ACEIs), β-adrenergic blockers, and ARBs;

d. promoting patient compliance and self-regulation through education; and

e. selecting appropriate patients for cardiac transplantation.

Table 34-2   SUBSTANCES THAT MAY EXACERBATE HEART FAILURE

Promote Sodium Retention	Produce Osmotic Effect	Decrease Contractility
Androgens	Albumin	Antiarrhythmic agents (e.g., disopyramide, flecainide, quinidine)
Corticosteroids	Glucose	β-Adrenergic blockers
Diazoxide	Mannitol	Select calcium-channel blockers
Estrogens	Saline	(e.g., diltiazem, nifedipine, verapamil)
Licorice	Urea	Direct cardiotoxins (e.g., doxorubicin, ethanol, cocaine, amphetamines)
Lithium carbonate		Tricyclic antidepressants
NSAIDs		

NSAIDs, nonsteroidal anti-inflammatory drugs.

3. During recent years, several sets of guidelines have been developed for the treatment of HF. Most recently, a panel of leading physicians and researchers in the field of HF provided recommendations. See within the following citations:

Hunt SA, Abraham WT, Chin MH, et al. 2009 focused update incorporated into the ACC/AHA 2005 guidelines for the diagnosis and management of heart failure in adults: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines. Developed in collaboration with the International Society for Heart and Lung Transplantation. *J Am Coll Cardiol*. 2009;53(15):e1–e90.

Jessup M, Abraham WT, Casey DE, et al. Writing on behalf of the 2005 Guideline Update for the Diagnosis and Management of Chronic Heart Failure in the Adult Writing Committee. 2009 focused update: ACCF/AHA guidelines for the diagnosis and management of heart failure in adults: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. *J Am Coll Cardiol*. 2009;53:1343–1382.

4. These guidelines represent the most up-to-date standards for the prevention, diagnosis, and treatment of HF (*Table 34-3*).

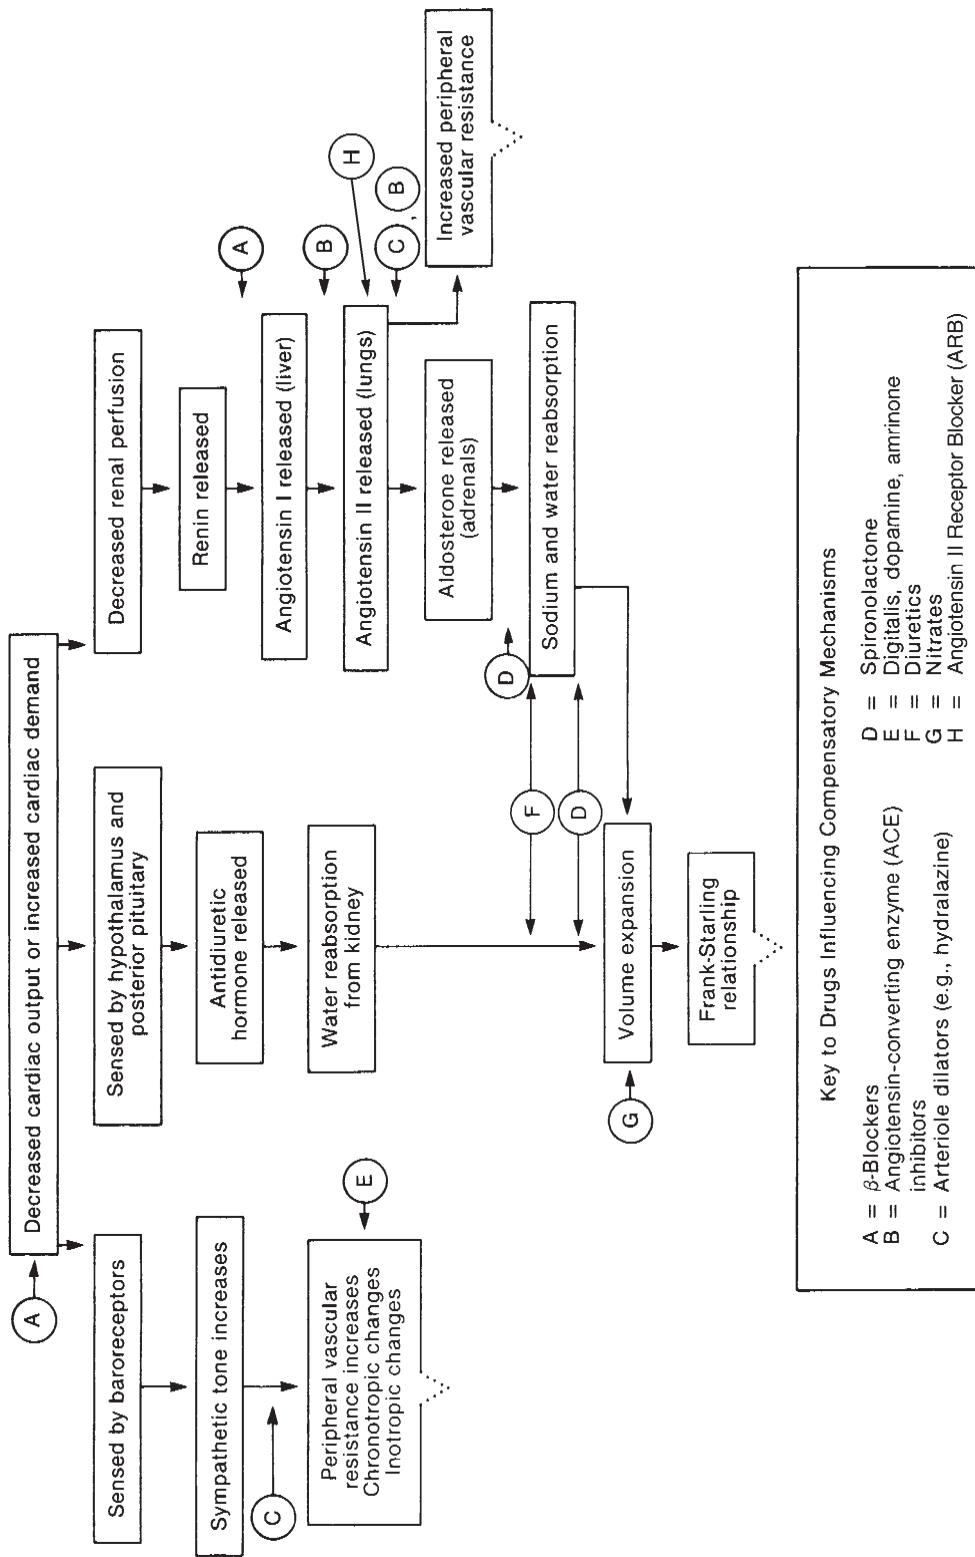
    a. The guidelines focus on four stages in the development of HF: stages A and B include patients "**at risk**" for HF, and stages C and D include patients who have developed HF. Each of the four stages of HF is associated with select treatment strategies and recommendations, which will be included in the following sections.

    b. Treatment of patients with refractory end-stage HF (stage D) should include the primary therapeutic agents that are used for stages A, B, and C. However, lack of an acceptable response will require specialized nonpharmacologic modalities, such as mechanical circulatory support, transplantation, and end-of-life care for those exhibiting no benefit.

    c. Ranking recommendations

Ranking Based on Size of Treatment Effect	Assessment of Benefit versus Risk	Recommended Action
Class I	Benefit >>> risk	Treatment should be used
Class IIa	Benefit >> risk	Reasonable to use treatment
Class IIb	Benefit ≥ risk	Treatment may be considered
Class III	No benefit; potentially harmful	No proven benefit; even harmful

Estimate of Certainty for Treatment Effect	Extent of Populations Studied	Types of Trials Utilized
Level A	Multiple populations evaluated	Data derived from multiple trials/meta-analyses
Level B	Limited populations evaluated	Data derived from a single trial or nonrandomized study
Level C	Very limited populations evaluated	Consensus opinion of experts or case reports

Table 34-3　APPROACH TO HEART FAILURE (HF)[a]


| | At Risk for Heart Failure | | Heart Failure | |
	Stage A	Stage B	Stage C	Stage D
Patients	Patients at high risk of developing HF because of presence of conditions that are strongly associated with development of condition; such patients have no identified structural or functional abnormalities of the pericardium, myocardium, or cardiac valves, and have never shown signs or symptoms of HF.	Patients who have developed structural heart disease that is strongly associated with development of HF but who have never shown signs or symptoms of the condition.	Patients who have structural heart disease with current or prior symptoms of HF.	Patients with refractory HF who require specialized interventions.
Goals	Treat hypertension. Encourage smoking cessation. Treat lipid disorders. Encourage regular exercise Discourage alcohol intake, illicit drug use. Control metabolic syndrome.	Same as stage A	Same as stages A and B Dietary salt restriction	Same as stages A, B, and C Decision concerning appropriate level of care OPTIONS • Compassionate end-of-life care • Extraordinary measures 　○ Heart transplant 　○ Chronic inotropes 　○ Permanent mechanical support 　○ Experimental surgery or drugs
Drugs	• ACEIs or ARBs in appropriate patients with high risk diabetes, atherosclerotic vascular disease, etc.	• ACEIs or ARBs in appropriate patients • β-blockers in appropriate patients	• Diuretics for fluid retention • ACEIs • β-Blockers DRUGS IN SELECT PATIENTS • Aldosterone antagonists • ARBs • Digitalis • Hydralazine/nitrates	
Devices in select patients		• Implantable defibrillators	• Biventricular pacing • Implantable defibrillators	

[a]The guidelines listed here are definitive , based here are definitive, based on available evidence, and are not intended to reflect the entire set of guidelines with less-than-substancial evidence. Adapted from Hunt SA, Abraham WT, Chin MH, et al 2009 focused update incorporated into the ACC/AHA 2005 guidelines for the diagnosis and management of heart failure in adults: a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guildelines. *J Am Coll Cardiol.* 2009;53:e1–e90.
ACEIs, angiotensin-converting enzyme inhibitors; ARB, angiotensin II receptor blockers.

II. PATHOPHYSIOLOGY.
HF and decreased cardiac output trigger a complex scheme of compensatory mechanisms designed to normalize cardiac output (cardiac output = stroke volume × heart rate). The principal manifestation of progression in cardiac dysfunction is a change in the geometry of the left ventricle, resulting in ventricular dilation and hypertrophy, with a resultant increase in a more spherical shape—referred to as *cardiac remodeling*. This results in increases in ventricular wall tension, depression in mechanical performance, and retention of normal cardiac fluid, which worsen the remodeling process.

A. **Compensation.** These mechanisms are shown in *Figure 34-2*.
1. **Sympathetic responses.** Inadequate cardiac output stimulates reflex (norepinephrine and epinephrine) activation of the sympathetic nervous system and an increase in circulating catecholamines. The heart rate increases, and blood flow is redistributed to ensure perfusion of the most vital organs (the brain and the heart).
2. **Hormonal stimulation.** The redistribution of blood flow results in reduced renal perfusion, which decreases the glomerular filtration rate (GFR). Reduction in GFR results in
a. **s**odium and water retention and
b. activation of the renin–angiotensin–aldosterone system, which further enhances sodium retention and thus volume expansion.
3. **Concentric cardiac hypertrophy** describes a mechanism that thickens cardiac walls, providing larger contractile cells and diminishing the capacity of the cavity in an attempt to precipitate expulsion at lower volumes (See above-Pathophysiology-*cardiac remodeling*).
4. **Frank–Starling mechanism.** The premise of this response is that increased fiber dilation heightens the contractile force, which then increases the energy released.
a. Within physiological limits, the heart pumps all the blood it receives without allowing excessive accumulation within the veins or cardiac chambers.
b. As blood volume increases, the various cardiac chambers dilate (stretch) and enlarge in an attempt to accommodate the excess fluid.
c. As these stretched muscles contract, the contractile force increases in proportion to their distention. Then the extended fibers snap back (as a rubber band would), expelling the extra fluid into the arteries.
d. Additional evidence suggests that the release of cytokines (e.g., tumor necrosis factor) occurs in concert with elevated levels of circulating norepinephrine, angiotensin II, aldosterone, endothelin, and vasopressin, which may all play a role in adversely affecting the heart structure, resulting in depressed performance.
B. **Decompensation.** Over time, the compensatory mechanisms become exhausted and increasingly ineffective, entering a vicious spiral of decompensation in which the mechanisms surpass their limits and become self-defeating—as they work harder, they only exhaust the system's capacity to respond.
1. As the strain continues, total peripheral resistance and afterload increase, thereby decreasing the percentage of blood ejected per unit of time. Afterload is determined by the amount of contractile force needed to overcome intraventricular pressure and eject the blood.
a. **Afterload** is the tension in ventricular muscles during contraction. In the left ventricle, this tension is determined by the amount of force needed to overcome pressure in the aorta. Afterload (also known as intraventricular systolic pressure) is sometimes used to describe the amount of force needed in the right ventricle to overcome pressure in the pulmonary artery.
b. **Preload** is the force exerted on the ventricular muscle at the end of diastole, which determines the degree of muscle fiber stretch. This concept is also known as ventricular end-diastolic pressure. Preload is a key factor in contractility because the more these muscles are stretched in diastole, the more powerfully they contract in systole.
2. As the fluid volume expands, so do the demands on an already exhausted pump, allowing increased volume to remain in the ventricle.
3. The resulting fluid backup (from the left ventricle into the lungs; from the right ventricle into peripheral circulation) produces the signs and symptoms of HF.

Figure 34-2. Compensatory mechanisms in heart failure.

III. CLINICAL EVALUATION. Assessment of fluid status and LVEF (*Table 34-3*).

A. **Fluid accumulation behind the left ventricle**
   1. **Signs and symptoms**
      a. Dyspnea
         (1) As HF progresses, the amount of effort required to trigger **exertional dyspnea** lessens.
         (2) **Both paroxysmal nocturnal dyspnea** and **orthopnea** result from volume pooling in the recumbent position and can be relieved by propping up the patient with pillows or having the patient sit upright. (Orthopnea is often gauged by the number of pillows the patient needs to sleep comfortably.)
      b. Dry, wheezing cough
      c. Exertional fatigue and weakness
      d. Nocturia. Edematous fluids that accumulate during the day migrate from dependent areas when the patient is in a recumbent position and renal perfusion increases.
   2. **Physical findings**
      a. Rales (or crackles) indicate the movement of air through fluid-filled passages.
      b. Tachycardia is an early compensatory response detected through an increased pulse rate.
      c. S_3 ventricular gallop is a vibration produced by rapid filling of the left ventricle early in diastole.
      d. S_4 atrial gallop is a vibration produced by increased resistance to sudden, forceful ejection of atrial blood in late diastole; it does not vary with inspiration in left-sided failure and is more common in diastolic dysfunction.
   3. **Diagnostic test results**
      a. Cardiomegaly (heart enlargement), left ventricular hypertrophy, and pulmonary congestion may be evidenced by chest radiograph, electrocardiogram (ECG), and reduction in left ventricular function via echocardiography and radionuclide ventriculography.
      b. Arm-to-tongue circulation time is prolonged.
      c. Transudative pleural effusion may be suggested by radiograph and confirmed by analysis of aspirated pleural fluid.

B. **Fluid accumulation behind the right side of the heart**
   1. **Signs and symptoms**
      a. Complaints by the patient of tightness and swelling (e.g., "My ring is too tight," "My skin feels too tight") suggest edema.
      b. Nausea, vomiting, anorexia, bloating, or abdominal pain on exertion may reflect hepatic and visceral engorgement, resulting from venous pressure elevation.
   2. **Physical findings**
      a. JVD reflects increased venous pressure and is a cardinal sign of HF.
      b. S_3 ventricular gallop (see III.A.2.c).
      c. S_4 atrial gallop intensifies on inspiration in right-sided failure.
      d. Hepatomegaly (a tender, enlarged liver) is revealed when pushing on the edge of the liver results in a fluid reflux into the jugular veins, causing bulging (positive hepatojugular reflux).
      e. Bilateral leg edema is an early sign of right-sided HF; pitting ankle edema signals more advanced HF. However, edema is common to many disorders, and a pattern of associated findings, such as concurrent neck vein distention, is required for differential diagnosis.
   3. **Laboratory findings. Elevated levels of hepatic enzymes**—for example, alanine aminotransferase (ALT)—reflect hepatic congestion.
   4. **Evaluation of natriuretic peptides.** A class IIa recommendation that was given for the measurement of natriuretic peptides (brain natriuretic peptide [BNP] and N-terminal prohormone of BNP [NT-proBNP]) can be useful in the evaluation of patients presenting in the urgent care setting in whom the diagnosis of HF is uncertain. Elevated levels of BNP have been associated with a reduction in the LVEF, as well as in left ventricular hypertrophy, acute myocardial infarction, and ischemia, although they are not specific for HF and can occur in patients with obstructive lung disease and pulmonary emboli. The guidelines suggest that elevated levels of BNP tend to occur more in HF patients with low ejection fractions as compared to those with normal ejection fractions. In conclusion, elevated levels of natriuretic peptides may be helpful in adding weight

to a diagnosis of HF but should not be used as the sole evidence in making a diagnosis of HF or for eliminating a diagnosis of HF.

IV. THERAPY

A. **Bed rest**
  1. **Advantages**
     a. Bed rest decreases metabolic needs, which reduces cardiac workload.
     b. Reduced workload, in turn, reduces pulse rate and dyspnea.
     c. Bed rest also helps decrease excess fluid volume by promoting diuresis.
  2. **Disadvantages.** Physical activity (except during acute decompensation) should be encouraged to avoid physical deconditioning and exercise intolerance. The risk of venous stasis increases with bed rest and can result in thromboembolism. Antiembolism stockings help minimize this risk, as do passive or active leg exercises, when the patient's condition permits.
  3. **Progressive ambulation** should follow adequate bed rest.
B. **Dietary controls**
  1. **Consuming small but frequent meals** (four to six daily) that are low in calories and residue provide nourishment without unduly increasing metabolic demands.
  2. **Moderate sodium restriction** along with daily measurements of weight help maximize the lowest and safest doses of diuretics, a primary tool in reducing central volume in HF.
     a. Renal function should be evaluated to assess sodium conservation if severe sodium restriction is contemplated.
     b. Moderate sodium restriction (2 to 4 g of dietary sodium/day) can be achieved with relative ease by limiting the addition of salt during cooking and at the table.
     c. The patient should be advised about medications and common products that contain sodium and cautioned about their use (e.g., antacids, sodium bicarbonate or baking soda, commercial diet food products, water softeners). *Table 34-2* lists other substances that promote sodium retention.
C. **Drug-related considerations.** Therapeutic interventions might improve cardiac performance in the following ways:
  1. Drugs may increase the cardiac ejection fraction by directly stimulating cardiac contractility.
     a. The use of positive inotropic agents can produce immediate benefits; however, the long-term benefit has not been appreciated and in some cases may actually increase morbidity and mortality.
     b. The most recent national guidelines provide a class IIb recommendation with a level C level of evidence for intravenous inotropic drugs, such as dopamine, dobutamine, or milrinone, in patients presenting with documented several systolic dysfunction, low blood pressure, and evidence of low cardiac output, with or without congestion, in order to maintain systemic perfusion and preserve end-organ performance.
  2. Drugs may increase the ejection fraction by decreasing the impedance to ejection through relaxation of peripheral blood vessels.
     a. The use of vasodilators, such as nitroprusside, nitroglycerin, and nesiritide, may produce short-term benefit but do not necessarily produce clinical benefits in the long-term.
     b. The most recent national guidelines provide a class IIa recommendation with a level C level of evidence for hospitalized patients with HF who are fluid overloaded in the absence of hypotension, where such agents are added to diuretic therapy or in those patients who have not responded adequately to diuretic therapy.
     c. Hydralazine (Various), an arteriole dilator with afterload reducing properties, has received a class I recommendation with a level A level of evidence in the updated national guidelines, in combination with isosorbide dinitrate to standard medical (i.e., ACEIs, ARBs, β-adrenergic blockers) regimens, to improve outcomes in African Americans with NYHA III or IV HF.
  3. Drugs may improve the ejection fraction by affecting the cardiac remodeling process. Neurohormonal antagonists such as ACEIs, β-adrenergic receptor blockers, ARBs, and vasodilator-growth inhibitors, such as nitrates, may not produce immediate benefits, but long-term use might improve clinical status and decrease future cardiac events.
  4. ACEIs, ARBs, diuretics, and β-adrenergic blockers usually form the basic core of treatment for HF.

D. **ACEIs**
1. Recent guidelines recommend the use of ACEIs in many types of patients with HF owing to left ventricular systolic dysfunction unless the patients have a contraindication to their use or have demonstrated intolerance to their use.
   a. ACEIs received a class IIa recommendation with a level A level of evidence for prevention of HF in patients at risk, **stage A**, who have atherosclerotic vascular disease, diabetes mellitus, or hypertension with associated cardiovascular risk factors.
   b. ACEIs received a class I recommendation with a level A level of evidence for use in all patients with a recent or remote history of MI, **stage B**, regardless of ejection fraction or presence of HF, and a class I recommendation with a level A level of evidence for use in patients with a reduced ejection fraction and no symptoms of HF, even if they have not experienced an MI.
   c. ACEIs received a class I recommendation with a level A level of evidence for use in all patients with current or prior symptoms of HF (**stage C**), and reduced LVEF, unless contraindicated.
   d. ACEIs did not receive a recommendation for use in HF patients with **stage D** due to the need for special procedures, such as transplantation, implantable pumps, etc.
   e. ACEIs did receive a class IIb recommendation with a level C level of evidence for use in HF patients with normal LVEFs.
2. Relative contraindications include history of intolerance or adverse reactions, serum potassium > 5.5 mEq/L, serum creatinine levels > 3 mg/dL, symptomatic hypotension, severe renal artery stenosis, and pregnancy.
3. ACEIs have been shown to reduce symptoms, improve clinical status, enhance the overall quality of life, and reduce death, as well as the risk of death or hospitalization in mild, moderate, and severe HF patients with or without CAD.
4. They inhibit the enzyme responsible for the conversion of angiotensin I (a weak vasoconstrictor) to angiotensin II (a potent vasoconstrictor). This action significantly decreases total peripheral resistance, which aids in reducing afterload.
5. Inhibiting the production of angiotensin II interferes with stimulation of aldosterone release, thus indirectly reducing retention of sodium and water, which decreases venous return and preload.
6. In patients with a history of fluid retention or who present with fluid retention, a diuretic can be added to an ACEI.
7. ACEIs are indicated for the long-term management of chronic HF and are generally recommended in combination with a β-adrenergic blocker and diuretic.
8. All ACEIs that have been studied in the treatment of HF have shown benefit. The selection of agent and dose should be based on currently available large-scale studies in which target doses of ACEIs—captopril (Capoten®), enalapril (Vasotec®), lisinopril (Zestril®), perindopril (Aceon®), ramipril (Altace®), and trandolapril (Mavik®)—are different from those used to treat hypertension. *Table 34-4* provides a comparative review of ACEIs currently used in the treatment of HF.
9. Common side effects to be monitored include hypotension (patients should be well hydrated before initiation of ACEIs), dizziness, reduced renal function (increased serum creatinine of 0.5 mg/dL or more requires reassessment), cough, and potassium retention (if potassium levels are high without supplementation, discontinue the ACEI for several days and then try to restart at lower dose).
10. Angioedema is a life-threatening side effect of ACEIs that has been reported to occur in $< 1\%$ of patients. It has been reported to occur at a more frequent rate in black patients, and the suspicion of the reaction would justify the avoidance of ACEIs in such patients.

E. **ARBs**
1. This class of drugs is now considered a reasonable alternative to the use of ACEIs for similar usage in HF patients.
2. Currently available agents include azilsartan (Edarbi®), candesartan cilexetil (Atacand®), eprosartan (Teveten®), irbesartan (Avapro®), losartan (Cozaar®), olmesartan (Benicar®), telmisartan (Micardis®), and valsartan (Diovan®); and initial studies on several of the agents have shown potential benefits for treating HF.
3. Current guidelines suggest that ACEIs should be preferred over the ARBs. However, ARBs may be used in patients who initially responded to ACEIs and/or are intolerant to ACEIs.

Table 34-4 COMPARATIVE DOSES OF SELECT AGENTS USED IN THE TREATMENT OF HEART FAILURE (HF)

Drug	Initial Daily Dose(s)	Maximal Total Daily Dose
Loop diuretics		
Bumetanide (Various)	0.5–1.0 mg once or twice	10 mg
Furosemide (Lasix®)	20–40 mg once or twice	600 mg
Torsemide (Demadex®)	10–20 mg once	200 mg
Thiazide diuretics		
Chlorthalidone (various)	12.5–25 mg once	200 mg
Chlorothiazide (Diuril®)	250–500 mg once or twice	2000 mg
Hydrochlorothiazide (Microzide®)	25 mg once or twice	200 mg
Indapamide (Various)	2.5 mg once	5 mg
Metolazone (Zaroxolyn®)	2.5 mg once	20 mg
Potassium-sparing diuretics		
Amiloride (Midamor®)	5 mg once	20 mg
Spironolactone (Aldactone®)	12.5–25 mg once	50 mg
Triamterene (Dyrenium®)	50–75 mg twice	300 mg
ACEIs		
Benazepril (Lotensin®)	5 mg daily	20 mg daily
Captopril (Capoten®)	6.25 mg three times	450 mg
Enalapril (Vasotec®)	2.5 mg twice	40 mg
Fosinopril (Monopril®)	5–10 mg once	80 mg
Lisinopril (Zestril®)	2.5–5.0 mg once	40 mg
Moexipril (Univasc®)	Not indicated in HF	
Perindopril (Aceon®)	2 mg once	32 mg
Quinapril (Accupril®)	5 mg twice	40 mg
Ramipril (Altace®)	1.25–2.5 mg once	10 mg
Trandolapril (Mavik®)	1 mg once	4 mg
Angiotensin II receptor blockers		
Candesartan (Atacand®)	4–8 mg once	32 mg
Losartan (Cozaar®)	25–50 mg once	100 mg
Valsartan (Diovan®)	20–40 mg twice	320 mg
Aldosterone antagonists		
Spironolactone (Aldactone®)	12.5 mg once	50 mg
Eplerenone (Inspra®)	25 mg once	50 mg
β-Adrenergic receptor blockers		
Bisoprolol (Zebeta®)	1.25 mg once	10 mg
Carvedilol (Coreg®)	3.125 mg twice	50 mg; 100 mg for patients > 85 kg
Metoprolol succinate (Toprol XL®) (extended-release)	12.5–25 mg once	200 mg

F. **β-Adrenergic blocking agents**
1. Unlike ACEIs, which strictly work by blocking the effects of the renin–angiotensin system, β-adrenergic blockers interfere with the sympathetic nervous system—that is, norepinephrine-induced peripheral vasoconstriction, norepinephrine-induced sodium excretion by the kidney, norepinephrine-induced cardiac hypertrophy, norepinephrine-induced arrhythmia generation, norepinephrine-induced hypokalemia, or norepinephrine-induced cell death (apoptosis) through increased stress owing to norepinephrine stimulation.
2. β-Adrenergic blockers, specifically bisoprolol (Zebeta), sustained-release metoprolol (Toprol XL), and carvedilol (Coreg), have been shown to decrease the risk of death or hospitalization, as well as improve the clinical status of HF patients (*Table 34-4*).
3. β-Adrenergic blockers have been shown to be beneficial in select stages of patients with HF as a result of left ventricular dysfunction, unless they have a contraindication to their use or are unable to tolerate their effects owing to hypotension, bradycardia, bronchospasm, and the like.
   a. β-Adrenergic blockers received a class I with a level A level of evidence in the most recent national guidelines for patients with a recent or remote history of MI regardless of ejection fraction or presence of HF (**stage B**) or in all patients without a history of MI who have a reduced LVEF with no HF symptoms.
   b. β-Adrenergic blockers received a class I with a level A level of evidence in the most recent national guidelines for one of the three agents (i.e., bisoprolol [Zebeta®], carvedilol [Coreg®], and sustained-release metoprolol succinate [Toprol XL®] for all stable HF patients with current or prior symptoms of HF and reduced LVEF, unless contraindicated (**stage C**).
4. β-Adrenergic blockers are generally used in conjunction with diuretics, ACEIs, or ARBs. β-Adrenergic blockers should not be taken without diuretics in patients with a current or recent history of fluid retention to avoid its development and to maintain sodium balance.
5. Side effects of β-adrenergic blockers may occur during the early days of therapy but do not generally prevent their long-term use; and progression of the disease may be reduced, even if symptoms of the disease have not responded to β-adrenergic blocker therapy. Therapy should be initiated with low doses and titrated upward slowly as tolerated.
6. Patients should be monitored for signs of fluid retention by having patients weigh themselves daily and report any significant increases, which might warrant increases in diuretic doses or reductions in the dose of the β-adrenergic blocker. In addition, fatigue, hypotension, bradycardia, and heart block are reported side effects that should be monitored to ensure appropriate attention and management.
7. Studies support the use of β-adrenergic blockers in patients with stage C HF—and not in the acute management of patients, as in an intensive care unit (ICU). Patients should have no or minimal evidence of fluid retention and have no recent evidence for the use of an intravenous inotropic agent. In addition, β-adrenergic blockers should be considered in patients who develop HF post–MI if they are able to tolerate the negative inotropic effects.
8. Initiation of β-adrenergic blockers should not be undertaken until the patient is stable without fluid overload or hypotension and is on concomitant medications, which include diuretics and/or ACEIs or ARBs.
9. Patient education is an important aspect for initiating β-adrenergic blockers therapy, and patients need to be informed that they might not see positive effects for several months after obtaining the target dosage of the agent.

G. **Diuretics**
1. The most recently updated national guidelines provide a class I recommendation with a level C level of evidence for the use of diuretics in patients with current or prior symptoms of HF and reduced LVEF who have evidence of fluid retention (**stage C**). Diuretics are generally best used in conjunction with an ACEI, ARB, and/or β-adrenergic blocker.
2. Diuretics have been shown to cause a reduction in jugular venous pressures, pulmonary congestion, peripheral edema, and body weight in short-term studies and have been shown to improve cardiac function and exercise tolerance in intermediate-term studies.
3. The goal of diuretic therapy is to reduce and eventually eliminate signs and symptoms of fluid retention as assessed by JVD, peripheral edema, or both. Slow titration upward in doses may be necessary to minimize hypotension and should be continued until fluid retention is eliminated.

4. Body weight is an effective method of monitoring fluid losses and is best done on a daily basis by the patient.

5. Patients who experience diuretic resistance or tolerance to their effects might need intravenous administration, a combination of two agents with differing mechanisms (furosemide [Lasix®] and metolazone [Zaroxolyn®]) or the addition of agents, such as dopamine or dobutamine, which increase renal blood flow. Furthermore, evaluation of patient drug profiles may identify the addition of sodium-retaining agents, such as nonsteroidal anti-inflammatory drugs (NSAIDs).

6. All diuretics increase urine volume and sodium excretion but differ in their pharmacological properties.

7. **Select diuretic classes**
   a. **Thiazide diuretics** include chlorothiazide (Diuril®), hydrochlorothiazide (Microzide®), chlorthalidone (Various), and indapamide (Various). They are effective and commonly used in HF, specifically in patients with hypertension, but they deplete potassium stores in the process. These agents are relatively weak because they are able to increase the fractional excretion of sodium to only 5% to 10% of the filtered load. However, they have been shown to lose their effectiveness in HF patients with moderately impaired renal function (creatinine clearance < 30 mL/min).
   b. **Loop diuretics** include furosemide (Lasix®), ethacrynic acid (Edecrin®), bumetanide (Various), and torsemide (Demadex®) and have become the preferred diuretics. They have the ability to increase sodium excretion to 20% to 25% of the filtered load and to maintain their efficacy until renal function is severely impaired (creatinine clearance < 5 mL/min) plus have the added advantage of reducing venous return independent of diuresis. In addition, furosemide's action is more intense, making it useful as a rapid-acting intravenous agent in reversing acute pulmonary edema, owing to its direct dilating effects on pulmonary vasculature (see *Table 34-4* for dosage).
   c. **Potassium-sparing diuretics** include amiloride (Midamor®), spironolactone (Aldactone®), and triamterene (Dyrenium®) and may help avoid the incidence of hypokalemia. However, they also possess a weaker diuretic effect than the other diuretics. As the number of HF patients receiving ACEIs or ARBs continues to increase, fewer patients may require supplemental potassium therapy.

8. **Aldosterone antagonists.** Spironolactone (Aldactone®) is a potassium-sparing diuretic but was the first aldosterone antagonist available for clinical use in the United States, when it had been shown to have direct blocking effects on the actions of aldosterone. Results from a large study, the Randomized Aldactone Evaluation Study (RALES), revealed that the addition of low doses (12.5 to 25 mg daily) of spironolactone to patients with class IV symptoms (NYHA) taking ACEIs reduced the risk of death and hospitalization.
   a. Current national guidelines provide a class I recommendation with a level C level of evidence that spironolactone (Aldactone®) be considered in patients with **stage C** HF—as add-on therapy to ACEIs or ARBs and a β-adrenergic blocker—who can be closely monitored for changes in renal function and potassium levels in those patients where previous therapy was not effective in resolving congestion.
   b. Patients receiving spironolactone should have serum potassium levels evaluated and reduced to < 5.0 mEq/L along with a serum creatinine level < 2.5 mg/dL before initiation of therapy. Potassium levels should be routinely monitored to prevent the subsequent development of hyperkalemia.
   c. Eplerenone (Inspra®) was the second aldosterone receptor antagonist introduced and is currently indicated in the treatment of hypertension and in post-MI patients with HF. It has not yet been formalized into the current national guidelines as spironolactone (Aldactone®) has been.

H. **Vasodilators**
   1. The current national guidelines provide a class IIa and a level C for the use of vasodilators in hospitalized patients with evidence of severely symptomatic fluid overload in the absence of systemic hypotension, when added to diuretics and/or in those who do not respond to diuretics alone.
   2. These agents include nitroprusside (Nitropress®), nitroglycerin (Various), and nesiritide (Natrecor®)
   3. Individual agents
      a. **Nitroprusside** (**Nitropress®**) is administered intravenously in doses of 0.3 to 10 mcg/kg/min as a continuous infusion in order to provide potent dilation of both arteries and veins, with a resultant decrease in preload and afterload. It has a very short onset of action and very short duration of action. Nitroprusside is capable of causing a substantial fall in blood pressure and usually will

require intensive invasive monitoring to prevent large fluctuations in clinical outcomes. Long-term use is capable of causing thiocyanate toxicity, primarily in those with reduced renal function.

b. **Nesiritide (Natrecor®)** has been shown to effectively reduce left ventricular filling pressures, but the outcomes on cardiac output, urinary output, and sodium output have had varying results. An important adverse effect on the kidney has been reported resulting in the need for closer monitoring.

(1) **Nesiritide (Natrecor®)** is a recombinant form of human BNP, which is a naturally occurring hormone secreted by the ventricles. It is the first of this drug class to become available for human use in the United States.

(2) Nesiritide is approved for the intravenous treatment of patients with acutely decompensated HF associated with shortness of breath at rest or with minimal activity.

(3) Nesiritide binds to natriuretic peptide receptors in blood vessels, resulting in increased production of cyclic guanosine monophosphate (cGMP) in target tissues, which mediates vasodilation. In HF, nesiritide reduces pulmonary capillary wedge pressure and systemic vascular resistance.

(4) Initial treatment involves a bolus dose of 2.0 mcg/kg followed by a continuous intravenous infusion of 0.01 mcg/kg/min to a maximum dose of 0.03 mcg/kg/min.

(5) Monitoring for hypotension, elevated serum creatinine, headache, nausea, and dizziness is the key to successful use. Concomitant use of ACEIs may increase the risk of symptomatic hypotension (systolic blood pressure < 90 mm Hg and syncope).

(6) Nesiritide has been shown to improve symptoms in the setting of acute HF, but the effect on morbidity and mortality has not yet been proven. At this point in time, owing to lack of pivotal studies demonstrating its benefit, nesiritide's use as intermittent or continuous outpatient treatment is not recommended.

c. **Nitrates.** Venous dilation by nitrates increases venous pooling, which decreases preload.

(1) Their arterial effects seem to result in decreased afterload with continued therapy.

(2) Nitrates are available in many forms and doses. Because individual reactions to these agents vary widely, dosages have to be adjusted; but, in general, they are higher for HF than for angina. *Table 34-5* provides examples of nitrate doses that have been used in HF.

d. **Hydralazine (Various).** This arteriole dilator decreases afterload and increases cardiac output in patients with HF. As mentioned next, it is also used in combination with nitrates in select patient populations with HF.

e. **Combination therapy.** Hydralazine has been used with isosorbide dinitrate (Isordil) to reduce afterload (or with nitroglycerin to reduce preload) for treating chronic HF.

(1) As mentioned previously, hydralazine received a class I recommendation with a level A level of evidence in the updated national guidelines, in combination with isosorbide dinitrate to standard medical (i.e., ACEIs, ARBs, β-adrenergic blockers) regimens, in order to improve outcomes in African Americans with NYHA III or IV HF.

(2) The combination has also received a class IIa recommendation with a level B level of evidence, for adding to patients with reduced LVEF who are already receiving ACEIs and β-adrenergic blockers for symptomatic HF and who have persistent symptoms.

| Table 34-5 | EXAMPLES OF NITRATES THAT HAVE BEEN USED IN HEART FAILURE |

Form of Nitrate	Typical Dose	Dosing Interval
Intravenous nitroglycerin (Various)	5–200 mcg/min	Continuous infusion
Nitroglycerin buccal tablets (Nitrostat®)	1–3 mg	4–6 hrs
Nitroglycerin capsules (sustained release) (Various)	6.5–19.5 mg	4–6 hrs
Nitroglycerin ointment (Nitro-Bid®)	1–3 inches	4–6 hrs
Sublingual nitroglycerin (Various)	0.4 mg	1–2 hrs
Oral isosorbide dinitrate (Various)	10–60 mg	4–6 hrs
Sublingual isosorbide dinitrate (Various)	5–10 mg	4 hrs

(3) The combination of these two agents—hydralazine and isosorbide dinitrate (BiDil®), 37.5 mg/20 mg tablets respectively, should not be used as initial therapy over ACEIs, ARBs, or β-adrenergic blockers but could be considered in patients who have persistent symptoms despite the use of these agents.

(4) Suggested dosing regimens include hydralazine (various) 50 to 100 mg four times daily and isosorbide dinitrate (Isordil Titradose®) 10 to 40 mg three times daily.

I. Digitalis glycosides

1. Digitalis, specifically digoxin (Lanoxin®), continues to play a role in the treatment of HF, but ongoing evaluations have altered its place in the long-term management of HF. In the most recent national guidelines provided, digoxin (Lanoxin®) received a class IIa recommendation with a level B level of evidence, as beneficial in patients with current or prior symptoms.

2. Digitalis also received a class IIb recommendation with a level C level of evidence for its lack of proven usefulness to minimize symptoms of HF in patients with HF and normal LVEF.

3. Digoxin (Lanoxin®) received a class IIa recommendation with a level A level of evidence to control the ventricular rate in HF patients with atrial fibrillation.

4. Therapeutic effects

   a. Positive inotropic effects were previously felt to provide most of the benefits through increased cardiac output, decreased cardiac filling pressure, decreased venous and capillary pressure, increased renal blood flow, and decreased heart size.

   b. Recent evidence suggests that digitalis acts by furthering the activation of neurohormonal systems rather than as a positive inotropic agent. This results in deactivation of renin–angiotensin–aldosterone compensation, which promotes diuresis, reduces fluid volume, decreases renal sodium reabsorption, and diminishes edema.

   c. Negative chronotropic effects occur from the effect of digitalis on the sinoatrial (SA) node when given in doses that produce high total body stores (e.g., 15 to 18 mcg/kg). This effect is likely to be beneficial to control the ventricular rate in HF patients with atrial fibrillation.

5. Choice of agent. All of the digitalis glycosides have similar properties; however, digoxin is the most commonly used preparation in the United States.

   a. Digoxin is available in tablet, injection, elixir, and capsule forms.

   b. Calculation of doses must factor in the differences in systemic availability among these forms. For example, digoxin solution in capsules is more bioavailable than digoxin tablets; therefore, 0.125-mg tablets are equivalent to 0.1-mg capsules. In the majority of patients, the dosage of digoxin should be the equivalent of 0.125 to 0.25 mg daily of the tablet formulation.

6. Dosage and administration. The range between therapeutic and toxic doses is extremely narrow. There is no magic threshold level for digoxin therapy, but serum concentrations of 0.8 to 1.0 ng/mL have been associated with therapeutic response and minimal toxicity.

7. Precautions and monitoring effects

   a. Decreased potassium levels favor digoxin binding to cardiac cells and increase its effect, thus increasing the likelihood of digitalis toxicity. This antagonism is particularly significant for the HF patient who is receiving a diuretic (many of which decrease potassium levels). Conversely, increased potassium levels decrease digoxin binding and decrease its effect. This is likely in patients taking potassium or an ACEI or ARB (which increase potassium reabsorption).

   b. Calcium ions act synergistically with digoxin, and increased levels increase the force of myocardial contraction. At excessive levels, arrhythmias and systolic standstill can develop.

   c. Magnesium levels are inversely related to digoxin activity. As magnesium levels decrease, the predisposition to toxicity increases and, within reason, vice versa.

   d. Serum digoxin levels

     (1) In cardiac glycoside therapy, the patient's clinical state is the most practical barometer of a successful regimen. However, should questions arise about compliance, absorption, or a drug–drug interaction, serum digoxin levels may be helpful.

     (2) After oral ingestion of digoxin, serum levels rise rapidly, then drop sharply as the drug enters the myocardium and other tissues. Therefore, a meaningful evaluation requires a determination of the relationship between serum digoxin levels and myocardial tissue levels.

     (3) The most meaningful results are obtained if serum samples are taken after steady state has been reached and 6 to 8 hrs after an oral dose (3 to 4 hrs after an intravenous dose).

e. **Renal function studies.** Because the kidney is the primary metabolic route for **digoxin**, renal function studies, such as serum creatinine levels, aid the evaluation of elimination kinetics for digoxin.

8. Digitalis toxicity is a fairly common occurrence because of the narrow therapeutic range and can be fatal in a significant percentage of patients experiencing a toxic reaction. Patients should be routinely monitored for drug–drug interactions that might exist for patients receiving digitalis therapy.
   a. **Signs of toxicity** include the following:
      (1) Anorexia, a common and early sign
      (2) Fatigue, headache, and malaise
      (3) Nausea and vomiting
      (4) Mental confusion and disorientation
      (5) Alterations in visual perception (e.g., blurring, yellowing, a halo effect)
      (6) Cardiac effects:
         (a) Premature ventricular contractions and ventricular tachycardia and fibrillation
         (b) SA and atrioventricular (AV) block
         (c) Atrial tachycardia with AV block
   b. **Treatment of toxicity**
      (1) Digitalis is discontinued immediately, as is any potassium-depleting diuretic.
      (2) If the patient is hypokalemic, potassium supplements are administered and serum levels are monitored to avoid hyperkalemia through overcompensation. However, potassium supplements are contraindicated in a patient with severe AV block.
      (3) Arrhythmias may be treated with lidocaine (Xylocaine®) (usually a 100-mg bolus, followed by infusion at 2 to 4 mg/min) or phenytoin (Dilantin®) (as a slow intravenous infusion of 25 to 50 mg/min, to a maximum of 1 g).
      (4) Cholestyramine (Questran®) has been used effectively in an acute digoxin overdose by binding to digitalis, and which may help prevent absorption and reabsorption of digitalis in the bile.
      (5) Patients with very high serum digoxin levels (such as those resulting from a suicidal overdose) may benefit from the use of purified digoxin-specific Fab fragment antibodies (DigiFab). One vial (40 mg) will bind 0.5 mg of digitalis. The dosage is calculated based on the estimated total body store of digitalis.

J. **Calcium-channel blockers**
   1. Owing to the lack of evidence supporting efficacy, calcium-channel blockers should not be used for the treatment of HF. Current guidelines provides a class III recommendation with a level C level of evidence, and states that "Calcium-channel blockers with negative inotropic effects may be harmful in asymptomatic patients with low LVEF and no symptoms of HF after an MI."

K. **Inotropic agents**
   1. Have been used in the emergency treatment of patients with HF. However, long-term oral therapy with these agents has not improved symptoms or clinical status and has been reported to increase mortality, especially in patients with advanced HF.
   2. The current national guidelines provide a class IIb recommendation with a level C level of evidence for the use of intravenous inotropic drugs, such as dopamine (Various), dobutamine (Various), or milrinone (Various), as reasonable treatments for patients presenting to the hospital with documented severe systolic dysfunction, low blood pressure, and evidence of low cardiac output, with or without congestion, in order to maintain system perfusion and preserve end-organ performance.
   3. The current national guidelines also provide a class III recommendation with a level B level of evidence for the use of parenteral inotropic agents in normotensive patients in the hospitalized setting, with acute decompensated HF without evidence of decreased organ perfusion.
   4. Current national guidelines provide a class IIb recommendation with a level C for the use of continuous intravenous infusions of positive inotropic agents for palliation of symptoms in patients with refractory end-stage HF—**stage D**.
   5. Current national guidelines provide a class III recommendation with a level A level of evidence and states that the "routine intermittent infusions of vasoactive and positive inotropic agents are not recommended for patients with refractory end-stage HF—**stage D**."
      a. Dopamine (Various) continuous intravenous infusions
         (1) **Low doses** of 2 to 5 mcg/kg/min stimulate specific dopamine receptors within the kidney to increase renal blood flow, and thus increase urine output.

(2) Moderate doses of 5 to 10 mcg/kg/min increase cardiac output (positive inotropic effect) in HF patients.

(3) High doses

(a) As doses are raised above 10 mcg/kg/min, α-adrenergic stimulation occurs peripherally, resulting in increased total peripheral resistance and pulmonary pressures.

(b) When the infusion exceeds 8 to 9 mcg/kg/min, the patient should be monitored for tachycardia. If the infusion is slowed or interrupted, the adverse effect should disappear because dopamine has a very short half-life in plasma.

b. Dobutamine (Various) continuous intravenous infusions

(1) Patients who are unresponsive to, or adversely affected by, dopamine may benefit from dobutamine in doses of 5 to 20 mcg/kg/min.

(2) Although dobutamine resembles dopamine chemically, its actions differ somewhat. For example, dobutamine does not directly affect renal receptors and, therefore, does not act as a renal vasodilator. It increases urinary output only through increased cardiac output.

(3) Serious arrhythmias are a potential occurrence, although less likely to occur than with dopamine. Slowing or interrupting the infusion usually reverses this effect, as it does for dopamine.

(4) Dobutamine and dopamine have been used together to treat cardiogenic shock, but similar use in HF has yet to be accepted.

c. Inamrinone (Various) continuous intravenous infusion is referred to as nonglycoside, nonsympathomimetic, inotropic agents.

(1) A bipyridine derivative, inamrinone has both a positive inotropic effect and a vasodilating effect.

(2) By inhibiting phosphodiesterase located specifically in the cardiac cells, it increases the amount of cyclic adenosine monophosphate (cAMP).

(3) Inamrinone has been used in patients with HF that have been refractory to treatment with other inotropic agents.

(4) Effective regimens have used loading intravenous infusions of 0.75 mg/kg over 2 to 3 mins followed by maintenance infusions of 5 to 10 mg/kg/min.

(5) Precautions and monitoring effects

(a) Inamrinone is unstable in dextrose solutions and should be added to saline solutions instead. Because of fluid balance concerns, this can be a potential problem in patients with HF.

(b) Because of the peripheral dilating properties, patients should be monitored for hypotension.

(c) Thrombocytopenia has occurred and is dose dependent and asymptomatic.

(d) Ventricular rates may increase in patients with atrial flutter or fibrillation.

d. Milrinone (Various) continuous intravenous infusion is similar to inamrinone. It possesses both inotropic and vasodilatory properties.

(1) This agent has been used as short-term management to treat patients with HF.

(2) Most milrinone patients in clinical trials have also been receiving digoxin and diuretics.

(3) Effective dosing regimens have used a loading dose of 50 mcg/kg administered slowly over 10 mins intravenously, followed by maintenance doses of 0.375 mcg/kg/min by continuous infusion, based on the clinical status of the patient.

(4) Precautions and monitoring effects

(a) Renal impairment significantly prolongs the elimination rate of milrinone, and infusions need to be reduced accordingly.

(b) Monitoring is necessary for the potential arrhythmias occurring in HF, which may be increased by drugs such as milrinone and other inotropic agents.

(c) Blood pressure and heart rate should be monitored when administering milrinone, owing to its vasodilatory effects and its potential to induce arrhythmias.

(d) Additional side effects include mild-to-moderate headache, tremor, and thrombocytopenia.

L. Patient education

1. Patients should be made aware of the importance of taking their medications exactly as prescribed and should be advised to watch for signs of toxicity.

2. Patients should be educated on the need for lifestyle modifications that will have a positive effect on reducing HF development and reducing HF symptoms, including daily weight monitoring,

fluid management, sodium restriction, early intervention if symptoms appear, compliance with the treatment plan, modification of alcohol intake, exercise, and stress reduction.

3. The patient should understand the need for regular checkups and be able to recognize symptoms that require immediate physician notification—for example, an unusually irregular pulse rate, palpitations, shortness of breath, swollen ankles, visual disturbances, or weight gain exceeding 3 to 5 lb in 1 week.

4. The patient needs to be educated about drugs such as calcium-channel blockers; NSAIDs, which may cause a problem in HF by retaining fluid; and sodium. In addition, the patient needs to be informed of the potential dangers of use of over-the-counter medications that might also predispose him or her to HF symptoms and loss of symptom control. A thorough review of all medications (both prescription and over the counter) should be carried out as frequently as possible to ensure compliance with the treatment regimen.

Study Questions

Directions for questions 1–8: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following combinations of drugs, when used together, particularly in black patients, has been shown to effectively reduce both preload and afterload?

   (A) Nitroglycerin (Nitrostat®) and isosorbide dinitrate (Isordil Titradose®)
   (B) Hydralazine (Various) and isosorbide dinitrate (Isordil Titradose®)
   (C) Diltiazem (Cardizem®) and verapamil (Calan®)
   (D) Prazosin (Minipress®) and angiotensin II (Various)
   (E) Hydralazine (Various) and methyldopa (Aldomet®)

2. When spironolactone (Aldactone®) is used in a patient with heart failure (HF), it works through what primary mechanism?

   (A) Positive inotropic effect
   (B) Positive chronotropic effect
   (C) Aldosterone antagonism
   (D) Negative inotropic effect
   (E) Angiotensin II blockade

For questions 3–4: A 60-year-old hypertensive woman is currently being treated with nitroglycerin, carvedilol (Coreg®), furosemide (Various), nifedipine (Procardia®), ramipril (Altace®), aspirin (Various), and digoxin (Lanoxin®). She is admitted with a diagnosis of stage C HF.

3. Which agent is most likely to be discontinued in this patient?

   (A) Nifedipine (Procardia®)
   (B) Carvedilol (Coreg®)
   (C) Aspirin (Various)
   (D) Digoxin (Lanoxin®)
   (E) Furosemide (Lasix®)

4. Which of the following *does not* represent the goals of therapy for this patient?

   (A) Treat underlying causes such as hypertension, cigarette smoking, lipid disorders
   (B) Discourage the use of alcohol intake, illicit drug use, and dietary salt intake
   (C) Consideration for drastic measures (i.e., heart transplant, etc.)
   (D) Initiate therapy with diuretics for fluid retention
   (E) Potential addition of angiotensin-converting enzyme inhibitor (ACEIs) and β-adrenergic blockers

5. Because of proven beneficial effects on cardiac remodeling, a particular group of agents is now indicated as first-line therapy in a wide array of HF patients. Which of the following is a representative of this group of drugs?

   (A) Hydrochlorothiazide (Microzide®)
   (B) Ramipril (Altace®)
   (C) Losartan (Cozaar®)
   (D) Carvedilol (Atacand®)
   (E) Furosemide (Lasix®)

6. Which of the following statements is *not* correct as it relates to the current status of HF in the United States?

   (A) HF is the one cardiovascular disorder that is increasing in incidence and prevalence.
   (B) Medication costs for treating HF in the United States approaches $38 billion.
   (C) Patients with advanced disease have a 30% to 40% risk of death annually.
   (D) Approximately 5 million people in the United States currently suffer from HF.
   (E) Approximately 500,000 people each year are diagnosed with HF in the United States.

7. If treating a patient with HF, which of the following dosages of dopamine would be used to elicit its positive inotropic effects?

    (A) 2 mcg/kg/min
    (B) 5 to 10 mcg/kg/min
    (C) 10 to 20 mcg/kg/min
    (D) 40 mcg/kg/min
    (E) 40 mg/kg/min

8. The use of ACEIs in HF centers around what pharmacologic effect?

    (A) Direct reduction in renin levels with a resultant decrease in angiotensin II and aldosterone levels
    (B) Indirect reduction in angiotensin II and aldosterone levels owing to inhibition of angiotensin-converting enzyme
    (C) Direct reduction in aldosterone secretion and angiotensin I production by inhibiting angiotensin-converting enzyme
    (D) Increase in afterload owing to an indirect decrease in angiotensin II as well as a decrease in preload owing to an indirect reduction in aldosterone secretion
    (E) Inhibition of the angiotensin II receptor, which results in reduced angiotensin II levels and reduced secretion of aldosterone

Directions for questions 9–10: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E.**

    A   if **I only** is correct
    B   if **III only** is correct
    C   if **I and II** are correct
    D   if **II and III** are correct
    E   if **I, II, and III** are correct

9. Correct statements about dobutamine include which of the following?

    I. Doses of 5 to 20 mcg/kg/min have been associated with a positive inotropic effect in treating the patient with HF.
    II. Patients receiving dobutamine should be monitored for increases in peripheral vascular resistance.
    III. Dobutamine is considered a nonglycoside, nonsympathomimetic, positive inotropic agent.

10. Which statements accurately describe HF classification stage A?

    I. Patients have a high risk for HF without structural heart disease or symptoms.
    II. Patients need to receive ACEIs or angiotensin II receptor blockers (ARBs).
    III. Patients should be treated for any underlying causes that would be responsible for causing HF.

11. A recently released drug for use in patients with HF has unfortunately achieved recommendations stated to be class III with a level C level of evidence supporting its use for a special patient population. Which of the following statements adequately summarizes the outcomes associated with such recommendations based on the cardiology group models utilized?

    I. Risk of harm is greater than the potential benefit.
    II. Clinical trials have been limited to small populations.
    III. Literature demonstrating the evidence is derived from opinion and case reports.

Answers and Explanations

1. The answer is B *[see IV.C.2.c]*.
The venous dilating properties of isosorbide dinitrate (preload) in conjunction with the arteriolar dilating effects of hydralazine (afterload) make this combination effective in reducing both preload and afterload. The most recent national guidelines suggest that the combination of the vasodilators hydralazine and isosorbide dinitrate received a level I, class A recommendation for HF therapy, particularly in black patients with NYHA III or IV HF.

2. The answer is C *[see IV.G.7.c]*.
Spironolactone was the first aldosterone antagonist available for clinical use in the United States. In the completed RALES trial, spironolactone, given in 12.5- to 25-mg daily doses to HF patients with class IV symptoms who were taking ACEIs, reduced the risk of death and hospitalization. It is a weak diuretic but also works as a direct antagonist to the actions of aldosterone, which has demonstrated benefit in HF patients with moderate to severe symptoms.

3. The answer is A *[see IV.J.1 and IV.L.4]*.

Due to the potential to produce negative inotropic effects, calcium-channel blockers, such as nifedipine, have been identified as one of three groups of drugs to avoid in most HF patients. Besides calcium-channel blockers, antiarrhythmics, and NSAIDs should be avoided in most HF patients owing to their ability to induce HF symptoms.

4. The answer is D *[see Table 34-3]*.

The updated classification system was introduced with the newly established guidelines to demonstrate the progressive nature of HF and to provide a continuum of goals and treatment options as it progresses. Stage C represents the first stage in which the patient presents with structural heart disease, as well as current or prior symptoms of HF. Initial goals for earlier stages remain important goals for stage C, but the "restriction in dietary salt" is added to all of the previous goals. The use of diuretics for treatment of fluid retention as well as potential introduction of ACEIs and/or β-adrenergic blockers are also included within stage C. Stage D is the last of the four stages; and it is in this stage when more drastic measures such as "end-of-life planning," "cardiac transplantation," etc., are included within the recent guidelines.

5. The answer is B *[see Table 34-3 and IV.D.8]*.

ACEIs such as ramipril have shown an ability to have a positive effect on cardiac remodeling, which is believed to be the underlying change that results in the increased stresses and pathologic events that eventually cause the symptoms associated with HF. Recent studies have shown the positive benefits for each of the ACEIs used in HF patients, and today they represent a very critical component in the therapy for HF patients.

6. The answer is B *[see I.B–D]*.

The actual costs involved in the treatment of HF, including medical care, home health care, medication costs, and hospitalization costs, reported in 2005 were approximately $27.9 billion. Medication costs alone are a bit less but are still reported to be more than $2.9 billion annually.

7. The answer is B *[see IV.K.5.a.(1)–(3)]*.

Dopamine has shown great versatility in its effects. At doses of 2 to 5 mcg/kg/min, it increases renal blood flow through its dopaminergic effects through dopaminergic receptors. At doses of 5 to 10 mcg/kg/min, it increases cardiac output through its β-adrenergic stimulating effect. At doses of 10 to 20 mcg/kg/min, it increases peripheral vascular resistance through its α-adrenergic stimulating effects. There is no specific cutoff for any of these effects, so close titration is required to provide for individual response.

8. The answer is B *[see IV.D.4–5; Figure 34-2]*.

By directly inhibiting the angiotensin-converting enzyme, production of angiotensin II (potent vasoconstrictor) is reduced, as is angiotensin II-mediated secretion of aldosterone (sodium and water retention) from the adrenal gland. These effects are believed to have a beneficial effect on the prevention of cardiac remodeling, which has been shown to have a detrimental effect on cardiac function.

9. The answer is A (I) *[see Table 34-3 and IV.K.5.b]*.

Dobutamine in doses of 5 to 20 mcg/kg/min is an inotropic agent that is useful in the treatment of HF. Dobutamine does not have the versatility that dopamine offers, lacking comparable effects on renal blood flow and peripheral vascular resistance. Rather, dobutamine has a peripheral dilating effect that offers a benefit to patients who have reduced cardiac output due to elevated peripheral resistance.

10. The answer is E (I, II, III) *[see Table 34-3]*.

The recent guidelines for the diagnosis and management of chronic HF recognize four stages in the progression of HF, and each stage is associated with clinical findings, goals of treatment, and medications that should be considered. Stage A represents patients who are merely at risk for HF owing to underlying risk factors, such as hypertension, hyperlipidemia, and smoking. ACEIs are recognized for their beneficial effects in cardiac remodeling and have been recommended as first-line therapy for select patients with stage A HF.

11. The answer is E (I, II, and III) *[see I.G.4.c]*.

Two sets of criteria have been used by the cardiology associations to provide a clear recommendation based on the clinical effects associated with specific interventions: The first involves a risk-to-benefit assessment; and the second is a summary of populations studied, which results in the findings on any given intervention evaluated. A class III recommendation demonstrates that the risk is greater than the benefit; and a level C of evidence would refer to case studies, expert opinion, based on very limited populations of patients studied. This would not be a treatment intervention that would be widely accepted based on peer-reviewed evidence.

35

Thromboembolic Diseases

JAMES B. GROCE III

I. DEFINITION. Venous thromboembolic disease (VTED) occurs when one or more of the elements of **Virchow's triad** are present, resulting in deep venous thrombosis (DVT) and/or pulmonary embolism (PE).

A. Vascular injury

B. Venous stasis

C. Hypercoagulable state (i.e., decreased protein C, protein S, or antithrombin)

II. INCIDENCE. It is estimated that the annual incidence of venous thromboembolism (VTE) events exceeds 600,000, and the number of VTE-associated deaths is 296,370 annually.

III. RISK FACTORS FOR VTE

A. **Patient specific and those associated with medical illness and surgical procedures**

1. Surgery
2. Trauma (major or lower extremity)
3. Immobility or paresis
4. Malignancy
5. Cancer therapy (hormonal, chemotherapy, or radiotherapy)
6. Previous VTE
7. Increasing age ($>$ 40 years of age)
8. Pregnancy and the postpartum period
9. Estrogen-containing oral contraceptives or hormone-replacement therapy
10. Selective estrogen-receptor modulators
11. Acute medical illness
12. Heart or respiratory failure
13. Inflammatory bowel disease
14. Nephrotic syndrome
15. Myeloproliferative disorders (i.e., diseases in which malignant (cancer) bone marrow cells multiply and spread to the blood).
16. Paroxysmal nocturnal hemoglobinuria
17. Obesity
18. Smoking
19. Varicose veins
20. Central venous catheterization
21. Inherited or acquired thrombophilia (e.g., deficiency of antithrombin, protein C, or protein S; activated protein C resistance; antiphospholipid antibody; lupus anticoagulant)

IV. PREVENTION AND TREATMENT

A. **Nonpharmacologic prevention.** Mechanical methods of prophylaxis are recommended, primarily in patients who are at high risk of bleeding, and may include **external pneumatic compression**,

659

graduated compression stockings, or **venous foot pumps**. These devices **increase venous outflow and/or reduce stasis** within the leg veins.

B. **Pharmacologic prevention.** VTED can be prevented by counteracting increased blood coagulability with **unfractionated heparin (UFH)** (see V.A); **oral anticoagulant therapy with a vitamin K antagonist, such as warfarin** (see V.B); **low-molecular-weight heparin (LMWH)** (see V.C); a **synthetic pentasaccharide** (see V.D); or the new oral agents (factor Xa inhibitor [see V.E] and factor IIa inhibitor [see V.F]).

V. PHARMACOLOGIC AGENTS.

New recommendations for treatment of VTED have been promulgated that suggest a hierarchical approach to selection of pharmacologic agents for managing VTED. These recommendations are listed in *Table 35-1* and each of the recommended pharmacologic agents is discussed in the following sections:

A. **Unfractionated heparin**
1. **Indications.** Patients with proven VTED may receive concomitant UFH for acute treatment and warfarin therapy acutely, followed by warfarin therapy for continued prevention of recurrence of VTED (*Table 35.1*), unless contraindications to warfarin (e.g., pregnancy) are present.
2. **Mechanism of action.** The major mechanism by which heparin blocks coagulation is by catalyzing the inhibition of thrombin. UFH acts as an anticoagulant by catalyzing the **inactivation of thrombin (factor IIa), activated factor X (factor Xa),** and **activated factor IX (factor IXa) by antithrombin.**

Table 35-1   GUIDELINES FOR INITIAL TREATMENT OF VENOUS THROMBOEMBOLIC DISEASE

Clinical situation	Recommended treatment
Confirmed acute DVT of the leg High suspicion of DVT of the leg	SC LMWH, IV UFH, or SC UFH anticoagulants while awaiting the outcome of diagnostic tests

Selection	Treatment options
IV UFH	Continuous infusion
	Using weight-based dosing protocol, adjust dosage to prolong aPTT to a range that corresponds to a plasma heparin level of 0.3–0.7 units/mL antifactor Xa activity by amidolytic antifactor Xa assay
	If therapeutic levels of aPTT are not reached despite large daily doses of UFH, measure antifactor Xa levels for dosage guidance
SC UFH	An alternative to IV UFH
	Initial dose 35,000 units/24 hrs, then maintain aPTT within therapeutic range
SC LMWH	Recommended initial treatment once or twice a day over UFH (as outpatient therapy if possible; as inpatient therapy if necessary)
	Routine monitoring with antifactor Xa levels not recommended

Further recommendations

Once UFH therapy commences, check aPTT or antifactor Xa heparin level at 6 hrs for UFH and adjust to maintain aPTT corresponding to therapeutic antifactor Xa heparin level of 0.3–0.7 units/mL

Antifactor Xa heparin levels not recommended for LMWH therapy

Platelet count should be checked daily while on UFH or LMWM

Warfarin therapy should be commenced on day 1; adjust daily dosing based on PT/INR

Stop unfractionated heparin or LMWH after 5 days overlap with warfarin (minimally), when INR is stable and > 2.0

Anticoagulate (warfarin) for 6–12 months (depending on patient and disease state)

aPTT, activated partial thromboplastin time; *DVT*, deep venous thrombosis; *INR*, international normalized ratio; *IV*, intravenous; *LMWH*, low-molecular-weight heparin; *PT*, prothrombin time; *SC*, subcutaneous; *UFH*, unfractionated heparin.
Used with permission: Cone Health Clinical References-Anticoagulation Protocol.

3. **Pharmacokinetics.** The mechanisms of heparin clearance are complex.
   a. Heparin binds to a number of plasma proteins other than antithrombin, which competes with antithrombin heparin binding.
   b. UFH is cleared by rapid-phase (cellular) elimination followed by a more gradual (renal) clearance, which can best be explained by a **combination of saturable and nonsaturable first-order kinetic models**.
   c. When administered in fixed doses, the anticoagulant response to UFH varies among patients and within the same patient (i.e., interpatient and intrapatient variability). This variability is caused by differences in patients' plasma concentrations of heparin-neutralizing proteins and rates of heparin clearance.
4. **Administration and dosage**
   a. UFH's therapeutic effect is hastened by administration of a **loading dose**, which may be **empirically selected** (e.g., 5000-units bolus given intravenously) or individualized by the patient's **dosing weight**.
      (1) The weight-based approach has resulted in the use of loading doses varying from 70 to 100 units/kg.
      (2) In some instances, the indication for which heparin therapy is being initiated is to be considered, with 80 units/kg being used for all thrombotic indications other than suspected or proved PE, for which up to 100 units/kg may be used.
   b. **Variable approaches** to continuous dosing have been employed.
      (1) **Empiric dosing of 1000 units/hr** may be used but may result in subtherapeutic or supratherapeutic outcomes (i.e., an activated partial thromboplastin time [aPTT] below or above the targeted range).
      (2) Another approach to continuous dosing includes commencing with a fixed dose (other than the empiric dose of 1000 units/hr). One such approach may see an initial loading dose followed by 32,000 units/24 hrs by continuous infusion.
      (3) Yet another approach validated in the medical and pharmaceutical literature uses a **weight-based dosing nomogram** for commencing UFH therapy that varies between 15 and 25 units/kg/hr.
         (a) Lower doses are used initially for most thrombotic indications other than PE.
         (b) PE requires more aggressive therapy (i.e., up to 25 units/kg/hr) based on the consideration that the clearance of heparin may be increased, thus necessitating an increased dose.
      (4) **Initial heparin weight-based dosing nomograms and subsequent adjustment protocols** have been developed to assist the initial weight-based dosing efforts. Such protocols should be developed for a specific aPTT reagent (*Tables 35-2* and *35-3*).
5. **Monitoring the effects of UFH.** The anticoagulant effects of UFH are usually monitored by the **aPTT**. The aPTT should be **obtained at baseline** before commencing therapy and then **monitored 6 hrs** after commencing heparin therapy. Subsequent dosing adjustments are based on the results of this and additional aPTTs.
   a. The aPTT ratio used to determine therapeutic effect is measured by dividing the observed aPTT by the mean of the normal laboratory control aPTT.

| Table 35-2 | WEIGHT-BASED NOMOGRAM |

aPTT	Dose
Initial dose	80 units/kg bolus, then 18 units/kg/hr
< 35 secs	80 units/kg bolus, then 4 units/kg/hr
35–45 secs	40 units/kg bolus, then 2 units/kg/hr
46–70 secs[a]	No change
71–90 secs	Decrease infusion rate by 2 units/kg/hr
90 secs	Hold infusion 1 hr, then decrease infusion rate by 3 units/kg/hr

[a]This therapeutic range corresponds to antifactor Xa activity of 0.3–0.7 units/mL. The therapeutic range at any institution should be established by correlation with antifactor Xa levels in the range of 0.3–0.7 units/mL.
Used with permission: Cone Health Clinical References-Anticoagulation Protocol.

Table 35-3 HEPARIN DOSAGE ADJUSTMENT PROTOCOL[a]

Patient's aPTT (sec)[b]	Repeat Bolus Dose (units)	Stop Infusion (min)	Change Rate of Infusion (mL/hr)[c] [units/24 hrs]	Timing of Next aPPT
< 50	5000	0	+3 [2880]	6 hrs
50–59	0	0	+3 [2880]	6 hrs
60–85[d]	0	0	0	Next morning
86–95	0	0	−2 [−1920]	Next morning
96–120	0	30	−2 [−1920]	6 hrs
> 120	0	60	−4 [−3840]	6 hrs

[a]Starting dose of 5000 units intravenous IV bolus followed by 32,000 units/24 hrs as a continuous infusion. First aPTT performed 6 hrs after the bolus injection; dosage adjustments are made according to protocol and the aPTT is repeated as indicated in the far-right column.
[b]The normal range for aPTT with Dade Actin FS reagent is 27–35 secs; the range may vary, depending on the sensitivity of the reagent.
[c]Concentration of heparin equal to 40 units/mL.
[d]A therapeutic range of 60–85 secs is equivalent to a heparin level of 0.2–0.4 units/mL by whole blood protamine titration or 0.3–0.7 units/mL as a plasma antifactor Xa level. The therapeutic range varies with the responsiveness of the aPTT reagent to heparin.
aPTT, activated partial thromboplastin time.
Used with permission: Cone Health Clinical References-Anticoagulation Protocol.

    b. Traditionally, it was taught that for many aPTT reagents, a therapeutic effect was achieved with an **aPTT ratio of 1.5 to 2.5**.

    c. However, because aPTT reagents may vary in their sensitivity, it is **inappropriate to use the same aPTT ratio (i.e., 1.5 to 2.5) for all reagents**. The therapeutic range for each aPTT reagent should be calibrated to be equivalent to a heparin level of 0.2 to 0.4 units/mL by whole blood (protamine titration) or to an **antifactor Xa level (i.e., plasma heparin level) of 0.3 to 0.7 units/mL collected at the sixth hour for UFH.**

B. Oral anticoagulants—warfarin

  1. Indications

    a. Warfarin is proven effective in the

      (1) primary and secondary prevention of VTED;

      (2) prevention of systemic arterial embolism in patients with tissue and mechanical prosthetic heart valves or atrial fibrillation;

      (3) prevention of acute myocardial infarction (MI) in patients with peripheral arterial disease; and

      (4) prevention of stroke, recurrent infarction, and death in patients with acute MI.

    b. Warfarin may also be used in patients with valvular heart disease to prevent systemic arterial embolism, although its effectiveness has never been demonstrated by a randomized clinical trial.

  2. Mechanism of action

    a. Oral anticoagulants (e.g., warfarin) are vitamin K antagonists, producing their anticoagulant effect by **interfering with the cyclic interconversion of vitamin K and its 2-, 3-epoxide (vitamin K epoxide).**

    b. Inhibition of this process leads to the depletion of vitamin K_{H2} and **results in the production of hemostatically defective**, **vitamin K–dependent coagulant proteins or clotting factors (prothrombin or factors II**, **VII, IX, and X).**

    c. These vitamin K–dependent coagulant proteins or clotting factors (factors VII, IX, X, and II, respectively) decline over 6 to 96 hrs.

  3. Pharmacokinetics

    a. Warfarin is a **racemic mixture** of roughly equal amounts of two optically active isomers: the **R and S forms**.

    b. Warfarin is rapidly absorbed from the gastrointestinal tract and reaches maximal blood concentrations in healthy volunteers in 90 mins.

    c. Dose response to warfarin is influenced by

      (1) Pharmacokinetic factors (i.e., differences in absorption and metabolic clearance)

      (2) Pharmacodynamic factors (i.e., differences in the hemostatic response to given concentrations of warfarin)

      (3) Technical factors—for example, inaccuracies in prothrombin time (PT) and international normalized ratio (INR) testing and reporting

Table 35-4	FACTORS THAT MAY POTENTIATE OR INHIBIT WARFARIN EFFECTS	

Factor	Potentiate Anticoagulant Effect	Inhibit Anticoagulant Effect
Drugs	Phenylbutazone	Cholestyramine
	Metronidazole	Barbiturates
	Sulfinpyrazone	Rifampin
	Trimethoprim-sulfamethoxazole	Griseofulvin
	Disulfiram	Carbamazepine
	Amiodarone	
	Erythromycin	
	Anabolic steroids	
	Clofibrate	
	Cimetidine	
	Omeprazole	
	Thyroxine	
	Ketoconazole	
	Isoniazid	
	Fluconazole	
	Piroxicam	
	Tamoxifen	
	Quinidine	
	Vitamin E (large doses)	
	Phenytoin	
	Penicillin	
Other	Low vitamin K intake	High vitamin K intake
	Reduced vitamin K absorption	Alcohol (acute use)
	Liver disease	
	Hypermetabolic states (e.g., thyrotoxicosis)	
	Alcohol (chronic use)	

Used with permission: Cone Health Clinical References-Anticoagulation Protocol.

    (4) Patient-specific factors—for example, diet (increased intake of green, leafy vegetables), poor patient compliance (missed doses, self-medication, alcohol consumption) and poor communication between patient and physician (undisclosed use of drugs that may interact with warfarin) (*Table 35-4*).

  4. Administration and dosage

    a. Warfarin, a coumarin compound, is the most widely used oral anticoagulant in North America. Although it is primarily **administered orally**, an injectable preparation is available in the United States.

    b. Commence oral anticoagulant therapy in the inpatient setting with the **anticipated daily maintenance dose of warfarin**, which can be variable.

    c. The initial dose of warfarin therapy can be flexible (*Table 35-5*).

      (1) Patient-specific parameters used to determine the initial dose of warfarin include the patient's weight (e.g., obesity, concurrent use of interacting drugs known to inhibit the anticoagulant effect of warfarin and the desired rapid anticoagulant effect).

      (2) Based on these patient-specific parameters, some clinicians may use a larger initial dose of warfarin (e.g., 7.5 to 10 mg), which should not be misconstrued as a loading dose. For patients sufficiently healthy to be treated as outpatients—specific to VTE treatment—the suggestion is to commence warfarin therapy with 10 mg daily for the first 2 days, followed by dosing based upon the INR response.

    d. The initial dose of warfarin should be **overlapped with UFH**, **LMWH**, **or a pentasaccharide** for a minimum of **5** days for treating established embolic disease to 7 days (*Table 35-1*).

Table 35-5	PRACTICAL ORAL ANTICOAGULATION DOSING

Day	Rapid Anticoagulation	Anticoagulation[a]
1	5–10 mg	5 mg
2	5–10 mg	5 mg
3	2.5–7.5 mg (adjust based on INR)[b]	5 mg (adjust based on INR)[b]

[a]Rapid anticoagulation is not required or there is a risk of bleeding.
[b]Adjust dosage based on INR until the INR is stable and therapeutic.
INR, international normalized ratio.
Used with permission: Cone Health Clinical References-Anticoagulation Protocol.

    e. The **duration of warfarin therapy** depends on each patient's indication(s) for use (*Table 35-6*).
    f. **Reversal of warfarin effects** may be necessary owing to an elevated INR or bleeding complications associated with oral anticoagulant therapy (*Table 35-7*).
  5. **Monitoring warfarin therapy.** PT and INR monitoring are usually to be performed at baseline and daily when commencing warfarin in the inpatient acute care setting. Commencing warfarin in the outpatient setting after establishing a baseline INR may see the subsequent INR determinations being performed based upon well-established protocols specific to the outpatient setting. In either setting (inpatient or outpatient), INRs will be performed daily on commencing oral anticoagulant therapy (e.g., warfarin), until such time that the INR has been found to be therapeutic.
    a. Laboratory monitoring is performed by measuring the **PT** for calculation of the INR.
      (1) The PT is **responsive to suppression of three** of the four vitamin K–dependent procoagulant **clotting factors** (**prothrombin** or **factors II**, **VII**, and **X**).
      (2) The common commercial PT reagents vary markedly in their responsiveness to coumarin-induced reduction in clotting factors; therefore, PT results reported using different reagents are not interchangeable among laboratories.
    b. The problem of variability in responsiveness of PT reagents has been overcome by the introduction of a standardized test known as the **INR**.
      (1) The INR is equal to:

$$INR = \left(\frac{patient\ PT}{mean\ laboratory\ control\ PT} \right)^{ISI}$$

      where ISI (international sensitivity index) is a measure of the responsiveness of a given thromboplastin to reduction of the vitamin K–dependent coagulation factors. The **lower the ISI**, the **more responsive the reagent** and the closer the derived INR will be to the observed PT ratio.
      (2) Current recommendations suggest two levels of therapeutic intensity: a less-intense range corresponding to an INR of 2.0 to 3.0, and a more-intense range corresponding to an INR of 2.5 to 3.5. The range corresponds to the indication (*Table 35-8*).

Table 35-6	DURATION OF WARFARIN THERAPY[a]

Duration	Indications
3–6 months	First event with reversible[b] or time-limited risk factor
≥ 6 months	Idiopathic venous thromboembolism, first event
12 months to lifetime	First event[c] with cancer (until resolved), anticardiolipin antibody, antithrombin deficiency Recurrent event, idiopathic or with thrombophilia

[a]See Table 43-4 for factors that may influence warfarin effects. All recommendations are subject to modification by individual characteristics, including patient preference, age, comorbidity, and likelihood of recurrence.
[b]Reversible or time-limited risk factors: surgery, trauma, immobilization, estrogen use.
[c]Proper duration of therapy is unclear in first event with homozygous factor V Leiden, homocystinemia, deficiency of protein C or S or multiple thrombophilias, and in recurrent events with reversible risk factors.
Used with permission: Cone Health Clinical References-Anticoagulation Protocol.

Table 35-7 GUIDELINES FOR REVERSAL OF WARFARIN EFFECTS

Clinical Situation	Guidelines
INR > therapeutic range but < 5.0; no clinically significant bleeding, rapid reversal not indicated for reasons of surgical intervention	
INR significantly above therapeutic range	Lower the dose or omit the next dose; resume warfarin therapy at a lower dose when the INR approaches desired range.
INR minimally above therapeutic range	Dose reduction may not be necessary.
INR > 5.0 but < 9.0; no clinically significant bleeding	
No additional risk factors for bleeding	Omit the next dose or two of warfarin; monitor INR more frequently; resume warfarin therapy at a lower dose when the INR is in therapeutic range.
Increased risk of bleeding	Omit the next dose of warfarin; give vitamin K_1 (1.0–2.5 mg orally).
More rapid reversal needed before urgent surgery or dental extraction	Give vitamin K_1 (2–4 mg orally); closely monitor INR; repeat dose of vitamin K_1 if INR not substantially reduced by 24–48 hrs.
INR > 9.0; no clinically significant bleeding	Give vitamin K_1 (3–5 mg orally); closely monitor INR; repeat dose of vitamin K_1 if INR not substantially reduced by 24–48 hrs.
INR > 20.0; serious bleeding, major warfarin overdose requiring very rapid reversal of anticoagulant effect	Give vitamin K_1 (10 mg by slow intravenous infusion) with fresh frozen plasma transfusion or prothrombin complex concentrate, depending on urgency; vitamin K_1 injections may be needed every 12 hrs.
Life-threatening bleeding, serious warfarin overdose	Give prothrombin complex concentrate with vitamin K_1 (10 mg by slow intravenous infusion); repeat if necessary, depending on INR.
Continuing warfarin therapy indicated after high doses of vitamin K_1	Give heparin until the effects of vitamin K_1 have been reversed and patient is responsive to warfarin.

INR, international normalized ratio.
Used with permission: Cone Health Clinical References-Anticoagulation Protocol.

(3) Once the desired therapeutic INR has been achieved for 2 consecutive days (e.g., for concomitant heparin plus warfarin overlap therapy), follow-up INR monitoring can be performed according to the following protocol:
   (a) Week 1: monitor INR two or three times
   (b) Week 2: monitor INR two times
   (c) Weeks 3 to 6: monitor INR once a week

Table 35-8 RECOMMENDED THERAPEUTIC GOAL AND RANGE FOR ORAL ANTICOAGULANT THERAPY

Indication	INR Goal	INR Range
Prophylaxis of venous thrombosis (high-risk surgery)	2.5	2.0–3.0
Treatment of venous thrombosis	2.5	2.0–3.0
Treatment of pulmonary embolism	2.5	2.0–3.0
Prevention of systemic embolism	2.5	2.0–3.0
Tissue heart valves	2.5	2.0–3.0
Anterior myocardial infarction (to prevent systemic embolism)	2.5	2.0–3.0
Anterior myocardial infarction (to prevent recurrent infarction)	3.0	2.5–3.5
Valvular heart disease	2.5	2.0–3.0
Atrial fibrillation	2.5	2.0–3.0
Mechanical prosthetic valves (high risk)	3.0	2.5–3.5

INR, international normalized ratio.
Used with permission: Cone Health Clinical References-Anticoagulation Protocol.

(d) Weeks 7 to 14: monitor INR once every 2 weeks

(e) Week 15 to end of therapy: monitor INR once every 4 weeks (if INR dose responsiveness remains stable; if dose adjustment is necessary, a more frequent monitoring schedule is employed until stable dose responsiveness is achieved)

c. Upon commencing oral anticoagulant therapy, **prolongation of the PT/INR** does not occur until depletion of the vitamin K–dependent procoagulant clotting factors occurs. This delay is **variable over 2 to 4 days**. During this delay, if active venous thrombosis is present, either UFH, LMWH, or a synthetic pentasaccharide is concomitantly commenced to adequately anticoagulate the patient while awaiting the therapeutic effect of warfarin.

C. **Low-molecular-weight heparin**

1. **Indications**

a. LMWH indications vary by manufacturer.

b. Each of the LMWHs has been evaluated in a large number of randomized clinical trials and has been proven to be safe and efficacious for **the prevention and treatment of VTE**.

c. To date, different LMWHs have been evaluated for their role in

(1) prevention of venous thrombosis,

(2) treatment of VTED, and

(3) management of unstable angina pectoris/non–Q-wave MI.

2. **Chemistry.** LMWHs are fragments of standard commercial-grade heparin produced by either chemical or enzymatic depolymerization. LMWHs are approximately one-third the size of heparin. Like **heparin**, which has a **mean molecular weight of 15,000 Da** (range 3000 to 30,000 Da), **LMWHs** are heterogeneous in size with a **mean molecular weight of 4000 to 5000 Da** (range 1000 to 10,000 Da).

3. Mechanism of action

a. LMWHs achieve their **major anticoagulant effect by binding to antithrombin** through a unique pentasaccharide sequence that enhances the ability of antithrombin **to inactivate factor IIa (thrombin) and factor Xa**.

(1) Heparin and **LMWHs catalyze the inactivation of factor IIa (thrombin) by binding to antithrombin through the unique pentasaccharide sequence and to thrombin to form a ternary complex**. A minimum chain length of 18 saccharides (including the pentasaccharide sequence) is required for ternary complex formation.

(a) Virtually, all heparin molecules contain at least 18 saccharide units.

(b) Only 20% to 50% of the different LMWHs contain fragments with 18 or more saccharide units.

(c) Therefore, **compared with heparin, which has an anti-factor Xa to anti-factor IIa binding affinity ratio of approximately 1:1**, the various commercial **LMWHs have an antifactor Xa to antifactor IIa binding affinity ratio varying from 2:1 up to 4:1**, depending on their molecular size distribution (*Table 35-9*).

(2) In contrast, inactivation of factor Xa by antithrombin does not require binding of the heparin molecules to the clotting enzyme. Therefore, inactivation of factor Xa is achieved by small molecular weight heparin fragments provided that they contain the high-affinity pentasaccharide.

Table 35-9 PHARMACOKINETIC AND PHARMACODYNAMIC PARAMETERS OF DIFFERENT LOW-MOLECULAR-WEIGHT HEPARINS (LMWHS)

LMWH	Brand Name	Average Molecular Weight	Bioavailability	Half-Life	Xa:IIa Binding-Affinity Ratio
Dalteparin	Fragmin	6000 Da	87%	3–5 hrs	2.7:1
Enoxaparin	Lovenox	4500 Da	92%	4.5 hrs	3.8:1
Tinzaparin	Innohep	6500 Da	87%	3.9 hrs	2.8:1

    b. The **antithrombotic and hemorrhagic effects** of heparin have been compared with LMWHs in a variety of **experimental animal models**.

        (1) When compared on a gravimetric basis, **LMWHs are said to cause decreased** potential for **hemorrhagic episodes**.

        (2) These differences in the relative antithrombotic to hemorrhagic ratios among these polysaccharides could be explained by the observation that **LMWHs have less inhibitory effects on platelet function** and vascular permeability.

  4. Pharmacokinetics. The plasma recoveries and pharmacokinetics of LMWHs differ from heparin because of differences in the binding properties of the two sulfated polysaccharides to plasma proteins and endothelial cells.

    a. LMWHs bind much less avidly to heparin-binding proteins than heparin; a property that contributes to the superior bioavailability of LMWHs at low doses and their more predictable anticoagulation effect.

    b. LMWHs do not bind to endothelial cells in culture; a property that could account for their longer plasma half-life and their dose-independent clearance. Principally, the renal route clears LMWHs; therefore, the biologic half-life of LMWHs is increased in patients with renal failure.

  5. Administration and dosage

    a. Dosing of LMWHs is **disease state** and **product specific**; different doses are administered based on the indication for use and the manufacturer of the specific LMWH. *Table 35-10* shows manufacturer's suggested, U.S. Food and Drug Administration (FDA) approved dosing for specific indications.

D. Synthetic pentasaccharide

  1. Indications

    a. Synthetic pentasaccharide (fondaparinux [Arixtra]) is indicated for

        (1) thromboprophylaxis against DVT/PE after

            (a) hip fracture surgery

            (b) hip fracture surgery, extended prophylaxis

            (c) knee replacement surgery

            (d) hip replacement surgery

            (e) abdominal surgery

        (2) treatment of

            (a) acute DVT

            (b) acute PE

  2. Chemistry. Synthetic pentasaccharide is a selective **factor Xa inhibitor**. The molecular weight of the synthetic pentasaccharide product is 1728 Da.

  3. Mechanism of action

    a. The antithrombotic activity of fondaparinux is the result of antithrombin-mediated selective inhibition of factor Xa. Neutralization of factor Xa interrupts the blood coagulation cascade and thus inhibits thrombin formation and thrombus development.

    b. Fondaparinux does not inactivate thrombin (activated factor II) and has no known effect on platelet function.

  4. Pharmacokinetics

    a. After subcutaneous administration, the drug is completely bioavailable, and steady-state peak plasma levels are achieved in approximately 3 hrs after administration of the dose.

    b. The elimination half-life is 17 to 21 hrs, enabling once daily dosing.

    c. The drug does not seem to be metabolized, appears in the urine in active form, and is renally eliminated.

  5. Administration and dosage

    a. Fondaparinux must not be administered intramuscularly.

    b. For prophylaxis against VTE, the drug should not be used in patients with body weight < 50 kg because the incidence of major bleeding was found to double in this patient population during clinical trials.

    c. For prophylaxis against VTE, a usual **dose of 2.5 mg subcutaneously once daily for 5 to 9 days** is recommended for **all prophylaxis indications**. The initial dose should be started 6 to 8 hrs after surgery when hemostasis is established.

| Table 35-10 | DOSING OF LMWHs FOR VTE PREVENTION AND TREATMENT |

	Enoxaparin		Dalteparin	Tinzaparin
Indication	**Standard Dose**	**Dose in Severe Renal Impairment**	**Dose**	**Dose**
VTE prophylaxis				
Hip replacement surgery	30 mg SC q12h (initiated 12–24 hrs after surgery) or 40 mg SC q24h (initiated 10–12 hrs before surgery)	30 mg SC q24h	2500 units SC given 6–8 hrs after surgery, then 5000 units SC q24h or 5000 units SC q24h (initiated the evening before surgery)	75 units/kg SC q24h (initiated the evening before surgery or 12–24 hrs after surgery)* or 4500 units SC q24h (initiated 12 hrs before surgery)*
Knee replacement surgery	30 mg SC q12h	30 mg SC q24h	2500 units SC given 6–8 hrs after surgery, then 5000 units SC q24h*	75 units/kg SC q24h*
Hip fracture surgery	30 mg SC q12h*	30 mg SC q24h*	NA	NA
Abdominal surgery	40 mg SC q24h	30 mg SC q24h	2500 units SC q24h (patients at risk of VTE) or 5000 units SC q24h (patients at high risk of VTE, such as malignancy) or 2500 units SC 1–2 hrs before surgery followed by 2500 units SC 12 hrs later, and then 5000 units SC q24h (patients with malignancy)	3500 units SC q24h*
Acutely ill medical patients	40 mg SC q24h	30 mg SC q24h	5000 units SC q24h	NA
VTE treatment				
DVT +/ PE	1 mg/kg SC q12h or 1.5 mg/kg SC q24h	1 mg/kg SC q24h	100 units/kg SC q12h* or 200 units/kg SC q24h*	175 units/kg SC q24h
Extended VTE treatment in cancer patients	1 mg/kg SC q12h or 1.5 mg/kg SC q24h*	1 mg/kg SC q24h*	200 units/kg SC q24h (first 30 days), then 150 units/kg SC q24h (months 2–6) with a dose cap of 18,000 units per day	175 units/kg SC q24h*

*Non-FDA approved for indication.
DVT, deep venous thrombosis; *NA*, data not available; *PE*, pulmonary embolism; *qh*, every hour; *SC*, subcutaneous; *VTE*, venous thromboembolism.

    d. For treatment of established VTE, administer a once daily subcutaneous dose as follows:
      (1) Patients with body weight between 50 and 100 kg: 7.5 mg
      (2) Patients with body weight < 50 kg: 5 mg
      (3) Patients with body weight > 100 kg: 10 mg
  6. Cautions
    a. Contraindications
      (1) Severe renal impairment
      (2) Patients weighing < 50 kg when used for prophylaxis
      (3) Patients with active major bleeding

(4) Bacterial endocarditis

(5) Thrombocytopenia associated with positive in vitro test for antiplatelet antibody in the presence of fondaparinux

(6) Known hypersensitivity to fondaparinux

  b. Precautions

(1) Conditions or procedures that may enhance the risk of severe bleeding (e.g., trauma, hemophilia, gastrointestinal ulceration, concurrent use of antiplatelet agents, history of cerebrovascular hemorrhage, severe uncontrolled hypertension)

(2) Renal impairment

(3) Heparin-induced thrombocytopenia

(4) Neuraxial anesthesia and indwelling epidural catheter use

(5) Elderly patients

(6) Pregnancy category B and lactating (the drug is excreted into breast milk)

(7) Protamine is **ineffective** as an antidote

E. Oral factor Xa inhibitor

  1. Indications

    a. Direct factor Xa inhibitor (rivaroxaban [Xarelto])

(1) Thromboprophylaxis against DVT/PE after

  (a) elective hip replacement surgery

  (b) elective knee replacement surgery

(2) To reduce the risk of stroke and systemic embolism in patients with atrial fibrillation.

  2. Chemistry. Direct competitive specific inhibitor of factor Xa

  3. Mechanism of action

    a. The antithrombotic activity of rivaroxaban is the result of direct specific inhibition of factor Xa.

    b. Rivaroxaban potentially inhibits both free and clot-associated factor Xa activity and has no direct effect upon platelet aggregation.

  4. Pharmacokinetics

    a. After oral administration, the drug is approximately 80% bioavailable and is rapidly absorbed with an onset of action achieved in approximately 2 to 4 hrs after administration of the dose.

    b The drug undergoes oxidative metabolism (mainly via CYP3A4) and hydrolysis and is eliminated one-third by renal excretion and two-thirds by hepatic metabolism.

    c. The elimination half-life is 5 to 9 hrs, enabling once daily dosing for the orthopedic prophylaxis indication.

  5. Administration and dosage

    a. For prevention of VTE in adult patients undergoing elective hip or knee replacement surgery, the dosage recommendation is 10 mg orally once daily. For elective hip replacement surgery, the duration of therapy should be 35 days. For elective knee replacement surgery, the duration of therapy should be 12 days minimally.

    b. No routine monitoring of INR or aPTT is necessary for this drug.

  6. Cautions

    a. Contraindications

(1) Hypersensitivity to the active substance or to any of the excipients; clinically significant active bleeding; hepatic disease associated with coagulopathy and clinically relevant bleeding risk, pregnancy, and lactation.

    b. Precautions

(1) **Treatment** with rivaroxaban is not recommended in the following patients: concomitantly treated systemically with strong concurrent CYP3A4 inhibitor and plasma glycoprotein (P-gp) inhibitors, i.e., azole antimycotics (such as ketoconazole, itraconazole, voriconazole, and posaconazole) or HIV protease inhibitors (e.g., ritonavir); with severe renal impairment (creatinine clearance [Clcr]<15 mL/min); and, due to lack of data, younger than 18 years of age; undergoing hip fracture surgery.

(2) Strong CYP3A4 inducers (e.g., rifampicin, phenytoin, carbamazepine, phenobarbital, or St. John's Wort) should be used with caution because they may lead to reduced rivaroxaban plasma concentrations and thus may reduce efficacy.

(3) Special care is to be taken when neuraxial anesthesia or spinal/epidural puncture is employed.

F. Oral direct thrombin inhibitor

1. **Indications**

   a. **Direct factor IIa (thrombin) inhibitor (dabigatran [Pradaxa])**

      (1) Reduce the risk of stroke and systemic embolism in patients with nonvalvular atrial fibrillation.

2. **Chemistry.** The drug binds rapidly and specifically to both free and clot-bound thrombin whose inhibition results in prevention of thrombus.

3. **Mechanism of action**

   a. The antithrombotic activity of dabigatran is the result of directly and selectively inhibiting factor IIa (thrombin).

4. **Pharmacokinetics**

   a. After oral administration, the drug is rapidly absorbed, converted to active drug and eliminated primarily by renal excretion, with an onset of action achieved in approximately 1 hr after administration of the dose.

   b. The drug undergoes conjugation (esterase catalyzed hydrolysis in liver or plasma).

   c. The elimination half-life is 12 to 17 hrs, requiring twice daily administration for the atrial fibrillation indication.

5. **Administration and dosage**

   a. For reduction of risk of stroke and systemic embolism in patients with nonvalvular atrial fibrillations, the recommendation is 150 mg orally twice daily if renal function is greater than 30 mL/min Clcr. For renal function 15 to 30 mL/min, the recommended dose is 75 mg orally twice daily. For renal function < 15 mL/min, the drug is not recommended. For patients with moderate renal impairment (Clcr 30–50 mL/min) consider reducing the dose of dabigatran to 75 mg orally twice daily if co-administered with dronedarone or systemic ketoconazole.

   b. Routine monitoring (INR or aPTT) is not necessary for this drug.

6. **Cautions**

   a. **Contraindications**

      (1) Hypersensitivity to the active substance or to any of the excipients and clinically significant active pathologic bleeding.

   b. **Precautions**

      (1) **Treatment** with dabigatran increases the risk of bleeding and can sometimes cause significant and sometimes fatal bleeding. Risk factors for bleeding include certain medications known, to increase this risk (e.g., antiplatelet agents, heparin, fibrinolytic therapy, chronic use of nonsteroidal anti-inflammatory drugs (NSAIDs), and labor and delivery).

      (2) The concomitant use of dabigatran with P-gp inducers (e.g., rifampin) reduces dabigatran exposure and should generally be avoided; P-gp inhibitors (e.g., ketoconazole, verapamil, amiodarone, and clarithromycin) do not require dose adjustment. These results should not be extrapolated to other P-gp inhibitors.

      (3) Special care is to be taken when neuraxial anesthesia or spinal/epidural puncture is employed.

Study Questions

Directions for questions 1–4: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A 67-year-old man who weighs 100 kg (212 lb) and is 60 inches tall presents to his physician after a transatlantic flight complaining of pain and swelling of his right lower extremity. The patient had total knee arthroplasty 2 weeks before his travel. His medical history reveals that he has an ejection fraction of 15%, he is in remission for non-Hodgkin lymphoma, and he had a previous MI. His mother, father, and sister are dead as a result of stroke, pulmonary embolism (PE), and childbirth, respectively. Given this patient's history, he is most likely suffering from which of the following?

   (A) ruptured Baker cyst
   (B) deep venous thrombosis (DVT) of the lower extremity
   (C) torn medial meniscus
   (D) septic arthritis

2. Prophylaxis against venous throboembolic disease (VTED) may include

   (A) nonpharmacological prophylaxis.
   (B) pharmacological prophylaxis.
   (C) nonpharmacological and pharmacological prophylaxis.
   (D) neither nonpharmacological nor pharmacological prophylaxis.

3. Unfractionated heparin binds to antithrombin III and inactivates clotting factor(s)

   (A) Xa
   (B) IXa
   (C) IIa
   (D) All of the above
   (E) None of the above

4. Initiation of UFH therapy for the patient described in question 1 would best be achieved with

   (A) 5000 U loading dose followed by 1000 U/hr.
   (B) 5000 U loading dose followed by 1800 U/hr.
   (C) 8000 U loading dose followed by 1800 U/hr.
   (D) 1000 U loading dose followed by 1000 U/hr.

Directions for questions 5–11: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

   A   if **I only** is correct
   B   if **III only** is correct
   C   if **I and II** are correct
   D   if **II and III** are correct
   E   if **I, II, and III** are correct

Directions for questions 5–10: Upon confirmation of diagnosis, the attending physician asks you, the pharmacist, to commence low-molecular-weight-heparin (LMWH) therapy for the patient described in question 1 as mentioned earlier. The following questions pertain to your pharmaceutical care for this patient:

5. When choosing an Food and Drug Administration (FDA)-approved LMWH to treat this patient, you would administer

   I. enoxaparin 1.0 mg/kg/dose subcutaneously every 12 hrs.
   II. enoxaparin 1.5 mg/kg/dose subcutaneously every 24 hrs.
   III. tinzaparin 175 IU/kg/dose subcutaneously every 24 hrs.

6. Which of the following tests are used to monitor heparin antithrombotic therapy?

   I. international normalized ratio (INR)
   II. activated partial thromboplatin time (aPTT)
   III. heparin assay

7. A patient to be commenced on oral anticoagulant therapy for DVT would be treated with

   I. oral anticoagulant therapy with warfarin for a goal INR of 2.0 to 3.0.
   II. oral anticoagulant therapy with warfarin for a goal INR of 2.5 to 3.5.
   III. oral anticoagulant therapy with aspirin for a goal INR of 2.0 to 3.0.

8. A patient on oral anticoagulant therapy is commenced on sulfamethoxazole-trimethoprim, double-strength twice daily. One may expect to see the INR

   I. increase.
   II. decrease.
   III. remain unchanged.

9. If a patient has an INR > 20 and active bleeding that is clinically significant (i.e., hematuria), the pharmacist should

   I. hold the drug therapy.
   II. administer vitamin K.
   III. administer fresh frozen plasma.

10. Compared to unfractionated heparin (UFH), LMWHs have

   I. preferential binding affinity to factor Xa relative to IIa (thrombin).
   II. shorter half-lives.
   III. dose-dependent renal clearance.

11. An 87-year-old woman who weighs 49 kg (108 lb) and is 66 inches tall has sustained a hip fracture requiring open reduction with internal fixation (ORIF) surgery. She has a documented serum creatine value recorded in the chart and in the laboratory results as 4.3 mg/dL. The orthopedic surgeon asks you, the pharmacist, about the appropriate fondaparinux dosing for this patient to prevent venous thromboembolism after the surgery. Which of the following are contraindications to the use of fondaparinux in this patient?

   I. Patient weighs < 50 kg.
   II. Patient has severe renal impairment.
   III. Patient is elderly.

Answers and Explanations

1. **The answer is B** *[see I.A–C].*
The patient has the classic triad of risk factors predisposing him to DVT injury (recent knee arthroplasty), venous stasis (transatlantic travel), and hypercoagulable state (family history of VTED). The patient has other risk factors as well, including age > 40, recent surgery, oncologic disease (although in remission), congestive heart failure, previous MI with low ejection fraction, and obesity.

2. **The answer is C** *[see IV.A–B].*
Prophylaxis of VTED can involve a nonpharmacological approach, a pharmacological approach, or a combination of nonpharmacological and pharmacological approaches. The method of prophylaxis used is determined based on the patient's degree of risk. For example, a patient at high to extremely high risk for development of VTED requires nonpharmacological and pharmacological prophylaxis.

3. **The answer is D** *[see V.A.2].*
Unfractionated heparin acts as an anticoagulant by catalyzing the inactivation of factor IIa, factor Xa, and factor IXa by antithrombin III.

4. **The answer is C** *[see V.A.4.b.(4)].*
Several nomograms for dosing continuous infusion UFH exist in the medical and pharmaceutical literature. The loading dose is typically 70 to 100 units/kg. In this case, the patient weighs 100 kg (212 lb) and the loading dose is 80 units/kg. Maintenance doses of 15 to 25 units/kg/hr are typically used. In this case, the maintenance dose is 18 units/kg/hr.

5. **The answer is E (I, II, III)** *[see Table 35-10].*
Primary literature reveals appropriate randomized prospective trials examining the role of LMWH compared to UFH. From these trials, evidence of efficacy and safety for enoxaparin and tinzaparin at the treatment doses listed exists and has been approved by FDA for treatment of established VTE.

6. **The answer is D (II, III)** *[see V.A.5.a–c].*
UFH may be appropriately monitored by either the aPTT or heparin assay. Because different laboratories use aPTT reagents with different sensitivities, the aPTT range and its corresponding ratio must be correlated to a heparin level of 0.2 to 0.4 units/mL by whole-blood (protamine titration) assay or 0.3 to 0.7 units/mL by plasma-amidolytic assay. The safety and efficacy of LMWH cannot be reliably evaluated by aPTT determinations. LMWH safety and efficacy can be evaluated by heparin assay. Because of the reliability of dose responsiveness seen with LMWH therapy, the need to perform heparin assays is controversial.

7. **The answer is A (I)** *[see V.B.5.a–b; Table 35-8].*
Oral anticoagulant therapy is monitored by measuring the prothrombin time (PT). The PT is responsive to depression of three of the four vitamin K–dependent procoagulant clotting factors (prothrombin or factors II, VII, and X). These respective clotting factors take approximately 96 hrs to be depleted, at which time the PT should be sufficient to arrive at an INR of 2.0 to 3.0 for patients with DVT (by appropriately converting the PT ratio to the power of the international sensitivity index [ISI]). Patients with mechanical prosthetic heart valves have INRs targeted in the 2.5 to 3.5 range. Aspirin therapy is not monitored by INR determinations.

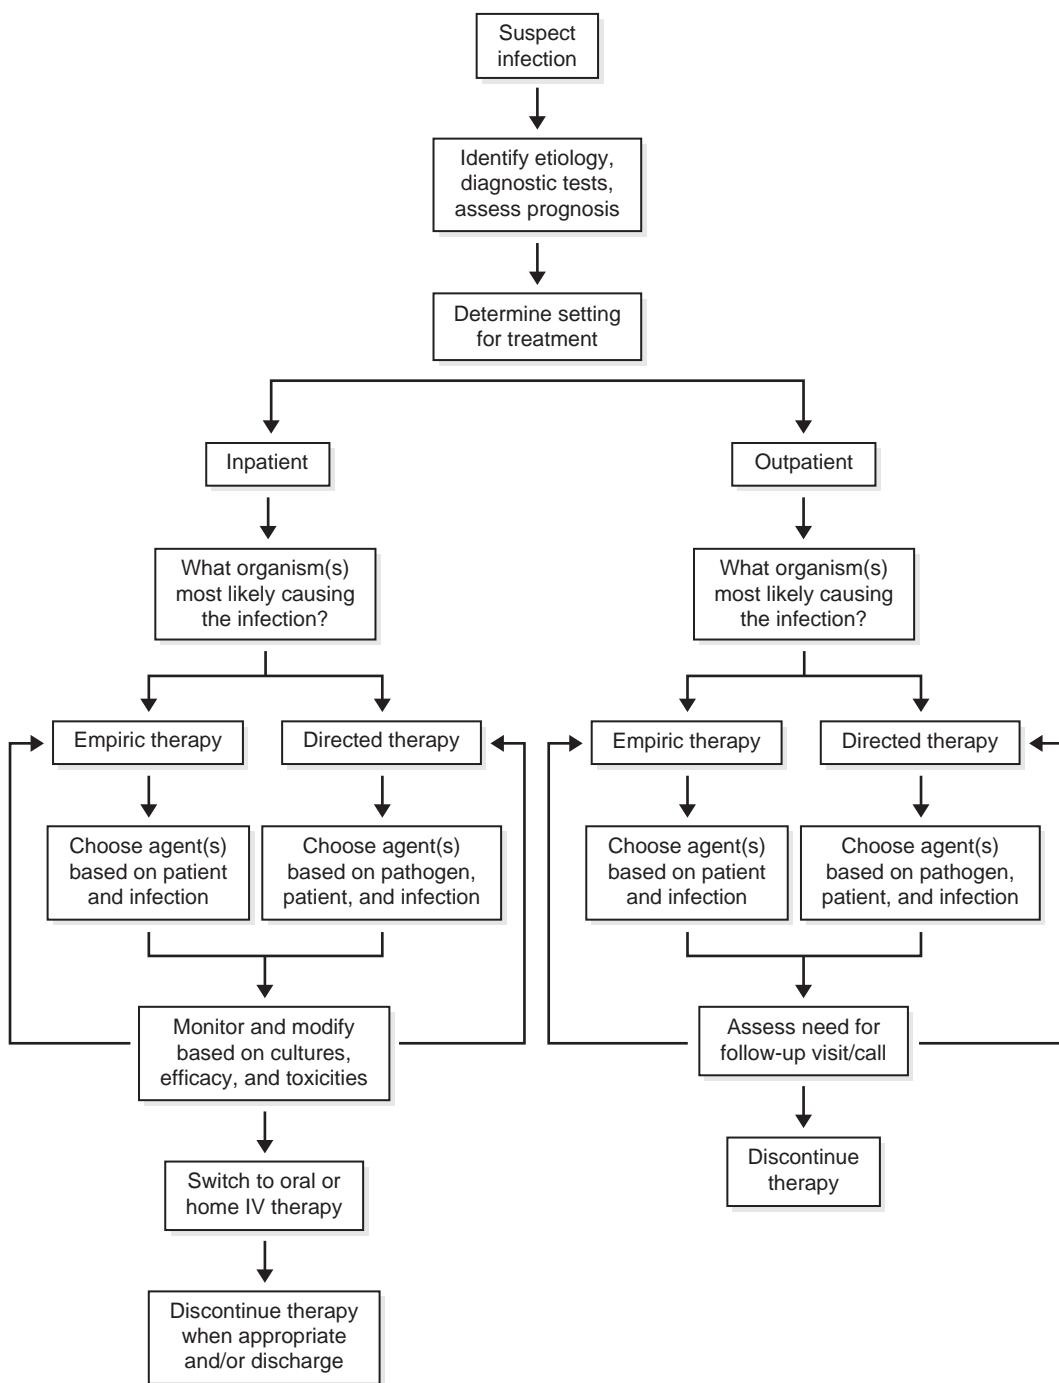
8. **The answer is A (I)** *[see Table 35-4].*
Oral anticoagulant therapy with warfarin may be complicated by myriad drug–drug interactions owing to the highly protein-bound state of warfarin. Such drug interactions may potentiate (prolong) PT:INR ratio, inhibit (shorten) the anticoagulant effect of warfarin, or have no effect on the actions of warfarin. Sulfamethoxazole-trimethoprim and other antibiotics have the potential to augment the anticoagulant effect of warfarin by eliminating bacterial flora and, thereby, producing vitamin K deficiency.

9. **The answer is E (I, II, III)** *[see Table 35-7].*
Pharmacists may be called on to offer advice regarding reversal of warfarin therapy or may be empowered using Pharmacy and Therapeutics Committee or Medical Board-approved protocols to reverse warfarin's effect. In all instances, the pharmacist must critically and clinically evaluate the situation and communicate with the physician regarding management issues. A need for immediate surgery or invasive procedures will always hasten the urgency of warfarin reversal. In the setting of active bleeding, its clinical significance must be demonstrated by consultation with the patient's physician. If the INR is > 20 and the patient has active bleeding that is clinically significant, the pharmacist must hold drug therapy, consider the most appropriate dose and route of vitamin K delivery, and administer fresh frozen plasma to replete the vitamin K–dependent clotting factors.

10. The answer is A (I) *[see V.C.3.a.(1); V.C.4.b]*.

UFH has a factor Xa:IIa binding-affinity ratio of approximately 1:1 and the various commercial LMWHs have factor Xa:IIa binding-affinity ratios of 2:1 up to 4:1, depending on their molecular size distribution. This increased binding affinity for factor Xa relative to factor IIa (thrombin) is said to account for the improved ability of LMWHs to catalyze inactivation of thrombin; the smaller fragments cannot bind to thrombin and, therefore, retain their ability to inactivate factor Xa. LMWHs have longer half-lives than UFH. LMWHs are cleared primarily via the kidneys, and their biologic half-life is increased in patients with renal failure *independent* of dose.

11. The answer is C (I, II) *[see V.D.5.b; V.D.6.a.(1)–(2)]*.

The synthetic pentasaccharide fondaparinux is contraindicated in patients who have severe renal impairment and who weigh < 50 kg. Calculation of the patient's estimated Clcr by the Crockcroft–Gault method reveals an estimated clearance of approximately 8.5 mL/min, which would be defined as severe renal impairment. Her stated weight is 49 kg. Thus, this patient's severe renal impairment and low weight constitute contraindications to the use of fondaparinux. Fondaparinux is recommended for use with *precaution* in the elderly patient population.


36 Infectious Diseases

PAUL F. SOUNEY, ANTHONY E. ZIMMERMANN, LINDA M. SPOONER

I. PRINCIPLES OF ANTI-INFECTIVE THERAPY

A. **Definition.** Anti-infective agents treat infection by suppressing or destroying the causative microorganisms—bacteria, mycobacteria, fungi, protozoa, or viruses. Anti-infective agents derived from natural substances are called **antibiotics**; those produced from synthetic substances are called **antimicrobials**. These two terms are now used interchangeably.

B. **Indications.** Confirm the presence of infection by completing a careful history and physical examination, searching for signs and symptoms of infection as well as predisposing factors. Anti-infective agents should be used only when

1. A significant infection has been diagnosed or is strongly suspected.
2. An established indication for prophylactic therapy exists.

C. **Gram stain**, **microbiological culturing**, and **susceptibility tests** should be performed before anti-infective therapy is initiated. Test materials must be obtained by a method that avoids contamination of the specimen by the patient's own flora.

1. **Gram stain.** Performed on all specimens except blood cultures, the gram stain helps identify the cause of infection immediately. By determining if the causative agent is gram positive or gram negative, the test allows a better choice of drug therapy, particularly when an anti-infective regimen must begin without delay.

   a. **Gram-positive** microorganisms stain **blue** or **purple**.
   b. **Gram-negative** microorganisms stain **red** or **rose-pink**.
   c. **Fungi** may also be identified by gram stain.

2. **Microbiological cultures.** To identify the specific causative agent, specimens of body fluids or infected tissue are collected for analysis.

3. **Susceptibility tests.** Different strains of the same pathogenic species may have widely varying susceptibility to a particular anti-infective agent. Susceptibility tests determine microbial susceptibility to a given drug and thus can be used to predict whether the drug will combat the infection effectively.

   a. **Microdilution method.** The drug is diluted serially in various media containing the test microorganism.

      (1) The lowest drug concentration that prevents microbial growth after 18 to 24 hrs of incubation is called the **minimum inhibitory concentration (MIC)**.
      (2) The lowest drug concentration that reduces bacterial density by 99.9% is called the **minimum bactericidal concentration (MBC)**.
      (3) **Breakpoint** concentrations of antibiotics are used to characterize antibiotic activity: The interpretive categories are **susceptible**, **moderately susceptible (intermediate)**, and **resistant**. These concentrations are determined by considering pharmacokinetics, serum and tissue concentrations following normal doses, and the **population distribution** of MICs of a group of bacteria for a given drug.

   b. **Kirby–Bauer disk diffusion technique.** This test is less expensive but less reliable than the microdilution method; however, it provides qualitative susceptibility information.

      (1) Filter paper disks impregnated with specific drug quantities are placed on the surface of agar plates streaked with a microorganism culture. After 18 hrs, the size of a clear inhibition zone is determined; drug activity against the test strain is then correlated to zone size.

(2) The Kirby–Bauer technique does not reliably predict therapeutic effectiveness against certain microorganisms (e.g., *Staphylococcus aureus*, *Shigella*).

D. Choice of agent. An anti-infective agent should be chosen on the basis of its pharmacological properties and spectrum of activity as well as on various host (patient) factors (*Figure 36-1*).

1. Pharmacological properties include the drug's ability to reach the infection site and to attain a desired level in the target tissue.

2. Spectrum of activity. To treat an infectious disease effectively, an anti-infective drug must be active against the causative pathogen. Susceptibility testing or clinical experience in treating a given infection may suggest the effectiveness of a particular drug.

Figure 36-1. Approach to management of infection.

3. **Patient factors.** Selection of an anti-infective drug regimen must take various patient factors into account to determine which type of drug should be administered, the correct drug dosage and administration route, and the potential for adverse drug effects.

   a. **Immunological status.** A patient with impaired immune mechanisms may require a drug that rapidly destroys pathogens (i.e., **bactericidal agent**) rather than one that merely suppresses a pathogen's growth or reproduction (i.e., **bacteriostatic agent**).

   b. **Presence of a foreign body.** The effectiveness of anti-infective therapy is reduced in patients who have prosthetic joints or valves, cardiac pacemakers, and various internal shunts.

   c. **Age.** A drug's pharmacokinetic properties may vary widely in patients of different ages. In very young and very old patients, drug metabolism and excretion commonly decrease. Elderly patients also have an increased risk of suffering ototoxicity when receiving certain antibiotics.

   d. **Underlying disease**
      (1) Preexisting **kidney** or **liver disease** increases the risk of nephrotoxicity or hepatotoxicity during the administration of some antibacterial drugs.
      (2) Patients with **central nervous system (CNS) disorders** may suffer neurotoxicity (motor seizures) during penicillin therapy.
      (3) Patients with **neuromuscular disorders** (e.g., myasthenia gravis) are at increased risk for developing neuromuscular blockade during aminoglycoside or polymyxin B therapy.

   e. **History of drug allergy or adverse drug reactions.** Patients who have had previous allergic or other untoward reactions to a particular antibiotic have a higher risk of experiencing the same reaction during subsequent administration of that drug. Except in life-threatening situations, patients who have had serious allergic reactions to penicillin, for example, should not receive the drug again.

   f. **Pregnancy and lactation.** Because drug therapy during pregnancy and lactation can cause unwanted effects, the mother's need for the antibiotic must be weighed against the drug's potential harm.
      (1) Pregnancy can increase the risk of adverse drug effects for both mother and fetus. Also, plasma drug concentrations tend to decrease in pregnant women, reducing a drug's therapeutic effectiveness.
      (2) Most drugs, including antibiotics, appear in the breast milk of nursing mothers and may cause adverse effects in infants. For example, sulfonamides may lead to toxic bilirubin accumulation in a newborn's brain.

   g. **Genetic traits**
      (1) Sulfonamides may cause hemolytic anemia in patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency.
      (2) Patients who rapidly metabolize drugs (i.e., rapid acetylators) may develop hepatitis when receiving the antitubercular drug isoniazid.

E. **Empiric therapy.** In serious or life-threatening disease, anti-infective therapy must begin before the infecting organism has been identified. In this case, the choice of drug (or drugs) is based on clinical experience, suggesting that a particular agent is effective in a given setting.
   1. A **broad-spectrum antibiotic** usually is the most appropriate choice until the specific organism has been determined.
   2. In all cases, **culture specimens must be obtained** before therapy begins.

F. **Multiple antibiotic therapy.** A combination of drugs should be given only when clinical experience has shown such therapy to be more effective than single-agent therapy in a particular setting. A multiple-agent regimen can increase the risk of toxic drug effects and, in a few cases, may result in drug antagonism and subsequent therapeutic ineffectiveness. Indications for multiple-agent therapy include
   1. **Need for increased antibiotic effectiveness.** The **synergistic** (intensified) effect of two or more agents may allow a dosage reduction or a faster or enhanced drug effect.
   2. **Treatment of an infection caused by multiple pathogens** (e.g., intra-abdominal infection)
   3. **Prevention of proliferation of drug-resistant organisms** (e.g., during treatment of tuberculosis)

G. **Duration of anti-infective therapy.** To achieve the therapeutic goal, anti-infective therapy must continue for a sufficient duration.
   1. **Acute uncomplicated infection.** Treatment generally should continue until the patient has been afebrile and asymptomatic for at least 72 hrs.

2. **Chronic infection** (e.g., endocarditis, osteomyelitis). Treatment may require a longer duration (4 to 6 weeks) with follow-up culture analyses to assess therapeutic effectiveness.

H. **Monitoring therapeutic effectiveness.** To assess the patient's response to anti-infective therapy, appropriate specimens should be cultured and the following parameters monitored.

1. **Fever curve.** An important assessment tool, the fever curve may be a reliable indication of response to therapy. Defervescence usually indicates favorable response.

2. **White blood cell (WBC) count.** In the initial stage of infection, the neutrophil count from a peripheral blood smear may rise above normal (neutrophilia), and immature neutrophil forms ("bands") may appear ("left shift"). In patients who are elderly, debilitated, or suffering overwhelming infection, the WBC count may be normal or subnormal.

3. **Radiographic findings.** Small effusions, abscesses, or cavities that appear on radiographs indicate the focus of infection.

4. **Pain** and **inflammation** (as evidenced by swelling, erythema, and tenderness) may occur when the infection is superficial or within a joint or bone, also indicating a possible focus of infection.

5. **Erythrocyte sedimentation rate (ESR or "sed rate").** Large elevations in ESR are associated with acute or chronic infection, particularly endocarditis, chronic osteomyelitis, and intra-abdominal infections. A normal ESR does not exclude infection; more often, ESR is elevated as a result of noninfectious causes such as collagen vascular disease.

6. **Serum complement concentrations**, particularly the C3 component, are often reduced in serious infections because of consumption during the host defense process.

I. **Lack of therapeutic effectiveness.** When an antibiotic drug regimen fails, other drugs should not be added indiscriminately or the regimen otherwise changed. Instead, the situation should be reassessed and diagnostic efforts intensified. Causes of therapeutic ineffectiveness include the following:

1. **Misdiagnosis.** The isolated organism may have been misidentified by the laboratory or may not be the causative agent for infection (e.g., the patient may have an unsuspected infection).

2. **Improper drug regimen.** The drug dosage, administration route, dosing frequency, or duration of therapy may be inadequate or inappropriate.

3. **Inappropriate choice of antibiotic agent.** As discussed in I.D, patient factors and the pharmacological properties and spectrum of activity of a given drug must be considered when planning anti-infective drug therapy.

4. **Microbial resistance.** By acquiring resistance to a specific antibiotic, microorganisms can survive in the drug's presence. Many gonococcal strains, for instance, now resist penicillin. Drug resistance is particularly common in geographical areas in which a specific drug has been used excessively (and perhaps improperly).

5. **Unrealistic expectations.** Antibiotics are ineffective in certain circumstances.

   a. Patients with conditions that require **surgical drainage** frequently cannot be cured by anti-infective drugs until the drain has been removed. For example, the presence of necrotic tissue or pus in patients with pneumonia, empyema, or renal calculi is a common cause of antibiotic failure.

   b. **Fever** should not be treated with anti-infective drugs unless infection has been identified as the cause. Although fever frequently signifies infection, it sometimes stems from noninfectious conditions (e.g., drug reactions, phlebitis, neoplasms, metabolic disorders, arthritis). These conditions do not respond to antibiotics. One exception to this position is neutropenic cancer patients; such patients with no signs or symptoms of infection other than fever are widely treated with antimicrobial agents.

6. **Infection by two or more types of microorganisms.** If not detected initially, an additional cause of infection may lead to therapeutic failure.

J. **Antimicrobial prophylaxis for surgery**

1. **Definition.** Antibiotic prophylaxis is a short course of antibiotic administered before there is clinical evidence of infection.

2. **General considerations**

   a. **Timing.** The antibiotic should be administered to ensure that appropriate antibiotic levels are available at the site of contamination before the incision. Initiation of prophylaxis is often at induction of anesthesia, within 1 hr or just before the surgical incision. This ensures peak serum and tissue antibiotic levels.

b. **Duration.** Prophylaxis should be maintained for the duration of surgery. Long surgical procedures (e.g., > 3 hrs) may require additional doses. There is little evidence to support continuation of prophylaxis beyond 24 hrs.

c. **Antibiotic spectrum** should be appropriate for the usual pathogens.

   (1) In general, **first-generation cephalosporins** (e.g., cefazolin) are the drugs of choice for most procedures and patients. These agents have an appropriate spectrum, a low frequency of side effects, a favorable half-life, and a low cost.

   (2) **Vancomycin** is a suitable alternative in penicillin-sensitive patients and in situations in which methicillin-resistant *S. aureus* is a concern.

d. **Route of administration.** Intravenous (IV) or intramuscular (IM) routes are preferred to guarantee good serum and tissue levels at the time of incision.

II. ANTIBACTERIAL AGENTS

A. **Definition and classification.** Used to treat infections caused by **bacteria**, antibacterial agents fall into several major categories: **aminoglycosides**, **carbapenems**, **cephalosporins**, **erythromycins**, **penicillins** (including various subgroups), **sulfonamides**, **tetracyclines**, **fluoroquinolones**, **metronidazole** (see V.C.2.b**), urinary tract antiseptics**, and **miscellaneous anti-infectives** (*Table 36-1*).

B. **Aminoglycosides.** These drugs, containing amino sugars, are used primarily in infections caused by gram-negative enterobacteria and in suspected sepsis. They have little activity against anaerobic and facultative organisms. The toxic potential of these drugs limits their use. Major aminoglycosides include **amikacin (Amikin)**, **gentamicin (Garamycin)**, **kanamycin**, **neomycin**, **netilmicin**, **streptomycin**, and **tobramycin (Nebcin)**.

1. **Mechanism of action.** Aminoglycosides are **bactericidal**; they inhibit bacterial protein synthesis by binding to and impeding the function of the 30S ribosomal subunit. (Some aminoglycosides also bind to the 50S ribosomal subunit.) Their mechanism of action is not fully known.

2. **Spectrum of activity**

a. **Streptomycin** is active against both gram-positive and gram-negative bacteria. However, widespread resistance to this drug has restricted its use to the organisms that cause plague and tularemia, gram-positive streptococci (given in combination with penicillin), and *Mycobacterium tuberculosis* (given in combination with other antitubercular agents as described in VI.C.2).

b. **Amikacin**, **kanamycin**, **gentamicin**, **tobramycin**, **neomycin**, and **netilmicin** are active against many gram-negative bacteria (e.g., *Proteus*, *Serratia*, and *Pseudomonas* organisms).

   (1) **Gentamicin** is active against some *Staphylococcus* strains; it is more active than tobramycin against *Serratia* organisms.

   (2) **Amikacin** is the broadest spectrum aminoglycoside with activity against most aerobic gram-negative bacilli as well as many anaerobic gram-negative bacterial strains that resist gentamicin and tobramycin. It is also active against *M. tuberculosis* and *Mycobacterium avium-intracellulare* (MAI).

   (3) **Tobramycin** may be more active against *Pseudomonas aeruginosa* than gentamicin.

   (4) **Netilmicin** may be active against gentamicin-resistant organisms; it appears to be less ototoxic than other aminoglycosides.

   (5) **Neomycin**, in addition to its activity against such gram-negative organisms as *Escherichia coli* and *Klebsiella pneumoniae*, is active against several gram-positive organisms (e.g., *S. aureus*). *P. aeruginosa* and most streptococci are now neomycin resistant.

3. **Therapeutic uses**

a. **Streptomycin** is used to treat plague, tularemia, acute brucellosis (given in combination with tetracycline), and tuberculosis (given in combination with other antitubercular agents, as described in VI.C.2).

b. **Gentamicin**, **tobramycin**, **amikacin**, and **netilmicin** are therapeutic for serious gram-negative bacillary infections (e.g., those caused by *Enterobacter*, *Serratia*, *Klebsiella*, and *P. aeruginosa*), bacterial endocarditis caused by *Streptococcus viridans* (given in combination with penicillin), pneumonia (given in combination with a cephalosporin or penicillin), meningitis, complicated urinary tract infections, osteomyelitis, bacteremia, and peritonitis.

c. **Neomycin** is used for preoperative bowel sterilization; hepatic coma (as adjunctive therapy); and, in topical form, for skin and mucous membrane infections (e.g., burns).

| Table 36-1 | SOME IMPORTANT PARAMETERS OF ANTI-INFECTIVE DRUGS |

Agent	Elimination Route	Half-Life	Administration Route	Common Dosage Range (Adults)
Aminoglycosides				
Amikacin	Renal	2–3 hrs	IV, IM	15 mg/kg/day (once daily dose)
Gentamicin	Renal	2 hrs	IV, IM	3 mg/kg/day (standard dose); 6–7 mg/kg/day (once daily dose)
Kanamycin	Renal	2–4 hrs	Oral, IV	15 mg/kg every 8–12 hrs
Neomycin	Renal	2–3 hrs	Oral, topical	50–100 mg/kg/day (oral); 10–15 mg/day (topical)
Netilmicin	Renal	2–7 hrs	IV, IM	3–6 mg/kg/day
Streptomycin	Renal	2–3 hrs	IM	15 mg/kg/day[a]
Tobramycin	Renal	2–5 hrs	IV, IM	3 mg/kg/day (standard dose); 6–7 mg/kg/day (once daily dose)
Carbapenems				
Doripenem	Renal	1 hr	IV	500 mg every 8 hrs
Imipenem	Renal	1 hr	IV	250 mg to 1 g every 6 hrs
Ertapenem	Renal	4 hrs	IV, IM	1 g/day
Meropenem	Renal	1.5 hr	IV, IM	0.5–2 g every 8 hrs
Cephalosporins				
First-generation				
Cefadroxil	Renal	1.5 hr	Oral	1–2 g/day
Cefazolin	Renal	1.4–2.2 hrs	IV	250 mg to 1 g every 8 hrs
Cephalexin	Renal	0.9–1.3 hrs	Oral	250–500 mg every 6 hrs
Cephapirin	Renal (H)	0.6–0.8 hr	IV, IM	500 mg to 2 g every 4–6 hrs
Cephradine	Renal	1.3 hr	Oral, IV	250–500 mg every 6 hrs
Second-generation				
Cefaclor	Renal (H)	0.8 hr	Oral	250–500 mg every 8 hrs
Cefmetazole	Renal	72 mins	IV	2 g every 6–12 hrs
Cefotetan	Renal	2.8–4.6 hrs	IV, IM	1–2 g every 12 hrs
Cefoxitin	Renal	0.8 hr	IV	1–2 g every 6–8 hrs
Cefprozil	Renal	78 mins	Oral	250–500 mg every 12–24 hrs
Cefuroxime	Renal	1.5–2.2 hrs	IV, IM	750 mg to 1.5 g every 8 hrs
Third-generation				
Cefixime	Renal	3–4 hrs	Oral	400 mg/day
Cefdinir	Renal	1.7–1.8 hr	Oral	300 mg every 12 hrs
Cefditoren	Renal	1.6 hr	Oral	400 mg every 12 hrs
Cefoperazone	Hepatic	1.6–2.4 hrs	IV	2–4 g every 12 hrs
Cefotaxime	Renal (H)	1.5 hr	IV	1–2 g every 6–8 hrs
Cefpodoxime	Renal	2.5 hrs	Oral	100–400 mg every 12 hrs
Ceftazidime	Renal	1.8 hr	IV, IM	1–2 g every 8–12 hrs
Ceftibuten	Renal	2.5 hrs	Oral	400 mg/day
Ceftizoxime	Renal	1.7 hr	IV	1–2 g every 8–12 hrs
Ceftriaxone	Renal	8 hrs	IV, IM	1–2 g/day
Fourth-generation				
Cefepime	Renal	2.0–2.3 hrs	IV, IM	1–2 g every 8–12 hrs
Ceftaroline	Renal	2.6 hrs	IV	600 mg every 12 hrs
Erythromycins and other macrolides				
Azithromycin	Hepatic	68 hrs	Oral	250 mg/day
Clarithromycin	Renal	3–7 hrs	Oral	250–500 mg every 12 hrs

(**Table 36-1**) Continued.

Agent	Elimination Route	Half-Life	Administration Route	Common Dosage Range (Adults)
Erythromycins and other macrolides (continued)				
Erythromycin base estolate, ethylsuccinate, and stearate	Hepatic	1.2–2.6 hrs	Oral	250–500 mg every 6 hrs
Erythromycin gluceptate and lactobionate			IV	0.5–2.0 g every 6 hrs
Natural penicillins				
Penicillin G	Renal (H)	0.5 hr	Oral, IV, IM	200,000–500,000 U every 6–8 hrs
Penicillin V	Renal	1 hr	Oral	500 mg to 2 g/day
Penicillin G procaine	Renal	24–60 hrs	IM	300,000–600,000 U/day
Penicillin G benzathine	Renal	24–60 hrs	IM	300,000–600,000 U/day
Penicillinase-resistant penicillins				
Dicloxacillin	Renal (H)	0.5–0.9 hr	Oral	500 mg to 1 g/day
Methicillin	Renal (H)	0.5–1.0 hr	IV, IM	1–2 g every 4–6 hrs
Nafcillin	Hepatic (R)	0.5 hr	Oral, IV, IM	0.25–2.00 g every 6 hrs
Oxacillin	Renal (H)	0.5 hr	Oral, IV, IM	500 mg to 2 g every 4–6 hrs 500–875 mg every 12 hrs
Aminopenicillins				
Amoxicillin	Renal (H)	0.9–2.3 hrs	Oral	250–500 mg every 8 hrs
Amoxicillin/clavulanic acid	Renal	1 hr	Oral	250–500 mg every 8 hrs
Ampicillin	Renal (H)	0.8–1.5 hrs	Oral, IV, IM	250 mg to 2 g every 4–6 hrs
Ampicillin/sulbactam	Renal	1.0–1.8 hr	IV, IM	1.5–3.0 g every 6 hrs
Extended-spectrum penicillins				
Piperacillin	Renal (H)	0.8–1.4 hr	IV, IM	1.0–1.5 mg/kg every 6–12 hrs
Piperacillin/tazobactam	Renal	0.7–1.2 hr	IV	3.375 g every 6 hrs
Ticarcillin/clavulanic acid	Renal	1.0–1.5 hr	IV	3.1 g every 4–6 hrs
Sulfonamides				
Sulfacytine	Renal	4.0–4.5 hrs	Oral	250 mg every 6 hrs
Sulfadiazine	Renal (H)	6 hrs	Oral, IV	2–4 g/day
Sulfamethoxazole	Hepatic (R)	9–11 hrs	Oral	1–3 g/day
Sulfisoxazole	Renal (H)	3–7 hrs	Oral, IV	2–8 g/day
Sulfamethizole	Renal	—	Oral	0.5–1.0 g every 6–8 hrs
Tetracyclines				
Demeclocycline	Renal	10–17 hrs	Oral	300 mg to 1 g/day
Doxycycline	Hepatic	14–25 hrs	Oral, IV	100–200 mg every 12 hrs
Minocycline	Hepatic	12–15 hrs	Oral, IV	100–200 mg every 12 hrs
Oxytetracycline	Renal	6–12 hrs	Oral, IM	250–500 mg every 6 hrs 250–500 mg q.i.d. or 300 mg/day in one or two divided doses
Tetracycline[b]	Renal	6–12 hrs	Oral, IV, IM	1–2 g/day
Fluoroquinolones				
Ciprofloxacin	Renal (H)	5–6 hrs	IV	200–600 mg every 12 hrs
Gemifloxacin	Fecal (R)	4–12 hrs	Oral	320 mg once daily
Levofloxacin	Renal	8 hrs	IV, Oral	250–500 mg every 24 hrs
Moxifloxacin	Hepatic	12 hrs	Oral	400 mg once daily
Ofloxacin	Renal	5.0–7.5 hrs	Oral	100 mg/day–400 mg

| Table 36-1 | Continued. | | | |

Agent	Elimination Route	Half-Life	Administration Route	Common Dosage Range (Adults)
Urinary tract antiseptics				
Cinoxacin	Renal	1.0–1.5 hr	Oral	250 mg every 6 hrs or 500 mg every 12 hrs
Fosfomycin	Renal/fecal	5.7 hrs	Oral	One packet (3 g) in 90–120 mL water × one dose
Methenamine hippurate and mandelate	Renal	1–3 hrs	Oral	0.5–2 g q.i.d.
Nalidixic acid	Renal	8 hrs	Oral	4 g/day
Nitrofurantoin	Renal	0.3–1.0 hr	Oral	5–7 mg/kg/day
Norfloxacin	Hepatic	3–4 hrs	Oral	400 b.i.d.
Miscellaneous anti-infectives				
Atovaquone	Fecal	50–84 hrs	Oral	750 mg b.i.d. 21 days
Aztreonam	Renal	1.7 hr	Oral, IV	50–100 mg/kg/day
Clindamycin	Hepatic	2–4 hrs	Oral, IM, IV	300–900 mg every 6–8 hrs
Clofazimine	Hepatic	70 days	Oral	50–100 mg/day
Dapsone	Hepatic (R)	28 hrs	Oral	50–100 mg/day
Daptomycin	Renal	8 hrs	IV	4 mg/kg/day
Fidaxomicin	Fecal	11.7 hrs	Oral	200 mg b.i.d. × 10 days
Lincomycin	Hepatic (R)	4.4–6.4 hrs	IV, IM	600 mg to 1 g every 8–12 hrs
Linezolid	Renal	4–6 hrs	Oral, IV	600 mg every 12 hrs
Mupirocin	Renal	19–35 mins	Topical	Apply every 8–12 hrs
Quinupristin/dalfopristin	Hepatic	1 hr/0.4–0.5 hr	IV	7.5 mg/kg every 8 hrs
Rifaximin	Fecal	6 hrs	Oral	200 mg t.i.d.
Spectinomycin	Renal	1.2–2.8 hrs	IM	2–4 g (single dose)
Telavancin	Renal	6–8 hrs	IV	10 mg/kg/day
Telithromycin	Hepatic (R)	10 hrs	Oral	800 mg/day
Tigecycline	Biliary (R)	42 hrs	IV	100 mg load, 50 mg every 12 hrs
Trimethoprim	Renal (H)	8–15 hrs	Oral	100–200 mg/day
Vancomycin	Renal	6–8 hrs	Oral, IV	500 mg every 6 hrs
Antifungal agents				
Amphotericin B	Unknown	24 hrs	IV	1.0–1.5 mg/kg/day
Anidulafungin	Fecal (R)	40–50 hrs	IV	Candidemia: 200 mg day 1, then 100 mg/day
				Esophageal candidiasis: 100 mg day 1, then 50 mg/day
Caspofungin	Hepatic	9–11 hrs	IV	70 mg on day 1, then 50 mg q.d.
Fluconazole	Renal	22–37 hrs	IV, Oral	100–800 mg/day
Flucytosine	Renal	6 hrs	Oral	50–150 mg/kg/day
Griseofulvin	Hepatic (R)	9–24 hrs	Oral	300–375 mg/day
Itraconazole	Hepatic	24–42 hrs	Oral	200–600 mg/day
Ketoconazole	Hepatic/fecal	3.3 hrs	Oral	200–400 mg/day b.i.d.
Micafungin	Hepatic	11–17 hrs	IV	Esophageal candidiasis: 150 mg/day
				HSCT prophylaxis: 50 mg/day
Miconazole	Hepatic	20–24 hrs	Oral	200–400 mg/day
Nystatin	Fecal	—	Oral	500,000–1,000,000 U t.i.d.
Terbinafine	Hepatic (R)	11–16 hrs	Oral	250 mg/day
Voriconazole	Hepatic	6 hrs	IV, Oral	IV: 6 mg/kg every 12 hrs × two doses, then 4 mg/kg every 12 hrs; oral: 200 mg every 12 hrs for > 40 kg, 100 mg every 12 hrs for < 40 kg

Table 36-1   Continued.

Agent	Elimination Route	Half-Life	Administration Route	Common Dosage Range (Adults)
Antiprotozoal agents				
Atovaquone	Hepatic	67 hrs	Oral	750 mg b.i.d.
Chloroquine	Renal/fecal	72–120 hrs	IM, Oral	Depends on disease
Coartem	Hepatic	3–6 days	Oral	Day 1: four tablets initially and 8 hrs later
				Day 2 and 3: four tabs b.i.d.
Diloxanide	Renal	—	IM	500 mg t.i.d.
Eflornithine	Renal	3 hrs	IV	100 mg/kg/dose every 6 hrs
Fansidar	Renal	100–231 hrs	Oral	1 tablet every week
	Renal	72–120 hrs	Oral	310 mg every week
Hydroxychloroquine				
Iodoquinol	Fecal	—	Oral	650 mg t.i.d. for 20 days
Mefloquine	Hepatic	15–33 days	Oral	1250 mg single dose
Metronidazole	Hepatic (R)	6–14 hrs	Oral, IV	250–500 mg every 6–8 hrs
Nitazoxanide	Hepatic	1.0–1.6 hr	Oral	100–200 mg b.i.d. based on age
Paromomycin	Fecal	—	Oral	25–35 mg/kg/day
Pentamidine	Renal	6–9 hrs	IM, IV, inhalation	IV, IM: 3–4 mg/kg every day; inhalation: 300 mg every 4 weeks
Primaquine	Hepatic	3.7–9.6 hrs	Oral	15 mg (base)/day
Pyrimethamine	Renal	111 hrs	Oral	25 mg every week
Quinacrine		5 days	Oral	100 mg/day
Quinine	Renal	12 hrs	Oral	325 mg b.i.d.
Tinidazole	Hepatic (R)	13.2 hrs	Oral	2 g q.d. × 1–3 days
Antitubercular agents				
Aminosalicylic acid	Renal	1 hr	Oral	150 mg/kg daily (maximum acid 12 g/day)
Capreomycin	Renal	4–6 hrs	IM	15 mg/kg/day to 1 g/day maximum
Cycloserine	Renal	10 hrs	Oral	15–20 mg/kg (maximum 1 g/day)
Ethambutol	Hepatic	3.3 hrs	Oral	15–25 mg/kg/day
Ethionamide	Hepatic	3 hrs	Oral	500 mg to 1 g/day
Isoniazid	Hepatic	1–4 hrs	Oral, IV	5–10 mg/kg daily (maximum dose = 300 mg)
Pyrazinamide	Hepatic	9–10 hrs	Oral	15–30 mg/kg daily (maximum 2 g/day)
Rifampin	Hepatic	2–3 hrs	Oral, IV	10 mg/kg (up to 600 mg) q.d.
Rifabutin	Hepatic	45 hrs	Oral	300 mg q.d.
Rifapentine	Hepatic	13.9 hrs (active metabolite /13.4 hrs)	Oral	600 mg every 3 days
Antiviral agents				
Abacavir	Hepatic	1.5 hr	Oral	300 mg b.i.d. or 600 mg every day
Adefovir	Renal	7.5 hrs	Oral	10 mg every day
Acyclovir	Renal	2.2 hrs	Oral, IV, topical	IV: 5–10 mg/kg every 8 hrs; oral: 200–800 mg 3–5 × daily (depending upon indication)
Amantadine	Renal	17 hrs	Oral	100 mg b.i.d. or 200 mg every day
Atazanavir	Hepatic	7 hrs	Oral	400 mg every day or 300 mg plus 100 mg ritonavir every day
Boceprevir	Hepatic	3 hrs	Oral	800 mg every 7–9 hrs
Cidofovir	Renal	6.5 hrs	IV	5 mg/kg/week × 2 (induction); 5 mg/kg every 2 weeks (maintenance)

| Table 36-1 | Continued. |

Agent	Elimination Route	Half-Life	Administration Route	Common Dosage Range (Adults)
Antiviral agents (continued)				
Darunavir	Hepatic	15 hrs	Oral	600 mg plus 100 mg ritonavir b.i.d. or 800 mg plus 100 mg ritonavir every day
Delavirdine	Hepatic	5.8 hrs	Oral	400 mg t.i.d.
Didanosine	Renal	1.5 hrs	Oral	≥ 60 kg: 400 mg every day (EC caps); < 60 kg: 250 mg every day (EC caps)
Emtricitabine	Renal	10 hrs	Oral	200 mg every day (caps)
Enfuvirtide	n/a	3.8 hrs	SC	90 mg b.i.d.
Entecavir	Renal	128–149 hrs	Oral	0.5 mg every day, or 1 mg every day in patients with lamivudine resistance
Efavirenz	Hepatic	40–55 hrs	Oral	600 mg at bedtime
Etravirine	Hepatic	41 hrs	Oral	200 mg b.i.d.
Famciclovir	Renal	2.0–2.3 hrs	Oral	250–500 mg every 8–12 hrs
Fosamprenavir	Hepatic	7.7 hrs	Oral	1400 mg b.i.d. or 1400 mg plus 100–200 mg ritonavir every day or 700 mg plus 100 mg ritonavir every day
Foscarnet	Renal	3–6 hrs	IV	90 mg/kg every 12 hrs × 14–21 days (CMV induction); 90 mg/kg every day (CMV maintenance)
Ganciclovir	Renal	2.9 hrs	IV	5 mg/kg every 12 hrs (induction) × 14–21 days; 5 mg/kg every day (maintenance)
		4.8 hrs	Oral	1000 mg t.i.d. (after induction)
Indinavir	Hepatic	1.5–2.0 hrs	Oral	800 mg every 8 hrs
Lamivudine	Renal	5–7 hrs	Oral	150 mg b.i.d. or 300 mg daily
Lopinavir/ritonavir	Hepatic	5–6 hrs	Oral	200 mg/50 mg per tab (2 tablets b.i.d. or 4 tablets every day)
Maraviroc	Hepatic	14–18 hrs	Oral	150–600 mg b.i.d. (depending upon concomitant medications)
Nelfinavir	Hepatic	3.5–5.0 hrs	Oral	1250 mg b.i.d.
Nevirapine	Hepatic	25–30 hrs	Oral	Immediate-release: 200 mg every day × 14 days, then 200 mg b.i.d. Extended-release: 200 mg every day × 14 days, 400 mg every day
Oseltamivir	Renal	6–10 hrs	Oral	75 mg b.i.d. (treatment); 75 mg every day (prophylaxis)
Raltegravir	Hepatic	9 hrs	Oral	400 mg b.i.d.
Ribavirin	Renal	298 hrs	Oral	800–1200 mg daily, divided into 2 doses
Rilpivirine	Hepatic	50 hrs	Oral	25 mg daily
Rimantadine	Renal	25 hrs	Oral	100 mg b.i.d.
Ritonavir	Hepatic	3–5 hrs	Oral	100–400 mg daily, divided in 1 or 2 doses (as booster agent with other PIs)
Saquinavir	Hepatic	1–2 hrs	Oral	1000 mg (Invirase) plus 100 mg ritonavir b.i.d.
Stavudine	Renal	1 hrs	Oral	≥ 60 kg: 40 mg b.i.d.; < 60 kg: 30 mg b.i.d.
Telaprevir	Hepatic	9–11 hrs	Oral	750 mg every 7–9 hrs

Table 36-1   Continued.

Agent	Elimination Route	Half-Life	Administration Route	Common Dosage Range (Adults)
Antiviral agents (continued)				
Telbivudine	Renal	40–49 hrs	Oral	600 mg every day
Tenofovir	Renal	17 hrs	Oral	300 mg daily
Tipranavir	Hepatic	6 hrs	Oral	500 mg plus 200 mg ritonavir b.i.d.
Valacyclovir	Renal	2.5–3.6 hrs	Oral	0.5–1.0 g every day or b.i.d. or t.i.d.
Valganciclovir	Renal	4 hrs	Oral	900 mg b.i.d. × 21 days (induction), 900 mg every day (maintenance)
Zanamivir	Renal	2.5–5.1 hrs	Inhalation (Diskhaler)	2 inhalations (10 mg) b.i.d. (treatment); 10 mg every day (prophylaxis)
Zidovudine	Renal (H)	1.1 hr	Oral	300 mg b.i.d.
			IV	2 mg/kg over 1 hr, then 1 mg/kg/hr until delivery (intrapartum perinatal prophylaxis for pregnant women)
Anthelmintics				
Albendazole	Hepatic	8–12 hrs	Oral	400–800 mg daily
Diethylcarbamazine	Renal	8 hrs	Oral	25 mg/day for 3 days, then 50 mg/day for 5 days, then 100 mg/day for 3 days, then 150 mg/day for 12 days
Ivermectin	Hepatic	16–35 hrs	Oral	150–200 mcg/kg × 1 dose
Mebendazole	Hepatic	8 hrs	Oral	100 mg b.i.d. × 3 consecutive days
Praziquantel	Hepatic	0.8–3.0 hrs	Oral	60–75 mg/kg in 3 divided doses on the same day
Pyrantel	Hepatic	—	Oral	11 mg/kg (maximum = 1 g) as a single dose

[a]Dosage applies to infections other than tuberculosis; for tuberculosis, dosage is 1 g/day.
[b]Intravenous agent withdrawn from U.S. market.
CMV, cytomegalovirus; *EC cap*, enteric-coated capsule; *H*, additional significant hepatic elimination; *HSCT*, hematopoietic stem cell transplant; *IM*, intramuscular; *IV*, intravenous; *PIs*, protease inhibitors *R*, additional significant renal elimination; *SC*, subcutaneous.

4. **Precautions and monitoring effects.** Aminoglycosides can cause serious adverse effects. To prevent or minimize such problems, blood drug concentrations and blood urea nitrogen (BUN) and serum creatinine levels should be monitored during therapy.
   a. **Ototoxicity.** Aminoglycosides can cause vestibular or auditory damage. The relative ototoxicity is as follows:

   streptomycin = kanamycin > amikacin = gentamicin = tobramycin > netilmicin

   (1) Gentamicin and streptomycin cause primarily **vestibular** damage (manifested by tinnitus, vertigo, and ataxia). Such damage may be bilateral and irreversible.
   (2) Amikacin, kanamycin, and neomycin cause mainly **auditory** damage (hearing loss).
   (3) Tobramycin can result in both vestibular and auditory damage.
   b. **Nephrotoxicity.** Because aminoglycosides accumulate in the proximal tubule, mild renal dysfunction develops in up to 25% of patients receiving these drugs for several days or more. Usually, this adverse effect is reversible. Use of once-daily administration (ODA) has been reported in the literature to be as effective and less nephrotoxic than traditional dosing.
   (1) Neomycin is the most nephrotoxic aminoglycoside; streptomycin is the least nephrotoxic. Gentamicin and tobramycin are nephrotoxic to approximately the same degree.
   (2) **Risk factors** for increased nephrotoxic effects include the following:
      (a) Preexisting renal disease
      (b) Previous or prolonged aminoglycoside therapy
      (c) Concurrent administration of another nephrotoxic drug

        (d) Impaired renal flow unrelated to renal disease (e.g., from hypotension, severe hepatic disease)

      (3) Trough levels > 2 μg/mL for gentamicin and tobramycin and > 10 μg/mL for amikacin are associated with nephrotoxicity.

    c. Neuromuscular blockade. This problem may arise in patients receiving high-dose aminoglycoside therapy.

      (1) Risk factors for neuromuscular blockade include the following:

        (a) Concurrent administration of a neuromuscular blocking agent or an anesthetic

        (b) Preexisting hypocalcemia or myasthenia gravis

        (c) Intraperitoneal or rapid IV drug administration

      (2) Apnea and respiratory depression may be reversed with administration of calcium or an anticholinesterase.

    d. Hypersensitivity and **local reactions** are rare adverse effects of aminoglycosides.

    e. Therapeutic levels

      (1) Gentamicin and tobramycin peak at 6 to 10 μg/mL for traditional dosing; when using the ODA method, the peak is 16 to 20 μg/mL or 8 to 10 times the MIC of targeted bacteria. Their trough level is 0.5 to 1.5 μg/mL for traditional or once-daily regimens.

      (2) Amikacin peaks at 25 to 30 μg/mL. The trough level is 5 to 8 μg/mL.

  5. Significant interactions

    a. IV loop diuretics can result in increased ototoxicity.

    b. Other aminoglycosides, **cisplatin**, **and amphotericin B** can cause increased nephrotoxicity when given concurrently with streptomycin.

C. Carbapenems. These agents are β-lactams that contain a fused β-lactam ring and a five-membered ring system that differs from penicillins in being unsaturated and containing a carbon atom instead of a sulfur atom. The class has a broader spectrum of activity than do most β-lactams. Formerly known as thienamycin, **imipenem (Primaxin)** was the first carbapenem compound introduced in the United States, followed by **meropenem (Merrem)** and, most recently, **ertapenem (Invanz)** and **doripenem (Doribax)**. Because it is inhibited by renal dipeptidases, imipenem must be combined with **cilastatin** sodium, a dipeptidase inhibitor (cilastatin is not required with the others because these are not sensitive to renal dipeptidase).

  1. Mechanism of action. Carbapenems are **bactericidal**, inhibiting bacterial cell wall synthesis.

  2. Spectrum of activity. These drugs have the broadest spectrum of all β-lactam antibiotics. The group is active against most gram-positive cocci (including many enterococci), gram-negative rods (including many *P. aeruginosa* strains), and anaerobes. This class has good activity against many bacterial strains that resist other antibiotics. Ertapenem has a narrower spectrum of activity than the other carbapenems. It has little or no activity against *P. aeruginosa* and *Acinetobacter*. These β-lactam antibiotics resist destruction by most β-lactamases.

  3. Therapeutic uses. Carbapenems are most valued in the treatment of severe infections caused by drug-resistant organisms susceptible to these agents. These agents are effective against urinary tract and lower respiratory infections; intra-abdominal and gynecological infections; and skin, soft tissue, bone, and joint infections.

  4. Precautions and monitoring effects

    a. Carbapenems may cause nausea, vomiting, diarrhea, and pseudomembranous colitis.

    b. Seizures, dizziness, and hypotension may develop; seizures appear less frequently with meropenem or ertapenem (1.5% of patients receiving imipenem vs. 0.5% of those receiving meropenem or ertapenem).

    c. Patients who are allergic to penicillin or cephalosporins may suffer cross-sensitivity reactions during carbapenem therapy.

D. Cephalosporins. These agents are known as **β-lactam antibiotics** because their chemical structure consists of a β-lactam ring adjoined to a thiazolidine ring. Cephalosporins generally are classified in four major groups based mainly on their spectrum of activity (*Table 36-2*).

  1. Mechanism of action. Cephalosporins are **bactericidal**; they inhibit bacterial cell wall synthesis, reducing cell wall stability and thus causing membrane lysis.

  2. Spectrum of activity

    a. First-generation cephalosporins are active against most gram-positive cocci (except enterococci) as well as enteric aerobic gram-negative bacilli (e.g., *E. coli*, *K. pneumoniae*, *Proteus mirabilis*).

| Table 36-2 | CLASSIFICATION OF CEPHALOSPORINS |

First-Generation	Second-Generation	Third-Generation	Fourth-Generation

Cefadroxil*
  (Duricef, Ultracef)
Cefazolin (Ancef, Kefzol)
Cephalexin* (Keflex)
Cephapirin (Cefadyl)
Cephradine*
  (Anspor, Velosef)
	Cefaclor* (Ceclor)
	Cefmetazole (Zefazone)
	Cefotetan (Cefotan)
	Cefoxitin (Mefoxin)
	Cefuroxime (Zinacef)
	Cefuroxime axetil* (Ceftin)
	Cefprozil* (Cefzil)
		Cefdinir (Omnicef)*
		Cefixime (Suprax)*
		Cefoperazone (Cefobid)
		Cefotaxime (Claforan)
		Cefpodoxime proxetil* (Vantin)
		Ceftazidime (Fortaz, Tazicef,
		  Tazidime)
		Ceftibuten* (Cedax)
		Ceftizoxime (Cefizox)
		Ceftriaxone (Rocephin)
		Cefditoren* (Spectracef)
			Cefepime (Maxipime)
			Ceftaroline (Teflaro)

*Oral agents.

    b. Second-generation cephalosporins are active against the organisms covered by first-generation cephalosporins and have extended gram-negative coverage, including β-lactamase–producing strains of *Haemophilus influenzae*.

    c. Third-generation cephalosporins have wider activity against most gram-negative bacteria, for example, *Enterobacter, Citrobacter, Serratia, Providencia, Neisseria*, and *Haemophilus* organisms, including β-lactamase–producing strains. Some members have antipseudomonal activity.

    d. Fourth-generation cephalosporins include **cefepime (Maxipime) and ceftaroline (Teflaro)**. However, their designation as a fourth-generation cephalosporin is debatable. Cefepime is highly resistant to β-lactamases and has a low propensity for selection of β-lactam–resistant mutant strains. It shows evidence of greater activity versus gram-positive cocci, *Enterobacteriaceae*, and *Pseudomonas* than third-generation cephalosporins. Ceftaroline has extended coverage of gram-positive bacteria including methicillin-resistant *Staphylococcus aureus* (MRSA), multidrug-resistant *Streptococcus pneumonia* (MDRSP), and common gram-negative bacteria. However, it has poor activity against anaerobes; atypical bacteria; and *Stenotrophomonas, Acinetobacter*, and *Pseudomonas* species. It is not stable against several β-lactamases.

    e. Each generation of cephalosporin has shifted toward increased gram-negative activity but has lost activity toward gram-positive organisms. Fourth-generation agents should have improved activity toward gram-positive organisms (including MRSA) over third-generation agents, as well as greater aerobic and anaerobic gram-negative coverage.

  3. Therapeutic uses

    a. First-generation cephalosporins commonly are administered to treat serious *Klebsiella* infections and gram-positive and some gram-negative infections in patients with mild penicillin allergy. These agents also are used widely in perioperative prophylaxis. For most other indications, they are not the preferred drugs.

    b. Second-generation cephalosporins are valuable in the treatment of urinary tract infections resulting from *E. coli* organisms, acute otitis media, sinusitis, and gonococcal disease caused by organisms that resist other agents.

      (1) Cefaclor (Ceclor) is useful in otitis media and sinusitis in patients who are allergic to ampicillin and amoxicillin. **Cefprozil (Cefzil)**, a second-generation cephalosporin can be administered twice daily but offers no important spectrum differences.

      (2) Cefoxitin (Mefoxin) is therapeutic for mixed aerobic–anaerobic infections, such as intra-abdominal infection. The **cefotetan (Cefotan)** spectrum is similar, but this agent can be given twice daily.

      (3) Cefuroxime (Zinacef) is commonly administered for outpatient community-acquired pneumonia.

    c. Third-generation cephalosporins penetrate the cerebrospinal fluid (CSF) and thus are valuable in the treatment of meningitis caused by such organisms as meningococci, pneumococci, *H. influenzae*, and enteric gram-negative bacilli.

      (1) These agents also are used to treat sepsis of unknown origin in immunosuppressed patients and to treat fever in neutropenic immunosuppressed patients (given in combination with an aminoglycoside).

      (2) Third-generation cephalosporins are useful in infections caused by many organisms resistant to older cephalosporins.

      (3) These agents are frequently administered as empiric therapy for life-threatening infection in which resistant organisms are the most likely cause.

      (4) Initial therapy of mixed bacterial infections (e.g., sepsis) commonly involves third-generation cephalosporins.

    d. The **fourth-generation** agent, cefepime, is approved for treatment of urinary tract infections, uncomplicated skin and skin structure infections, pneumonia, and empiric use in febrile neutropenic patients. Cefepime has a spectrum of activity similar to third-generation agents but is more resistant to some β-lactamases. Ceftaroline is approved only for the treatment of community-acquired bacterial pneumonia and acute bacterial skin and skin structure infections caused by susceptible isolates.

  4. Precautions and monitoring effects

    a. Because all cephalosporins (except cefoperazone) are eliminated renally, doses must be adjusted for patients with renal impairment.

    b. Cross-sensitivity with penicillin has been reported in up to 10% of patients receiving cephalosporins. More recent information indicates that true cross-reactivity is rare.

    c. Cephalosporins can cause hypersensitivity reactions similar to those resulting from penicillin (see II.F.1.e.[1]). Manifestations include fever, maculopapular rash, anaphylaxis, and hemolytic anemia.

    d. Other adverse effects include nausea, vomiting, diarrhea, superinfection, nephrotoxicity, and *Clostridium difficile*–induced colitis; with cefoperazone, cefmetazole, and cefotetan, bleeding diatheses may occur. Bleeding can be reversed by vitamin K administration.

    e. Cephalosporins may cause false-positive glycosuria results on tests using the copper-reduction method.

    f. Ceftriaxone now contraindicated in newborns receiving concurrent administration of calcium-containing solutions or products due to risk of fatal precipitation in lungs and kidneys. New warning added also stating that ceftriaxone and IV calcium-containing solutions should not be administered within 48 hrs of each other.

  5. Significant interactions

    a. Probenecid may impair the excretion of cephalosporins (except ceftazidime), causing increased cephalosporin levels and possible toxicity.

    b. Alcohol consumption may result in a disulfiram-type reaction in patients receiving cefmetazole, cefotetan, and cefoperazone.

    c. Plasma concentrations of cefaclor extended-release tablets, cefdinir, and cefpodoxime may be reduced by coadministration with **antacids**.

    d. H$_2$-antagonists may reduce plasma levels of cefpodoxime and cefuroxime.

    e. Iron supplements and **iron-fortified foods** reduce absorption of cefdinir by 80% and 30%, respectively.

E. Erythromycins. The chemical structure of these macrolide antibiotics is characterized by a lactone ring to which sugars are attached. Erythromycin base and the estolate, ethylsuccinate, and stearate salts are given orally; erythromycin lactobionate and glucoptate are given parenterally.

  1. Mechanism of action. Erythromycins may be **bactericidal** or **bacteriostatic**; they bind to the 50S ribosomal subunit, inhibiting bacterial protein synthesis.

  2. Spectrum of activity. Erythromycins are active against many gram-positive organisms, including streptococci (e.g., *Streptococcus pneumoniae*), and *Corynebacterium* and *Neisseria* species as well as some strains of *Mycoplasma*, *Legionella*, *Treponema*, and *Bordetella*. Some *Staphylococcus aureus* strains that resist penicillin G are susceptible to erythromycins.

  3. Therapeutic uses

    a. Erythromycins are the preferred drugs for the treatment of *Mycoplasma pneumoniae* and *Campylobacter* infections, Legionnaires disease, chlamydial infections, diphtheria, and pertussis.

    b. In patients with penicillin allergy, erythromycins are important alternatives in the treatment of pneumococcal pneumonia, *S. aureus* infections, syphilis, and gonorrhea.

    c. Erythromycins may be given prophylactically before dental procedures to prevent bacterial endocarditis.

  4. Precautions and monitoring parameters

    a. Gastrointestinal (GI) distress (e.g., nausea, vomiting, diarrhea, epigastric discomfort) may occur with all erythromycin forms and are the most common adverse effects.

    b. Allergic reactions (rare) may present as skin eruptions, fever, and eosinophilia.

    c. Cholestatic hepatitis may arise in patients treated for 1 week or longer with erythromycin estolate; symptoms usually disappear within a few days after drug therapy ends. There have been infrequent reports of hepatotoxicity with other salts of erythromycin.

    d. IM injections of more than 100 mg produce severe pain persisting for hours.

    e. Transient hearing impairment may develop with high-dose erythromycin therapy.

  5. Significant interactions

    a. Erythromycin inhibits the hepatic metabolism of **theophylline**, resulting in toxic accumulation.

    b. Erythromycin interferes with the metabolism of **digoxin**, **corticosteroids**, **carbamazepine**, **cyclosporin**, and **lovastatin**, possibly potentiating the effect and toxicity of these drugs.

    c. **Clarithromycin (Biaxin)** may potentiate **oral anticoagulants** (monitor prothrombin time), increase **cyclosporine** levels with increased toxicity, and increase **digoxin** and **theophylline** levels.

    d. Coadministration of clarithromycin and **cisapride** may increase risk of serious cardiac arrhythmias; coadministration is contraindicated.

    e. Sudden deaths have been reported when clarithromycin was added to ongoing **pimozide** therapy; coadministration is contraindicated.

  6. Alternatives to erythromycin

    a. Clarithromycin and azithromycin (Zithromax) are semisynthetic macrolide antibiotics. These expensive but well-tolerated alternatives to erythromycin are administered once daily.

      (1) Clarithromycin

        (a) Spectrum of activity. Clarithromycin is more active than erythromycin against staphylococci and streptococci. In addition to activity against other organisms covered by erythromycin, it is also active in vitro against MAI, *Toxoplasma gondii*, and *Cryptosporidium* spp.

        (b) Therapeutic uses. This agent is indicated for the prevention of *Mycobacterium avium* complex (MAC) infection and is useful in otitis media, sinusitis, mycoplasmal pneumonia, and pharyngitis. Clarithromycin is also used with proton pump inhibitors (PPIs) for *Helicobacter pylori* eradication.

      (2) Azithromycin

        (a) Spectrum of activity. Azithromycin is less active than erythromycin against gram-positive cocci but more active against *H. influenzae* and other gram-negative organisms. Azithromycin concentrates within cells, and tissue levels are higher than serum levels.

        (b) Therapeutic uses. This agent is useful in nongonococcal urethritis caused by chlamydia, lower respiratory tract infections, *Mycobacterium avium-intracellulare* (MAC or MAI) infection and prophylaxis, pharyngitis, pelvic inflammatory disease, and Legionnaires disease. Azithromycin is also indicated for pediatric use.

 F. Penicillins

  1. Natural penicillins. As with cephalosporins and all other penicillins, natural penicillins are β-lactam antibiotics. Among the most important antibiotics, natural penicillins are the preferred drugs in the treatment of many infectious diseases.

    a. Available agents

      (1) Penicillin G sodium and potassium salts can be administered orally, intravenously, or intramuscularly.

      (2) Penicillin V (Pen-Vee K), a soluble drug form, is administered orally.

      (3) Penicillin G procaine and **penicillin G benzathine** are repository drug forms. Administered intramuscularly, these insoluble salts allow slow drug absorption from the injection site and thus have a longer duration of action (12 to 24 hrs).

    b. Mechanism of action. Penicillins are **bactericidal**; they inhibit bacterial cell wall synthesis in a manner similar to that of the cephalosporins.

c. Spectrum of activity
   (1) Natural penicillins are highly active against gram-positive cocci and against some gram-negative cocci.
   (2) Penicillin G is 5 to 10 times more active than penicillin V against gram-negative organisms and some anaerobic organisms.
   (3) Because natural penicillins are readily hydrolyzed by penicillinases (β-lactamases), they are ineffective against *S. aureus* and other organisms that resist penicillin.

d. Therapeutic uses
   (1) Penicillin G is the preferred agent for all infections caused by penicillin-susceptible *S. pneumoniae* organisms, including
      (a) Pneumonia
      (b) Arthritis
      (c) Meningitis
      (d) Peritonitis
      (e) Pericarditis
      (f) Osteomyelitis
      (g) Mastoiditis
   (2) Penicillins G and V are highly effective against other streptococcal infections, such as pharyngitis, otitis media, sinusitis, and bacteremia.
   (3) Penicillin G is the preferred agent in gonococcal infections, syphilis, anthrax, actinomycosis, gas gangrene, and *Listeria* infections.
   (4) Administered when an oral penicillin is needed, penicillin V is most useful in skin, soft tissue, and mild respiratory infections.
   (5) Penicillin G procaine is effective against syphilis and uncomplicated gonorrhea.
   (6) Used to treat syphilis infections outside the CNS, penicillin G benzathine also is effective against group A β-hemolytic streptococcal infections.
   (7) Penicillins G and V may be used prophylactically to prevent streptococcal infection, rheumatic fever, and neonatal gonorrheal ophthalmia. Patients with valvular heart disease may receive these drugs preoperatively.
   (8) There is emerging resistance to penicillin G by *S. pneumoniae* in some areas of the United States. The alternative therapy is vancomycin.

e. Precautions and monitoring effects
   (1) Hypersensitivity reactions. These occur in up to 10% of patients receiving penicillin. Manifestations range from mild rash to anaphylaxis.
      (a) The rash may be urticarial, vesicular, bullous, scarlatiniform, or maculopapular. Rarely, thrombopenic purpura develops.
      (b) Anaphylaxis is a life-threatening reaction that most commonly occurs with parenteral administration. Signs and symptoms include severe hypotension, bronchoconstriction, nausea, vomiting, abdominal pain, and extreme weakness.
      (c) Other manifestations of hypersensitivity reactions include fever, eosinophilia, angioedema, and serum sickness.
      (d) Before penicillin therapy begins, the patient's history should be evaluated for reactions to penicillin. A positive history places the patient at heightened risk for a subsequent reaction. In most cases, such patients should receive a substitute antibiotic. (However, hypersensitivity reactions may occur even in patients with a negative history.)
   (2) Other adverse effects of natural penicillins include GI distress (e.g., nausea, diarrhea), bone marrow suppression (e.g., impaired platelet aggregation, agranulocytosis), and superinfection. With high-dose therapy, seizures may occur, particularly in patients with renal impairment.

f. Significant interactions
   (1) Probenecid increases blood levels of natural penicillins and may be given concurrently for this purpose.
   (2) Antibiotic antagonism occurs when **erythromycins**, **tetracyclines**, or **chloramphenicol** is given within 1 hr of the administration of penicillin. The clinical significance of such antagonism is not clear.

     (3) With penicillin G procaine and benzathine, precaution must be used in patients with a history of hypersensitivity reactions to penicillins because prolonged reactions may occur. Intravascular injection should be avoided. Procaine hypersensitivity is a contraindication to the use of procaine penicillin G.

     (4) Parenteral products contain either potassium (1.7 mEq/million units) or sodium (2 mEq/million units).

2. Penicillinase-resistant penicillins. These penicillins are not hydrolyzed by staphylococcal penicillinases (β-lactamases). These agents include **methicillin**, **nafcillin**, and the **isoxazolyl penicillins—dicloxacillin (Dynapen)** and **oxacillin**.

    a. Mechanism of action (see II.F.1.b)

    b. Spectrum of activity. Because these penicillins resist penicillinases, they are active against staphylococci that produce these enzymes.

    c. Therapeutic uses

     (1) Penicillinase-resistant penicillins are used solely in staphylococcal infections resulting from organisms that resist natural penicillins.

     (2) These agents are less potent than natural penicillins against organisms susceptible to natural penicillins and thus make poor substitutes in the treatment of infections caused by these organisms.

     (3) Nafcillin is excreted by the liver and thus may be useful in treating staphylococcal infections in patients with renal impairment.

     (4) Oxacillin and **dicloxacillin** are most valuable in long-term therapy of serious staphylococcal infections (e.g., endocarditis, osteomyelitis) and in the treatment of minor staphylococcal infections of the skin and soft tissues.

    d. Precautions and monitoring effects

     (1) As with all penicillins, the penicillinase-resistant group can cause hypersensitivity reactions (see II.F.1.e.[1]).

     (2) Methicillin may cause nephrotoxicity and interstitial nephritis.

     (3) Oxacillin may be hepatotoxic.

     (4) Complete cross-resistance exists among the penicillinase-resistant penicillins.

    e. Significant interactions. Probenecid increases blood levels of these penicillins and may be given concurrently for that purpose.

3. Aminopenicillins. This penicillin group includes the semisynthetic agents **ampicillin** and **amoxicillin (Amoxil)**. Because of their wider antibacterial spectrum, these drugs are also known as **broad-spectrum penicillins**.

    a. Mechanism of action (see II.F.1.b)

    b. Spectrum of activity. Aminopenicillins have a spectrum that is similar to but broader than that of the natural and penicillinase-resistant penicillins. Easily destroyed by staphylococcal penicillinases, aminopenicillins are ineffective against most staphylococcal organisms. Against most bacteria sensitive to penicillin G, aminopenicillins are slightly less effective than this agent.

    c. Therapeutic uses. Aminopenicillins are used to treat gonococcal infections, upper respiratory infections, uncomplicated urinary tract infections, and otitis media caused by susceptible organisms.

     (1) For infections resulting from penicillin-resistant organisms, **ampicillin** may be given in combination with sulbactam (**Unasyn**).

     (2) Amoxicillin is less effective than ampicillin against shigellosis.

     (3) Amoxicillin is more effective against *S. aureus*, *Klebsiella*, and *Bacteroides fragilis* infections when administered in combination with clavulanic acid—amoxicillin/potassium clavulanate (**Augmentin**) because clavulanic acid inactivates penicillinases.

    d. Precautions and monitoring effects

     (1) Hypersensitivity reactions may occur (see II.F.1.e.[1]).

     (2) Diarrhea is most common with ampicillin.

     (3) In addition to the urticarial hypersensitivity rash seen with all penicillins, ampicillin and amoxicillin frequently cause a generalized erythematous, maculopapular rash. (This occurs in 5% to 10% of patients receiving ampicillin.)

    e. Significant interactions (see II.F.2.e)

4. **Extended-spectrum penicillins.** These agents have the widest antibacterial spectrum of all penicillins. Also called **antipseudomonal penicillins**, this group includes the **carboxypenicillin** (e.g., **ticarcillin**) and the **ureidopenicillin** (e.g., **piperacillin**).
   a. **Mechanism of action** (see II.F.1.b)
   b. **Spectrum of activity.** These drugs have a spectrum similar to that of the aminopenicillins but also are effective against *Klebsiella* and *Enterobacter* spp., some *B. fragilis* organisms, and indole-positive *Proteus* and *Pseudomonas* organisms.
      (1) **Ticarcillin** is active against *P. aeruginosa*. Combined with clavulanic acid (**Timentin**), ticarcillin has enhanced activity against organisms that resist ticarcillin alone.
      (2) **Piperacillin** is more active than ticarcillin against *Pseudomonas* organisms.
      (3) **Piperacillin and tazobactam (Zosyn).** Tazobactam is a β-lactamase inhibitor that expands the spectrum of activity to include some organisms not sensitive to piperacillin alone (if resistance is the result of β-lactamase production), including strains of staphylococci, *Haemophilus*, *Bacteroides*, and *Enterobacteriaceae*. Generally, tazobactam does not enhance activity against *Pseudomonas*.
   c. **Therapeutic uses.** Extended-spectrum penicillins are used mainly to treat serious infections caused by gram-negative organisms (e.g., sepsis; pneumonia; infections of the abdomen, bone, and soft tissues). Piperacillin/tazobactam is effective in the treatment of nosocomial pneumonia.
   d. **Precautions and monitoring effects**
      (1) Hypersensitivity reactions may occur (see II.F.1.e.[1]).
      (2) Ticarcillin may cause hypokalemia.
      (3) The high sodium content of ticarcillin may pose a danger to patients with heart failure (HF).
      (4) All inhibit platelet aggregation, which may result in bleeding.
   e. **Significant interactions** (see II.F.2.e)
G. **Sulfonamides.** Derivatives of sulfanilamide, these agents were the first drugs to prevent and cure human bacterial infection successfully. Although their current usefulness is limited by the introduction of more effective antibiotics and the emergence of resistant bacterial strains, sulfonamides remain the drugs of choice for certain infections. The major sulfonamides are **sulfadiazine**, **sulfamethoxazole**, **sulfisoxazole**, and **sulfamethizole**.
   1. **Mechanism of action.** Sulfonamides are **bacteriostatic**; they suppress bacterial growth by triggering a mechanism that blocks folic acid synthesis, thereby forcing bacteria to synthesize their own folic acid.
   2. **Spectrum of activity.** Sulfonamides are broad-spectrum agents with activity against many gram-positive organisms (e.g., *S. pyogenes*, *S. pneumoniae*) and certain gram-negative organisms (e.g., *H. influenzae*, *E. coli*, *P. mirabilis*). They also are effective against certain strains of *Chlamydia trachomatis*, *Nocardia*, *Actinomyces*, and *Bacillus anthracis*.
   3. **Therapeutic uses**
      a. Sulfonamides most often are used to treat urinary tract infections caused by *E. coli*, including acute and chronic cystitis and chronic upper urinary tract infections.
      b. These agents have value in the treatment of nocardiosis, trachoma and inclusion conjunctivitis, and dermatitis herpetiformis.
      c. **Sulfadiazine** may be administered in combination with pyrimethamine to treat toxoplasmosis.
      d. **Sulfamethoxazole** may be given in combination with trimethoprim (**Bactrim**) to treat such infections as *Pneumocystis carinii* pneumonia, *Shigella* enteritis, *Serratia* sepsis, urinary tract infections, respiratory infections, and gonococcal urethritis. It is the drug of choice in the treatment of *Stenotrophomonas maltophilia*.
      e. **Sulfisoxazole** is sometimes used in combination with erythromycin ethylsuccinate to treat acute otitis media caused by *H. influenzae* organisms. For the initial treatment of uncomplicated urinary tract infections, sulfisoxazole may be given in combination with phenazopyridine for relief of symptoms of pain, burning, or urgency.
      f. Prophylactic sulfonamide therapy has been used successfully to prevent streptococcal infections and rheumatic fever recurrences.
   4. **Precautions and monitoring effects**
      a. Sulfonamides may cause blood dyscrasias (e.g., hemolytic anemia—particularly in patients with G6PD deficiency, aplastic anemia, thrombocytopenia, agranulocytosis, and eosinophilia).

b. Hypersensitivity reactions to sulfonamides probably result from sensitization and most commonly involve the skin and mucous membranes. Manifestations include various types of skin rash, exfoliative dermatitis, and photosensitivity. Drug fever and serum sickness also may develop.

c. Crystalluria and hematuria may occur, possibly leading to urinary tract obstruction. (Adequate fluid intake and urine alkalinization can prevent or minimize this risk.) Sulfonamides should be used cautiously in patients with renal impairment.

d. Life-threatening hepatitis caused by drug toxicity or sensitization is a rare adverse effect. Signs and symptoms include headache, nausea, vomiting, and jaundice.

e. AIDS patients have increased frequency of cutaneous hypersensitivity reactions to sulfamethoxazole.

5. Significant interactions. Sulfonamides may potentiate the effects of **phenytoin**, **oral anticoagulants**, and **sulfonylureas**.

H. Tetracyclines. These broad-spectrum agents are effective against certain bacterial strains that resist other antibiotics. Nonetheless, they are the preferred drugs in only a few situations. The major tetracyclines include **demeclocycline (Declomycin)**, **doxycycline (Vibramycin)**, **minocycline (Minocin)**, and **oxytetracycline (Terramycin)**.

1. Mechanism of action. Tetracyclines are **bacteriostatic**; they inhibit bacterial protein synthesis by binding to the 30S ribosomal subunit.

2. Spectrum of activity. Tetracyclines are active against gram-negative and gram-positive organisms, spirochetes, *Mycoplasma* and *Chlamydia* organisms, rickettsial species, and certain protozoa.

a. *Pseudomonas* and *Proteus* organisms are now resistant to tetracyclines. Many coliform bacteria, pneumococci, staphylococci, streptococci, and *Shigella* strains are increasingly resistant.

b. Cross-resistance within the tetracycline group is extensive.

3. Therapeutic uses

a. Tetracyclines are the agents of choice in rickettsial (Rocky Mountain spotted fever), chlamydial, and mycoplasmal infections; amebiasis; and bacillary infections (e.g., cholera, brucellosis, tularemia, some *Salmonella* and *Shigella* infections).

b. Tetracyclines are useful alternatives to penicillin in the treatment of anthrax, syphilis, gonorrhea, Lyme disease, nocardiosis, and *H. influenzae* respiratory infections.

c. Oral or topical tetracycline may be administered as a treatment for acne.

d. Doxycycline is highly effective in the prophylaxis of "traveler's diarrhea" (commonly caused by *E. coli*). Because the drug is excreted mainly in the feces, it is the safest tetracycline for the treatment of extrarenal infections in patients with renal impairment.

e. Demeclocycline is used commonly as an adjunctive agent to treat the **syndrome of inappropriate antidiuretic hormone (SIADH)** secretion.

4. Precautions and monitoring effects

a. GI distress (e.g., diarrhea, abdominal discomfort, nausea, anorexia) is a common adverse effect of tetracyclines. This problem can be minimized by administering the drug with food or temporarily decreasing the dosage.

b. Skin rash, urticaria, and generalized exfoliative dermatitis signify a hypersensitivity reaction. Rarely, angioedema and anaphylaxis occur.

c. Cross-sensitivity within the tetracycline group is common.

d. Phototoxic reactions (severe skin lesions) can develop with exposure to sunlight. This reaction is most common with demeclocycline and doxycycline.

e. Tetracyclines may cause hepatotoxicity, particularly in pregnant women. Manifestations include jaundice, acidosis, and fatty liver infiltration.

f. Renally impaired patients may experience a significant increase in BUN secondary to catabolic effects of tetracyclines.

g. Tetracyclines may induce permanent tooth discoloration, tooth enamel defects, and retarded bone growth in infants and children.

h. Use of outdated and degraded tetracyclines can lead to renal tubular dysfunction, possibly resulting in renal failure.

i. Minocycline can cause vestibular toxicity (e.g., ataxia, dizziness, nausea, vomiting).

j. IV tetracyclines are irritating and may cause phlebitis.

5. **Significant interactions**
   a. **Dairy products** and other foods, **iron preparations**, and **antacids** and **laxatives** containing aluminum, calcium, or magnesium can cause reduced tetracycline absorption. Absorption of doxycycline is not inhibited by these factors.
   b. **Methoxyflurane** may exacerbate the tetracyclines' nephrotoxic effects.
   c. **Barbiturates** and **phenytoin** decrease the antibiotic effectiveness of tetracyclines.
   d. Demeclocycline antagonizes the action of **antidiuretic hormone (ADH)** and may be given as a diuretic in patients with SIADH.

I. **Fluoroquinolones** are agents related to nalidixic acid—see II.J.1.c; II.J.2.c; II.J.4.c—and include **ciprofloxacin (Cipro)**, **norfloxacin (Noroxin)**, **ofloxacin (Floxin)**, **moxifloxacin (Avelox)**, **levofloxacin (Levaquin)**, and **gemifloxacin (Factive)**. They are bactericidal for growing bacteria.
   1. **Mechanism of action.** Fluoroquinolones inhibit DNA gyrase.
   2. **Spectrum of activity.** Fluoroquinolones are highly active against enteric gram-negative bacilli, *Salmonella*, *Shigella*, *Campylobacter*, *Haemophilus*, and *Neisseria*.
      a. **Ciprofloxacin** has activity against *P. aeruginosa*, but the fluoroquinolones as a group have variable activity against non–*P. aeruginosa*. Ciprofloxacin is active against some anaerobes; it has moderate activity against *M. tuberculosis*.
      b. **Gram-positive organisms** are less susceptible than gram-negative organisms but usually are sensitive, except for *Enterococcus faecalis* and methicillin-resistant staphylococci.
      c. **Ofloxacin** has the greatest activity against *Chlamydia*.
   3. **Therapeutic uses** (*Table 36-3*)
      a. Norfloxacin is indicated for the oral treatment of urinary tract infections, uncomplicated gonococcal infections, and prostatitis.
      b. Ciprofloxacin, ofloxacin, and levofloxacin are available orally and intravenously. Ciprofloxacin is approved for use in urinary tract infections; lower respiratory infections; sinusitis; bone, joint, and skin structure infections; empiric use in febrile neutropenic patients; typhoid fever; urethral and cervical gonococcal infections; and infectious diarrhea. Ofloxacin is approved for use in lower respiratory infections, uncomplicated gonococcal and chlamydial cervicitis and urethritis, skin and skin structure infections, prostatitis, and urinary tract infections.
      c. Levofloxacin is approved for the treatment of urinary tract infections. Gemifloxacin, moxifloxacin, and levofloxacin are also used in lower respiratory tract infections. Gemifloxacin is only available orally.
      d. Moxifloxacin is approved for the treatment of complicated intra-abdominal infections but should not be used for urinary tract infections.
   4. **Precautions and monitoring effects**
      a. Occasional adverse effects include nausea, dyspepsia, headache, dizziness, insomnia, cardiac QT prolongation, arthropathy, tendonitis, CNS effects, photosensitivity, and hypoglycemia.

Table 36-3   QUINOLONE AGENTS CLASSIFIED BY GENERATION

	Agent	Spectrum of Coverage	Site of Infection
First-generation	Cinoxacin (Cinoxacin, Cinobac) Nalidixic acid (NegGram) Norfloxacin (Noroxin)	Gram negatives	Urinary tract
Second-generation	Ciprofloxacin (Cipro) Ofloxacin (Floxin)	Gram negatives Gram positives	Systemic, urinary tract
Third-generation	Levofloxacin (Levaquin)	Gram positives Gram negatives Atypicals	Systemic, urinary tract
	Gemifloxacin (Factive) Moxifloxacin (Avelox)	Gram negatives Gram positives Atypicals	Systemic only

    b. Infrequent adverse effects include rash, urticaria, leukopenia, and elevated liver enzymes. Crystalluria occurs with high doses at alkaline pH.

    c. The FDA has added a black box warning about the increased risk of developing tendinitis and tendon rupture in patients taking this class of medications.

5. Significant interactions

    a. Ciprofloxacin has been shown to increase **theophylline** levels. Variable effects on theophylline levels have been reported from other members of the group. In patients requiring fluoroquinolones, theophylline levels should be monitored.

    b. **Antacids** and **sucralfate** and divalent or trivalent cations such as iron significantly decrease the absorption of fluoroquinolones.

    c. Fluoroquinolones may increase prothrombin times in patients receiving **warfarin**.

    d. Concurrent use with **nonsteroidal anti-inflammatory drugs** (NSAIDs) may increase the risk of CNS stimulation (seizures).

    e. Fluoroquinolones may produce prolonged QT interval when administered with **antiarrhythmic agents**. Some fluoroquinolones (i.e., gemifloxacin, moxifloxacin) should be avoided in patients with known prolongation of the QTC interval, with uncorrected hypocalcemia, or who are receiving class IA or class III antiarrhythmic drugs.

    f. Some fluoroquinolones have been reported to enhance the effects of oral anticoagulants.

    g. Hyperglycemia and hypoglycemia have been reported in patients receiving quinolones and an antidiabetic agent. Blood glucose monitoring is recommended in such patients.

J. Urinary tract antiseptics. Concentrating in the renal tubules and bladder, these agents exert local antibacterial effects; most do not achieve blood levels high enough to treat systemic infections. However, some new quinolone derivatives, such as ciprofloxacin and ofloxacin, are valuable in the treatment of certain infections outside the urinary tract (see II.I.3.b).

1. Mechanism of action

    a. **Methenamine** is hydrolyzed to ammonia and formaldehyde in acidic urine; formaldehyde is antibacterial against gram-positive and gram-negative organisms. Mandelic and hippuric acids, with which methenamine is combined, provide supplementary antibacterial action.

    b. **Nitrofurantoin** is **bacteriostatic**; in high concentrations, it may be **bactericidal**. Presumably, it disrupts bacterial enzyme systems.

    c. **Quinolones. Nalidixic acid** and its analogs and derivatives—**oxolinic acid, norfloxacin, cinoxacin, ciprofloxacin,** and others—interfere with DNA gyrase and inhibit DNA synthesis during bacterial replication.

    d. **Fosfomycin tromethamine** is bactericidal in the urine at therapeutic doses. The bactericidal action is because of its inactivation of the enzyme enolpyruvyl transferase, thereby blocking the condensation of uridine diphosphate-*N*-acetylglucosamine with p-enolpyruvate, one of the first steps in bacterial cell wall synthesis.

2. Spectrum of activity

    a. **Methenamine** is active against both gram-positive and gram-negative organisms (e.g., *Enterobacter*, *Klebsiella*, *Proteus*, *P. aeruginosa*, *S. aureus*).

    b. **Nitrofurantoin** is active against many gram-positive and gram-negative organisms, including some strains of *E. coli*, *S. aureus*, *Proteus*, *Enterobacter*, and *Klebsiella*.

    c. **Quinolones** (see II.I.2)

        (1) **Nalidixic acid** and **oxolinic acid** are active against most gram-negative organisms that cause urinary tract infections, including *P. mirabilis*, *E. coli*, *Klebsiella*, and *Enterobacter* organisms. These drugs are not effective against *Pseudomonas* organisms.

        (2) **Norfloxacin** is active against *E. coli*, *Enterobacter*, *Klebsiella*, *Proteus*, *P. aeruginosa*, *S. aureus*, *Citrobacter*, and some *Streptococcus* organisms.

        (3) **Cinoxacin** is active against *E. coli*, *Klebsiella*, *P. mirabilis*, *Proteus vulgaris*, *Proteus morganii*, *Serratia*, and *Citrobacter* organisms.

3. Therapeutic uses

    a. **Methenamine** and **nitrofurantoin** are used to prevent and treat urinary tract infections.

    b. **Quinolones** are administered to treat urinary tract infections; some also are used in such diseases as osteomyelitis and respiratory tract infections.

    c. **Fosfomycin** is indicated for treatment of uncomplicated urinary tract infection (acute cystitis) in women caused by susceptible strains of *E. coli* or *E. faecalis*.

4. **Precautions and monitoring effects**
   a. **Methenamine** may cause nausea, vomiting, and diarrhea; in high doses, it may lead to urinary tract irritation (e.g., dysuria, frequency, hematuria, albuminuria). Skin rash also may develop.
   b. **Nitrofurantoin** may cause various adverse effects.
      (1) GI distress (e.g., nausea, vomiting, diarrhea) is relatively common.
      (2) Hypersensitivity reactions to nitrofurantoin may involve the skin, lungs, blood, or liver; manifestations include fever, chills, hepatitis, jaundice, leukopenia, hemolytic anemia, granulocytopenia, and pneumonitis.
      (3) Adverse CNS effects include headache, vertigo, and dizziness. Polyneuropathy may develop with high doses or in patients with renal impairment.
   c. **Quinolones**
      (1) **Nalidixic acid** and **oxolinic acid** may cause nausea; vomiting; abdominal pain; urticaria; pruritus; skin rash; fever; eosinophilia; and CNS effects such as headache, dizziness, confusion, vertigo, drowsiness, and weakness.
      (2) **Cinoxacin** may induce nausea, vomiting, diarrhea, headache, insomnia, skin rash, pruritus, and urticaria.

5. **Significant interactions**
   a. The effects of methenamine are inhibited by **alkalinizing agents** and are antagonized by **acetazolamide**.
   b. Nitrofurantoin absorption is decreased by **magnesium-containing antacids**. Nitrofurantoin blood levels are increased and urine levels decreased by **sulfinpyrazone** and **probenecid**, leading to increased toxicity and reduced therapeutic effectiveness.
   c. **Quinolones**
      (1) Cinoxacin urine levels are decreased by **probenecid**, reducing therapeutic effectiveness.
      (2) Norfloxacin is rendered less effective by **antacids**.

K. **Miscellaneous antibacterial agents**
   1. **Aztreonam (Azactam).** This agent was the first commercially available monobactam (monocyclic β-lactam compound). It resembles the aminoglycosides in its efficacy against many gram-negative organisms but does not cause nephrotoxicity or ototoxicity. Other advantages of this drug include its ability to preserve the body's normal gram-positive and anaerobic flora, activity against many gentamicin-resistant organisms, and lack of cross-allergenicity with penicillin.
      a. **Mechanism of action.** Aztreonam is **bactericidal**; it inhibits bacterial cell wall synthesis.
      b. **Spectrum of activity.** This drug is active against many gram-negative organisms, including *Enterobacter* and some strains of *P. aeruginosa*.
      c. **Therapeutic uses.** Aztreonam is therapeutic for urinary tract infections, septicemia, skin infections, lower respiratory tract infections, and intra-abdominal infections resulting from gram-negative organisms. Increased incidence of *P. aeruginosa* resistant to aztreonam has been reported.
      d. **Precautions and monitoring effects**
         (1) Aztreonam sometimes causes nausea, vomiting, and diarrhea.
         (2) Liver enzymes may increase transiently during aztreonam therapy.
         (3) This drug may induce skin rash.
   2. **Chloramphenicol.** A nitrobenzene derivative, this drug has broad activity against rickettsia as well as many gram-positive and gram-negative organisms. It also is effective against many ampicillin-resistant strains of *H. influenzae*.
      a. **Mechanism of action.** Chloramphenicol is primarily **bacteriostatic**, although it may be bactericidal against a few bacterial strains.
      b. **Spectrum of activity.** This agent is active against rickettsia and a wide range of bacteria, including *H. influenzae*, *Salmonella typhi*, *Neisseria meningitidis*, *Bordetella pertussis*, *Clostridium*, *B. fragilis*, *S. pyogenes*, and *S. pneumoniae*.
      c. **Therapeutic uses.** Because of its toxic side effects, chloramphenicol is used only to suppress infections that cannot be treated effectively with other antibiotics. Such infections typically include
         (1) Typhoid fever
         (2) Meningococcal infections in cephalosporin-allergic patients
         (3) Serious *H. influenzae* infections, particularly in cephalosporin-allergic patients
         (4) Anaerobic infections (e.g., those originating in the pelvis or intestines)

(5) Anaerobic or mixed infections of the CNS

(6) Rickettsial infections in pregnant patients, tetracycline-allergic patients, and renally impaired patients

d. Precautions and monitoring effects

(1) Chloramphenicol can cause bone marrow suppression (dose-related) with resulting pancytopenia; rarely, the drug leads to aplastic anemia (not related to dose).

(2) Hypersensitivity reactions may include skin rash and, in extremely rare cases, angioedema or anaphylaxis.

(3) Chloramphenicol therapy may lead to gray baby syndrome in neonates (especially premature infants). This dangerous reaction, which stems partly from inadequate liver detoxification of the drug, is manifested by vomiting, gray cyanosis, rapid and irregular respirations, vasomotor collapse, and in some cases death.

e. Significant interactions

(1) Chloramphenicol inhibits the metabolism of **phenytoin**, **tolbutamide**, **chlorpropamide**, and **dicumarol**, leading to prolonged action and intensified effect of these drugs.

(2) **Phenobarbital** shortens chloramphenicol's half-life, thereby reducing its therapeutic effectiveness.

(3) **Penicillins** can cause antibiotic antagonism.

(4) **Acetaminophen** elevates chloramphenicol levels and may cause toxicity.

3. Clindamycin (Cleocin). This agent has essentially replaced lincomycin, the drug from which it is derived. It is used to treat skin, respiratory tract, and soft tissue infections caused by staphylococci, pneumococci, and streptococci.

a. Mechanism of action. Clindamycin is **bacteriostatic**; it binds to the 50S ribosomal subunit, thereby suppressing bacterial protein synthesis.

b. Spectrum of activity. This agent is active against most gram-positive and many anaerobic organisms, including *B. fragilis.*

c. Therapeutic uses. Because of its marked toxicity, clindamycin is used only against infections for which it has proven to be the most effective drug. Typically, such infections include abdominal and female genitourinary tract infections caused by *B. fragilis.*

d. Precautions and monitoring effects

(1) Clindamycin may cause rash, nausea, vomiting, diarrhea, and pseudomembranous colitis as evidenced by fever, abdominal pain, and bloody stools.

(2) Blood dyscrasias (e.g., eosinophilia, thrombocytopenia, leukopenia) may occur.

e. Significant interactions. Clindamycin may potentiate the effects of **neuromuscular blocking agents**.

4. Dapsone. A member of the sulfone class, this drug is the primary agent in the treatment of all forms of leprosy.

a. Mechanism of action. Dapsone is **bacteriostatic** for *Mycobacterium leprae*; its mechanism of action probably resembles that of the sulfonamides.

b. Spectrum of activity. This drug is active against *M. leprae*; however, drug resistance develops in up to 40% of patients. Dapsone also has some activity against *P. carinii* organisms and the malarial parasite *Plasmodium.*

c. Therapeutic uses

(1) Dapsone is the drug of choice for treating leprosy.

(2) This agent may be used to treat dermatitis herpetiformis, a skin disorder.

(3) Maloprim, a dapsone–pyrimethamine product, is valuable in the prophylaxis and treatment of malaria.

(4) Dapsone, with or without trimethoprim, is used for prophylaxis of *P. carinii* pneumonia in patients with AIDS.

d. Precautions and monitoring effects

(1) Hemolytic anemia can occur with daily doses > 200 mg. Other adverse hematological effects include methemoglobinemia and leukopenia.

(2) Nausea, vomiting, and anorexia may develop.

(3) Adverse CNS effects include headache, dizziness, nervousness, lethargy, paresthesias, and psychosis.

      (4) Dapsone occasionally results in a potentially lethal mononucleosis-like syndrome.

      (5) Paradoxically, this drug sometimes exacerbates leprosy.

      (6) Other adverse effects include skin rash, peripheral neuropathy, blurred vision, tinnitus, hepatitis, and cholestatic jaundice.

   e. Significant interactions. Probenecid elevates blood levels of dapsone, possibly resulting in toxicity.

5. Clofazimine is phenazine dye with antimycobacterial and anti-inflammatory activity.

   a. Mechanism of action. Clofazimine appears to bind preferentially to mycobacterial DNA, inhibiting replication and growth. It is **bactericidal** against *M. leprae*, and it appears to be **bacteriostatic** against MAI.

   b. Spectrum of activity. Clofazimine is active against various mycobacteria, including *M. leprae*, *M. tuberculosis*, and MAI.

   c. Therapeutic uses. Clofazimine is used to treat leprosy and a variety of atypical *Mycobacterium* infections.

   d. Precautions and monitoring effects

      (1) Pigmentation (pink to brownish) occurs in 75% to 100% of patients within a few weeks. This skin discoloration has led to severe depression (and suicide).

      (2) Urine, sweat, and other body fluids may be discolored.

      (3) Other effects include ichthyosis and dryness of skin (8% to 28%), rash and pruritus (1% to 5%), and GI intolerance (e.g., abdominal/epigastric pain, diarrhea, nausea, vomiting) in 40% to 50% of patients. Clofazimine should be taken with food.

6. Daptomycin (Cubicin) is a unique lipopeptide antibiotic with clinical activity in the treatment of resistant gram-positive infections.

   a. Mechanism of action. Daptomycin is bactericidal; unlike other antibiotics, it binds to the bacterial cell membrane, causing depolarization of the membrane potential leading to inhibition of RNA, DNA, and protein synthesis.

   b. Spectrum of activity. This drug is active against vancomycin-susceptible *E. faecium* and *S. aureus* (including methicillin-resistant strains) as well as other aerobic gram-positive bacteria.

   c. Therapeutic uses. Daptomycin is indicated for the treatment of complicated skin and skin structure infections and intravascular line and *S. aureus* bacteremia. It is *not* indicated for the treatment of pneumonia.

   d. Precautions and monitoring effects

      (1) Reported side effects are generally mild and self-limiting and include constipation, abnormal liver function tests, and renal failure.

      (2) Cases of myalgia and/or muscle weakness, exacerbations of myasthenia gravis, and increases in creatine phosphokinase (CPK) have been reported.

7. Fidaxomicin (Dificid) is the first of a new class of antibiotics called macrocycles.

   a. Mechanism of action. Fidaxomicin is bactericidal against *C. difficile* in vitro, inhibiting RNA synthesis by RNA polymerases.

   b. Spectrum of activity. Fidaxomicin eradicates *C. difficile* selectively with minimal disruption to normal GI flora.

   c. Therapeutic uses. To reduce the development of drug-resistant bacteria and maintain the effectiveness of fidaxomicin and other antibacterial drugs, fidaxomicin should be used only to treat infections that are proven or strongly suspected to be caused by *Clostridium difficile*. Fidaxomicin is indicated in adults ($\geq$ 18 years of age) for treatment of *C. difficile*–associated diarrhea (CDAD).

   d. Precautions and monitoring effects. Because there is minimal systemic absorption of fidaxomicin, it is not effective for treatment of systemic infections. The most common adverse reactions are nausea (11%), vomiting (7%), abdominal pain (6%), gastrointestinal hemorrhage (4%), anemia (2%), and neutropenia (2%).

8. Linezolid (Zyvox) is a synthetic oxazolidinone that has clinical use in the treatment of infections caused by aerobic gram-positive bacteria.

   a. Mechanism of action. Linezolid is bacteriostatic against *Enterococci* and *Staphylococci*, and bactericidal against *Streptococci*. Linezolid binds to the 23S ribosomal RNA of the 50S subunit and thus inhibits protein synthesis.

    b. Spectrum of activity. The drug is active against vancomycin-resistant *Enterococcus faecium* and *S. aureus* (methicillin-susceptible and -resistant strains) as well as other aerobic gram-positive bacteria.

    c. Therapeutic uses. Linezolid is indicated for treatment of infections caused by vancomycin-resistant *E. faecium*, nosocomial pneumonia caused by methicillin-susceptible and -resistant strains of *S. aureus*, community-acquired pneumonia caused by penicillin-susceptible strains of *S. pneumoniae*, and skin and skin structure infections owing to these organisms.

    d. Precautions and monitoring effects

      (1) Safety data are limited. Adverse effects generally are minor (e.g., gastrointestinal complaints, headache, rash).

      (2) Thrombocytopenia or a significant reduction in platelet count has been reported (2.4%) and is related to duration of therapy. Monitor platelets in patients with risk of bleeding, preexisting thrombocytopenia, platelet disorders (including those caused by concurrent medications) and in patients receiving linezolid lasting longer than 2 weeks.

      (3) Myelosuppression owing to direct bone marrow suppression has been reported rarely.

    e. Significant interactions. Patients receiving concomitant therapy with adrenergic or serotonergic agents or consuming more than 100 mg of tyramine a day may experience an enhancement of the drug's effect or serotonin syndrome.

  9. Quinupristin/dalfopristin (Synercid) is an intravenous streptogramin antibiotic composed of two chemically distinct compounds.

    a. Mechanism of action. Quinupristin binds to the 50S subunit, and dalfopristin binds tightly to the 70S ribosomal particle.

    b. Spectrum of activity. Synercid has activity against *Staphylococci* spp., including resistant strains. This combination has better activity against *E. faecium* than *Enterococcus faecalis* and is also active against some gram-negative organisms and anaerobes; activity has not been shown against *Enterobacteriaceae*.

    c. Therapeutic uses. It is used for treatment of vancomycin-resistant *E. faecium* (VREF) bacteremia and skin and skin structure infections caused by *S. aureus* and *S. pyogenes*.

    d. Precautions and monitoring effects

      (1) Reported side effects are generally mild and infusion related: pain, erythema, or itching at the infusion site; increases in pulse and diastolic pressure; headache; nausea or vomiting; and diarrhea. It may increase liver function tests slightly.

      (2) Drug interactions are a result of cytochrome P450 3A4 inhibition. Potential drug interactions include **cyclosporin**, **nifedipine**, and **midazolam**.

      (3) Concomitant use of medications that may prolong QTc interval should be avoided.

      (4) Mild to life-threatening pseudomembranous colitis has been reported.

  10. Rifaximin. Is a semisynthetic antibiotic that is structurally related to rifamycin.

    a. Mechanism of action. It inhibits bacterial RNA synthesis by binding to the β subunit of bacterial DNA-dependent RNA polymerase.

    b. Spectrum of activity. This nonsystemically absorbed drug has activity against both enterotoxigenic and enteroaggregative strains of *Escherichia coli*.

    c. Therapeutic uses. Rifaximin is used in the treatment of travelers diarrhea with noninvasive strains of *E. coli* and prophylaxis of hepatic encephalopathy. High resistance rates have been reported after 5 days of treatment.

    d. Precautions and monitoring effects. Because of its limited systemic absorption, adverse effects are few but include constipation, vomiting, flatulence, and headache.

  11. Spectinomycin. An aminocyclitol agent related to the aminoglycosides, this antibiotic is useful against penicillin-resistant strains of gonorrhea.

    a. Mechanism of action. Spectinomycin is **bacteriostatic**; it selectively inhibits protein synthesis by binding to the 30S ribosomal subunit.

    b. Spectrum of activity. This agent is active against various gram-negative organisms.

    c. Therapeutic uses. Spectinomycin is used only to treat gonococcal infections in patients with penicillin allergy or when such infection stems from penicillinase-producing gonococci (PPNG).

    d. Precautions and monitoring effects. Because spectinomycin is given only as a single-dose IM injection, it causes few adverse effects. Nausea, vomiting, urticaria, chills, dizziness, and insomnia occur rarely.

12. **Telavancin (Vibativ)** is the first of a new class of antimicrobials known as the lipoglycopeptides. It is a semisynthetic derivative of vancomycin.
    a. **Mechanism of action.** Telavancin is bacteriocidal; it inhibits peptidoglycan and cell wall synthesis as well as disrupts membrane potential.
    b. **Spectrum of activity.** This drug is active against gram-positive bacteria, including MRSA and vancomycin-susceptible *Enterococcus faecalis*.
    c. **Therapeutic uses.** Telavancin is indicated for the treatment of complicated skin and skin structure infections caused by susceptible gram-positive bacteria, including MRSA.
    d. **Precautions and monitoring effects**
        (1) Taste disturbance, nausea and vomiting, and foamy urine were the most common side effects.
        (2) Nephrotoxicity and QT prolongation have been reported in patients.
        (3) Use of telavancin should be avoided in pregnant women.
13. **Telithromycin (Ketek)** is the first of a new class of antimicrobials called the ketolides. It is an oral semisynthetic derivative of erythromycin.
    a. **Mechanism of action.** Telithromycin may be bactericidal or bacteriostatic; it inhibits bacterial protein synthesis.
    b. **Spectrum of activity.** This drug is active against many aerobic and anaerobic gram-positive organisms, including multidrug-resistant *S. pneumoniae*, some gram-negative organisms, as well as atypical pathogens.
    c. **Therapeutic uses.** Telithromycin is indicated for the treatment of mild to moderate community-acquired pneumonia only. The FDA removed the previous two approved indications and added a black box warning.
    d. **Precautions and monitoring effects**
        (1) GI effects (including diarrhea, nausea, and vomiting) were the most common side effects followed by dizziness and visual disturbances (such as diplopia and blurred and abnormal vision); serious liver toxicity has been reported.
        (2) Cross-sensitivity with the other macrolides occurs.
        (3) Concomitant use of drugs or conditions that may prolong the QTc interval should be avoided.
        (4) Contraindicated in patients with myasthenia gravis, hepatitis, or jaundice.
    e. **Significant interactions**
        (1) Coadministration of telithromycin with either cisapride or pimozide is contraindicated.
        (2) Concomitant administration of drugs metabolized by cytochrome P450 3A4 in patients with telithromycin should be closely monitored.
        (3) Patients on bepridil, mesoridazine, terfenadine, thioridazine, or ziprasidone should not be prescribed telithromycin owing to the high potential for toxicity.
        (4) **This agent has a high potential to interact with many drugs. Check product information for the most current interaction information.**
14. **Tigecycline (Tygacil).** An intravenous glycylcycline antibiotic developed as a semisynthetic analogue of tetracycline with a broad spectrum of activity.
    a. **Mechanism of action.** Tigecycline is bacteriostatic; it inhibits bacterial protein synthesis by reversibly binding to the 30S ribosome subunit.
    b. **Spectrum of activity.** The drug is active against vancomycin-susceptible *E. faecalis*, methicillin-resistant *S. epidermidis*, and *S. aureus* (methicillin-susceptible and -resistant strains) as well as some gram-negative aerobes and anaerobes.
    c. **Therapeutic uses.** Tigecycline is indicated for the treatment of complicated intra-abdominal infections caused by *E. coli*, vancomycin-susceptible *E. faecalis*, *S. aureus* (methicillin-susceptible strains only) and *B. fragilis*. Also indicated for the treatment of complicated skin and skin structure infections caused by *E. faecalis* (vancomycin-susceptible strains), *S. pyogenes* and *S. aureus* (methicillin-susceptible and -resistant strains).
    d. **Precautions and monitoring effects**
        (1) Safety data are limited. Side effects are generally mild with GI disturbances—for example, nausea (22% to 35%) and vomiting (13% to 19%)—the most commonly reported. The mechanism of these reactions is uncertain.
        (2) May cause permanent discoloration of the teeth similar to the tetracyclines.
        (3) Caution in patients with a history of hypersensitivity reactions to tetracyclines.
        (4) Phototoxic reactions, pancreatitis, and increases in BUN may occur.

e. **Significant interactions.** Closely monitor the prothrombin time or international sensitivity index (INR) in patients on warfarin during concomitant administration of tigecycline.

15. **Trimethoprim.** A substituted pyrimidine, trimethoprim is most commonly combined with sulfamethoxazole (a sulfonamide discussed in II.G) in a preparation called co-trimoxazole. However, it may be used alone for certain urinary tract infections.

a. **Mechanism of action.** Trimethoprim inhibits dihydrofolate reductase, thus blocking bacterial synthesis of folic acid.

b. **Spectrum of activity**

(1) Trimethoprim is active against most gram-negative and gram-positive organisms. However, drug resistance may develop when this drug is used alone.

(2) Trimethoprim–sulfamethoxazole is active against a variety of organisms, including *Streptococcus pneumoniae*, *N. meningitidis*, and *Corynebacterium diphtheriae*; some strains of *Staphylococcus aureus*, *Staphylococcus epidermidis*, *P. mirabilis*, *Enterobacter*, *Salmonella*, *Shigella*, *Serratia*, and *Klebsiella* spp.; and *Escherichia coli*.

(3) The trimethoprim–sulfamethoxazole combination is synergistic; many organisms resistant to one component are susceptible to the combination.

c. **Therapeutic uses**

(1) Trimethoprim may be used alone or in combination with sulfamethoxazole to treat uncomplicated urinary tract infections caused by *Escherichia coli*, *P. mirabilis*, and *Klebsiella* and *Enterobacter* organisms.

(2) Trimethoprim–sulfamethoxazole is therapeutic for acute gonococcal urethritis, acute exacerbation of chronic bronchitis, shigellosis, and *Salmonella* infections.

(3) Trimethoprim–sulfamethoxazole may be given as prophylactic or suppressive therapy in *P. carinii* pneumonia. It is the drug of choice for the treatment of *Stenotrophomonas maltophilia* infections.

d. **Precautions and monitoring effects**

(1) Most adverse effects involve the skin (possibly from sensitization). These include rash, pruritus, and exfoliative dermatitis.

(2) Rarely, trimethoprim–sulfamethoxazole causes blood dyscrasias (e.g., acute hemolytic anemia, leukopenia, thrombocytopenia, methemoglobinemia, agranulocytosis, aplastic anemia).

(3) Adverse GI effects including nausea, vomiting, and epigastric distress glossitis may occur.

(4) Neonates may develop kernicterus.

(5) Patients with AIDS sometimes suffer fever, rash, malaise, and pancytopenia during trimethoprim therapy.

16. **Vancomycin.** This glycopeptide destroys most gram-positive organisms.

a. **Mechanism of action.** Vancomycin is **bactericidal**; it inhibits bacterial cell wall synthesis.

b. **Spectrum of activity.** This drug is active against most gram-positive organisms, including methicillin-resistant strains of *S. aureus and Enterococci*.

c. **Therapeutic uses.** Vancomycin usually is reserved for serious infections, especially those caused by methicillin-resistant staphylococci. It is particularly useful in patients who are allergic to penicillin or cephalosporins. Typical uses include endocarditis, osteomyelitis, and staphylococcal pneumonia.

(1) Oral vancomycin is valuable in the treatment of antibiotic-induced pseudomembranous colitis caused by *C. difficile* or *S. aureus* enterocolitis. Because vancomycin is not absorbed after oral administration, it is not useful for systemic infections. Because of resistance, the Centers for Disease Control and Prevention (CDC) recommend vancomycin as the second choice to metronidazole for *C. difficile* infections.

(2) Because 1 g provides adequate blood levels for 7 to 10 days, IV vancomycin is particularly useful in the treatment of anephric patients with gram-positive bacterial infections.

d. **Precautions and monitoring effects**

(1) Ototoxicity may arise; nephrotoxicity is rare but can occur with high doses.

(2) Vancomycin may cause hypersensitivity reactions, manifested by such symptoms as anaphylaxis and skin rash.

(3) Therapeutic levels peak at 20 to 40 μg/mL. The trough is < 15 μg/mL.

(4) Red man's syndrome may occur. This is facial flushing and hypotension owing to too rapid infusion of the drug. Infusion should be over a minimum of 60 mins for a 1-g dose.

(5) IV solutions are very irritating to the vein.

e. Vancomycin-resistant enterococci. A few strains of vancomycin-resistant enterococci are susceptible to teicoplanin (investigational by Hoechst Marion Roussel), linezolid (Zyvox), or quinupristin/dalfopristin (Synercid). These agents may be useful for multiple-drug–resistant *E. faecium*.

III. SYSTEMIC ANTIFUNGAL AGENTS

A. Definition. These agents treat systemic and local fungal (mycotic) infections—diseases that resist treatment with antibacterial drugs.

B. Amphotericin B (Fungizone). This polyene antifungal antibiotic is therapeutic for various fungal infections that frequently proved fatal before the drug became available. It is used increasingly in the empiric treatment of severely immunocompromised patients in certain clinical situations.

1. Mechanism of action. Amphotericin B is both **fungistatic** in clinically obtained concentrations and may be fungicidal in the presence of susceptible organisms. It binds to sterols in the fungal cell membrane, thereby increasing membrane permeability and permitting leakage of intracellular contents. Other mechanisms may be involved as well.

2. Spectrum of activity. Amphotericin B is a broad-spectrum antifungal agent with activity against *Aspergillus*, *Blastomyces*, *Candida* spp. (*albicans*, *krusei tropicalis*, and *glabrata*), *Cryptococcus*, *Coccidioides*, *Histoplasma*, *Paracoccidioides*, *Phycomycetes* (*mucor*), and *Sporothrix*. It is also useful against some protozoa such as *Leishmania*, *Naegleria*, and *Acanthamoeba*.

3. Therapeutic uses. Amphotericin B is the most effective antifungal agent in the treatment of systemic fungal infections, especially in immunocompromised patients.

a. It is the treatment of choice for pulmonary *Aspergillus* infections; *Blastomyces* infections, which are life-threatening with AIDS or CNS involvement; deep-organ infections with *Candida*; *Coccidioides* infections with severe pulmonary involvement or with disseminated nonmeningeal immunocompetent or immunocompromised patients; all *Cryptococcus* infections; disseminated *Histoplasma* infections involving CNS or immunosuppressed patients; *Malassezia furfur* fungemia; pulmonary and extrapulmonary *Phycomycetes* (mucormycosis); *Penicillium marneffei*; and extracutaneous *Sporothrix*.

b. This agent may be used to treat coccidioidal arthritis.

c. Topical preparations are given to eradicate cutaneous and mucocutaneous candidiasis.

d. It may be used as empiric therapy in febrile, neutropenic patients.

e. It is used as secondary prophylaxis of fungal infections in HIV-positive patients, guarding against recurrence of infection.

f. It may be used prophylactically in neutropenic cancer patients and bone marrow transplant or solid-organ transplant patients to reduce the incidence of *Aspergillus* and *Candida* infections.

4. Precautions and monitoring effects. Because amphotericin B can cause many serious adverse effects, it should be administered in a hospital setting—at least during the initial therapeutic stage. The adverse effects are divided into infusion reactions and others.

a. Infusion reactions occur while the drug is being administered and include fever, shaking chills, hypotension, anorexia, nausea, vomiting, headache, dyspnea, and tachypnea. Premedication with acetaminophen and diphenhydramine has been helpful in prophylaxing against infusion reactions. In addition, hydrocortisone 10 to 50 mg may be added to the infusion as prophylaxis against infusion-related reactions. Meperidine 25 to 50 mg IV is effective treatment of active shaking chills/rigors. Meperidine is also effective in prophylaxis of rigors.

b. Nephrotoxicity frequently occurs. Dosage adjustment or drug discontinuation or changing to a liposomal amphotericin B product may be necessary as renal impairment progresses.

c. Electrolyte abnormalities, including hypokalemia, hypomagnesemia, and hypocalcemia, are common. Monitor and replace electrolytes as needed.

d. Normocytic, normochromic anemia will develop over long-term use (10 weeks). Monitor hematocrit periodically.

e. Bronchospasm, wheezing, and anaphylaxis or anaphylactoid reactions have occurred. A test dose of 1 mg of amphotericin B is often administered before infusion of large quantities of the drug.

    f. Phlebitis or thrombophlebitis is reported with conventional amphotericin B. Heparin (500 to 1000 U) can be added to the infusion to aid in prevention.

    g. CNS effects include headache, peripheral neuropathy, malaise, depression, seizure, myasthenia, and hallucinations.

    h. Elevated liver transaminases, aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, bilirubin, γ-glutamyltransferase (GGT), and lactate dehydrogenase (LDH) may occur.

    i. Amphotericin B parenteral use should be mixed only in dextrose 5% in water (D$_5$W) and should be protected from light.

5. Significant interactions. Other nephrotoxic drugs (aminoglycosides, capreomycin, colistin, cisplatin, cyclosporine, methoxyflurane, pentamidine, polymyxin B, and vancomycin) may cause additive nephrotoxicity.

6. Amphotericin B lipid complex (Abelcet), amphotericin B cholesterol sulfate complex (Amphotec), and liposomal amphotericin B (AmBisome) offer alternative formulations of amphotericin B for the treatment of severe fungal infections in patients who are intolerant of or whose disease is refractory to conventional treatment.

C. Echinocandins. Three echinocandins are approved in the United States: caspofungin (Cancidas), micafungin (Mycamine), and anidulafungin (Eraxis). These agents have a broad spectrum of activity against *Candida* species with micafungin and anidulafungin having similar MICs that are generally lower than the MIC of caspofungin.

    1. Mechanism of action. Caspofungin works by causing fungal cell wall lysis. By being a noncompetitive inhibitor of β (1,3) synthase, which is an essential component of fungal cell wall synthesis, it causes osmotic instability within the fungus and fungal cell wall lysis.

    2. Spectrum of activity. Echinocandins have fungicidal activity against Candida species and fungistatic activity against *Aspergillus* species. All three agents in this class appear to have good activity in vitro for most isolates of Candida species, including those that are either Amphotericin-B or fluconazole and itraconazole-resistant, such as *C. glabrata*.

    3. Therapeutic uses. All three agents are indicated for the treatment of esophageal candidiasis.

        a. Caspofungin and anidulafungin are also indicated for the treatment of candidemia and other infections caused by *Candida* species, including intra-abdominal abscesses and peritonitis.

        b. Caspofungin may also be used for the treatment of candidal pleural space infections, empiric treatment of presumed fungal infections in neutropenic patients, and treatment of invasive aspergillosis in patients refractory to or intolerant of other antifungals (i.e., amphotericin B, itraconazole).

        c. Micafungin is indicated for the prophylaxis of candidal infections in patients undergoing hematopoietic stem cell transplantation (HSCT).

    4. Precautions and monitoring effects. Although this class has adverse events associated with its use, the overall toxicity profile is significantly better than that of amphotericin B.

        a. Infusion vein complications (not defined by manufacturer) and thrombophlebitis have been seen on infusion of caspofungin.

        b. Hematological decreases in hemoglobin and hematocrit may occur; however, the incidence does not differ from that of having a fungal disease.

        c. Headache may occur.

        d. Slight decreases in serum potassium may occur, but nowhere near the magnitude of that caused by amphotericin B.

        e. Anorexia, nausea, vomiting, and diarrhea have occurred.

        f. Rare increases in serum creatinine; however, there have been no reported cases of nephrotoxicity.

        g. Possible slight increases in serum aminotransferases

        h. Allergic reactions occur in < 5% of patients and anaphylaxis in < 2% of patients.

        i. Pregnancy category C embryotoxic reactions have occurred in animals.

    5. Significant interactions

        a. When cyclosporine is combined with caspofungin, clinically significant rises in ALT were observed. Serum transaminases should be monitored, and this combination should be avoided in patients with preexisting liver disease.

        b. When used in combination, carbamazepine, nelfinavir, nevirapine, phenytoin, and rifampin increases the clearance of caspofungin. Higher doses of caspofungin (70 mg every day) should be considered when this combination is administered.

     c. Tacrolimus clearance will be increased when the combination is used; monitor tacrolimus serum levels closely.

D. Flucytosine (Ancobon). This fluorinated pyrimidine usually is given in combination with amphotericin B.

    1. Mechanism of action. Flucytosine penetrates fungal cells and is converted to fluorouracil, a metabolic antagonist. Incorporated into the RNA of the fungal cell, flucytosine causes defective protein synthesis. It is either **fungistatic** or **fungicidal**, depending on the concentration of the drug.

    2. Spectrum of activity. This drug is primarily active against *Cryptococcus* and *Candida*. It is most commonly used in conjunction with amphotericin B. Fungal resistance against flucytosine alone has been well documented. Flucytosine may also possess some activity against chromomycosis and some strains of *Aspergillus* (in vitro testing only).

    3. Therapeutic uses. Flucytosine is adjunctively used with amphotericin B for severe systemic infections (e.g., septicemia, endocarditis, pulmonary and urinary tract infections, meningitis). Use of flucytosine alone is not recommended.

    4. Precautions and monitoring effects

      a. Frequent adverse effects include GI intolerance with nausea, vomiting, and diarrhea.

      b. Occasional adverse reactions are more severe and include marrow suppression with leukopenia or thrombocytopenia (dose related, especially with renal failure or concurrent amphotericin B use). Confusion, rash, hepatitis, enterocolitis, headache, and photosensitivity reactions can also occur.

      c. Rare reactions include hallucinations, blood dyscrasias with agranulocytosis and pancytopenia, fatal hepatitis, anaphylaxis, and anemia.

      d. Flucytosine may cause a markedly false elevation of serum creatinine if an Ektachem analyzer is used.

    5. Significant interactions. Beneficial drug interactions occur with flucytosine. Flucytosine has demonstrated synergy with **amphotericin B** and **fluconazole** against *Cryptococcus* and *Candida* spp.

E. Griseofulvin (Fulvicin). Produced from *Penicillium griseofulvin Dierckx*, this drug is deposited in the skin, bound to keratin.

    1. Mechanism of action. This agent is **fungistatic**; it inhibits fungal cell activity by interfering with mitotic spindle structure. Its mechanism of action is similar to colchicine.

    2. Spectrum of activity. Griseofulvin is active against various strains of *Microsporum*, *Epidermophyton*, and *Trichophyton*.

    3. Therapeutic uses. Griseofulvin is effective in tinea infections of the skin, hair, and nails (including athlete's foot, jock itch, and ringworm) caused by *Microsporum*, *Epidermophyton*, and *Trichophyton*.

      a. Generally, this agent is given only for infections that do not respond to topical antifungal agents.

      b. Griseofulvin is available only in oral form.

      c. It possesses vasodilatory activity and may be used in Raynaud disease.

      d. It may be used to treat gout.

    4. Precautions and monitoring effects

      a. Griseofulvin rarely results in serious adverse effects. However, the following problems have been reported.

        (1) *Common*: headache, fatigue, confusion, impaired performance, syncope, and lethargy, which generally resolve with continued use

        (2) *Occasional*: leukopenia, neutropenia, and granulocytopenia

        (3) *Rare*: serum sickness, angioedema, urticaria, erythema, and hepatotoxicity

      b. The dosage depends on the particle size of the product: 250 mg of ultramicrosize (Fulvicin P/G) is equivalent in therapeutic effects to 500 mg of microsize (Fulvicin U/F).

    5. Significant interactions

      a. Griseofulvin may increase the metabolism of **warfarin**, leading to decreased prothrombin time.

      b. **Barbiturates** may reduce griseofulvin absorption.

      c. **Alcohol consumption** may cause tachycardia and flushing.

      d. **Oral contraceptives** may cause amenorrhea or increased breakthrough bleeding.

F. Imidazoles. The substituted imidazole derivatives **ketoconazole (Nizoral)**, **miconazole (Monistat)**, **fluconazole (Diflucan)**, **itraconazole (Sporanox)**, **voriconazole (Vfend)** and **posaconazole (Noxafil)** are valuable in the treatment of a wide range of systemic fungal infections.

    1. Mechanism of action. Imidazoles inhibit sterol synthesis in fungal cell membranes and increase cell wall permeability; this in turn makes the cell more vulnerable to osmotic pressure. These agents are **fungistatic**.

2. **Spectrum of activity.** These agents are active against many fungi, including yeasts, dermatophytes, actinomycetes, and some *Phycomycetes*.
3. **Therapeutic uses**
   a. **Ketoconazole,** an oral agent, successfully treats many fungal infections that previously yielded only to parenteral agents.
      (1) It is therapeutic for systemic and vaginal candidiasis, mucocandidiasis, candiduria, oral thrush, histoplasmosis, coccidioidomycosis, chromomycosis, dermatophytosis (tinea), and paracoccidioidomycosis.
      (2) Because ketoconazole is slow acting and requires a long duration of therapy (up to 6 months for some chronic infections), it is less effective than other antifungal agents for the treatment of severe and acute systemic infections.
   b. **Miconazole,** primarily administered as a topical agent, the parenteral form has been discontinued in the United States. It was a relatively toxic formulation which has been replaced by other members of this class (e.g., fluconazole).
      (1) Topical miconazole is highly effective in vulvovaginal candidiasis, ringworm, and other skin infections.
   c. **Fluconazole.** Available in oral and parenteral forms, fluconazole can be used against systemic and CNS infections involving *Cryptococcus* and *Candida*. *Candida* oropharyngeal infection and esophagitis may also be treated with fluconazole. *Aspergillus*, *Coccidioides*, and *Histoplasma* have demonstrated in vitro sensitivity.
   d. **Itraconazole** is available as an oral agent with activity against systemic and invasive pulmonary aspergillosis without the hematological toxicity of amphotericin B. Other deep mycotic infections susceptible to itraconazole include blastomycosis, coccidioidomycosis, cryptococcosis, and histoplasmosis.
   e. **Voriconazole.** Voriconazole is available as both an intravenous and an oral agent for the treatment of fungal infections involving invasive aspergillosis, *Scedosporium apiospermum*, and *Fusarium* spp., including those species that are refractory to other therapy.
   f. **Posaconazole.** Available as an oral suspension indicated for the prevention of invasive infections caused by *Aspergillus* and *Candida* species in patients receiving HSCT or with neutropenis. Posaconazole may also be used to treat invasive fungal infections in patients who have previously failed or are intolerant to other antifungals.
4. **Precautions and monitoring effects**
   a. **Ketoconazole** may cause nausea, vomiting, diarrhea, abdominal pain, and constipation. Rarely, it leads to headache, dizziness, gynecomastia, and fatal hepatotoxicity.
   b. **Fluconazole** commonly causes GI disturbances (e.g., nausea, vomiting, epigastric pain, diarrhea). Reversible elevations in serum aminotransferase, exfoliative skin reactions, and headaches have been reported.
   c. **Itraconazole** may cause nausea, vomiting, hypertriglyceridemia, hypokalemia, rash, and elevations in liver enzymes.
   d. **Voriconazole.** Visual disturbances, fever, rash, vomiting, nausea, diarrhea, headache, sepsis, peripheral edema, abdominal pain, and respiratory disorders rarely occurred. Liver function test abnormalities have occurred.
   e. **Posaconazole.** Most common adverse events have been nausea and headache. Rash, dry skin, taste disturbances, abdominal pain, dizziness, hypokalemia, thrombocytopenia, and flushing can occur. Posaconazole can cause abnormalities in liver function and has been associated with prolongation of the QT interval.
5. **Significant interactions**
   a. Both **ketoconazole** and **miconazole** may enhance the anticoagulant effect of **warfarin**.
   b. **Ketoconazole** may antagonize the antibiotic effects of **amphotericin B**.
   c. **Fluconazole** has been shown to elevate serum levels of **phenytoin, cyclosporine, warfarin,** and **sulfonylureas.** Concurrent hepatic enzyme inducers, such as **rifampin**, have resulted in increased elimination of both fluconazole and itraconazole.
   d. Coadministration of **itraconazole** or **ketoconazole** with **astemizole** or **terfenadine** may result in increased astemizole or terfenadine levels, possibly leading to life-threatening dysrhythmias and death.
   e. Both **ketoconazole** and **itraconazole** need the presence of stomach acid for adequate absorption. Use with antacids, H_2-blockers, or proton pump inhibitors is contraindicated.

      f. Concomitant use of imidazole antifungal agents with **cisapride** may result in increased concentrations of cisapride, which has been associated with adverse cardiac events such as torsades de pointes leading to sudden death.

      g. Voriconazole. Cytochrome P450 2C19 is the major enzyme involved in metabolism. Voriconazole inhibits cytochrome P450 2C19, 2C9, and 3A4. Any medication that is metabolized via these routes may be affected, and monitoring of blood levels (if appropriate) or clinical signs and symptoms is necessary when taking concomitant medications.

      h. Posaconazole serum levels are reduced by concurrent administration with cimetidine, phenytoin or rifabutin; avoid concomitant use if possible. Posaconazole may increase concentrations of cyclosporine, tacrolimus, rifabutin, midazolam, and phenytoin; dosage adjustments may be required.

        (1) Food increases the oral bioavailability; take posaconazole with a full meal or liquid nutritional supplement

G. Nystatin (Mycostatin). A polyene antibiotic, nystatin has a chemical structure similar to that of amphotericin B.

  1. Mechanism of action. Nystatin is **fungicidal** and **fungistatic**; binding to sterols in the fungal cell membrane, it increases membrane permeability and permits leakage of intracellular contents.

  2. Spectrum of activity. Nystatin is active primarily against *Candida* spp.

  3. Therapeutic uses

    a. This drug is used primarily as a topical agent in vaginal and oral *Candida* infections.

    b. Oral nystatin is therapeutic for *Candida* infections of the GI tract, especially oral and esophageal infections; because the drug is not readily absorbed, it maintains good local activity.

  4. Precautions and monitoring effects. Oral nystatin occasionally causes GI distress (e.g., nausea, vomiting, diarrhea). Rarely, hypersensitivity reactions occur.

H. Terbinafine (Lamisil) is a synthetic allylamine with structure and activity related to naftifine.

  1. Mechanism of action. Terbinafine inhibits squalene monooxygenase, leading to an interruption of fungal sterol biosynthesis. Terbinafine may be **fungicidal** or **fungistatic**, depending on drug concentration and species.

  2. Spectrum of activity. Terbinafine has activity against dermatophytic fungi (*Trichophyton*, *Microsporum*, and *Epidermophyton*), filamentous fungi (*Aspergillus*), and dimorphic fungi (*Blastomyces*). It may also possess some activity against yeasts.

  3. Therapeutic uses

    a. Oral terbinafine is useful against infections of the toenail and fingernail (onychomycosis, tinea unguium). Time to cure is reduced over imidazole antifungals for these indications. It is useful in patients who may not tolerate the adverse effect profile of imidazole antifungals.

    b. It is also used in tinea capitis and tinea corporis infections.

  4. Precautions and monitoring effects. Adverse effects include taste or ocular disturbances, symptomatic hepatobiliary dysfunction, decrease in lymphocyte count and neutropenia, and serious skin reactions.

IV. TOPICAL ANTIFUNGAL AGENTS

A. Definition. These agents are for topical use for fungal infections.

B. Amphotericin B (Fungizone) is available as a 3% cream or lotion or an oral suspension that is not absorbed through the GI tract.

  1. Mechanism of action. See III.B.1.

  2. Spectrum of activity. See III.B.2.

  3. Therapeutic uses. Amphotericin B is used for oropharyngeal candidiasis, cutaneous and mucocutaneous candidal infections, or as a local irrigant for the bladder and intrapleural or intraperitoneal areas.

  4. Precautions and monitoring effects. Compared with systemic administration, the topical formulations have relatively low toxicity.

    a. Dry skin and local irritation with erythema, pruritus, or burning, along with mild skin discoloration, has occurred with the lotion and cream.

    b. Rash and GI effects (e.g., nausea, vomiting, steatorrhea, diarrhea) tend to occur with the suspension. In addition, there have been case reports of urticaria, angioedema, Stevens–Johnson syndrome, and toxic epidermal necrolysis.

C. **Butenafine (Mentax)** is a synthetic benzylamine related to the allylamine antifungal agents (naftifine, terbinafine).
1. **Mechanism of action.** Butenafine alters fungal membrane permeability and growth inhibition, interferes with sterol biosynthesis by allowing squalene to accumulate within the cell, and may be fungicidal in certain concentrations against susceptible organisms such as the dermatophytes.
2. **Spectrum of activity.** Butenafine is active against *Trichophyton rubrum*, *T. mentagrophytes*, *Microsporum canis*, *Sporothrix schenckii*, and yeasts, including *Candida parapsilosis* and *C. albicans*.
3. **Therapeutic uses.** The 1% cream is used in dermatophytoses, including tinea corporis, tinea cruris, and tinea pedis.
4. **Precautions and monitoring effects.** If clinical improvement of fungal infection does not improve after the treatment period, the diagnosis should be reevaluated.
D. **Butoconazole (Mycelex)** is an azole antifungal cream available for vaginal use.
1. **Mechanism of action.** Butoconazole has fungistatic activity against susceptible organisms. The drug interferes with membrane permeability, secondary metabolic effects, and growth inhibition. Butoconazole contains antibacterial effects against some gram-positive organisms.
2. **Spectrum of activity.** Butoconazole is active against dermatophytes (*Trichophyton concentricum*, *T. mentagrophytes*, *T. rubrum*, *T. tonsurans*, *Epidermophyton floccosum*, *M. canis*, *M. gypseum*), yeasts (*C. albicans*, *C. glabrata*), and some gram-positive organisms (*S. aureus*, *E. faecalis*, and *S. pyogenes*).
3. **Therapeutic uses.** A 2% cream is used for vulvovaginal candidiasis and complicated, recurrent vulvovaginal candidiasis.
4. **Precautions and monitoring effects**
   a. Vulvovaginal burning and itching are the most common; however, their incidence is low. Headache; itching of fingers; urinary frequency and burning; and vulvovaginal discharge, irritation, soreness, stinging, odor, and swelling rarely occur.
   b. Butoconazole may damage birth-control devices such as condoms and diaphragms, leading to inadequate protection. Consider alternative methods of birth control.
   c. Tampon use should be avoided with the use of butoconazole.
E. **Ciclopirox (Loprox)** is a synthetic antifungal agent that is chemically unrelated to any other antifungal agent. The ethanolamine contained in ciclopirox appears to enhance epidermal penetration.
1. **Mechanism of action.** Ciclopirox causes intracellular depletion of amino acids and ions necessary for normal cellular function.
2. **Spectrum of activity.** Ciclopirox is active against dermatophytes, yeasts, some gram-positive and gram-negative bacteria, *Mycoplasma*, and *Trichomonas vaginalis*. Specifically, ciclopirox has activity against *T. mentagrophytes*, *T. rubrum*, *E. floccosum*, *M. canis*, *M. furfur*, and *C. albicans*.
3. **Therapeutic uses.** Ciclopirox is used topically for the treatment of tinea pedis, tinea cruris, tinea corporis, tinea versicolor (from *Malassezia*), and cutaneous candidiasis (moniliasis) from *C. albicans*.
4. **Precautions and monitoring effects.** Local irritation manifested by erythema, pruritus, burning, blistering, swelling, and oozing has occurred. If this occurs, ciclopirox should be discontinued.
F. **Clioquinol** (formerly iodochlorhydroxyquin) is a topical antifungal in a 3% ointment that can be used alone or in combination with hydrocortisone.
1. **Mechanism of action.** Unknown
2. **Spectrum of activity.** It is active against dermatophytic fungi.
3. **Therapeutic uses.** It is used topically against the following:
   a. Tinea pedis and tinea cruris (ringworm infections)
   b. Previously used to treat diaper rash; however, it is no longer recommended, and use in children < 2 years of age is contraindicated
4. **Precautions and monitoring effects**
   a. Local irritation, rash, and sensitivity reactions are common.
   b. Systemic absorption after topical application may occur.
   c. High doses of clioquinol over long periods have been associated with oculotoxic/neurotoxic effects, including optic neuritis, optic atrophy, and subacute myelo-optic neuropathy.
G. **Clotrimazole (Lotrimin)** is an azole antifungal agent that is an imidazole derivative. It is related to other azole antifungal agents, such as **butoconazole**, **econazole**, **ketoconazole**, **miconazole**, **oxiconazole**, **sulconazole**, and **tioconazole**.
1. **Mechanism of action.** Clotrimazole alters fungal cell membrane permeability by binding with phospholipids in the membrane.

2. **Spectrum of activity.** It is active against yeasts, dermatophytes (*T. rubrum*, *T. mentagrophytes*, *E. floccosum*, *M. canis*), and some gram-positive bacteria. At higher concentrations, clotrimazole inhibits *M. furfur*, *Aspergillus fumigatus*, *C. albicans*, and some strains of *S. aureus*, *S. pyogenes*, *Proteus vulgaris*, and *Salmonella*. At very high concentrations, clotrimazole has an effect on *Sporothrix*, *Cryptococcus*, *Cephalosporium*, *Fusarium*, and *T. vaginalis*.

3. **Therapeutic uses**
   a. The lozenges, which are administered five times per day, are useful in treating oropharyngeal candidiasis. Lozenges are also used for primary prophylaxis of mucocutaneous candidiasis in HIV-infected infants or children with severe immunosuppression.
   b. The cream, lotion, or solution is used to treat dermatophytoses, superficial mycoses, and cutaneous candidiasis.
   c. Intravaginal dosage forms are useful in treating vulvovaginal candidiasis.

4. **Precautions and monitoring effects**
   a. Cutaneous reactions with topical administration may include blistering, erythema, edema, pruritus, burning, stinging, peeling, skin fissures, and general irritation.
   b. The vaginal tablets are associated with mild burning, skin rash, itching, vulval irritation, lower abdominal cramps, bloating, slight cramping, vaginal soreness during intercourse, and an increase in urinary frequency.
   c. Cross-sensitization occurs with imidazole; however, it is unpredictable.
   d. Abnormal liver function tests (elevated AST) have occurred in patients taking the lozenges.

H. **Econazole (Spectazole)** is an azole antifungal agent that is an imidazole derivative.
   1. **Mechanism of action.** Econazole alters cell membranes and increases permeability (like many other azole agents).
   2. **Spectrum of activity.** Econazole is active against dermatophytes, yeasts, some gram-positive bacteria, and *T. vaginalis*.
   3. **Therapeutic uses**
      a. The 1% topical cream, lotion, or solution is useful in treating dermatophytoses and cutaneous candidiasis (tinea corporis and tinea cruris).
      b. Econazole is also used to treat pityriasis (tinea) versicolor (*M. furfur*).
   4. **Precautions and monitoring effects.** In general, there is a low incidence of toxicity. Topically, a patient may experience burning, stinging sensations, pruritus, and erythema (after 2 to 4 days).

I. **Gentian violet** is a dye that possesses the ability to kill fungi, yeasts, and some gram-positive bacteria.
   1. **Mechanism of action.** None known
   2. **Spectrum of activity.** Gentian violet is active against *Candida*, *Epidermophyton*, *Cryptococcus*, *Trichophyton*, and some *Staphylococcus* spp.
   3. **Therapeutic uses.** It is used to treat cutaneous *C. albicans* infections (monilia or thrush).
   4. **Precautions and monitoring effects**
      a. Gentian violet may cause irritation or sensitivity reactions or possibly ulceration of the mucous membranes. If the solution is swallowed, esophagitis, laryngitis, or tracheitis may occur.
      b. Skin tattooing may occur if gentian violet is applied to granulation tissue.
      c. Gentian violet should not be used in areas of extensive ulceration.
      d. This drug is a dye and will stain clothing.

J. **Ketoconazole (Nizoral)** is an imidazole-derived antifungal drug that is available topically as a cream and a shampoo.
   1. **Mechanism of action.** See III.E.1.
   2. **Spectrum of activity.** See III.E.2.
   3. **Therapeutic uses**
      a. The 2% topical cream is used in treating tinea corporis, tinea cruris, and tinea pedis caused by the dermatophytes (*E. floccosum*, *T. mentagrophytes*, and *T. rubrum*).
      b. It is used for cutaneous candidiasis.
      c. The 2% topical cream or 2% shampoo may be used in treating tinea versicolor (*M. furfur*). Selenium-based shampoos may also be useful in this area.
      d. The 2% topical cream is useful against seborrheic dermatitis. The 2% shampoo is useful in reducing scaling caused by dandruff.

      e. When combined with a steroid, ketoconazole is useful in treating the following: atopic dermatitis, diaper rash, eczema, folliculitis, impetigo, intertrigo, lichenoid dermatitis, and psoriasis.

      f. An ophthalmic suspension can be extemporaneously prepared to treat fungal keratitis.

   4. Precautions and monitoring effects

      a. Reactions from the 2% topical cream include local irritation, pruritus, and stinging. Contact dermatitis is possible and occurs with other imidazole derivatives.

      b. The 2% shampoo may lead to increased hair loss, irritation, abnormal hair texture, scalp pustules, dry skin, pruritus, and oiliness or dryness of hair and scalp. It may in addition straighten otherwise curly hair.

K. Miconazole (Monistat) is an imidazole-derived antifungal drug that is available topically as a 2% aerosol, 2% aerosol powder, 2% cream, a kit, 2% powder and 2% tincture, 2% vaginal cream, and 100 mg and 200 mg vaginal suppositories.

   1. Mechanism of action. See III.E.1.

   2. Spectrum of activity. See III.E.2.

   3. Therapeutic uses. Miconazole is advantageous over other agents such as nystatin and tolnaftate in that its activity covers dermatophytes as well as *Candida*.

      a. Topical use is effective against tinea pedis, tinea cruris, and tinea corporis caused by dermatophytes (*T. mentagrophytes*, *T. rubrum*, and *E. floccosum*).

      b. It is also effective against tinea versicolor from *M. furfur*.

      c. Like other imidazole derivatives, it is useful in treating cutaneous fungal infections.

      d. The vaginal cream and vaginal suppositories are effective in treating vulvovaginal candidiasis.

   4. Precautions and monitoring parameters

      a. Topical creams have caused local irritation and burning.

      b. Vaginal preparations have led to vulvovaginal burning, itching, irritation, pelvic cramps, vaginal burning, headache, hives, and skin rash.

      c. If vulvovaginal candidiasis persists for longer than 3 days, seek further medical attention.

      d. Tampons should be avoided in patients using vaginal suppositories or cream; sanitary pads should be substituted.

      e. Vaginal suppositories are manufactured from a vegetable oil base that may interact with latex products. Avoid using diaphragms or condoms concurrently with suppositories. Seek an alternative form of birth control.

L. Naftifine (Naftin) is a synthetic allylamine similar to terbinafine. It is available as a 1% topical cream and a 1% topical gel.

   1. Mechanism of action. Naftifine is **fungistatic** and interferes with sterol biosynthesis by accumulating squalene in the fungal cell. Naftifine also possesses some local anti-inflammatory activity.

   2. Spectrum of activity

      a. Naftifine is active against *T. mentagrophytes*, *T. rubrum*, *T. tonsurans*, *Trichophyton verrucosum*, *Trichophyton violaceum*, *E. floccosum*, *Microsporum audouinii*, *M. canis*, and *M. gypseum*.

      b. *C. albicans*, *Candida krusei*, *Candida parapsilosis*, and *Candida tropicalis* are affected by naftifine; however, the concentrations of naftifine vary for *Candida* killing, depending on the species.

      c. In vitro activity has been demonstrated against *Aspergillus flavus* and *Aspergillus fumigatus*. Others include *Sporothrix schenckii*, *Cryptococcus neoformans*, *Petriellidium boydii*, *Blastomyces dermatitidis*, and *Histoplasma capsulatum*.

   3. Therapeutic uses. Naftifine is active against dermatophytoses and cutaneous candidiasis.

      a. It is also used to treat tinea cruris, tinea pedis, tinea corporis, and tinea manus (*T. mentagrophytes*, *T. rubrum*, *T. verrucosum*, *T. violaceum*, *E. floccosum*, or *M. canis*).

      b. It is also useful in treating tinea unguium (onychomycosis).

   4. Precautions and monitoring effects. Transient burning and stinging

M. Nystatin (Mycostatin). A polyene antibiotic, nystatin has a chemical structure similar to that of amphotericin B. It is available as an oral suspension, tablet, lozenge, topical cream, ointment, topical powder, and vaginal tablet.

   1. Mechanism of action. Nystatin is **fungicidal** and **fungistatic**; binding to sterols in the fungal cell membrane, it increases membrane permeability and permits leakage of intracellular contents.

2. **Spectrum of activity.** Nystatin is active primarily against *Candida* spp.

3. **Therapeutic uses.** This drug is used primarily as a topical agent in vaginal and oral *Candida* infections.

4. **Precautions and monitoring effects.** Irritation has occurred in extremely rare instances.

N. Oxiconazole (Oxistat) is an imidazole-derived antifungal drug that is available as a 1% topical cream or 1% topical lotion.

1. **Mechanism of action.** See III.E.1.

2. **Spectrum of activity.** See III.E.2.

3. **Therapeutic uses**

   a. The 1% cream or lotion is useful in treating tinea cruris, tinea corporis, tinea manus, and tinea pedis from dermatophytes.

   b. Oxiconazole is also effective against tinea versicolor caused by *M. furfur*.

4. **Precautions and monitoring effects**. Adverse effects are rare and are confined to local irritation.

O. Sulconazole (Exelderm) is an imidazole-derived antifungal drug that is available as a 1% topical cream and a 1% topical solution.

1. **Mechanism of action** (see III.E.1). The antibacterial effects exerted by sulconazole are thought to be the result of a direct physicochemical effect on the destruction of unsaturated fatty acids present in bacterial cell membranes.

2. **Spectrum of activity**

   a. Sulconazole has activity against dermatophytes, including *E. floccosum*, *M. audouinii*, *M. canis*, *M. gypseum*, *T. mentagrophytes*, *T. rubrum*, *T. tonsurans*, and *T. violaceum*. It also has activity against *M. furfur*.

   b. Sulconazole also has activity against selected gram-positive aerobes (*S. aureus*, *S. epidermidis*, *Staphylococcus saprophyticus*, *E. faecalis*, *Micrococcus luteus*, and *Bacillus subtilis*) and anaerobes (*Clostridium* and *Propionibacterium acnes*, *Clostridium perfringens*, *Clostridium tetani*, and *Clostridium botulinum*).

3. **Therapeutic uses**

   a. The 1% topical cream or 1% topical solution is useful in treating tinea corporis and tinea cruris.

   b. The 1% topical cream has been studied for use against tinea pedis; the solution has not been evaluated for this indication.

   c. The 1% cream is useful against tinea versicolor (*M. furfur*).

   d. There is not an approved indication for cutaneous candidiasis; however, sulconazole 1% is as effective as miconazole 2% or clotrimazole 1% in treating cutaneous candidiasis.

   e. Sulconazole is useful in treating infections caused by bacteria such as impetigo (*S. pyogenes*) and ecthyma (*S. aureus*).

4. **Precautions and monitoring effects.** Adverse reactions include local effects such as burning and irritation, skin edema, dryness, scaling, fissuring, cracking, generalized red papules, and severe eczema.

P. Terbinafine (Lamisil AT) is a synthetic allylamine available as a 1% cream with structure and activity related to naftifine.

1. **Mechanism of action.** Terbinafine inhibits squalene monooxygenase, leading to an interruption of fungal sterol biosynthesis. Terbinafine may be **fungicidal** or **fungistatic**, depending on drug concentration and species.

2. **Spectrum of activity.** Terbinafine has activity against dermatophytic fungi (*Trichophyton*, *Microsporum*, and *Epidermophyton*), filamentous fungi (*Aspergillus*), and dimorphic fungi (*Blastomyces*). It may also possess some activity against yeasts.

3. **Therapeutic uses**. It is useful for tinea pedis, tinea corporis, and tinea cruris.

4. **Precautions and monitoring effects.** It can cause local irritation.

Q. Terconazole (Terazol 7) is an imidazole-derived antifungal drug that is available as a 0.4% and 0.8% vaginal cream and an 80-mg vaginal suppository.

1. **Mechanism of action.** It is **fungicidal** against *C. albicans*. Like other imidazole agents, terconazole alters cellular membranes, resulting in increased membrane permeability.

2. **Spectrum of activity.** It is active against dermatophytes; yeasts; and, at high concentrations, gram-positive and gram-negative bacteria.

3. **Therapeutic uses** are for complicated and uncomplicated vulvovaginal candidiasis.

      4. Precautions and monitoring effects. Adverse reactions include burning, pruritus, irritation, headache, body pain, and pain of female genitalia.

R. Tioconazole (Vagistat-1) is an imidazole-derived antifungal drug that is available as a 6.5% vaginal ointment.

    1. Mechanism of action. Tioconazole is **fungicidal** against *C. albicans*. Like other imidazole agents, tioconazole alters cellular membranes, resulting in increased membrane permeability.

    2. Spectrum of activity

      a. Activity against fungi includes most strains of *Candida* and the dermatophytes. There is also activity against *Aspergillus* and *C. neoformans*.

      b. Tioconazole is active against the following aerobic gram-positive bacteria: *Gardnerella vaginalis*, *Corynebacterium minutissimum*, *E. faecalis*, *S. aureus*, *S. epidermidis*, and some *Streptococci* spp. Gram-negative bacteria: it is active against *H. pylori*, *Haemophilus ducreyi*, *Moraxella catarrhalis*, *Neisseria gonorrhoeae*, and *N. meningitidis*.

      c. Other organisms that tioconazole has activity against are *T. vaginalis*, *Lymphogranuloma venereum*, and *Chlamydia trachomatis*.

    3. Therapeutic uses. Tioconazole is used for simple and complicated vulvovaginal candidiasis. Other uses have been explored; however, topical creams for use in those scenarios are not available in the United States.

    4. Precautions and monitoring effects. Local irritation has been manifested as vulvovaginal burning, vaginitis, and pruritus.

S. Tolnaftate (Tinactin) is available topically as a 1% aerosol, 1% powder, 1% cream, and 1% solution.

    1. Mechanism of action. It may distort hyphae and stunt mycelial growth in susceptible fungi.

    2. Spectrum of activity. Tolnaftate may be either **fungistatic** or **fungicidal** to the following organisms: *M. gypseum*, *M. canis*, *M. audouinii*, *Microsporum japonicum*, *T. rubrum*, *T. mentagrophytes*, *Trichophyton schoenleinii*, *T. tonsurans*, *E. floccosum*, *Aspergillus niger*, *C. albicans*, *C. neoformans*, and *A. fumigatus*.

    3. Therapeutic uses. Tolnaftate is used for dermatophytoses and tinea versicolor.

    4. Precautions and monitoring effects. There may be slight local irritation.

V. ANTIPROTOZOAL AGENTS

A. Classification. These drugs fall into two main categories: **antimalarial agents**, used to treat malaria infection, and **amebicides** and **trichomonacides**, used to treat amebic and trichomonal infections.

B. Antimalarial agents. Still a leading cause of illness and death in tropical and subtropical countries, malaria results from infection by any of four species of the protozoal genus *Plasmodium*. Antimalarial agents are selectively active during different phases of the protozoan life cycle. Major antimalarial drugs include **chloroquine (Aralen)**, **hydroxychloroquine (Plaquenil)**, **primaquine**, **pyrimethamine (Daraprim)**, **quinine**, and **mefloquine (Lariam)**. In addition, three combination brands are available: sulfadoxine plus pyrimethamine (Fansidar), atovaquone plus proguanil (Malarone), and artemether plus lumefantrine (Coartem).

    1. Mechanism of action

      a. Chloroquine and **hydroxychloroquine** bind to and alter the properties of microbial and mammalian DNA.

      b. The mechanism of action of **primaquine**, **quinine**, **Fansidar**, and **mefloquine** is unknown.

      c. Pyrimethamine impedes folic acid reduction by inhibiting the enzyme dihydrofolate reductase.

    2. Spectrum of activity

      a. Chloroquine and **hydroxychloroquine** are suppressive blood **schizonticidal** agents and are active against the asexual erythrocyte forms of *Plasmodium vivax* and *Plasmodium falciparum* and gametocytes of *P. vivax*, *Plasmodium malariae*, and *Plasmodium ovale*.

      b. Primaquine, a curative agent, is active against liver forms of *P. vivax* and *P. ovale* and the primary exoerythrocytic forms of *P. falciparum*.

      c. Pyrimethamine is active against chloroquine-resistant strains of *P. falciparum* and some strains of *P. vivax*.

      d. Quinine, a generalized protoplasmic poison, is toxic to a wide range of organisms. In malaria, this drug has both suppressive and curative action against chloroquine-resistant strains.

    e. Fansidar (sulfadoxine plus pyrimethamine) is a blood **schizonticidal** agent that is active against the erythrocytic forms of susceptible plasmodia. It is also active against *T. gondii*.

    f. Malarone (atovaquone plus proguanil) is active against the erythrocytic and exoerythrocytic forms of *Plasmodium* spp.

    g. Mefloquine is a blood **schizonticidal** agent that is active against *P. falciparum* (both chloroquine-susceptible and -resistant strains) and *P. vivax*.

    h. Coartem is a fixed dose oral combination of artemether (20 mg), an artemisinin derivative, and lumefantrine (120 mg), two antimalarials. Both components are blood schizontocides **active against *P. falciparum*.**

3. Therapeutic uses

    a. Chloroquine is the preferred agent used to suppress malaria symptoms and to terminate acute malaria attacks resulting from *P. falciparum* and *P. malariae* infections.

      (1) It is more potent and less toxic than quinine.

      (2) Except where drug-resistant *P. falciparum* strains are prevalent, chloroquine is the most useful antimalarial agent.

    b. Hydroxychloroquine is used as an alternative to chloroquine in patients who cannot tolerate chloroquine or when chloroquine is unavailable.

    c. Primaquine is used to cure relapses of *P. vivax* and *P. ovale* malaria and to prevent malaria in exposed persons returning from regions where malaria is endemic.

    d. Pyrimethamine is effective in the prevention and treatment of chloroquine-resistant strains of *P. falciparum*. It is now used almost exclusively in combination with a sulfonamide or sulfone.

    e. Quinine

      (1) Quinine sulfate, an oral form, is therapeutic for acute malaria caused by chloroquine-resistant strains.

      (2) Quinine dihydrochloride, a parenteral form, is used in severe cases of chloroquine-resistant malaria (it is available only from the CDC).

      (3) Quinine is almost always given in combination with another antimalarial agent.

    f. Fansidar

      (1) Fansidar is used for the suppression or prophylaxis of chloroquine-resistant *P. falciparum* malaria.

      (2) It has been used for the prophylaxis of *P. carinii* infections in AIDS patients unable to tolerate cotrimoxazole (trimethoprim–sulfamethoxazole).

    g. Mefloquine is indicated for the treatment of acute malaria and the prevention of *P. falciparum* and *P. vivax* infections.

    h. Coartem is indicated for treatment of acute, uncomplicated malaria infections due to *Plasmodium falciparum* in patients of 5 kg body weight and above.

    i. Malarone

      (1) Prophylaxis of *P. falciparum* malaria, including areas where chloroquine resistance has been reported.

      (2) Treatment of acute, uncomplicated *P. falciparum* malaria. This combination has been shown to be effective in regions where the drugs chloroquine, halofantrine, mefloquine, and amodiaquine may have unacceptable failure rates, presumably because of drug resistance.

4. Precautions and monitoring effects

    a. Chloroquine and hydroxychloroquine

      (1) Because these drugs concentrate in the liver, they should be used cautiously in patients with hepatic disease.

      (2) Chloroquine must be administered with extreme caution in patients with neurological, hematological, or severe GI disorders.

      (3) Visual disturbances, headache, skin rash, and GI distress have been reported.

    b. Primaquine

      (1) This agent is contraindicated in patients with rheumatoid arthritis and lupus erythematosus and in those receiving other potentially hemolytic drugs or bone marrow suppressants.

      (2) Primaquine may cause agranulocytosis, granulocytopenia, and mild anemia. In patients with G6PD deficiency, it may cause hemolytic anemia.

      (3) Abdominal cramps, nausea, vomiting, and epigastric distress sometimes occur.

    c. Pyrimethamine
      (1) In high doses, this drug may cause agranulocytosis, megaloblastic anemia, aplastic anemia, and thrombocytopenia.
      (2) Erythema multiforme (Stevens–Johnson syndrome), nausea, vomiting, and anorexia may develop during pyrimethamine therapy.
    d. Quinine
      (1) Quinine is contraindicated in patients with G6PD deficiency, tinnitus, and optic neuritis.
      (2) Quinine overdose or hypersensitivity reactions may be fatal. Manifestations of quinine poisoning include visual and hearing disturbances; GI symptoms (e.g., nausea, vomiting); hot, flushed skin; headache; fever; syncope; confusion; shallow, then depressed, respirations; and cardiovascular collapse.
      (3) Quinine must be used cautiously in patients with atrial fibrillation.
      (4) Renal damage and anuria have been reported.
    e. Fansidar
      (1) Severe, sometimes fatal, hypersensitivity reactions have occurred. In most cases, death resulted from severe cutaneous reactions, including erythema multiforme, Stevens–Johnson syndrome, and toxic epidermal necrolysis.
      (2) Adverse hematological and hepatic effects as seen with sulfonamides have been reported.
    f. Mefloquine
      (1) Concomitant use of mefloquine with quinine, quinidine, or β-adrenergic blockade may produce electrocardiographic abnormalities or cardiac arrest.
      (2) Concomitant use of mefloquine and quinine or chloroquine may increase the risk of convulsions.
    g. Coartem
      (1) Coartem tablets should be taken with food.
      (2) Avoid use in patients with known QT prolongation, those with hypokalemia or hypomagnesemia, and those taking other drugs that prolong the QT interval.
      (3) The most common adverse reactions in adults ($>$ 30%) are headache, anorexia, dizziness, asthenia, arthralgia, and myalgia. The most common adverse reactions in children ($>$ 12%) are pyrexia, cough, vomiting, anorexia, and headache.
    h. Malarone
      (1) Concomitant administration with tetracycline has been associated with 40% reduction in plasma concentrations of atovaquone. Similarly, concurrent rifampin is known to reduce atovaquone levels by 50%.
      (2) Take malarone with food or milk.

C. Amebicides and trichomonacides. These agents are crucial in the treatment of amebiasis, giardiasis, and trichomoniases—the most common protozoal infections in the United States. The major amebicides include **diloxanide, iodoquinol (Yodoxin), metronidazole (Flagyl), nitazoxanide (Alinia), paromomycin (Humatin), quinacrine, and tinidazole (Tindamax).**

  1. Mechanism of action
    a. Diloxanide, a dichloroacetamide derivative, is **amebicidal**; its mechanism of action is unknown. (Not available commercially but can be compounded by Panorama Compounding Pharmacy, Van Nuys, CA—per Medical Letter 8/04.)
    b. Metronidazole is a synthetic compound with direct **amebicidal** and **trichomonacidal** action; it works at both intestinal and extraintestinal sites. Its mechanism of action involves disruption of the helical structure of DNA.
    c. Nitazoxanide is designated by the U.S. Food and Drug Administration (FDA) as an orphan drug. Its antiprotozoal activity is believed to be the result of interference with the pyruvate: ferredoxin oxidoreductase (PFOR) enzyme-dependent electron transfer reaction essential for energy metabolism.
    d. Quinacrine is an acridine derivative that inhibits DNA metabolism.
    e. Iodoquinol is a luminal or contact amebicide that is effective against the trophozoites of *Entamoeba histolytica* located in the lumen of the large intestine.
    f. Paromomycin is a poorly absorbed amebicidal aminoglycoside whose mechanism of action parallels other aminoglycosides (i.e., protein synthesis inhibitor). It is also effective against enteric bacteria *Salmonella* and *Shigella*.
    g. Tinidazole precise mechanism of action is unknown.

2. **Spectrum of activity and therapeutic uses**
   a. **Diloxanide**
      (1) This drug is used to treat asymptomatic carriers of amebic and *Giardia* cysts.
      (2) Diloxanide is therapeutic for invasive and extraintestinal amebiasis (given in combination with a systemic or mixed amebicide).
      (3) Diloxanide is not effective as single-agent therapy for extraintestinal amebiasis.
   b. **Metronidazole**
      (1) This agent is the preferred drug in amebic dysentery, giardiasis, and trichomoniasis.
      (2) Metronidazole also is active against all anaerobic cocci and gram-negative anaerobic bacilli.
      (3) This agent is the treatment of choice by the CDC for the treatment of *C. difficile* colitis infections owing to the emerging use of broad-spectrum antibiotics. This therapy is cost-effective.
   c. **Quinacrine** is useful in the treatment of giardiasis and tapeworms.
   d. **Iodoquinol** is indicated for treatment of intestinal amebiasis. It is active against the protozoa *E. histolytica.*
   e. **Nitazoxanide** is indicated for treatment of diarrhea caused by *Cryptosporidium parvum* and *Giardia lamblia* in children.
   f. **Paromomycin** is indicated for acute and chronic intestinal amebiasis; it is not useful for extraintestinal amebiasis because it is not absorbed. Paromomycin has been used for *Dientamoeba fragilis, Taenia saginata, Dipylidium caninum*, and *Hymenolepis nana.*
   g. **Tinidazole** is a second-generation synthetic nitroimidazole active against trichomoniasis, *Giardia duodenalis/G. lamblia, and E. histolytica.*
3. **Precautions and monitoring effects**
   a. **Diloxanide** rarely causes serious adverse effects. Vomiting, flatulence, and pruritus have been reported.
   b. **Metronidazole**
      (1) The most common adverse effects of this drug are nausea, epigastric distress, and diarrhea.
      (2) Metronidazole is carcinogenic in mice and should not be used unnecessarily.
      (3) Headache, vomiting, metallic taste, and stomatitis have been reported.
      (4) Occasionally, neurological reactions (e.g., ataxia, peripheral neuropathy, seizures) develop.
      (5) A disulfiram-type reaction may occur with concurrent ethanol use.
   c. **Quinacrine**
      (1) This drug frequently causes dizziness, headache, nausea, and vomiting. Nervousness and seizures also have been reported.
      (2) Quinacrine should not be taken in combination with primaquine because this may increase primaquine toxicity.
      (3) Quinacrine should be administered with extreme caution in patients with psoriasis because it may cause marked exacerbation of this disease.
   d. **Iodoquinol** may produce optic neuritis or atrophy or peripheral neuropathy with high-dose, long-term use. Protein-bound iodine levels may be increased during treatment and may interfere with the results of thyroid tests for 6 months after treatment. Iodoquinol should not be used in patients who are hypersensitive to 8-hydroxy-quinolone (e.g., iodoquinol, iodochlorhydroxyquin) or iodine-containing agents or in patients with hepatic disorders.
   e. **Paromomycin** may cause nausea, cramping, and diarrhea at high doses (> 3 g/day). Inadvertent absorption through ulcerative bowel lesions may result in ototoxicity or renal damage.
   f. **Nitazoxanide** may cause abdominal pain, diarrhea, vomiting, headache, flatulence, fever, eye discoloration, rhinitis, and discolored urine.
   g. **Tinidazole** may produce metallic taste, nausea, anorexia, dyspepsia, vomiting, weakness, dizziness, and headache.
D. **Pentamidine isethionate (Pentam 300)** is an aromatic diamide antiprotozoal agent. It can be administered intramuscularly, intravenously, or by inhalation.
   1. **Mechanism of action** is not fully understood, but in vitro studies indicate interference with nuclear metabolism and inhibition of DNA, RNA, phospholipid, and protein synthesis.

   2. Therapeutic uses
   a. Pentamidine is indicated for the prevention and treatment of infections caused by *P. carinii*.
   b. Unlabeled uses include treatment of trypanosomiasis, visceral leishmaniasis, and babesiosis.
   3. Precautions and monitoring effects
   a. Nephrotoxicity, bronchospasm, and cough are the most common effects produced by intravenous or inhaled pentamidine.
   b. Severe hypotension may occur after a parenteral dose of pentamidine. Cardiorespiratory arrest can occur after a single rapid infusion of the drug.
   c. Pain, erythema, and tenderness may occur after an IM administration of the drug. This can be minimized by using the Z-track technique of drug administration. Phlebitis may occur following IV administration.
   d. Hypoglycemia may occur with initial administration of drug via the IV, IM, or inhalational route. After the patient has been on the drug for a period, hyperglycemia will result. The effect of the drug may actually induce a reversible insulin-dependent diabetes mellitus.
   e. Leukopenia and thrombocytopenia, which can be severe, occur occasionally.
   f. Pentamidine may result in elevated liver function tests, AST, and ALT.
   g. GI effects can also occur, including nausea, vomiting, abdominal discomfort, pain, diarrhea, and dysgeusia.
   h. Neurological effects can occur with parenteral administration and may include dizziness, tremors, confusion, anxiety, insomnia, and seizures.
   i. Hypocalcemia and fever have also been reported and may be severe at times.
E. Atovaquone (Mepron) is a hydroxynaphthoquinone initially synthesized as an antimalarial drug.
   1. Mechanism of action. Atovaquone blocks mitochondrial electron transport at complex III of the respiratory chain of protozoa, resulting in inhibition of pyrimidine synthesis.
   2. Spectrum of activity. It is active against *P. carinii*, *T. gondii*, *C. parvum*, *P. falciparum*, isosporidia, and microsporidia.
   3. Therapeutic uses. Atovaquone is used for second-line treatment of mild to moderate *P. carinii* pneumonia in patients intolerant of co-trimoxazole or other sulfonamides or who are nonresponsive to co-trimoxazole.
   4. Precautions and monitoring effects
   a. Oral absorption significantly increases when administered with food (especially a high-fat meal).
   b. Rash, nausea, diarrhea, headache, fever, abdominal pain, dizziness, and elevated liver function tests commonly are reported.
   5. Significant interactions. Atovaquone is highly bound to plasma protein. It should be used with caution when administered with other highly protein-bound drugs with a narrow therapeutic range.
F. Eflornithine HCl (Ornidyl). This is an IV antiprotozoal agent. Its activity has been attributed to the inhibition of the enzyme ornithine decarboxylase.
   1. Mechanism of action. This is a specific, enzyme-activated, irreversible inhibitor of ornithine decarboxylase.
   2. Spectrum of activity and therapeutic uses. Eflornithine is active in the treatment of the meningoencephalitic stage of *Trypanosoma brucei gambiense* (sleeping sickness).
   3. Precautions and monitoring effects
   a. Myelosuppression is the most frequent serious side effect.
   b. Seizures occur in about 8% of treated patients.
   c. Cases of hearing impairment have been reported.

VI. ANTITUBERCULAR AGENTS

A. Definition and classification. Drugs used to treat tuberculosis suppress or kill the slow-growing mycobacteria that cause this disease. Antitubercular agents fall into two main categories: first-line and second-line drugs. Because the causative organisms tend to develop resistance to any single drug, combination drug therapy has become standard in the treatment of tuberculosis.
   1. The **incidence** of tuberculosis in the United States is increasing owing to shifts in populations considered to be endemic for tuberculosis, the rise in HIV-positive patients, and drug resistance.

2. Agents chosen for **therapy** must eradicate mycobacterium. First-line agents available include isoniazid, ethambutol, pyrazinamide, rifampin, rifabutin, and rifapentine. **Combination chemotherapy** is essential. Agents showing the lowest incidence of resistance (isoniazid, rifampin) are usually used in combination with pyrazinamide or ethambutol.

3. Choice of therapy depends on many patients and disease factors (e.g., duration of therapy needed, likelihood of drug resistance, and HIV status).

4. **Treatment choices based on CDC recommendations** (*Table 36-4*).

B. **First-line.** These drugs, isoniazid, ethambutol, rifampin, rifabutin, rifapentine, and pyrazinamide, usually offer the greatest effectiveness with the least toxicity; they are successful in most tuberculosis patients. At least three to four drug combinations are recommended. The CDC recommends daily treatment with isoniazid, rifampin, pyrazinamide, and ethambutol for the initial phase of 2 months, followed by a continuation phase of isoniazid and rifampin for 4 to 5 months (*Table 36-4*).

1. **Ethambutol (Myambutol)** is a synthetic water-based compound.

    a. **Mechanism of action.** This drug is **bacteriostatic**. Its precise mechanism of action is unknown; however, it has demonstrated activity only against susceptible bacteria actively undergoing cell division.

    b. **Spectrum of activity and therapeutic uses.** Ethambutol is active against many *M. tuberculosis* strains as well as many other mycobacterial species. However, drug resistance develops fairly rapidly when it is used alone. In most cases, ethambutol is given adjunctively in combination with isoniazid or rifampin for tuberculosis. It is also useful in combination with other agents such as clarithromycin or azithromycin and rifabutin in treating MAC.

    c. **Precautions and monitoring effects.** Rarely, ethambutol causes such adverse effects as reversible dose-related (= 15 mg/kg/day) optic neuritis, drug fever, abdominal pain, headache, dizziness, and confusion. Liver function tests should be periodically monitored. Visual testing and renal function (reduce dose with impairment) should also be monitored.

| **Table 36-4** | TREATMENT FOR ACTIVE TUBERCULOSIS |

	Initial Phase		Continuation Phase	
Rank	**Agent**	**Dosage**	**Agent**	**Dosage**
1	INH RIF PZA EMB	7 days a week × 8 weeks *or* 5 days a week × 8 weeks	INH/RIF	7 days a week × 18 weeks *or* 5 days a week × 18 weeks

2	INH
	RIF
	PZA
	EMB
		7 days a week × 2 weeks, *then*
		   2 times a week × 6 weeks
		or
		5 days a week × 2 weeks, *then*
		   2 times a week × 6 weeks
			INH/RIF	2 times a week × 18 weeks

3	INH RIF PZA EMB	3 times a week × 8 weeks	INH/RIF	3 times a week × 19 weeks
4	INH RIF EMB	7 days a week × 8 weeks *or* 5 days a week × 8 weeks	INH/RIF	7 days a week × 31 weeks *or* 5 days a week × 31 weeks *or* 2 times a week × 31 weeks

EMB, ethambutol; *INH*, isoniazid; *PZA*, pyrazinamide; *RIF*, rifampin.
Adapted with permission from CDC guidelines for treatment of tuberculosis. *MMWR.* 2003;52 (RR11);1–77.

2. **Isoniazid (Nydrazid)** is a hydrazide of isonicotinic acid. The mainstay of antitubercular therapy, this drug should be included (if tolerated) in all therapeutic regimens.

   a. **Mechanism of action.** Isoniazid is **bacteriostatic** for resting bacilli and **bactericidal** for rapidly dividing organisms. Its mechanism of action is not fully known; the drug probably disrupts bacterial cell wall synthesis by inhibiting mycolic acid synthesis.

   b. **Spectrum of activity.** Isoniazid has activity only against organisms in the genus *Mycobacterium*. More specifically, it has demonstrated activity against *M. tuberculosis*, *Mycobacterium bovis*, and select strains of *Mycobacterium kansasii.*

   c. **Therapeutic uses**
      (1) The most widely used antitubercular agent, isoniazid should be given in combination with other antitubercular drugs (such as rifampin, ethambutol, and pyrazinamide) to prevent drug resistance in tuberculosis.
      (2) **Treatment of latent infection** (previously referred to as preventive therapy of chemoprophylaxis). Isoniazid may be administered alone for up to 1 year in adults or children who have a positive tuberculin test result but lack active lesions.

   d. **Precautions and monitoring effects**
      (1) The most common adverse effects of isoniazid are skin rash, fever, jaundice, and peripheral neuritis.
      (2) Hepatitis, an occasional reaction, can be severe and, in some cases, fatal. The risk of hepatitis increases with the patient's age and rises with alcohol abuse. Monitor liver function tests.
      (3) Blood dyscrasias (e.g., agranulocytosis, aplastic or hemolytic anemia, thrombocytopenia) may occur. Monitor complete blood count (CBC) routinely.
      (4) Adverse GI effects include nausea, vomiting, and epigastric distress.
      (5) CNS toxicity may result from pyridoxine deficiency. Signs and symptoms include insomnia, restlessness, hyperreflexia, and convulsions. Pyridoxine 15 to 50 mg/day should be administered to patients taking isoniazid to minimize the peripheral neuropathy associated with its use (especially in patients with diabetes, HIV, uremia, alcoholism, malnutrition, pregnancy, or seizure disorder).

   e. **Significant interactions**
      (1) With concurrent **phenytoin** therapy, blood levels of both phenytoin and isoniazid may increase, possibly causing toxicity.
      (2) **Aluminum-containing antacids** may reduce isoniazid absorption.
      (3) Concurrent **carbamazepine** therapy may increase the risk of hepatitis.
      (4) Use of isoniazid with other antitubercular agents, such as cycloserine or ethionamide, may cause additive nervous system effects.
      (5) There is the potential for the serotonin syndrome to exist when isoniazid is used in combination with selective serotonin reuptake inhibitors or in patients taking meperidine. Isoniazid has been shown to have some monoamine oxidase (MAO)–inhibiting activity.

3. **Rifampin (Rimactane)** is a complex macrocyclic agent.

   a. **Mechanism of action.** This drug is **bactericidal**; it impairs bacterial RNA synthesis by binding to DNA-dependent RNA polymerase.

   b. **Spectrum of activity.** Rifampin has activity against most mycobacterial strains. In addition, rifampin has activity against many other organisms, including *N. meningitidis*, *S. aureus*, *H. influenzae*, *Legionella pneumophila*, and *C. trachomatis*.

   c. **Therapeutic uses**
      (1) In recommended combinations for treatment of active tuberculosis
      (2) Prophylactic rifampin is effective when administered to carriers of *N. meningitidis* disease and chemoprophylaxis of patients with *H. influenzae* type b organisms.
      (3) Rifampin may be used in combination with dapsone for the treatment of leprosy.

   d. **Precautions and monitoring effects**
      (1) Serious hepatotoxicity may result from rifampin therapy. Liver function tests should be routinely conducted.
      (2) In rare cases, this drug induces an influenza-like syndrome.
      (3) Other adverse effects include skin rash, drowsiness, headache, fatigue, confusion, nausea, vomiting, and abdominal pain.
      (4) Rifampin colors urine, sweat, tears, saliva, and feces orange-red.

  e. **Significant interactions**
  1. (1) Rifampin induces hepatic microsomal cytochrome P450 isoenzymes and thus may decrease the therapeutic effectiveness of **corticosteroids, warfarin, oral contraceptives, quinidine, digitoxin, protease inhibitors (PIs), nonnucleoside reverse transcriptase inhibitors, ketoconazole, verapamil, methadone, oral antidiabetic agents, cyclosporine, dapsone, chloramphenicol,** and **barbiturates.**
  2. (2) **Probenecid** may increase blood levels of rifampin.
  3. (3) **Aminosalicylic acid** may impair absorption of rifampin secondary to bentonite, an excipient used in preparation of aminosalicylic granules.
  f. The newer rifamycins, **rifabutin (Mycobutin)** and **rifapentine (Priftin)** may be substituted for rifampin in special situations, for example, intolerance or serious drug interactions.

4. **Rifabutin (Mycobutin)** is an antimycobacterial agent that is similar to rifampin, with activity against both tubercular and nontubercular mycobacterial, and offers no clear advantage over rifampin.
  a. **Mechanism of action.** In addition to its antimycobacterial activity against tubercular and nontubercular mycobacterial, rifabutin has been reported to inhibit reverse transcriptase and block the in vitro infectivity and replication of HIV.
  b. **Therapeutic uses.** Rifabutin is indicated for the prevention of disseminated MAI complex disease in patients with advanced HIV infections.
  c. **Precautions and monitoring effects.** The use of rifabutin has resulted in mild elevation of liver enzymes and thrombocytopenia.
  d. **Significant interactions**
  1. (1) Rifabutin antagonizes and potentially negates the immune response mediated by the bacillus Calmette–Guérin (BCG) vaccine.
  2. (2) Rifabutin may increase the clearance of drugs by inducing hepatic microsomal enzymes, but does so to a lesser extent than rifampin. The concentrations of the following drugs may be reduced while taking rifabutin: **cyclosporine, zidovudine, prednisone, digitoxin, quinidine, ketoconazole, protease inhibitors, propranolol, phenytoin, sulfonylureas,** and **warfarin.** Serum cyclosporine levels should be monitored in patients receiving both agents.

5. **Rifapentine (Priftin)** is a long-acting rifamycin-derivative and has a similar profile of microbiological activity to rifampin. It is usually administered once or twice weekly.
  a. **Mechanism of action.** Rifapentine is bactericidal against intracellular and extracellular *M. tuberculosis* at therapeutic levels.
  b. **Spectrum of activity and therapeutic uses.** Indicated for treatment of primary tuberculosis. Rifapentine should always be used in conjunction with ≥ 1 other antituberculosis drug to which the isolate is susceptible.
  c. **Precautions and monitoring effects.** Rifapentine induces cytochrome P450 isoenzymes 3A4 and 2C8/9 responsible for inactivation of certain calcium channel–blocking agents (verapamil, diltiazem, nifedipine), antifungals (ketoconazole, fluconazole, itraconazole), sulfonylurea antidiabetic agents, methadone, corticosteroids, cardiac glycosides, certain antiarrhythmic agents (disopyramide, mexiletine, quinidine, tocainide), quinine, dapsone, chloramphenicol, clarithromycin, doxycycline, fluoroquinolones, transcriptase inhibitor cyclosporin, tacrolimus, and warfarin. Concomitant use of rifapentine with these drugs may decrease plasma concentrations, and dosage adjustments may be required.

6. **Pyrazinamide** is a pyrazine analog of nicotinamide.
  a. **Mechanism of action.** This drug is **bactericidal** and/or **bacteriostatic**, depending on the cell concentration achieved.
  b. **Spectrum of activity and therapeutic uses.** Pyrazinamide is a highly specific agent and has activity only against *M. tuberculosis.* Pyrazinamide is used as a primary agent with isoniazid and rifampin for at least 2 months, followed by isoniazid and rifampin.
  c. **Precautions and monitoring effects.** This agent may result in hepatotoxicity and, rarely, hepatic necrosis resulting in death. Anorexia, nausea, vomiting, malaise, and fever have been reported. Hyperuricemia may result in gouty exacerbations. Both liver function tests and uric acid levels should routinely be monitored.

C. **Second-line agents.** These agents include aminosalicylic acid **(Paser)**, capreomycin **(Capastat)**, cycloserine **(Seromycin)**, ethionamide **(Trecator-SC)**, quinolones (ciprofloxacin, ofloxacin, levofloxacin, sparfloxacin), streptomycin, and kanamycin. Second-line drugs are mainly substituted or added to preferred therapy owing to intolerance or drug resistance. These agents are less effective, more toxic, and are used in combination with primary agents.

1. **Mechanism of action**
   a. **Aminosalicylic acid** is **bacteriostatic**; it probably inhibits the enzymes responsible for folic acid synthesis.
   b. **Cycloserine** can be **bacteriostatic** or **bactericidal**, depending on its concentration at the infection site; it impairs amino acid use, thereby inhibiting bacterial cell wall synthesis.
   c. The mechanism of action of capreomycin (**bacteriostatic**), ethionamide (**bactericidal**), and pyrazinamide (**bactericidal**) is unknown.

2. **Spectrum of activity and therapeutic uses.** Second-line antitubercular agents are active against various microorganisms, including *M. tuberculosis*. These agents generally are reserved for patients with extensive extrapulmonary or drug-resistant disease or for patients who need retreatment. These drugs are almost always administered in combination.

3. **Precautions and monitoring effects**
   a. Adverse effects of **aminosalicylic acid** include leukopenia, agranulocytopenia, thrombocytopenia, hemolytic anemia, mononucleosis-like syndrome, malaise, joint pain, fever, and skin rash.
   b. **Capreomycin** and **streptomycin** are ototoxic and nephrotoxic; they should not be administered together.
   c. **Cycloserine** may cause adverse CNS effects including headache, suicidal and psychotic tendencies, hyperirritability, confusion, paranoia, and nervousness.
   d. **Ethionamide** may induce nausea, vomiting, orthostatic hypotension, metallic taste, epigastric distress, and peripheral neuropathy.
   e. **Streptomycin.** See II.B.3.

D. **Alternative agents**
1. **Rifater.** A combination of rifampin 120 mg, isoniazid 50 mg, and pyrazinamide 300 mg in one tablet is used in patients expected to have low compliance with tuberculosis drug therapy. One **disadvantage** is that many patients are required to take as many as five to six tablets daily, which may reduce compliance.
2. **Quinolones.** Ciprofloxacin and levofloxacin are used in tuberculosis therapy. Levofloxacin is preferred owing to increased serum concentrations. Levofloxacin is usually used in combination with other tuberculosis agents for active treatment. For prophylaxis, levofloxacin is combined with pyrazinamide.
3. **Macrolides.** Clarithromycin and azithromycin have shown limited activity against *M. tuberculosis*.

VII. ANTIVIRAL AGENTS

A. **Definition.** These drugs treat viral infections by affecting viral replication. Because viruses lack independent metabolic activity and can replicate only within living host cells, antiviral agents tend to injure host as well as viral cells. Although most antiviral drugs are active against either DNA or RNA viruses, some (e.g., adefovir, ribavirin) are active against both.

B. **DNA viruses.** Currently approved antiviral therapies against the Herpesviridae family of DNA viruses—herpes simplex virus 1 and 2 (HSV-1, HSV-2), varicella zoster virus (VZV), cytomegalovirus (CMV)—are **virustatic** and arrest DNA synthesis by inhibiting viral DNA polymerase. Many of these agents are prodrugs and require viral and host cellular enzymes (e.g., thymidine, deoxyguanosine kinase) to phosphorylate them into the active triphosphate form before exerting their antiviral activity. Hence, a common mechanism of resistance is a deficiency or structural alteration in viral thymidine kinase (*Table 36-5*). Some of these agents also demonstrate activity against RNA viruses, including hepatitis C and HIV.

1. **Acyclovir (Zovirax)** is a synthetic acyclic analog of guanosine with activity against various herpes viruses.
   a. **Mechanism of action.** Acyclovir monophosphate is phosphorylated to the triphosphate, where it becomes incorporated into viral DNA and inhibits viral replication.
   b. **Spectrum of activity.** This agent is active against herpes viruses, particularly HSV-1, HSV-2, VZV, and chickenpox (varicella).

Table 36-5	ACTIVITY OF VARIOUS ANTI-DNA VIRAL AGENTS					
Agent	**HSV-1**	**HSV-2**	**VZV**	**CMV**	**Influenza A**	**Influenza B**
Acyclovir[a]	+	+	+	—	—	—
Amantadine	—	—	—	—	+	—
Cidofovir	—	—	—	+	—	—
Famciclovir	+	+	+	—	—	—
Foscarnet	+	+	+	+	—	—
Ganciclovir[a]	—	—	—	+	—	—
Oseltamivir	—	—	—	—	+	+
Rimantadine	—	—	—	—	+	—
Valacyclovir[a]	+	+	+	—	—	—
Valganciclovir[a]	—	—	—	+	—	—
Zanamivir	—	—	—	—	+	+

[a]Requires activation into triphosphate form.
HSV, herpes simplex virus; *VZV*, varicella zoster virus; *CMV*, cytomegalovirus.

   c. **Therapeutic uses**

     (1) Acyclovir is used to treat initial and recurrent HSV-1 and HSV-2 infections and for acute treatment of herpes zoster (shingles) and chickenpox. It is also used orally for long-term suppression of genital HSV infections.

     (2) This agent is available in topical, oral, and IV forms. Topical acyclovir is applied directly on herpes lesions in recurrent herpes labialis (cold sores). It is not recommended for use on genital herpes lesions due to poor efficacy.

     (3) Acyclovir may be administered intravenously in the treatment of initial and recurrent mucocutaneous HSV infection and VZV infection in immunocompromised patients as well as in the treatment of HSV infections that are disseminated or affect the central nervous system.

   d. **Precautions and monitoring effects**

     (1) Oral acyclovir may induce nausea, vomiting, diarrhea, and headache.

     (2) IV administration may cause dose-dependent renal impairment, crystalline nephropathy, neurological effects (e.g., lethargy, confusion, tremors, agitation, seizures, coma, obtundation), hypotension, rash, itching, and phlebitis at the injection site.

     (3) Local discomfort and pruritus may result from topical administration.

     (4) Acyclovir is removed by hemodialysis. Doses should be adjusted in renal impairment and hemodialysis.

   e. **Significant interactions. Probenecid** reduces the renal clearance of acyclovir, resulting in increases in acyclovir half-life and serum concentration. Acyclovir may decrease plasma concentrations of **phenytoin** and **valproic acid**.

  2. **Adefovir dipivoxil** (Hepsera) is a phosphonate nucleotide analog with activity against various DNA and RNA viruses.

   a. **Mechanism of action.** Adefovir is phosphorylated to the active diphosphate form by cellular kinases. It is then incorporated into viral DNA, resulting in termination of replication.

   b. **Spectrum of activity and therapeutic uses**

     (1) Adefovir is active against hepatitis B virus (including lamivudine-resistant strains), herpes viruses, and HIV.

     (2) However, adefovir is approved for use only for treatment of chronic hepatitis B infection in adults with evidence of active viral replication with persistently elevated liver function tests or histologically active disease.

   c. **Precautions and monitoring effects**

     (1) Severe acute hepatitis exacerbations have occurred in patients who discontinue therapy (**black box warning**). If therapy is discontinued, liver function tests must be monitored closely.

(2) Nephrotoxicity has been reported with adefovir, especially in patients with underlying renal dysfunction or those taking concomitant nephrotoxins (**black box warning**).

(3) Other adverse effects include rash, GI disturbances, headache, and weakness.

(4) Dose adjustment is required for renal insufficiency.

3. **Amantadine (Symmetrel)** is a synthetic tricyclic amine with a unique chemical structure similar to rimantadine. It demonstrates activity against influenza A viral infection.

   a. Mechanism of action. Amantadine inhibits replication of the influenza A virus by interfering with viral attachment and uncoating.

   b. Spectrum of activity and therapeutic uses

      (1) Due to increasing rates of resistance, amantadine is no longer recommended for prophylaxis or treatment of influenza A virus.

      (2) This drug may also be used to treat parkinsonism as well as drug-induced extrapyramidal symptoms.

   c. Precautions and monitoring effects

      (1) The most pronounced adverse effects of amantadine are ataxia, nightmares, and insomnia. Other CNS effects include depression, confusion, dizziness, fatigue, anxiety, and headache. Elderly patients may be at increased risk of CNS adverse reactions. Patients with a history of seizures or psychiatric disorders should be monitored closely during therapy.

      (2) Anticholinergic reactions (e.g., dry mouth, blurred vision) have been reported.

      (3) Dosage adjustment is needed for patients with impaired renal function.

4. **Cidofovir (Vistide)** is a synthetic acyclic purine nucleoside phosphonate derivative.

   a. Mechanism of action. Cidofovir diphosphate suppresses CMV replication by selective inhibition of viral DNA synthesis.

   b. Spectrum of activity. In vitro activity has been demonstrated against CMV, VZV, Epstein–Barr virus (EBV), and HSV-1 and HSV-2. Controlled clinical studies are limited to patients with AIDS and CMV retinitis.

   c. Therapeutic use includes the treatment, but not the cure, of CMV retinitis in patients with AIDS.

   d. Precautions and monitoring effects

      (1) Cases of acute renal failure leading to dialysis or death have occurred (**black box warning**). It is also carcinogenic and teratogenic.

      (2) Avoid using this drug in patients with serum creatinine > 1.5 mg/dL or creatinine clearance (CrCl) < 55 mL/min or in patients who are receiving (or have received in the past 7 days) nephrotoxic agents.

      (3) Cidofovir is contraindicated in patients with a history of severe hypersensitivity to probenecid or sulfa-containing medications.

      (4) The dose-limiting toxicity of cidofovir is **nephrotoxicity**; neutropenia, peripheral neuropathy, and diarrhea are common adverse effects.

      (5) Probenecid must be administered before and after each cidofovir dose. The patient must be hydrated with 1 L of normal saline before infusing. Cidofovir is available only in IV form.

5. **Entecavir (Baraclude)** is a carbocyclic analog of guanosine used for treatment of chronic hepatitis B infection.

   a. Mechanism of action. Once phosphorylated to the active triphosphate form, entecavir inhibits hepatitis B viral polymerase and ultimately halts hepatitis B DNA synthesis.

   b. Spectrum of activity. Entecavir exhibits activity against hepatitis B virus, including lamivudine-resistant strains. Development of HIV resistance to nucleoside reverse transcriptase inhibitors is possible if entecavir is used without antiretroviral treatment in HIV and hepatitis B virus coinfection.

   c. Therapeutic uses

      (1) Entecavir is approved for treatment of chronic hepatitis B infection in adults with evidence of active viral replication and persistent elevations in liver function tests or histologically active disease.

      (2) It is effective for patients who have failed treatment with lamivudine owing to resistance development.

      (3) Entecavir is not recommended for use in patients with hepatitis B virus infection who are coinfected with HIV and are not receiving antiretroviral therapy.

    d. Precautions and monitoring effects

      (1) Severe acute exacerbations of hepatitis B have been observed in patients who discontinue therapy, necessitating close monitoring (**black box warning**).

      (2) Common adverse effects include dizziness, fatigue, headache, and nausea.

      (3) Dose adjustment is required for renal insufficiency.

      (4) Counsel patients to take entecavir on an empty stomach.

6. Famciclovir (Famvir) is a prodrug of the antiviral agent penciclovir.

    a. Mechanism of action. Famciclovir is rapidly phosphorylated in virus-infected cells by viral thymidine kinase to penciclovir monophosphate. Penciclovir is a competitive inhibitor of viral DNA polymerase and prevents viral replication by inhibition of herpes virus DNA synthesis.

    b. Spectrum of activity and therapeutic uses

      (1) Famciclovir has activity against HSV-1, HSV-2, and VZV. The drug is indicated for management of acute herpes zoster (shingles) and oral and genital herpes.

      (2) Therapy must be promptly initiated as soon as herpes zoster is diagnosed (within 48 to 72 hrs), at a dose of 500 mg every 8 hrs for 7 days.

    c. Precautions and monitoring effects

      (1) **Common adverse events** include fatigue, GI complaints (nausea, diarrhea, vomiting, constipation), and anorexia. Headache is also commonly reported.

      (2) Dose adjustment is necessary in patients with renal dysfunction. Famciclovir is removed by hemodialysis.

7. Foscarnet (Foscavir) is a synthetic pyrophosphate analog that directly inhibits enzymes involved in viral DNA synthesis without incorporation into viral DNA. It is a broad-spectrum antiviral agent and is an option in cases of acyclovir or ganciclovir resistance.

    a. Mechanism of action

      (1) Viral DNA replication requires the addition of deoxynucleoside triphosphates at the end of the DNA strand by DNA polymerase and the subsequent cleavage of pyrophosphate from the newly attached nucleotide. Foscarnet binds noncompetitively to DNA polymerase to form an inactive complex and prevents pyrophosphate cleavage. Viral DNA chain elongation is thus terminated.

      (2) Foscarnet is also active against HIV. It is a noncompetitive, reversible inhibitor of HIV reverse transcriptase, the enzyme responsible for converting viral RNA to viral DNA.

    b. Spectrum of activity and therapeutic uses. Foscarnet has in vitro activity against HSV-1 and HSV-2, CMV, VZV, EBV DNA polymerases, influenza polymerase, and HIV reverse transcriptase. Therapeutically, the drug is used to treat CMV disease as well as acyclovir-resistant HSV and VZV infections.

      (1) Foscarnet is an alternative to ganciclovir and valganciclovir for treatment of CMV infection in immunocompromised patients. Foscarnet causes less hematologic toxicity than ganciclovir in patients who have received allogeneic stem cell transplants. An initial induction therapy lasts 2 to 3 weeks. Maintenance therapy is needed to prevent relapse.

      (2) Foscarnet is indicated for the treatment of acyclovir-resistant mucocutaneous HSV in immunocompromised patients. It is not, however, a cure for HSV infections.

      (3) Foscarnet is able to cross the blood–brain barrier.

    c. Precautions and monitoring effects

      (1) IV foscarnet is highly **nephrotoxic**, causing acute tubular necrosis. The incidence of acute renal failure can be markedly reduced if adequate hydration and daily monitoring of BUN and serum creatinine are maintained throughout therapy.

      (2) Other common adverse effects include electrolyte abnormalities (e.g., hypocalcemia, hypomagnesemia, hypophosphatemia and hyperphosphatemia, hypokalemia), anemia, fever, headache, and seizures.

      (3) Dose adjustment for renal dysfunction is required. Foscarnet is removed by hemodialysis.

      (4) Foscarnet must be administered using an infusion pump over at least 1.5 to 2 hrs. Do not administer the drug as an IV bolus.

    d. Significant interactions

      (1) Concomitant nephrotoxins (aminoglycosides, amphotericin B, etc.) increase the risk of renal toxicity.

      (2) Foscarnet is exclusively eliminated by glomerular filtration; concurrent nephrotoxic agents should be avoided whenever possible.

8. Ganciclovir (Cytovene) is a synthetic purine nucleoside analog that is approved for the treatment and prophylaxis of CMV infections in immunocompromised patients (e.g., HIV-positive patients, transplant recipients).

    a. Mechanism of action. After conversion to ganciclovir triphosphate, ganciclovir is incorporated into viral DNA, which inhibits viral DNA polymerase, thereby terminating viral replication.

    b. Spectrum of activity. Ganciclovir has in vitro activity against HSV-1 and HSV-2, VZV, EBV, and CMV (owing to its enhanced ability to penetrate host cells).

    c. Therapeutic uses. It is indicated for treatment of CMV retinitis in patients with HIV/AIDS. It is also used for prophylaxis of CMV infection in HIV-positive patients (secondary prophylaxis) and transplant recipients at risk for CMV disease.

      (1) Conversion into the triphosphate form is greater in infected host cells, even though drug penetration occurs in both uninfected and infected cells.

      (2) Inhibitory concentrations for the viral DNA polymerase are lower than those for the host cellular polymerase.

      (3) It is available in oral and IV formulations as well as an intraocular implant. Although the oral formulation is approved for prevention and maintenance treatment of CMV, its poor bioavailability has limited its use. Valganciclovir has become the drug of choice for these indications, owing to its markedly improved bioavailability.

    d. Precautions and monitoring effects

      (1) Ganciclovir has a **black box warning** concerning increased potential for neutropenia, anemia, and thrombocytopenia. It is also teratogenic, carcinogenic, and mutagenic.

      (2) Adverse effects commonly include fever, rash, and GI disturbances. Phlebitis and pain may occur at the site of infusion.

      (3) Because ganciclovir is cleared by glomerular filtration and tubular secretion, renal function and adequate hydration should be monitored. Doses should be adjusted in cases of renal impairment and hemodialysis.

      (4) Solutions of ganciclovir are extremely alkaline. Avoid direct contact with skin.

    e. Significant interactions

      (1) **Probenecid** may increase ganciclovir concentrations and possibly toxicity.

      (2) Use of **zidovudine**, **azathioprine**, or **mycophenolate mofetil** in combination with ganciclovir may result in neutropenia; careful monitoring of neutrophil count is required when these are taken concurrently with ganciclovir.

      (3) **Imipenem–cilastatin** in combination with ganciclovir may increase the potential for seizures.

9. Oseltamivir (Tamiflu) is pharmacologically similar to zanamivir but structurally different. Both of these agents are in a class known as the neuraminidase inhibitors and have a unique mechanism of action.

    a. Mechanism of action. Oseltamivir is a prodrug that must be hydrolyzed to oseltamivir carboxylate in vivo to exert its antiviral activity. It is a potent selective inhibitor of the influenza virus enzyme, neuraminidase. Inhibition of this enzyme prevents viral replication and spread to other host cells.

    b. Spectrum of activity. This agent is active against both influenza A and B viruses. It is one of the preferred agents for use against the 2009 H1N1 strain of influenza.

    c. Therapeutic uses

      (1) It is approved for the symptomatic treatment of influenza A and B infections in patients 1 year of age and older who present with symptoms within 48 hrs.

      (2) Oseltamivir has been shown to decrease the duration of symptoms by 1 to 2 days if taken within 48 hrs of onset of viral symptoms.

      (3) It is also approved for the prophylaxis of influenza infections in patients 1 year of age and older. Dosing recommendations are available for prevention and treatment of H1N1 influenza in children younger than 1 year of age. *Note:* The influenza virus vaccine is still the gold standard for prophylaxis.

(4) Oseltamivir demonstrates some activity against strains of avian influenza, making it a possible option for treatment and prophylaxis.

    d. Precautions and monitoring effects

      (1) The most common adverse effects are nausea and vomiting. There have been postmarketing reports of self-injury and delirium (mostly in Japan) among pediatric patients. Close monitoring for abnormal behavior is recommended.

      (2) Dosage adjustments are required for patients with impaired renal function.

      (3) Cross-resistance between oseltamivir and zanamivir has been reported.

      (4) Dosing errors have resulted when prescribers dosed oseltamivir suspension in mL instead of mg. Be sure to verify and communicate doses in mg only.

10. Ribavirin (Rebetol, Copegus) is a synthetic nucleoside analog.

    a. Mechanism of action. Ribavirin may inhibit RNA and DNA synthesis by depleting intracellular nucleotide reserves.

    b. Spectrum of activity. This agent is active in vitro against a broad spectrum of DNA and RNA viruses, including influenza A and B, RSV, herpes simplex, and hepatitis C virus.

    c. Therapeutic uses. The aerosolized form of ribavirin is no longer recommended for treatment of RSV in infants and children, owing to inconsistent clinical benefits observed in clinical trials. Combination therapy with oral ribavirin and subcutaneous interferon-alpha is effective in treatment of non-genotype1 chronic hepatitis C.

    d. Precautions and monitoring effects

      (1) Common adverse effects of oral ribavirin include hemolytic anemia (**black box warning**) and GI disturbances. Hemoglobin and hematocrit should be monitored carefully, especially during the first 4 weeks of treatment.

      (2) Ribavirin is teratogenic; its use is contraindicated in pregnancy and in the male partners of pregnant women.

      (3) Ribavirin should be avoided in patients with a CrCl < 50 mL/min.

      (4) Ribavirin should never be used as monotherapy in treatment of chronic hepatitis C.

11. Rimantadine (Flumadine) is a synthetic antiviral agent and an α-methyl derivative of amantadine that blocks the early step in the replication of the influenza A virus.

    a. Mechanism of action. Rimantadine inhibits the early viral replication cycle, possibly inhibiting the uncoating of the virus. It has the same mechanism of action and spectrum of activity as amantadine.

    b. Spectrum of activity and therapeutic uses

      (1) Due to increasing rates of resistance, rimantadine is no longer recommended for prophylaxis or treatment of influenza A virus.

      (2) Influenza vaccination is the method of choice for prevention of influenza infection.

    c. Precautions and monitoring effects

      (1) Rimantadine may increase the incidence of seizure in patients with seizure disorder.

      (2) The most frequent adverse reactions include GI disturbance (e.g., nausea, vomiting, anorexia) and CNS toxicity (e.g., insomnia, dizziness, headache), which are less than those observed with amantadine.

      (3) Dose reductions are recommended in patients with hepatic or renal dysfunction.

12. Telbivudine (Tyzeka) is a synthetic thymidine nucleoside analog used for treatment of chronic hepatitis B infection.

    a. Mechanism of action. Telbivudine is phosphorylated into the active triphosphate form that inhibits hepatitis B viral DNA polymerase, with ultimate termination of the DNA chain and inhibition of viral replication.

    b. Spectrum of activity

      (1) Telbivudine exhibits activity against hepatitis B virus but not HIV.

      (2) There is a high incidence of cross-resistance between lamivudine-resistant hepatitis B virus and telbivudine.

    c. Therapeutic uses

      (1) Telbivudine is indicated for treatment of chronic hepatitis B infection in adults with active viral replication and persistent elevations in liver function tests or histologically active disease.

      (2) When compared with lamivudine, telbivudine produced a greater virologic response in controlled clinical trials.

    d. Precautions and monitoring effects

      (1) There is a **black box warning** regarding severe exacerbations of hepatitis B in patients discontinuing therapy, requiring close monitoring.

      (2) Common adverse effects include elevations in creatine phosphokinase, headache, fatigue, nausea, and vomiting.

      (3) Dosage adjustment is required in patients with renal insufficiency.

      (4) May be taken without regard to meals.

13. Valacyclovir (Valtrex) is the L-valyl ester prodrug of the antiviral agent acyclovir.

    a. Mechanism of action. Valacyclovir is rapidly converted to acyclovir. Acyclovir is selective for the thymidine kinase enzyme, beginning the conversion of acyclovir to acyclovir triphosphate, stopping the replication of herpes viral DNA.

    b. Spectrum of activity and therapeutic uses

      (1) Valacyclovir is active against HSV-1, HSV-2, and VZV.

      (2) This agent is used for the acute treatment of herpes zoster (shingles), herpes labialis (cold sores), and genital herpes in immunocompetent adults. It is also effective for suppression of recurrent episodes of genital herpes in immunocompetent and HIV-infected people as well as reduction of transmission of genital herpes.

      (3) Advantages over acyclovir include oral dosing of only once to three times daily and attainment of higher plasma concentrations than oral acyclovir. A disadvantage is that there is no IV form available.

    c. Precautions and monitoring effects

      (1) Valacyclovir has caused thrombotic thrombocytopenic purpura/hemolytic uremic syndrome in immunocompromised individuals, including those with advanced HIV and transplant recipients.

      (2) Begin therapy within 72 hrs of herpes zoster rash onset.

      (3) Most commonly reported adverse reactions are mild and include nausea, headache, and vomiting. Dosage adjustment is needed in patients with renal dysfunction.

14. Valganciclovir (Valcyte) is the L-valyl ester prodrug of the antiviral agent ganciclovir.

    a. Mechanism of action. Valganciclovir is converted in vivo to ganciclovir. After conversion to the active form, ganciclovir triphosphate, ganciclovir is incorporated into viral DNA, which inhibits viral DNA polymerase, thereby terminating viral replication.

    b. Spectrum of activity and therapeutic uses

      (1) For in vitro activity, see VII.B.8.b.

      (2) Valganciclovir is indicated for the treatment of CMV retinitis in patients with AIDS and for prevention of CMV after transplantation of kidney, heart, and kidney-pancreas. It is not indicated for liver transplant recipients, due to an increased risk of tissue-invasive CMV as compared with ganciclovir.

      (3) The markedly improved bioavailability of valganciclovir over oral ganciclovir has resulted in the widespread use of valganciclovir for treatment and prevention of CMV disease.

    c. Precautions and monitoring effects

      (1) Same **black box warnings** as for ganciclovir.

      (2) Doses should be adjusted in cases of renal impairment. Do not use in hemodialysis patients; ganciclovir must be used.

      (3) Only available orally. Do not substitute doses of oral valganciclovir 1:1 for oral ganciclovir; they are not equivalent.

      (4) A potential carcinogen and teratogen; common adverse effects are the same as for ganciclovir.

      (5) If the tablet is broken, avoid contact with skin owing to teratogenic and carcinogenic potential.

      (6) Be aware of the potential for errors as a result of the look-alike and sound-alike names of valganciclovir and valacyclovir.

    d. Significant interactions. Same as for ganciclovir; see VII.B.8.e.

15. Zanamivir (Relenza) is the first of a class of antiviral agents called neuraminidase inhibitors approved by the FDA for the treatment of influenza A and B infections in adults and children at least 7 years of age. It is also indicated for prevention of influenza in adults and children at least 5 years of age.

    a. Mechanism of action. Zanamivir inhibits replication of the influenza A and B viruses by selective inhibition of the influenza virus neuraminidase enzyme.

    b. **Spectrum of activity.** This agent is active against both the influenza A and B viruses. It demonstrates activity against avian influenza in animal studies. It is one of the preferred agents for use against the 2009 H1N1 strain of influenza.

    c. **Therapeutic uses**

      (1) It is approved for the treatment of uncomplicated influenza A and B infection for patients who have been symptomatic for $<$ 48 hrs. It is also indicated for influenza prophylaxis.

      (2) Zanamivir is approved for oral inhalation use only, using the Diskhaler device provided by the manufacturer.

      (3) Zanamivir may be considered for prevention or treatment of avian and swine (H1N1) influenza.

      (4) Shown to decrease duration of symptoms by approximately 1.5 days if taken within 48 hrs of onset of viral symptoms.

    d. **Precautions and monitoring effects**

      (1) The use of zanamivir is not recommended in patients with a history of asthma or chronic obstructive pulmonary disease, owing to the risk of bronchospasm and acute decline in lung function.

      (2) The most common adverse effects were mild and included diarrhea, nausea, and vomiting. The incidence of these was no different than placebo.

      (3) Do not puncture the Rotadisk blister until immediately before administering the dose to ensure full dosage. Manual dexterity required for this device.

      (4) Do not use in a nebulizer or mechanical ventilator.

C. **HIV (RNA virus)**

  1. Currently, six classes of antiretroviral agents are approved. These drugs are active against HIV and include the nucleoside reverse transcriptase inhibitors (NRTIs) **abacavir, didanosine, emtricitabine, lamivudine, stavudine,** and **zidovudine**; the nucleotide reverse transcriptase inhibitor (NtRTI) **tenofovir disoproxil fumarate**; the nonnucleoside reverse transcriptase inhibitors (NNRTIs) **delavirdine, efavirenz, etravirine, nevirapine**, and **rilpivirine** and the protease inhibitors (PIs) **atazanavir, darunavir, fosamprenavir, indinavir, lopinavir/ritonavir, nelfinavir, ritonavir, saquinavir**, and **tipranavir**; the fusion inhibitor **enfuvirtide**; the entry inhibitor **maraviroc**; and the integrase inhibitor **raltegravir**.

  2. These agents are virustatic and require lifelong therapy. They are currently approved for use in various combinations known as potent combination antiretroviral therapy.

    a. Appropriate combinations include those that have demonstrated efficacy and safety in controlled clinical trials (*Table 36-6*).

    b. Monotherapy with any single antiretroviral agent is unacceptable in the treatment of HIV infection owing to rapid development of viral resistance.

    c. Before designing a treatment plan, a $CD4^+$ cell count, an HIV RNA level (viral load), genotypic resistance testing, along with baseline lab values (e.g., basic chemistry, complete blood count, etc.) should be obtained to determine if treatment should be initiated. After starting therapy, repeat these measurements in 2 to 8 weeks, followed by every 3 to 6 months once undetectable.

    d. A minimum of 0.5 to $\log_{10}$ copies/mL decline in HIV RNA levels should be seen after the first 2 to 8 weeks of therapy for clinical response; a subsequent decrease to undetectable levels should be achieved by 12 to 24 weeks.

  3. **Reverse transcriptase inhibitors** are classified as either nucleosides or nucleotides. These agents are competitive inhibitors of reverse transcriptase, which leads to chain termination when incorporated into the viral DNA chain. They are inactive until phosphorylated by human cellular kinases into the active triphosphate metabolite. Each agent has a corresponding three-letter acronym as well as a brand name. With the exception of abacavir, each agent in this class of antiretrovirals requires dosage adjustment in patients with renal dysfunction. **All agents in this class have a black box warning concerning the potential for development of lactic acidosis and severe hepatomegaly with steatosis**.

    a. **Abacavir (ABC; Ziagen)** is a synthetic carbocyclic nucleoside analog indicated for the treatment of both adult and pediatric patients with HIV.

      (1) **Mechanism of action.** See VII.C.3.

Table 36-6   DEPARTMENT OF HEALTH AND HUMAN SERVICES (DHHS) GUIDELINES FOR THE USE OF ANTIVIRAL AGENTS IN HIV-1-INFECTED ADULTS AND ADOLESCENTS

When to begin treatment

Treat all individuals, regardless of $CD4^+$ cell count

Treat individuals who are pregnant, have HIV-associated nephropathy, those co-infected with hepatitis B virus (when treatment for hepatitis B is indicated), and those with a history of an AIDS-defining illness

Treat individuals who are at risk for transmitting HIV to a sexual partner, as effective treatment has been shown to prevent transmission

Regimen selection

Selection of a treatment regimen should be individualized for each patient based on adverse effect profiles, drug interactions, comorbidities, pill burden, etc. Preferred and alternative treatment regimens in previously untreated patients are as follows:

NNRTI-based regimens

Preferred regimen	efavirenz[a] + tenofovir + emtricitabine[b]
Alternative regimens	efavirenz[a] + abacavir + lamivudine[b]
	rilpivirine[c] + tenofovir + emtricitabine[b]
	rilpivirine[c] + abacavir + lamivudine[b]

PI-based regimens

Preferred regimen	atazanavir/ritonavir + tenofovir + emtricitabine[b]
	darunavir/ritonavir + tenofovir + emtricitabine[b]
Alternative regimens	atazanavir/ritonavir + abacavir + lamivudine[b]
	darunavir/ritonavir + abacavir + lamivudine[b]
	fosamprenavir/ritonavir + either [abacavir + lamivudine[b]] or [tenofovir + emtricitabine[b]]
	lopinavir/ritonavir + either [abacavir + lamivudine[b]] or [tenofovir + emtricitabine[b]]

Integrase inhibitor-based regimen

Preferred regimen	raltegravir + tenofovir + emtricitabine[b]
Altertnative regimen	raltegravir + abacavir + lamivudine[b]

Regimen for pregnant patients

Preferred regimen	lopinavir/ritonavir (twice daily) + zidovudine + lamivudine[b]

Agents or combinations that should not be offered at any time

Monotherapy with NRTI

2-NRTI regimens

Abacavir + zidovudine + lamivudine as a triple NRTI regimen in treatment-naïve patients

Abacavir + zidovudine + lamivudine as a quadruple NRTI regimen in treatment-naïve patients

Zidovudine + stavudine

Didanosine + stavudine

Didanosine + tenofovir

Didanosine + lamivudine or emtricitabine

Lamivudine + emtricitabine

Atazanavir + indinavir

Efavirenz in first trimester of pregnancy or those with significant childbearing potential

Unboosted darunavir, saquinavir, indinavir, or fosamprenavir

Nevirapine in treatment-naive women with $CD4^+$ cell counts > 250/mm^3 or men with $CD4^+$ cell counts > 400/mm^3

Delavirdine, etravirine, nelfinavir, enfuvirtide in treatment-naïve patients

| **Table 36-6** | Continued. |

Monitoring

Before initiating drug therapy, must obtain CD4$^+$ cell count and plasma HIV RNA levels plus complete blood count, chemistry, lipid profile, liver enzymes, and genotypic resistance testing

HIV RNA level should be checked within 2–8 weeks of initiating treatment and repeated every 4–8 weeks until it reaches undetectable levels (<20–75 copies/mL)

^{a}Cannot be used in first trimester of pregnancy or in those women not using consistent and effective contraception who may become pregnant.
^{b}May substitute lamivudine for emtricitabine or vice versa.
^{c}Must be used with caution in patients with pretreatment HIV RNA >100,000 copies/mL.
NNRTI, nonnucleoside reverse transcriptase inhibitor; *NRTI*, nucleoside reverse transcriptase inhibitor; *PI*, protease inhibitor.

(2) Spectrum of activity and therapeutic uses. Abacavir is approved for use in adults and children ≥ 3 months of age only in combination with other antiretroviral agents.

    (a) Abacavir is available alone or coformulated as a combination tablet with lamivudine and zidovudine (Trizivir), which is dosed twice daily.

    (b) Abacavir is also available in a combination tablet with lamivudine (Epzicom) which is dosed once daily.

(3) Precautions and monitoring effects

    (a) Abacavir has a **black box warning** for a life-threatening hypersensitivity reaction that can lead to death. It occurs in approximately 5% of patients taking this drug, typically within the first 6 weeks of therapy. This reaction involves respiratory symptoms, fever, rash, and GI complaints. Reexposure following these symptoms can mimic anaphylaxis and may result in death. Therefore, rechallenge is contraindicated. A medication guide describing this reaction should be dispensed with each new prescription and refill of abacavir-containing products. The HLA-B*5701 screening test should be used prior to initiating therapy to determine if a patient is at risk for having this reaction.

    (b) There are cohort studies indicating increased risk of myocardial infarction with abacavir; however, this has not been shown in other studies, and this remains a controversial association.

(4) Significant interactions. Alcohol increases the area under the curve (AUC) of abacavir by 41%.

  b. Didanosine (ddI; Videx), a synthetic purine analog, inhibits HIV replication and has a longer intracellular half-life (> 20 hrs) than zidovudine (7 hrs).

    (1) Mechanism of action. See VII.C.3.

    (2) Spectrum of activity and therapeutic uses. Didanosine is approved for the treatment of adults and children only in combination with other antiretroviral agents.

    (3) Precautions and monitoring effects

      (a) Didanosine can cause reversible peripheral neuropathy and acute, potentially lethal pancreatitis (**black box warning**). Serum triglycerides should be monitored, and didanosine should be withheld when initiating potential pancreatitis-inducing agents (e.g., IV pentamidine, sulfonamides). Transiently elevated serum amylase may not reflect pancreatitis.

      (b) Didanosine has been associated with noncirrhotic portal hypertension, with some patients presenting with esophageal varices.

      (c) Other adverse effects include headache, diarrhea, nausea, and hyperuricemia (because didanosine is catalyzed to uric acid).

      (d) Didanosine is available in an enteric-coated capsule or buffered oral tablet formulation to prevent degradation at acidic pH. It must be taken on an empty stomach.

      (e) Do not use in combination with stavudine because of additive potential for toxicity.

      (f) Do not use the combination regimen of didanosine and tenofovir in treatment-naive patients, owing to high rates of early virologic failure and toxicity.

    (4) Significant interactions. Pancreatitis-inducing drugs, **alcohol**, and **those known to cause peripheral neuropathy** should not be used with didanosine. Ribavirin should not be coadministered with didanosine.

    c. Emtricitabine (FTC; Emtriva) is a synthetic nucleoside analog structurally related to lamivudine with activity against HIV infection.

        (1) Mechanism of action. See VII.C.3.

        (2) Spectrum of activity and therapeutic uses. Emtricitabine is indicated for use in HIV-infected adults and children in combination with other antiretroviral agents. It is available by itself or as a combination tablet with tenofovir (Truvada), as a combination tablet with tenofovir and efavirenz (Atripla), and as a combination tablet with tenofovir and rilpivirine (Complera). Although it demonstrates activity against hepatitis B virus, it is not approved for use in treatment of this infection. Emtricitabine and tenofovir are approved for daily use in combination to prevent HIV infection in HIV-negative men who have sex with men.

        (3) Precautions and monitoring effects

            (a) Adverse effects most commonly observed in clinical trials were mild-moderate and include headache, rash, diarrhea, and nausea. Hyperpigmentation of the palms or soles may occur.

            (b) Serious acute exacerbations of hepatitis B have been documented in HIV/hepatitis B coinfected patients who discontinued therapy with emtricitabine (**black box warning**); therefore, liver function tests should be monitored for several months after discontinuation.

            (c) Do not use in combination with lamivudine, due to similar resistance profiles and no additional benefits.

        (4) Significant interactions. None have been identified.

    d. Lamivudine (3TC; Epivir) is a synthetic nucleoside analog with activity against HIV and hepatitis B virus.

        (1) Mechanism of action. See VII.C.3.

        (2) Spectrum of activity and therapeutic uses. Lamivudine is indicated for use in HIV-positive adults and children > 3 months of age in combination with other antiretroviral agents. It is also used in a lower dosage for the treatment of chronic hepatitis B in patients with active liver inflammation and evidence of hepatitis B viral replication.

            (a) Lamivudine is available alone or within a twice daily combination tablet containing lamivudine, zidovudine, and abacavir (Trizivir).

            (b) Lamivudine is also available as a combination tablet with abacavir (Epzicom) and zidovudine (Combivir).

        (3) Precautions and monitoring effects

            (a) Reported adverse reactions are minor and include headache, fatigue, and GI reactions such as nausea, vomiting, and diarrhea. CNS toxicity includes neuropathy, dizziness, and insomnia.

            (b) Do not use in combination with emtricitabine, due to similar resistance profiles and no additional benefits.

            (c) Lamivudine has the same **black box warning** regarding acute exacerbations of hepatitis B as emtricitabine (see VII.C.3.c).

        (4) Significant interactions. Coadministration with **co-trimoxazole** results in increased lamivudine levels. No dose adjustment is required.

    e. Stavudine (d4T; Zerit) is a synthetic thymidine nucleoside analog that is active against HIV.

        (1) Mechanism of action. See VII.C.3.

        (2) Spectrum of activity and therapeutic uses. Stavudine is indicated for use in combination with other antiretroviral agents in adults and children of all ages.

        (3) Precautions and monitoring effects

            (a) The major toxicity with stavudine is a dose related, but reversible peripheral neuropathy occurring in up to 21% of patients.

            (b) Other adverse effects include headache, rash, diarrhea, nausea, and vomiting.

            (c) Fatal episodes of pancreatitis have been reported.

        (4) Significant interactions. Do not use in combination with zidovudine.

    f. Tenofovir disoproxil fumarate (TDF; Viread) is an acyclic nucleoside phosphonate diester analog (**nucleotide**) with antiviral activity against HIV and hepatitis B virus.

        (1) Mechanism of action. Tenofovir (a prodrug) is rapidly hydrolyzed by plasma esterases to tenofovir, with subsequent conversion to the active tenofovir diphosphate. *Note:* NtRTIs are active as the diphosphate, unlike the NRTIs, which require conversion to the triphosphate.

(2) Spectrum of activity and therapeutic uses. Tenofovir is approved for use in combination with other antiretroviral agents for the treatment of HIV in adults. It is also available as a once daily combination tablet containing tenofovir and emtricitabine (Truvada) as well as tenofovir, emtricitabine, and efavirenz (Atripla) and tenofovir, emtricitabine, and rilpivirine (Complera). Tenofovir and emtricitabine are approved for daily use in combination to prevent HIV infection in HIV-negative men who have sex with men.

(3) Precautions and monitoring effects
- **(a)** Minor adverse effects have been reported in clinical trials. These include complaints of diarrhea, nausea, vomiting, headache, and asthenia.
- **(b)** Additional adverse effects observed during postmarketing surveillance include renal insufficiency and decreases in bone mineral density.
- **(c)** Tenofovir has the same **black box warning** that emtricitabine has for patients with concomitant hepatitis B (see VII.C.3.c).
- **(d)** Dose adjustment is required for renal insufficiency.

(4) Significant interactions
- **(a)** Tenofovir increases **didanosine** serum concentrations, resulting in increased risk of toxicity. Additionally, there is a high rate of early virologic failure and development of resistance mutations. Thus, this combination is not recommended for use.
- **(b)** Tenofovir decreases serum concentrations of **atazanavir**. When these two agents are used together, ritonavir must be added to the regimen.

g. Zidovudine (AZT; Retrovir) is a synthetic thymidine analog. This agent was the first available drug for the treatment of HIV infection.

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses
- **(a)** Zidovudine is indicated in the treatment of adults and children for the treatment of HIV.
- **(b)** It is indicated for the prevention of maternal–fetal HIV transmission.
- **(c)** Zidovudine is available as oral capsules, tablets, and solution as well as an IV solution.
- **(d)** Oral zidovudine is also available as a coformulation with lamivudine (Combivir) and with lamivudine and abacavir (Trizivir).

(3) Precautions and monitoring effects
- **(a)** Zidovudine can cause severe bone marrow suppression, including macrocytic anemia and neutropenia after the first few weeks to months of therapy. The risk is increased in patients with preexisting bone marrow suppression or who are taking concomitant medications that cause bone marrow suppression.
- **(b)** Erythropoietin can be considered as an adjunctive therapy in patients with zidovudine-induced anemia, in cases for which it cannot be discontinued.
- **(c)** Other adverse effects include headache, malaise, seizures, anxiety, fever, and rash.
- **(d)** Prolonged use may lead to symptomatic myopathy.

(4) Significant interactions
- **(a)** **Co-trimoxazole**, **atovaquone**, **valproic acid**, **methadone**, and **probenecid** may increase zidovudine concentrations, causing increased risk of zidovudine toxicity.
- **(b)** Other **cytotoxic drugs**, such as **ganciclovir**, **dapsone**, **ribavirin**, and **interferon-alpha**, can cause additive bone marrow suppression.
- **(c)** Rifabutin and rifampin may decrease levels of zidovudine.

4. Nonnucleoside reverse transcriptase inhibitors (NNRTIs). The NNRTI class binds directly to and produces a noncompetitive inhibition of the HIV reverse transcriptase, leading to chain termination. These agents are indicated for use in adults and pediatric patients in combination with NRTIs or possibly protease inhibitors (PIs). Efavirenz is the preferred NNRTI for initial treatment, whereas the others are currently recommended as alternatives. NNRTI-based regimens provide potent antiviral activity with less pill burden than many PI-based regimens. All NNRTIs may cause **rash and hepatotoxicity**; patients should be monitored closely for these adverse effects.

a. Delavirdine (Rescriptor)

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Delavirdine is approved for use in adults in the treatment of HIV in combination with other antiretroviral agents. Its use has fallen out of favor owing to its three times daily dosing schedule.

(3) Precautions and monitoring effects
- **(a)** In clinical trials, 4.3% of patients discontinued delavirdine because of rash. Cases of Stevens–Johnson syndrome have been reported.
- **(b)** Other adverse effects include headache and nausea.

(4) Significant interactions
- **(a)** The concentrations of the following medications are greatly increased by delavirdine and must be avoided: **alprazolam**, **midazolam**, **triazolam**, **simvastatin**, **lovastatin**, **rifabutin**, and **cisapride**.
- **(b)** Decreased delavirdine concentrations result when it is administered with **St. John's wort**, **carbamazepine**, **phenobarbital**, **phenytoin**, or **rifampin**. Concomitant use should be avoided.
- **(c)** Because delavirdine requires an acidic GI tract for optimal absorption, its use should be avoided with **proton pump inhibitors** and **H$_2$-receptor antagonists**.

b. Efavirenz (Sustiva)

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Efavirenz is approved for use in combination with other antiretroviral agents for the treatment of HIV infection in adults and pediatric patients. One advantage over other NNRTIs is its once-daily dosing. It is available alone or as a combination tablet with tenofovir and emtricitabine (Atripla).

(3) Precautions and monitoring effects
- **(a)** Most common adverse effects are CNS-related (52%), including insomnia, dizziness, drowsiness, nightmares, and hallucinations, necessitating a bedtime dosing to minimize these effects. These effects typically subside after 2 to 4 weeks of treatment.
- **(b)** Owing to its teratogenic effects, efavirenz should be avoided in the first trimester of pregnancy and in women of childbearing potential who wish to conceive or who are using unreliable contraception.
- **(c)** Other adverse effects include rash, increased transaminases, and GI disturbances.
- **(d)** False-positive results may occur with screening tests for cannabinoids and benzodiazepines.

(4) Significant interactions
- **(a)** Efavirenz induces and inhibits the cytochrome P450 3A4 isoenzyme system. It should not be used concomitantly with **cisapride**, **midazolam**, **triazolam**, or **ergot derivatives**.
- **(b)** **St. John's wort** decreases efavirenz concentrations and should be avoided.
- **(c)** Efavirenz decreases **methadone** AUC by 52%; patients should be monitored for opiate withdrawal and have their doses titrated accordingly.
- **(d)** Efavirenz decreases **levonorgestrel** concentrations, resulting in possible decreased effectiveness of emergency postcoital contraception.

c. Etravirine (Intelence)

(1) Mechanism of action. See VII.C.3.

(2) Spectrum of activity and therapeutic uses. Etravirine is indicated for use in combination with at least two additional antiretroviral agents in treatment-experienced adults who demonstrate viral replication and documented resistance to other NNRTIs. It is not for use in treatment-naive patients.

(3) Precautions and monitoring effects
- **(a)** Adverse effects include nausea and rash. Hypersensitivity reactions have occurred, resulting in rash, constitutional symptoms, and possible hepatic failure.
- **(b)** Because food increases the absorption of etravirine by 50%, it should be taken following a meal.

(4) Significant interactions
- **(a)** Etravirine induces and inhibits a variety of cytochrome P450 isoenzymes. It should not be used concomitantly with **carbamazepine**, **phenobarbital**, **phenytoin**, **unboosted PIs**, **atazanavir/ritonavir**, **fosamprenavir/ritonavir**, **tipranavir/ritonavir**, **ritonavir**, or **other NNRTIs**.

       (b) **St. John's wort** and **rifampin** decrease etravirine concentrations and should be avoided.

       (c) Etravirine may decrease serum concentrations of **phosphodiesterase Type 5 (PDE 5) inhibitors** used for erectile dysfunction, requiring a dosage increase.

       (d) Etravirine may decrease **clopidogrel** activation and should not be used concomitantly.

  d. Nevirapine (Viramune) was the first NNRTI approved for use by the FDA for the treatment of HIV infection.

    (1) **Mechanism of action.** See VII.C.3.

    (2) **Spectrum of activity and therapeutic uses.** Nevirapine is indicated in combination with other antiretrovirals in adult and pediatric HIV patients. An extended-release tablet became available in early 2011.

    (3) **Precautions and monitoring effects**

       (a) Nevirapine has the highest incidence of Stevens–Johnson syndrome of all NNRTIs.

       (b) Symptomatic hepatitis, including fatal hepatic necrosis, has been observed with nevirapine (**black box warning**). The frequency of this adverse effect is increased in women with pre-nevirapine $CD4^+$ counts > 250 cells/mm^3 and men with $CD4^+$ counts > 400 cells/mm^3. Nevirapine should not be initiated in these patients.

       (c) Other adverse effects include fever, nausea, and headache.

       (d) To decrease the frequency of adverse effects, a 2-week dose escalation is required.

    (4) **Significant interactions**

       (a) Nevirapine induces cytochrome P450 3A4, resulting in decreased concentrations of **oral contraceptives, efavirenz, atazanavir ± ritonavir, and ketoconazole**. These combinations should be avoided.

       (b) Use of **rifampin** and **St. John's wort** should be avoided, as they decrease the serum concentrations of nevirapine.

       (c) **Methadone** concentrations decrease significantly with nevirapine, often necessitating a dose increase.

  e. Rilpivirine (Edurant)

    (1) **Mechanism of action.** See VII.C.3

    (2) **Spectrum of activity and therapeutic uses.** Rilpivirine is approved for use in combination with other antiretroviral agents for the treatment of HIV infection in treatment-naïve adults. It is available alone and as a combination tablet with tenofovir and emtricitabine (Complera).

    (3) **Precautions and monitoring effects**

       (a) In clinical trials, virologic failure was more likely with rilpivirine in those patients with high viral loads (e.g.: $> 100,000$ copies/mL) as compared to those with viral loads $< 100,000$ copies/mL. Therefore, it is especially important to consider the patient's baseline viral load prior to initiating therapy with rilpivirine.

       (b) In clinical trials, virologic failure with rilpivirine was more likely to result in resistance to other NNRTIs as compared to efavirenz.

       (c) In order to improve absorption, rilpivirine should be taken with a meal.

       (d) Most common adverse effects are nausea, dizziness, insomnia, headache, and rash. The incidence of rash and CNS adverse effects is lower than efavirenz.

    (4) **Significant interactions**

       (a) At therapeutic doses, rilpivirine does not inhibit or induce the CYP450 isoenzyme system.

       (b) Since rilpivirine is a substrate of CYP450 3A4, concomitant use with inducers of this enzyme system, including **rifampin, carbamazepine, phenobarbital, phenytoin, dexamethasone, and St. John's wort** should be avoided.

       (c) Because rilpivirine requires an acidic GI tract for optimal absorption, its use should be avoided with **proton pump inhibitors**. If other acid suppressants are used with rilpivirine, the doses should be separated by as much time as possible (e.g: 12 hours before or 4 hours after rilpivirine dosing).

5. Protease inhibitors (PIs). The PIs competitively inhibit the viral protease enzyme, preventing the enzyme from cleaving the gag and gag-pol polyproteins necessary for virion

production. PIs are used in combination with other antiretroviral agents, including other PIs, to suppress HIV replication. All of the PIs are cytochrome P450 inhibitors; ritonavir is the most potent inhibitor. All PIs are contraindicated with numerous drugs, including **simvastatin**, **lovastatin**, **rifampin**, **cisapride**, **pimozide**, **midazolam**, **triazolam**, **ergots**, **alfuzosin**, **salmeterol**, and **St. John's wort**. Concomitant therapy with antiepileptic drugs, erectile dysfunction drugs, colchicine, and azole antifungals must be undertaken with caution. Most PIs interact with warfarin, necessitating close INR monitoring and warfarin dosage adjustment. Owing to the wide array of drug interactions with PIs, always assess medication profiles carefully for drug interactions before initiation. Many PIs require dose adjustment for hepatic insufficiency.

- a. **Atazanavir (Reyataz)**
    - (1) **Mechanism of action.** See VII.C.5.
    - (2) **Spectrum of activity and therapeutic uses.** Atazanavir is a component of preferred and alternative PI-based regimens for HIV. It is dosed once daily.
    - (3) **Precautions and monitoring effects**
        - (a) Atazanavir may prolong the PR interval and possibly cause first-degree AV block. Caution should be used in patients with underlying conduction defects or in those taking concomitant medications that prolong the PR interval.
        - (b) Other adverse effects include fat maldistribution, hyperglycemia, and indirect hyperbilirubinemia. Atazanavir may increase lipids when used with ritonavir booster doses. Rash may occur in up to 20% of patients.
        - (c) Dose adjustment is required for hepatic insufficiency.
    - (4) **Significant interactions** (see VII.C.5). Atazanavir is the most problematic of all PIs in terms of drug interactions.
        - (a) Because atazanavir requires an acidic GI tract for optimal absorption, concomitant use of **proton pump inhibitors** is contraindicated when used without ritonavir booster doses or in PI-experienced patients. In PI-naive patients, atazanavir/ritonavir may be used with proton pump inhibitors in a dosage equivalent to no more than omeprazole 20 mg daily. Dosing of the proton pump inhibitor should be separated by 12 hrs from the atazanavir/ritonavir. If other acid suppressants are used with atazanavir, the doses must be separated by as much time as possible (up to 12 hrs apart).
        - (b) Atazanavir substantially increases concentrations of **clarithromycin**, resulting in possible QTc prolongation. The dose of clarithromycin should be decreased by 50%, or alternative therapy considered.
        - (c) Concentrations of **buprenorphine** and its active metabolite are substantially increased by atazanavir; concomitant use with unboosted atazanavir must be avoided.
- b. **Darunavir (Prezista)**
    - (1) **Mechanism of action.** See VII.C.5.
    - (2) **Spectrum of activity and therapeutic uses.** Darunavir is the newest PI to receive FDA approval for the treatment of HIV. It is considered a preferred PI for use in treatment-naive patients. Its dosing is dependent on treatment experience and number of resistance mutations present.
    - (3) **Precautions and monitoring effects**
        - (a) Darunavir must be coadministered with ritonavir.
        - (b) Because darunavir contains a sulfonamide moiety, cross-reactivity may occur in sulfa-allergic patients.
        - (c) Adverse effects include nausea, increased amylase, hepatotoxicity, hyperlipidemia, hyperglycemia, and rash.
    - (4) **Significant interactions.** See VII.C.5.
- c. **Fosamprenavir (Lexiva)**
    - (1) **Mechanism of action.** See VII.C.5. Fosamprenavir is the prodrug of amprenavir.
    - (2) **Spectrum of activity and therapeutic uses.** Fosamprenavir has largely replaced amprenavir because of its improved dosing convenience. It is recommended as one of the alternative components in PI-based regimens for initial treatment of HIV.

(3) Precautions and monitoring effects

(a) Fosamprenavir may be dosed once daily in treatment-naive patients. PI-experienced patients require twice daily dosing. In most cases, fosamprenavir is administered with low-dose ritonavir.

(b) Adverse effects include hyperlipidemia, hyperglycemia, fat maldistribution, rash, and GI disturbances.

(4) Significant interactions see VII.C.3.

d. Indinavir (Crixivan)

(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. Indinavir, in combination with ritonavir, is no longer recommended as part of regimen for patients receiving initial treatment for HIV due to a high incidence of nephrolithiasis.

(3) Precautions and monitoring effects

(a) Because indinavir may cause **nephrolithiasis** (kidney stones), patients should be instructed to drink at least 1.5 L of water daily to prevent this adverse effect.

(b) Indinavir can cause **indirect hyperbilirubinemia.** Combination therapy with atazanavir is not recommended owing to the potential for additive effects.

(c) Other adverse effects include hyperglycemia, hyperlipidemia, fat maldistribution, headache, and GI intolerance.

(d) Dose adjustment is required for hepatic insufficiency.

(4) Significant interactions (see VII.C.5). Vitamin C in doses > 1 g daily decreases indinavir concentrations. Caution patients not to exceed the recommended daily allowance for vitamin C.

e. Lopinavir/ritonavir (Kaletra)

(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. This product is available as a coformulation of lopinavir with a "booster" dose of ritonavir, which inhibits lopinavir metabolism and results in higher serum concentrations. Lopinavir/ritonavir is an alternative PI used in regimens for treatment-naive patients due to its risk of GI adverse effects and hyperlipidemia. It is the preferred PI in pregnancy.

(3) Precautions and monitoring effects

(a) Lopinavir/ritonavir is formulated as a film-coated tablet that does not require refrigeration. It is also available as an oral solution containing 42% alcohol.

(b) Adverse effects include GI intolerance, hyperlipidemia, hyperglycemia, fat maldistribution, PR interval prolongation, and pancreatitis.

(4) Significant interactions. See VII.C.5.

(a) Lopinavir/ritonavir decreases **methadone** concentrations, possibly necessitating a methadone dose increase to prevent opiate withdrawal.

(b) Concomitant administration with **voriconazole** is contraindicated because of the risk of decreased voriconazole efficacy.

(c) Concomitant administration with **efavirenz** or **nevirapine** requires increased doses of lopinavir/ritonavir due to enzyme induction.

(d) Once daily dosing of lopinavir/ritonavir should not be used in patients receiving **carbamazepine**, **phenytoin**, or **phenobarbital**, due to induction of lopinavir/ritonavir metabolism.

f. Nelfinavir (Viracept)

(1) Mechanism of action. See VII.C.5.

(2) Spectrum of activity and therapeutic uses. Nelfinavir is not generally recommended for treatment of HIV infection due to inferior virologic efficacy. Unlike the other PIs, it is never used in combination with ritonavir.

(3) Precautions and monitoring effects

(a) Diarrhea is commonly reported with nelfinavir. This can often be managed with antidiarrheals.

(b) Other adverse effects are similar to those with lopinavir/ritonavir.

(c) Use caution with look-alike, sound-alike names (nelfinavir and nevirapine).

(4) Significant interactions (see VII.C.5). Nelfinavir decreases **methadone** concentrations, necessitating increased monitoring and dose adjustment if indicated.

g. **Ritonavir (Norvir)**
   (1) **Mechanism of action.** See VII.C.5.
   (2) **Spectrum of activity and therapeutic uses.** Ritonavir is not used as the sole PI in a PI-based regimen owing to its poor tolerability and high pill burden when administered in full doses. Alternatively, it is used in low doses as a pharmacokinetic boosting agent with other PIs. Because it is such a potent cytochrome P450 enzyme inhibitor, ritonavir markedly increases the serum concentrations of other PIs, resulting in higher concentrations with improved viral suppression.
   (3) **Precautions and monitoring effects**
      (a) Capsules should be refrigerated before dispensing. Capsules then may be stored at room temperature for up to 30 days. A tablet formulation is also available that does not require refrigeration and should be taken with food.
      (b) Oral solution should **not** be refrigerated.
      (c) Adverse effects include GI intolerance, circumoral paresthesias, hyperlipidemia, hyperglycemia, fat maldistribution, increased liver function tests, and taste perversion.
   (4) **Significant interactions** (see VII.C.5). Many drug interactions occur with ritonavir because it is such a potent inhibitor of so many cytochrome P450 isoenzymes. Always refer to proper resources to assess for drug interactions.

h. **Saquinavir (Invirase)**
   (1) **Mechanism of action.** See VII.C.5.
   (2) **Spectrum of activity and therapeutic uses.** Use of saquinavir without booster doses of ritonavir is not recommended because of the poor bioavailability of saquinavir. Because saquinavir/ritonavir has been associated with significant QTc prolongation, its use should be avoided in patients with pretreatment QT intervals > 450 msec, refractory hypokalemia or hypomagnesemia, presence of or at risk for complete heart block, and concomitant medications that prolong QT interval. Thus, its use is greatly limited as compared with other PIs.
   (3) **Precautions and monitoring effects**
      (a) Saquinavir/ritonavir prolongs the PR and QT intervals; cases of torsades de pointes have been reported. A baseline electrocardiogram (ECG) should be obtained prior to treatment.
      (b) Other adverse effects are similar to lopinavir/ritonavir.
   (4) **Significant interactions.** (See VII.C.5). Saquinavir/ritonavir increases concentrations of **trazodone** and may result in prolonged QT interval. Concomitant use is contraindicated.

i. **Tipranavir (Aptivus)**
   (1) **Mechanism of action.** See VII.C.5.
   (2) **Spectrum of activity and therapeutic uses.** The use of tipranavir is limited to highly treatment-experienced patients with HIV who are resistant to other PIs as well as to other classes of antiretrovirals.
   (3) **Precautions and monitoring effects**
      (a) Owing to the poor bioavailability of tipranavir, it must be coadministered with ritonavir.
      (b) Capsules must be refrigerated. Once dispensed, they are stable at room temperature for up to 60 days.
      (c) Tipranavir has been associated with clinical hepatitis and fatal hepatic decompensation (**black box warning**). Liver function tests should be monitored closely, especially in patients with underlying liver disease.
      (d) Rarely, there have been reports of fatal and nonfatal intracranial hemorrhage with tipranavir (**black box warning**).
      (e) Because the structure of tipranavir contains a **sulfonamide** moiety, cross-reactivity may occur in sulfa-allergic patients.
      (f) Other adverse effects include rash, hyperlipidemia, hyperglycemia, and fat maldistribution.
   (4) **Significant interactions.** See VII.C.5.

6. **Fusion inhibitors. Enfuvirtide (T-20; Fuzeon)** is the first and only member of this class of antiretrovirals.
   a. **Mechanism of action.** Enfuvirtide inhibits the entry of HIV into CD4$^+$ cells by interfering with the fusion of viral and cellular membranes.
   b. **Spectrum of activity and therapeutic uses.** Enfuvirtide is primarily used in highly treatment-experienced patients with extensive viral resistance. It is not recommended for use as initial therapy in treatment-naive patients, as it has not been studied in this population.
   c. **Precautions and monitoring effects**
      (1) Enfuvirtide is injected subcutaneously twice daily. Local injection site reactions occur in almost all patients, including pain, redness, pruritus, and nodules.
      (2) Other adverse effects include hypersensitivity reactions and increased rate of bacterial pneumonia.
      (3) No dose adjustment is necessary for renal impairment.
   d. **Significant interactions.** There are no significant drug interactions with enfuvirtide.
7. **Entry inhibitor. Maraviroc (Selzentry)** is the first and only member of this class of antiretroviral therapy.
   a. **Mechanism of action.** Maraviroc is a chemokine receptor 5 (CCR5) coreceptor antagonist. It binds to the CCR5 receptor on the CD4 cell membrane, preventing entry of the virus into the cell.
   b. **Spectrum of activity and therapeutic uses.** Maraviroc is used along with other antiretrovirals in adult patients who are infected with HIV that binds to the CCR5 receptor.
   c. **Precautions and monitoring effects**
      (1) **Hepatotoxicity** was observed during clinical trials with maraviroc (**black box warning**). This may be preceded by a systemic allergic reaction. Patients should be evaluated immediately if either occurs.
      (2) Use caution in patients with liver disease or cardiovascular risk factors.
      (3) Adverse effects include cough, rash, fever, musculoskeletal symptoms, dizziness, abdominal pain, and orthostatic hypotension.
      (4) Not recommended for use in patients with severe or end-stage renal disease unless clinically warranted.
   d. **Significant interactions**
      (1) Dosing for maraviroc varies depending upon concomitant medications that interact:
         (a) When used with cytochrome P450 inhibitors, such as **PIs (except tipranavir/ ritonavir), delavirdine, ketoconazole, itraconazole**, and **clarithromycin**, administer maraviroc 150 mg twice daily.
         (b) When used with cytochrome P450 inducers (such as **carbamazepine, phenobarbital, phenytoin, efavirenz**, and **rifampin**) without a strong cytochrome P450 inhibitor, administer maraviroc 600 mg twice daily.
         (c) When used with other medications, including tipranavir/ritonavir, nevirapine, NRTIs, raltegravir, and enfuvirtide, administer maraviroc 300 mg twice daily.
      (2) Concomitant administration with **St. John's wort** or rifapentine is not recommended due to reduction in maraviroc serum concentrations.
8. **Integrase inhibitor. Raltegravir (Isentress)** is the first and only member of this class of antiretroviral therapy.
   a. **Mechanism of action.** Raltegravir inhibits the viral enzyme integrase, thereby preventing the insertion of HIV genetic material into the CD4 cell genome and halting the viral replication process.
   b. **Spectrum of activity and therapeutic uses.** Raltegravir is used along with other antiretrovirals as a preferred agent in treatment-naïve patients with HIV infection.
   c. **Precautions and monitoring effects**
      (1) Because elevations in creatine kinase, along with myopathy and rhabdomyolysis, may occur with raltegravir, use with caution in patients who are receiving concomitant medications that may cause these adverse effects.
      (2) The most common adverse effects include nausea, diarrhea, headache, and fever.

        d. Significant interactions. Because **rifampin** decreases the serum concentration of raltegravir, the dose of raltegravir should be increased to 800 mg twice daily when used concomitantly.

D. Hepatitis C virus (RNA virus): Direct-acting antiviral (DAA) agents

  1. Currently, there are two directly acting antiviral agents (DAAs) available for use in combination with interferon alfa and ribavirin for the management of genotype 1 hepatitis C virus (HCV) infection; these include **boceprevir** and **telaprevir**. The addition of either of these agents to standard interferon alfa and ribavirin therapy has resulted in improved sustained virologic response rates and the possibility of a shorter duration of treatment for patients with genotype 1 HCV infection.

  2. These agents are inhibitors of the HCV nonstructural 3/4A (NS3/4A) serine protease, an enzyme required for viral replication and virion assembly.

    a. Monotherapy with these agents is unacceptable, as the development of resistance with subsequent virologic failure occurs rapidly.

    b. These agents should only be used for treatment of genotype 1 HCV infection, in combination with interferon alfa and ribavirin.

    c. Limited data exists for use of these agents in patients coinfected with HCV and HIV; caution should be used in this population of patients.

  3. Boceprevir (Victrelis)

    a. Mechanism of action. See VII.D.2.

    b. Spectrum of activity and therapeutic uses. Boceprevir is approved for use in adults with genotype 1 HCV infection who are treatment-naïve or who have failed prior treatment with interferon and ribavirin. It is added to interferon alfa and ribavirin following 4 weeks of treatment with those two agents. The total treatment duration of this three drug regimen varies from 24-44 weeks, depending upon the patient's previous history of HCV treatment, HCV viral load measurements, and presence of cirrhosis.

    c. Precautions and monitoring effects.

      (1) Boceprevir must be administered **every 7-9 hours** with a meal or light snack. Patients should be counseled on how to avoid missing or delaying doses in order to optimize the effectiveness of this agent.

      (2) No dosage adjustments are necessary for renal or hepatic impairment.

      (3) Common adverse effects include headache, nausea, anemia, and taste disturbances.

    d. Significant interactions

      (1) Boceprevir is a substrate and strong **inhibitor** of CYP450 3A4/5, resulting in numerous drug-drug interactions. Avoid concomitant use with **alfuzosin, rifampin, phenobarbital, carbamazepine, phenytoin, ergot alkaloids, St. John's wort, simvastatin, lovastatin, drosperinone, triazolam, and oral midazolam.**

      (2) Careful review of concomitant medications is required during treatment with boceprevir, so that appropriate monitoring can be performed.

  4. Telaprevir (Incivek)

    a. Mechanism of action. See VII.D.2.

    b. Spectrum of activity and therapeutic uses. Telaprevir is approved for use in adults with genotype 1 HCV infection who are treatment-naïve or who have not responded to prior treatment with interferon-based therapy, including prior null responders, partial responders, and relapsers. It is added to interferon alfa and ribavirin at the start of therapy and continued for the first 12 weeks of treatment, depending upon response. The interferon and ribavirin are then continued for an additional 12 or 36 weeks, depending upon the virologic response observed.

    c. Precautions and monitoring effects.

      (1) Telaprevir must be administered **every 7–9 hours** with a meal or snack containing **at least 20 grams of fat**. The product labeling and educational materials provided with this agent include numerous examples of these food combinations.

      (2) No dosage adjustment is necessary for renal impairment.

      (3) Use of telaprevir is not recommended in moderate to severe hepatic impairment, owing to a lack of pharmacokinetic data in this population.

(4) Adverse effects include rash, anemia, nausea, diarrhea, rectal discomfort, dysgeusia, and fatigue.

d. Significant interactions.

(1) Telaprevir is a substrate and strong **inhibitor** of CYP450 3A, resulting in numerous drug-drug interactions. Avoid concomitant use with **alfuzosin, rifampin, ergot alkaloids, St. John's wort, simvastatin, lovastatin, triazolam, and oral midazolam.**

(2) Careful review of concomitant medications is required during treatment with telaprevir, so that appropriate monitoring can be performed.

VIII. ANTHELMINTICS

A. Definition. These drugs are used to rid the body of worms (**helminths**). These agents may act locally to rid the GI tract of worms or work systemically to eradicate worms that are invading organs or tissues.

B. Mebendazole (Vermox) is a synthetic benzimidazole-derivative anthelmintic. This project was discontinued in early 2012, although it will likely remain on pharmacy shelves until the last lots expire in mid-2014.

1. Mechanism of action. Mebendazole interferes with reproduction and survival of helminths by inhibiting the formation of microtubules and irreversibly blocking glucose uptake, thereby depleting glycogen stores in the helminth.

2. Spectrum of activity. Mebendazole is active against various nematodes that are pathogenic to humans, including *Ancylostoma duodenale* (common hookworm), *Ascaris lumbricoides* (roundworm), *Capillaria philippinensis* (Philippine threadworm), *Enterobius vermicularis* (pinworm), *Necator americanus* (American hookworm), and *Trichuris trichiura* (whipworm).

3. Therapeutic uses. Mebendazole is used for the treatment of single or mixed infections with the helminths listed in VIII.B.2. Immobilization and subsequent death of helminths are slow, with complete GI clearance up to 3 days after therapy.

4. Precautions and monitoring effects

a. In cases of massive infection, abdominal pain, nausea, and diarrhea associated with expulsion of organisms may result.

b. Myelosuppression (neutropenia and thrombocytopenia) can occur with high doses (40 to 50 mg/kg/day).

c. If the patient is not cured in 3 weeks, retreatment is necessary.

5. Significant interactions. Agents that may reduce the serum concentrations and subsequent efficacy of mebendazole include carbamazepine and phenytoin.

C. Albendazole (Albenza) is a synthetic benzimidazole-derivative anthelmintic.

1. Mechanism of action. See VIII.B.1.

2. Spectrum of activity. Albendazole is active against *Taenia solium* (pork tapeworm) and *Echinococcus granulosus* (dog tapeworm).

3. Therapeutic uses. Albendazole is used to treat parenchymal neurocysticercosis in combination with corticosteroids as well as cystic hydatid disease (before and after surgical removal of the disease).

4. Precautions and monitoring effects

a. The drug should be administered with a fatty meal to achieve optimal absorption.

b. Hepatotoxicity occurs in 16% of patients; liver function tests every 2 weeks are recommended while taking albendazole.

c. Rarely, leukopenia, thrombocytopenia, granulocytopenia, pancytopenia, and agranulocytosis occur. A CBC should be checked every 2 weeks while taking albendazole.

D. Diethylcarbamazine citrate (Hetrazan)

1. Mechanism of action. Diethylcarbamazine citrate is a synthetic organic compound highly specific for several common parasites.

2. Spectrum of activity. This agent is active against *Wuchereria bancrofti, Onchocerca volvulus, Brugia malayi, Mansonella perstans, Mansonella ozzardi, Ascaris lumbricoides,* and *Loa loa.*

3. Therapeutic uses. Diethylcarbamazine citrate is used for the treatment of Bancroft's filariasis, onchocerciasis, ascariasis, and loiasis. It is available directly from the Centers for Disease Control and Prevention.

    4. Precautions and monitoring effects
   - **a.** Patients treated for *W. bancrofti* infection often present with headache and general malaise. Severe allergic phenomena in conjunction with a skin rash have been reported.
   - **b.** Patients treated for onchocerciasis present with pruritus, facial edema, and systemic symptoms secondary to the inflammatory response caused by pathogen death (known as a **Mazzotti reaction**). Severe reactions may be noted after a single dose. For this reason, ivermectin is used to treat onchocerciasis.
   - **c.** Children who are undernourished or are suffering from debilitating ascariasis infection may experience giddiness, malaise, nausea, and vomiting after treatment. Other drugs are available to treat *Ascaris* (mebendazole and albendazole).

E. Pyrantel (Pin-X) is a pyrimidine-derivative anthelmintic.
   1. **Mechanism of action.** Pyrantel is a depolarizing neuromuscular blocking agent that causes a spastic paralysis of the helminth.
   2. **Spectrum of activity.** Pyrantel is active against *A. lumbricoides* (roundworm), *E. vermicularis* (pinworm), *A. duodenale* (hookworm), *N. americanus* (hookworm), and *Trichostrongylus orientalis* (hairworm).
   3. **Therapeutic uses.** Pyrantel is used for the treatment of roundworm, pinworm, and hookworm infections.
   4. **Precautions and monitoring effects**
      - **a.** Most commonly reported reactions include anorexia, nausea, vomiting, diarrhea, headache, and rash.
      - **b.** A single dose may be mixed with food, milk, juice, or taken on an empty stomach.

F. Ivermectin (Stromectol)
   1. **Mechanism of action.** Ivermectin potentiates the inhibitory effects of γ-aminobutyric acid (GABA) in various nematodes and arthropods, resulting in paralysis and death of the organisms.
   2. **Spectrum of activity.** This agent is active against *S. stercoralis* (intestinal forms only) and *O. volvulus* (immature forms only). It is also useful for treatment of infections with *A. lumbricoides*, *E. vermicularis*, *M. ozzardi*, *T. trichiura*, and *W. bancrofti*.
   3. **Therapeutic uses**
      - **a.** Ivermectin is useful for treatment of infections with the parasites listed in VIII.G.2.
      - **b.** Two studies demonstrated that ivermectin was more effective than albendazole for treatment of strongyloidiasis.
      - **c.** Ivermectin is often favored over diethylcarbamazine citrate owing to its less severe adverse effect profile.
   4. **Precautions and monitoring effects**
      - **a.** May cause a **Mazzotti reaction** (see VIII.D.4.b) that is less severe than with diethylcarbamazine citrate.
      - **b.** Reports of serious and possibly fatal encephalopathy have occurred in patients with concomitant *L. loa* infection.
      - **c.** Other adverse effects include edema, dizziness, headache, rash, and GI disturbances.
      - **d.** Counsel patients to take ivermectin with water.

G. Praziquantel (Biltricide)
   1. **Mechanism of action.** Praziquantel increases cell membrane permeability in susceptible helminths, with loss of intracellular calcium and paralysis of their musculature. Vacuolization and disintegration of the schistosome tegument results, followed by attachment of phagocytes to the parasite and death.
   2. **Spectrum of activity.** Praziquantel is active against trematodes (flukes), including all *Schistosoma* spp. and *Clonorchis sinensis*, *Opisthorchis viverrini*, *Fasciola hepatica* (liver flukes), *Paragonimus uterobilateralis*, *Paragonimus westermani* (lung flukes), *Metagonimus yokogawai*, *Fasciolopsis buski*, and *Heterophyes heterophyes* (intestinal flukes).
   3. **Therapeutic uses.** Praziquantel is active in treating all types of schistosomiasis that are pathogenic to humans; clonorchiasis and opisthorchiasis (Chinese and southeast Asian liver flukes); many other types of infections involving intestinal, liver, and lung flukes; and cestodiasis (tapeworm) infections.

4. **Precautions and monitoring effects**
   a. Treatment of ocular cysticercosis is contraindicated because parasite destruction within the eyes may cause irreparable lesions.
   b. In general, adverse effects are generally mild and well tolerated. It is difficult to differentiate between effects caused by the praziquantel versus effects demonstrated by dying parasites.
   c. The most common side effects are transient and may include malaise, headache, dizziness, and abdominal discomfort.
   d. Praziquantel may impair activities that require mental alertness.

Study Questions

Directions for questions 1–12: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Isoniazid is a primary antitubercular agent that

   (A) requires pyridoxine supplementation.
   (B) may discolor the tears, saliva, urine, or feces orange-red.
   (C) causes ocular complications that are reversible if the drug is discontinued.
   (D) may be ototoxic and nephrotoxic.
   (E) should never be used because of hepatotoxic potential.

2. All of the following factors may increase the risk of nephrotoxicity from gentamicin therapy *except* which one?

   (A) age > 70 years
   (B) prolonged courses of gentamicin therapy
   (C) concurrent amphotericin B therapy
   (D) trough gentamicin levels < 2 mg/mL
   (E) concurrent cisplatin therapy

3. In which of the following groups do all four drugs warrant careful monitoring for drug-related seizures in high-risk patients?

   (A) penicillin G, imipenem, amphotericin B, metronidazole
   (B) penicillin G, chloramphenicol, tetracycline, vancomycin
   (C) imipenem, tetracycline, vancomycin, sulfadiazine
   (D) cycloserine, metronidazole, vancomycin, sulfadiazine
   (E) metronidazole, imipenem, doxycycline, erythromycin

4. AC is a 34-year-old male admitted with a diagnosis of peritonitis. Cultures are positive for *Bacteroides fragilis*, *Enterococcus faecalis*, and *Staphylococcus aureus*. Which of the following would be the best initial therapy to recommend?

   (A) telithromycin
   (B) quinupristin/dalfopristin
   (C) tigecycline
   (D) trimethoprim/sulfamethoxazole
   (E) kanamycin

5. TJ is a 45-year-old female presenting with an *Enterobacter aerogenes* bacteremia with a low-grade fever (101.6°F). The most appropriate management of her fever would be to

   (A) give acetaminophen 1000 mg orally every 6 hrs.
   (B) give aspirin 650 mg orally every 4 hrs.
   (C) give alternating doses of aspirin and acetaminophen every 4 hrs.
   (D) withhold antipyretics and use the fever curve to monitor her response to antibiotic therapy.
   (E) use tepid water baths to reduce the fever.

6. BC has an upper respiratory infection. Two years ago, she experienced an episode of bronchospasm after penicillin therapy. Current cultures are positive for a strain of *Streptococcus pneumoniae* that is sensitive to all of the following drugs. Which of these drugs would be the best choice for this patient?

   (A) amoxicillin/clavulanate
   (B) telithromycin
   (C) ampicillin
   (D) cefaclor
   (E) loracarbef

7. All of the following drugs are appropriate therapies for a lower urinary tract infection owing to *Pseudomonas aeruginosa except*

   (A) norfloxacin.
   (B) trimethoprim–sulfamethoxazole.
   (C) ciprofloxacin.
   (D) tobramycin.
   (E) methenamine mandelate.

8. BT is a 43-year-old female seen by her primary-care physician for a mild staphylococcal cellulitis on the arm. Which of the following regimens would be appropriate oral therapy?

   (A) dicloxacillin 125 mg every 6 hrs
   (B) vancomycin 250 mg every 6 hrs
   (C) methicillin 500 mg every 6 hrs
   (D) cefazolin 1 g every 8 hrs
   (E) penicillin V 500 mg every 6 hrs

9. RC is a 33-year-old male with a history of HIV for 10 years who now presents with *Mycobacterium avium-intracellulare* (MAI). Which of the following drugs has demonstrated in vitro activity against MAI?

   (A) daptomycin
   (B) clarithromycin
   (C) erythromycin base
   (D) cloxacillin
   (E) minocycline

10. All of the following statements regarding pentamidine isethionate are true *except* which one?

    (A) It is indicated for treatment or prophylaxis of infection owing to *Pneumocystis carinii.*
    (B) It may be administered intramuscularly, intravenously, or by inhalation.
    (C) It has no clinically significant effect on serum glucose.
    (D) It is effective in the treatment of leishmaniasis.

11. RE is a 23-year-old male with a history of severe asthma. An outbreak of H1N1 influenza has just been reported in his community, and he is exhibiting initial symptoms of the infection. Which agent would be the most useful to treat RE?

    (A) cidofovir
    (B) famciclovir
    (C) oseltamivir
    (D) zanamivir
    (E) ribavirin

12. Dr. Jones requests your help in selecting a protease inhibitor as part of a regimen for a treatment-naive male patient. Which of the following would you recommend?

    (A) darunavir/ritonavir
    (B) lopinavir/ritonavir
    (C) nelfinavir
    (D) saquinavir/ritonavir
    (E) tipranavir/ritonavir

Directions for questions 13–14: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E.**

   A   if **I only** is correct
   B   if **III only** is correct
   C   if **I and II** are correct
   D   if **II and III** are correct
   E   if **I, II, and III** are correct

13. Drugs usually active against penicillinase-producing *Staphylococcus aureus* include which of the following?

    I. piperacillin–tazobactam
    II. amoxicillin–clavulanate
    III. nafcillin

14. Antiviral agents that are active against cytomegalovirus (CMV) include which of the following?

    I. ganciclovir
    II. foscarnet
    III. acyclovir

Directions for questions 15–17: Each description listed in this section is most closely associated with **one** of the following drugs. The drugs may be used more than once or not at all. Choose the **best** answer, **A–E.**

   A   clofazimine
   B   itraconazole
   C   levofloxacin
   D   neomycin

15. It may be administered once per day for the treatment of urinary tract infections.

16. It may cause pink to brownish skin pigmentation within a few weeks of initiation of therapy.

17. Coadministration with astemizole or terfenadine may lead to life-threatening cardiac dysrhythmias.

Answers and Explanations

1. **The answer is A** *[see VI.B.2.d.(5)].*
   Isoniazid increases the excretion of pyridoxine, which can lead to peripheral neuritis, particularly in poorly nourished patients. Pyridoxine (a form of vitamin B_6) deficiency may cause convulsions as well as the neuritis, involving synovial tenderness and swelling. Treatment with the vitamin can reverse the neuritis and prevent or cure the seizures.

2. **The answer is D** *[see II.B.4.b].*
   Trough serum levels < 2 mg/mL are considered appropriate for gentamicin and are recommended to minimize the risk of toxicity from this aminoglycoside. Because aminoglycosides accumulate in the proximal tubule of the kidney, nephrotoxicity can occur.

3. **The answer is A** *[see II.C.4.6; II.F.e.2; V.C.3.b.(4); VI.B.2.d.(5)].*
   Seizures have been attributed to the use of penicillin G, imipenem, amphotericin B, and metronidazole. Seizures are especially likely with high doses in patients with a history of seizures and in patients with impaired drug elimination.

4. **The answer is C** *[see II.K.14].*
   Although active against various gram-positive and negative organisms, tigecycline is only agent approved for the treatment of intra-abdominal infections caused by these organisms.

5. **The answer is D** *[see I.H.1].*
   The fever curve is useful for monitoring a patient's response to antimicrobial therapy. Antipyretics can be used to reduce high fever in patients at risk for complications (e.g., seizures) or, in some cases, to make the patient more comfortable.

6. **The answer is B** *[see II.K.13; II.D.4.6].*
   Amoxicillin and ampicillin are all penicillins and should be avoided in patients with histories of hypersensitivity to other penicillin compounds. Although the risk of cross-reactivity with cephalosporins (e.g., cefaclor, loracarbef) is now considered low, most clinicians avoid the use of these agents in patients with histories of type I hypersensitivity reactions (e.g., anaphylaxis, bronchospasm, giant hives).

7. **The answer is B** *[see II.B.2.b.(3); II.I.2.a; II.J.2.a; II.J.2.c.(1)].*
   Norfloxacin, ciprofloxacin, tobramycin, and methenamine mandelate achieve urine concentrations high enough to treat urinary tract infections caused by *P. aeruginosa*. Trimethoprim–sulfamethoxazole is not useful for treating infection caused by this organism, although the combination is useful for treating certain other urinary tract infections.

8. **The answer is A** *[see II.F.2.c.(4)].*
   Although vancomycin, methicillin, and cefazolin have excellent activity against staphylococci, they are not effective orally for systemic infections. Vancomycin is prescribed orally for infections limited to the gastrointestinal tract, but because it is poorly absorbed orally, it is not effective for systemic infections. Most hospital- and community-acquired staphylococci are currently resistant to penicillin. Thus, of the drugs listed, the most appropriate drug for oral therapy of staphylococcal cellulitis is dicloxacillin.

9. **The answer is B** *[see II.D.6.a–b].*
   Clarithromycin, an alternative to erythromycin, has demonstrated in vitro activity against MAI. Clarithromycin is also used against *Toxoplasma gondii* and *Cryptosporidium* spp., and it is more active than erythromycin against staphylococci and streptococci. Vancomycin and cloxacillin are used to treat staphylococci and streptococci, but has no demonstrated activity versus MAI.

10. **The answer is C** *[see V.D].*
    Pentamidine isethionate is indicated for both treatment and prophylaxis of infection from *P. carinii*. It can be administered intramuscularly, intravenously, or by inhalation. Inhalation may produce bronchospasm. Blood glucose should be carefully monitored because pentamidine may produce either hyperglycemia or hypoglycemia.

11. **The answer is C** *[see VII.B.9].*
    Cidofovir and famciclovir have little or no in vivo activity against H1N1 influenza. Ribavirin has some activity but is not used for influenza and is mainly indicated for treatment of hepatitis C in combination with interferon. Zanamivir and oseltamivir are agents that demonstrate activity against H1N1 influenza and are indicated for the treatment of influenza infections. Zanamivir is an inhaled agent that should be avoided in patients with a history of asthma or chronic obstructive pulmonary disease, due to the risk of bronchospasm and acute decline in lung function. Oseltamivir is an oral agent that is most appropriate in this case.

12. **The answer is A** *[see VII.C.5.a–i].*
    Lopinavir/ritonavir is a PI used in alternative regimens for treatment-naïve patients and is only a preferred PI in pregnant women. Nelfinavir, saquinavir/ritonavir, and tipranavir/ritonavir are not preferred PIs due to inferior virologic potency and/or adverse effects. Darunavir/ritonavir is considered a preferred PI.

13. The answer is E (I, II, III) *[see II.E.2–4].*
Piperacillin and amoxicillin each include a β-lactamase inhibitor. These combinations offer activity against *S. aureus* similar to that of the penicillinase-resistant penicillins, such as nafcillin.

14. The answer is C (I, II) *[see VII.B.1; VII.B.7–8].*
Only ganciclovir and foscarnet are active against CMV infections. These agents are virustatic and arrest DNA synthesis by inhibiting viral DNA polymerase. Foscarnet is a broad-spectrum antiviral agent and is used in patients with ganciclovir resistance. Acyclovir is not clinically useful for the treatment of CMV infections because CMV is relatively resistant to acyclovir in vitro.

15. The answer is C *[see II.I.3.c].*
Levofloxacin is appropriate for treatment of urinary tract infections, and may be dosed once daily.

16. The answer is A *[see II.K.5.d.(1)].*
Because clofazimine contains phenazine dye, it can cause pink to brown skin pigmentation. This change in pigmentation occurs in 75% to 100% of patients taking clofazimine, and it occurs within a few weeks of the initiation of therapy. The discoloration of skin has reportedly led to severe depression and even suicide in some patients. Clofazimine is used in the treatment of leprosy and several atypical *Mycobacterium* infections.

17. The answer is B *[see III.F.5.d].*
Administration of itraconazole or ketoconazole with astemizole or terfenadine may increase the level of astemizole or terfenadine, which can lead to life-threatening dysrhythmias and death. Itraconazole, which is an imidazole, is a fungistatic agent. Specifically, itraconazole can be taken orally to treat aspergillosis infections and other deep fungal infections, such as blastomycosis, coccidioidomycosis, cryptococcosis, and histoplasmosis.

Seizure Disorders

AZITA RAZZAGHI

I. INTRODUCTION

A. Definitions

1. **Seizures** are characterized by an excessive, hypersynchronous discharge of cortical neuron activity, which can be measured by the electroencephalogram (EEG). In addition, there may be disturbances in consciousness, sensory motor systems, subjective well-being, and objective behavior; seizures are usually brief, with a beginning and an end, and may produce post-seizure impairment.

2. **Epilepsy** is defined as a chronic seizure disorder or group of disorders characterized by seizures that usually recur unpredictably in the absence of a consistent provoking factor. The term *epilepsy* is derived from the Greek word meaning "to seize upon" or "taking hold of." It was first described by Hughlings Jackson in the 19th century as an intermittent derangement of the nervous system due to a sudden, excessive, disorderly discharge of cerebral neurons.

3. **Convulsions** are violent, involuntary contractions of the voluntary muscles. A patient may have epilepsy or a seizure disorder without convulsions.

B. Classification. An alternative seizure classification is being developed that is purely symptom based. This consists of four categories: sensorial (auras), consciousness, autonomic, and motor. Also, the international league against epilepsy is establishing a four-level descriptive seizure classification based on symptoms, a pathophysiological seizure, an epileptic syndrome, and functional disability. At present, there are two systems of classification of seizure disorder: one is based on the seizure type and characteristics (*Table 37-1*), and the other is based on the characteristics of the epilepsy (including age at onset, etiological factors, and frequency) and characteristics of the seizure (*Table 37-2*).

1. **Partial seizures** are the most common seizure type, occurring in approximately 80% of patients with epilepsy.

   a. **Clinical and EEG changes** indicate initial activation of a system of neurons limited to part of one cerebral hemisphere that may spread to other or all brain areas. Manifestations of the seizures depend on the site of the epileptogenic focus in the brain.

   b. Partial seizures are subclassified as **simple** (usually unilateral involvement) or **complex** (usually bilateral involvement). Impairment of consciousness is a feature of complex seizures. Consciousness is defined as the degree of awareness and responsiveness of the patient to externally applied stimuli.

      (1) **Simple partial seizures** generally do not cause loss of consciousness. **Signs and symptoms** of simple partial seizures may be primarily motor, sensory, somatosensory, autonomic, or behavioral. These signs and symptoms may help pinpoint the site of the abnormal brain discharge; for example, localized numbness or tingling reflects a dysfunction in the sensory cortex, located in the parietal lobe.

         (a) **Motor signs** include convulsive jerking, chewing motions, and lip smacking.

         (b) **Sensory and somatosensory manifestations** include paresthesias and auras.

         (c) **Autonomic signs** include sweating, flushing, and pupil dilation.

         (d) **Behavioral manifestations**, which are sometimes accompanied by impaired consciousness, include déjà vu experiences, structured hallucinations, and dysphasia.

743

Table 37-1   INTERNATIONAL CLASSIFICATION OF EPILEPTIC SEIZURES

I. **Partial seizures** (seizures beginning locally)
   A. **Simple partial seizures** (consciousness not impaired)
      1. With motor symptoms
      2. With somatosensory or special sensory symptoms
      3. With autonomic symptoms
      4. With behavioral symptoms
   B. **Complex partial seizures** (with impairment of consciousness)
      1. Beginning as simple partial seizures and progressing to impairment of consciousness
         a. Without automatisms
         b. With automatisms
      2. With impairment of consciousness at onset
         a. With no other features
         b. With features of simple partial seizures
         c. With automatisms
   C. **Partial seizures** (simple or complex), secondarily generalized
II. **Generalized seizures** (bilaterally symmetric, without localized onset)
   A. **Absence seizures**
      1. True absence seizures (petit mal)
      2. Atypical absence seizures
   B. **Myoclonic seizures**
   C. **Clonic seizures**
   D. **Tonic seizures**
   E. **Tonic–clonic seizures (grand mal)**
   F. **Atonic seizures**
III. **Unclassified seizures**

Reprinted from Commission on Classification and Terminology of the International League against Epilepsy. Proposal for classification of epilepsies and epileptic syndromes. *Epilepsia.* 1985;26:268–278.

    (2) **Complex partial seizures** are accompanied by impaired consciousness; however, in some cases, the impairment precedes or follows the seizure. These seizures have variable manifestations.
       (a) Purposeless behavior is common.
       (b) The affected person may have a glassy stare, may wander about aimlessly, and may speak unintelligibly.
       (c) Psychomotor (temporal lobe) epilepsy may lead to aggressive behavior (e.g., outbursts of rage or violence).
       (d) Postictal confusion usually persists for 1 to 2 mins after the seizure ends.
       (e) Automatism (e.g., picking at clothes) is common and may follow visual, auditory, or olfactory hallucinations.
  2. **Generalized seizures** are diffuse, affecting both cerebral hemispheres.
    a. **Clinical and EEG changes** indicate initial involvement of both hemispheres.
      (1) Consciousness may be impaired, and this impairment may be the initial manifestation.
      (2) Motor manifestations are bilateral.
      (3) The ictal EEG patterns initially are bilateral and presumably reflect neuronal discharge, which is widespread in both hemispheres.
    b. There are three **types** of generalized seizures.
      (1) **Idiopathic epilepsies** have an age-related onset, typical clinical and EEG characteristics, and a presumed genetic origin.
      (2) **Symptomatic epilepsies** are considered the consequence of a known or suspected underlying disorder of the central nervous system (CNS).
      (3) **Cryptogenic epilepsy** refers to a disorder for which the cause is hidden or occult; it is presumed to be symptomatic, but the causal factors are unknown. It is age related but often does not have well-defined clinical and EEG characteristics.

| **Table 37-2** | CLASSIFICATION OF EPILEPSIES AND EPILEPTIC SYNDROMES |

I. **Localized-related (focal, local, partial) epilepsies and syndromes**
   A. **Idiopathic** (with age-related onset)
      1. Benign childhood epilepsy with centrotemporal spikes (rolandic epilepsy)
      2. Childhood epilepsy with occipital paroxysms
   B. **Symptomatic**
      1. Chronic progressive epilepsia partialis continua of childhood
      2. Syndromes characterized by specific modes of precipitation
      3. Temporal lobe epilepsies
      4. Frontal lobe epilepsies
      5. Parietal lobe epilepsies
      6. Occipital lobe epilepsies
   C. **Cryptogenic**
II. **Generalized epilepsies and syndromes**
   A. **Idiopathic** (with age-related onset)
      1. Benign neonatal familial convulsions
      2. Benign neonatal convulsions
      3. Benign myoclonic epilepsy in infancy
      4. Childhood absence epilepsy (pyknolepsy)
      5. Juvenile absence epilepsy
      6. Juvenile myoclonic epilepsy
      7. Epilepsy with generalized tonic–clonic seizures on awakening
      8. Other generalized idiopathic epilepsies not defined above
      9. Epilepsies with seizures precipitated by specific modes of activation
   B. **Cryptogenic or symptomatic** (in order of age)
      1. West syndrome (infantile spasms)
      2. Lennox–Gastaut syndrome
      3. Epilepsy with myoclonic–astatic seizures
      4. Epilepsy with myoclonic absences
   C. **Symptomatic**
      1. **Nonspecific etiology**
         a. Early myoclonic encephalopathy
         b. Early infantile epileptic encephalopathy with suppression burst
         c. Other symptomatic generalized epilepsies not defined above
      2. **Specific syndromes and generalized seizures complicating other disease states**
III. **Epilepsies and syndromes undetermined whether focal or generalized**
   A. **With both focal and generalized seizures**
      1. Neonatal seizures
      2. Severe myoclonic epilepsy in infancy
      3. Epilepsy with continuous spike waves during slow-wave sleep
      4. Acquired epileptic aphasia (Landau–Kleffner syndrome)[a]
      5. Other undetermined epilepsies not defined above
   B. **Without unequivocal generalized or focal features**
IV. **Special situations**
   A. Febrile convulsions
   B. Isolated seizures or isolated status epilepticus
   C. Seizures occurring only when there is an acute metabolic or toxic event due to such factors as alcohol, drugs, eclampsia, and nonketotic hyperglycemia

[a]Believed to be a localized-related epilepsy.
Reprinted with permission from Bleck TP. Convulsive disorders: the use of anticonvulsant drugs. *Clin Neuropharmacol*. 1990;1:198–209.

    c. Signs and symptoms of generalized seizures may be minor or major.

       (1) Absence (petit mal) seizures present as alterations of consciousness (absences) lasting 10 to 30 secs.

          (a) Staring (with occasional eye blinking) and loss or reduction in postural tone are typical. If the seizure takes place during conversation, the individual may break off in midsentence.

          (b) Enuresis and other autonomic components may occur during absence seizures.

          (c) Some patients experience 100 or more absences daily.

          (d) Onset of this seizure type occurs from age 3 to 16 years; in most patients, absence seizures disappear by age 40.

       (2) Myoclonic (bilateral massive epileptic myoclonus) seizures present as involuntary jerking of the facial, limb, or trunk muscles, possibly in a rhythmic manner.

       (3) Clonic seizures are characterized by sustained muscle contractions alternating with relaxation.

       (4) Tonic seizures involve sustained tonic muscle extension (stiffening).

       (5) Generalized (grand mal) tonic–clonic seizures cause sudden loss of consciousness.

          (a) The individual becomes rigid and falls to the ground. Respirations are interrupted. The legs extend, and the back arches; contraction of the diaphragm may induce grunting. This tonic phase lasts for about 1 min.

          (b) A clonic phase follows, marked by rapid bilateral muscle jerking, muscle flaccidity, and hyperventilation. Incontinence, tongue biting, tachycardia, and heavy salivation sometimes occur.

          (c) During the postictal phase, the individual may experience headache, confusion, disorientation, nausea, drowsiness, and muscle soreness. This phase may last for hours.

          (d) Some patients with epilepsy have serial grand mal seizures, regaining consciousness briefly between attacks. In some cases, grand mal seizures occur repeatedly with no recovery of consciousness between attacks (**status epilepticus**); this disorder is discussed in III.A.

       (6) Atonic seizures (drop attacks) are characterized by a sudden loss of postural tone so that the individual falls to the ground. They occur primarily in children.

C. Epidemiology

  1. Most common neurological disorder

  2. Epilepsy has a prevalence of approximately 1% (i.e., 500,000 cases per 50 million persons worldwide).

  3. In the United States, the prevalence of epilepsy is 6.42 cases per 1000 people.

  4. The onset of seizures is greatest during the first year of life; this probability decreases each decade after the first year until age 60. Approximately 1 of 50 children and 1 of 100 adults are affected.

  5. Approximately 70% of people with epilepsy have only one seizure type; the remainder have two or more seizure types.

D. Cause. Some seizures arise secondary to other conditions. However, in most cases, the cause of the seizure is unknown.

  1. Primary (idiopathic) seizures have no identifiable cause.

    a. This type of seizure affects about 75% of people with epilepsy.

    b. The onset of primary seizures typically occurs before age 20.

    c. Birth trauma, hereditary factors, and unexplained metabolic disturbances have been proposed as possible causes.

  2. Secondary seizures (symptomatic or acquired seizures) occur secondary to an identifiable cause.

    a. Disorders that may lead to secondary seizures include

      (1) Intracranial neoplasms

      (2) Infectious diseases, such as meningitis, influenza, toxoplasmosis, mumps, measles, and syphilis

      (3) High fever (in children)

      (4) Head trauma

      (5) Congenital diseases

      (6) Metabolic disorders, such as hypoglycemia and hypocalcemia

Table 37-3	PROBABLE CAUSES OF RECURRENT SEIZURES BY AGE GROUP

Age at Seizure Onset	Probable Cause of Seizure
Birth to 1 month	Birth injury or anoxia, congenital hereditary diseases, and metabolic disorders
1–6 months	As above, plus infantile spasms
6 months to 2 years	Infantile spasms, febrile convulsions, birth injury or anoxia, meningitis, and head trauma
3–10 years	Birth injury or anoxia, meningitis, cerebral vessel thrombosis, and idiopathic epilepsy
10–18 years	Idiopathic epilepsy and head trauma
18–25 years	Idiopathic epilepsy, trauma, neoplasm, and withdrawal from alcohol or drugs
35–60 years	Trauma, neoplasm, vascular disease, and withdrawal from alcohol or drugs
> 60 years	Vascular disease, neoplasm, degenerative disease, and trauma

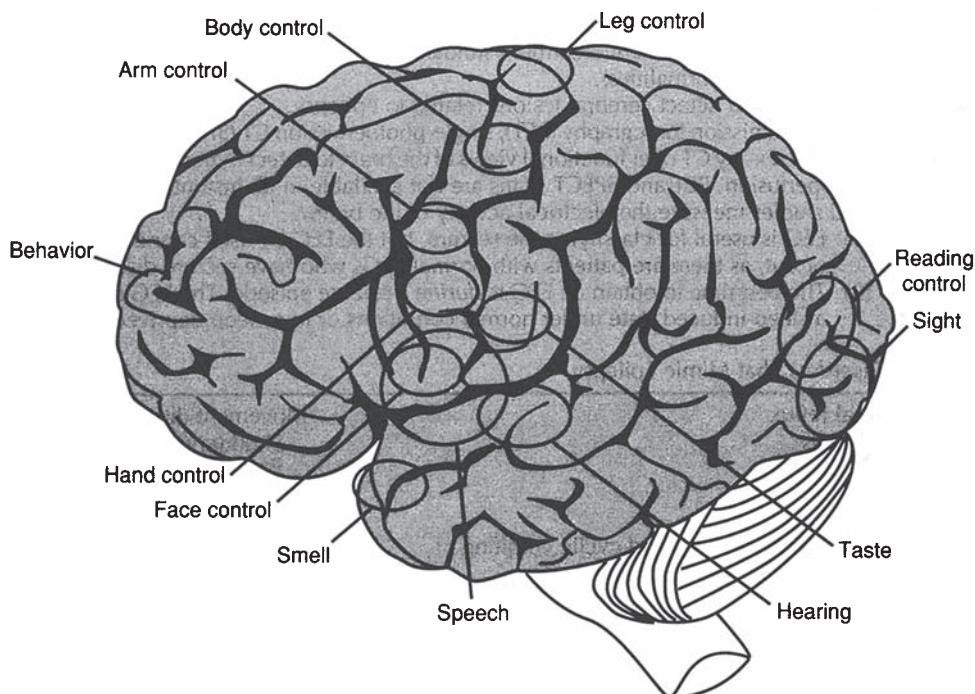
       (7) Alcohol or drug withdrawal
       (8) Lipid storage disorders
       (9) Developmental abnormalities
    b. Age at seizure onset is associated with specific causes (*Table 37-3*).
  E. Pathophysiology. Seizures reflect a sudden, abnormal, excessive neuronal discharge in the cerebral cortex. Any abnormal neuronal discharge could precipitate a seizure (*Figure 37-1*).
    1. Normal firing of neurons, which usually originate from the gray matter of one or more cortical or subcortical areas, requires the following elements:
      a. Voltage-dependent ion channels are involved in action-potential propagation or burst generation.
      b. Neurotransmitters control neuronal firing, including excitatory neurotransmitters, acetylcholine, norepinephrine, histamine, corticotropin-releasing factors (CRFs), inhibitory neurotransmitters, γ-aminobutyric acid (GABA), and dopamine; therefore, normal neuronal


Figure 37-1. Gross anatomy of the brain. Clinical manifestation of seizures depends on the area of the cortex that is affected and its function, the degree of irritability, and the identity of the impulse.

activity requires adequate ions (e.g., sodium, potassium, calcium); excitatory and inhibitory neurotransmitters; and glucose, oxygen, amino acids, and adequate systemic pH.

    c. People with epilepsy may be **genetically** predisposed to a **lower seizure threshold**.

    d. A diencephalic nerve group that normally suppresses excessive brain discharge may be deafferentated, hypersensitive, and vulnerable to activation by various stimuli in individuals with epilepsy.

    e. During seizures, there is an increased use of energy, oxygen, and, consequently, an increased production of carbon dioxide. Because of the limited capacity to increase the blood flow to the brain, the blood supply may be **oxygen deficient**. The ratio of supply to demand decreases when the seizure episode is prolonged, leading to increased ischemia and neuronal destruction. Thus, it is crucial to diagnose seizures and treat them as soon as possible.

2. Abnormal electrical brain activity occurring during a seizure usually produces **characteristic changes on the EEG**. Each part of the cortical area has its own function, and the clinical presentation of a seizure depends on the site, the degree of irritability of the area, and the intensity of the impulse.

3. Seizure activity may include three major **phases**.

    a. A prodrome may precede the seizure by hours or days.

        (1) Changes in behavior or mood typically occur during the prodrome.

        (2) This phase may include an aura—a subjective sensation, such as an unusual smell or flashing light.

    b. The **ictal phase** is the seizure itself. In some cases, its onset is heralded by a scream or cry.

    c. The **postictal phase** takes place immediately after the seizure.

        (1) Extensor plantar reflexes may appear.

        (2) The patient typically exhibits lethargy, confusion, and behavioral changes.

F. Clinical evaluation

1. History includes an evaluation of the seizure, including interviews of the patient's family and eyewitness accounts to establish.

    a. The frequency and duration of the episodes

    b. Precipitating factors

    c. The times at which episodes occur

    d. The presence or absence of an aura

    e. Ictal activity

    f. Postictal state

2. Physical and neurological examinations are the tools with which to identify an underlying cause to rule out diseases that manifest as seizures (*Table 37-4*).

3. Laboratory tests may also identify an underlying cause.

    a. Liver and kidney function tests, complete blood count (CBC), urinalysis, and serum drug levels (e.g., antidepressants and amphetamines may precipitate seizures) are necessary.

Table 37-4   DISORDERS THAT MIMIC EPILEPSY

Gastroesophageal reflux	Movement disorders
Breath-holding spells	Shuddering attacks
Migraine	Paroxysmal choreoathetosis
Confusional	Nonepileptic myoclonus
Basilar	Tics and habit spasms
With recurrent abdominal pain and cyclic vomiting	Psychological disorders
Sleep disorders (especially parasomnias)	Panic disorder
Cardiovascular events	Hyperventilation attacks
Pallid infantile syncope	Pseudoseizures
Vasovagal attacks	Rage attacks
Vasomotor syncope	
Arrhythmias

      b. Lumbar puncture may be required for evidence of cerebrospinal fluid (CSF) infection for patients with a fever who have seizures.

   4. **Neurological imaging studies**, including MRI and/or CT, complement electrophysiological studies and can identify structural brain disorders (anatomical abnormalities).

      a. An MRI can detect cerebral lesions related to epilepsy and should be used in all cases, especially in patients with partial seizure, to exclude brain abnormalities.

      b. Positron-emission tomography (PET), single-photon emission CT (SPECT), and stable xenon-enhanced x-ray CT offer functional views of the brain to detect hypometabolism or relative hypoperfusion. PET and SPECT scans are not available in all institutions.

      c. EEG studies measure the electrical activity of the brain. These studies help identify functional cerebral changes underlying structural abnormalities and are useful with MRI for patients considered for epilepsy surgery.

         (1) An EEG is useful for classifying the seizure or as an additional diagnostic tool, but the EEG by itself cannot rule seizures in or out, because some patients with normal interictal EEGs have seizure disorders.

         (2) The best time to obtain an EEG is *during* a seizure episode. EEG recordings done while the patient is asleep can often record the abnormal activity; therefore, EEGs performed during a sleep-induced state under normal conditions or in a sleep-deprived state can be more sensitive for making a diagnosis.

G. **Treatment objectives**

   1. To prevent or suppress seizures or reduce their frequency through drug therapy.

   2. To control or eliminate the factors that cause or precipitate seizures.

   3. To prevent serious consequences of seizures, such as anoxia, airway occlusion, or injury by protecting the tongue and placing a pillow under the victim's head.

   4. To encourage a normal lifestyle and prevent the patient from feeling like or being treated as an invalid.

   5. Short- and long-term side effects

   6. Drug interactions

II. THERAPY

A. **Principles of drug therapy**

   1. **Seizure control.** Approximately 50% of patients with epilepsy achieve complete seizure control through drug therapy. In another 25%, drugs reduce the frequency of seizures. People with epilepsy generally require continuous drug therapy for at least 2 seizure-free years before the drug discontinuation can be considered.

   2. **Initial treatment**

      a. Before anticonvulsive drug treatment is instituted, treatable underlying causes of the seizure activity should be excluded.

      b. A single primary drug that is most appropriate for the seizure type must be selected. If there is more than one appropriate primary drug, then age, sex, and compliance of the patient must be considered.

      c. For patients with newly diagnosed epilepsy, administer low doses for a few days. Patients may respond to a dosage that is lower than that traditionally prescribed initially by their physicians, and this may have important implications in terms of limiting adverse effects. The incidence of adverse effects increases with increasing drug levels, even when the plasma concentrations are maintained within the so-called therapeutic or optimal range.

      d. Between one-fourth and one-third of the maintenance dose of a single medication is used to begin therapy; it is then increased over 3 to 4 weeks. The exceptions are phenytoin and phenobarbital, which can be started with the loading or maintenance dose. The dose should be titrated until seizure control or intolerable side effects occur.

      e. With the initiation of therapy, blood concentrations of medications should be measured.

         (1) To establish therapeutic ranges and dosage regimens based on symptomatic toxicity or seizure frequency.

         (2) To assess the patient's compliance with therapy.

(3) To control the correlation among the dose, blood levels, and clinical therapeutic levels or toxicity.

    (a) Phenytoin follows nonlinear kinetics, as drug levels increase dramatically (more than onefold) with only a small increase in the dose. However, before this twofold increase in drug level with a small increase in dose, there is a predictable linear increase with dose increases; for this reason, it is recommended to increase the dose in small increments to be able to predict when the drug follows the nonlinear kinetic. When this happens, that means the maximum rate of hepatic enzyme clearance is reached and the body can no longer clear the drug as it is introduced into the body.

    (b) If physical examination reveals a new onset of nystagmus (except with phenytoin, in which nystagmus develops before clinical intoxication), ataxia, and unsteady wide gait, the next dose increase should be minimal.

    (c) There is no justification for increasing drug dosage when a patient's seizures are fully controlled, even if the plasma concentration is below the lower limit of the therapeutic range. If the patient continues to have seizures without any evidence of adverse effects at a plasma concentration near the toxic range, there are two approaches:

       (i) Some clinicians increase the dosage according to clinical response up to the highest tolerated limit.

       (ii) Some clinicians do not increase the dosage because of the likelihood of producing adverse effects.

    (d) Carbamazepine has an autoinduction metabolism property, which means that if the dose is increased twofold, blood levels increase less than twofold because of increased metabolism.

(4) To determine the free drug level, which is helpful in patients who are in the therapeutic range but have side effects or no response. The plasma protein binding may be altered in these patients by some other disease state or medication. Because of this alteration, there is more free drug available in the system than the total level shows, especially with phenytoin, valproic acid, and carbamazepine.

3. **Paradoxical intoxication** occurs when a high concentration of a single drug causes an increased frequency of seizures without classical adverse events. This is common with hydantoins and carbamazepine. The proposed reason is that their effect on the cerebellum is blocked at high concentrations. Management usually requires no more than withholding enough doses of the drug to allow the concentration to drift down.

4. When seizures cannot be controlled, there are two options.

    a. The initial drug can be substituted with another agent. This is accomplished by gradually discontinuing the initial drug while simultaneously increasing the dosage of the second agent. Then the dosage of the second agent is titrated up to the maintenance level as the initial agent is gradually discontinued. There are three main advantages of gradual substitution.

       (1) It allows evaluation of the effects of individual drugs.

       (2) It reduces the risk of toxicity.

       (3) It reduces the risk of adverse drug interactions.

    b. A second drug can be added. Combination therapy is reserved for patients with severe epilepsy to rapidly control the seizures. Rapid control can be important for psychosocial reasons as well as for the possibility of a more favorable prognosis.

5. **Long-term drug treatment.** Most physicians review the patient's condition when the patient has been seizure free for 2 years. This has important implications in children because early termination of treatment has better remission rates compared with adults. It is recommended to gradually decrease the dose, over at least 6 months. The age of onset of epilepsy, the presence of an underlying neurological condition, and any abnormal EEGs should be considered.

6. **Diseases and conditions that alter antiepileptic drug–protein bindings**

    a. Liver disease

    b. Hypoalbuminemia

    c. Burns

   d. Pregnancy

   e. High protein-binding drugs or antiepileptic agents. (Most important interactions are discussed under individual agents.)

7. **Medications.** Some medications decrease levels of phenytoin, carbamazepine, phenobarbital, and primidone by enhancing their metabolism. These drugs also cause false decreases in thyroid function tests.

   a. Oral contraceptives

   b. Oral hypoglycemics

   c. Glucocorticoids

   d. Tricyclic antidepressants

   e. Azathioprine

   f. Cyclosporine

   g. Quinidine

   h. Theophylline

   i. Warfarin

   j. Doxycycline

   k. Levodopa

8. **Overview of drug therapy in seizure disorder**

   a. Monotherapy. Start the drug therapy as single agent.

   b. Dosage treatment. Use a low dose for a few days. Patients with newly diagnosed epilepsy may respond to dosages that are lower than those prescribed initially by their physicians, and this may have important implications in terms of adverse effects. The incidence of adverse effects increases with increasing drug dosage, even when the plasma concentration is maintained within the so-called therapeutic or optimal range.

   c. Drug monitoring. There is no justification for increasing drug dosage when a patient is fully controlled, even if the plasma concentration is below the lower limit of the therapeutic range. If the patient continues to have seizures without any evidence of adverse effects at a plasma concentration near the toxic range, there are two approaches.

   (1) Some clinicians increase the dosage according to clinical response up to the highest tolerated limit.

   (2) Some clinicians do not increase the dosage because of the likelihood of producing adverse events.

9. **Adverse effects of anticonvulsive drugs**

   a. Alternation in cognition and mentation

   (1) Sedation and depression are the most common symptoms of overdose of anticonvulsive drugs, but they are difficult to assess. For example, barbiturates commonly cause depression, with primidone being the worst offender; diazepam and clorazepate are less likely to cause depression. Barbiturates, clonazepam, and trimethadione commonly cause cognitive impairment, ranging from sensation to confusion.

   (2) Excitation can be a paradoxical effect of barbiturates with younger children and the elderly. For example, felbamate can cause restlessness and hyperactivity.

   b. Deterioration of motor performance and primary coordination includes trembling hands, staggering when rounding corners, and mild limb ataxia. Drugs associated with these effects include hydantoins, methsuximide, carbamazepine, and primidone. These effects are less common with barbiturates and lamotrigine and are rarely seen with gabapentin.

   c. Gastrointestinal symptoms include nausea and vomiting. Two purposed mechanisms include

   (1) A local effect on the stomach, as in the case of valproic acid; divalproex acid, however, has less incidence compared with valproic acid. These symptoms decrease in incidence if the drug is given with meals.

   (2) A brainstem effect, as in the cases of felbamate and carbamazepine. Nausea and vomiting caused by these drugs are associated with brainstem involvement; therefore, drug levels play a role in these symptoms. Administration in smaller, more frequent doses decreases the incidence of these symptoms by lowering the transient peak concentration.

d. **Appetite and body weight.** Few anticonvulsants affect appetite separate from nausea and vomiting, including anorexia or increased appetite.
   (1) **Drugs that cause anorexia** are felbamate, and to a lesser extent, carbamazepine, ethosuximide, and valproic acid.
   (2) **Drugs that cause increased appetite** are valproic acid and to a lesser extent, carbamazepine.
e. **Headache and dizziness**
   (1) **Diffuse headaches** may be caused by ethosuximide and, to a lesser extent, by methsuximide and felbamate.
   (2) **Dizziness** seen in association with anticonvulsants is caused by a combination of ataxia and loss of eye movement coordination, which is part of motor coordination symptoms.
f. **Suicidability:** increased risk in patients who start receiving anticonvulsive as single and combination with other anticonvulsive medications.
g. Some products have REM program.
   Risk Evaluation and Mitigation Strategies (REM)
   - Minimize risk of a specific adverse effect with a drug or drug class
   May contain one or all of the following tools:
   Medication Guide (MedGuide)-Level 1
   - Patient education about risks
   Communication Plan-Level 2
   - **Health care provider** (HCP) letters (Dear Doctor and Dear Pharmacist letters)
   - HCP education (professional societies)
   - Web-based on-demand education materials
   - Medical science liaison presentations
   Elements to Assure Safe Use (ETASU)-Level 3—one or any combination of:
   - Specialized HCP training, education, or certification
   - Certification of pharmacies, HCPs, or health care settings
   - Dispensing only to patients within certain settings (hospital)
   - Evidence or documentation of safe-use conditions
   - Patient monitoring and/or patient registry
   - Implementation system such as registry programs for sponsor
   - Timetable for submission of assessments to regulatory agency by sponsor

B. **Specific antiseizure agents.** *Table 37-5* lists the uses of antiepileptic medications based on seizure type. *Table 37-6* lists classifications of anticonvulsive drugs. *Table 37-7* lists dosage characteristics of antiepileptic medications.
   1. **Carbamazepine (Tegretol)**
      a. **Mechanisms of action.** Carbamazepine is chemically related to tricyclic antidepressants. Its mechanism of action is unknown in the treatment of seizure disorders, but it is thought to act by reducing polysynaptic responses and blocking the posttetanic potentiation.
      b. **Administration and dosage** (*Table 37-7*)
         (1) **Adults and children > 12 years of age** receive an initial oral dose of 200 mg twice daily. This may be increased gradually to 800 to 1200 mg daily (usually given in divided doses).
         (2) **Children < 12** usually receive 10 to 35 mg/kg daily in two or three divided doses.
      c. **Precautions and monitoring effects**
         (1) Carbamazepine should be used with caution in patients with bone marrow depression. A CBC should be obtained and platelets measured to determine baseline levels before therapy, and levels should be monitored during therapy. Aplastic anemia and agranulocytosis have been reported.
         (2) Tricyclic antidepressants should be avoided if there is a history of hypersensitivity to tricyclics. Monoamine oxidase (MAO) inhibitors should be discontinued 2 weeks before carbamazepine therapy.
         (3) Carbamazepine should be used cautiously in patients with glaucoma because of its mild anticholinergic effects that may result in increase of intraocular pressure.
         (4) Carbamazepine is an enzyme inducer; therefore, the half-life ($t_{1/2}$) decreases over 3 to 4 weeks ($t_{1/2}$ 18 to 54 hrs; $t_{1/2}$ 10 to 25 hrs); for maximal enzyme induction, levels should be rechecked to avoid breakthrough seizures.

| Table 37-5 | USES OF ANTIEPILEPTIC MEDICATIONS BASED ON SEIZURE TYPE |

	Drug Therapy			
Seizure Type	Choice 1	Choice 2	Choice 3	Choice 4
Simple partial	Carbamazepine (alone or combination)	Phenytoin	Primidone Lamotrigine Oxcarbazepine Lacosamide	Gabapentin, levetiracetam Zonisamide Tiagabine
Complex partial	Carbamazepine Lamotrigine	Phenytoin	Phenobarbital Zonisamide Oxcarbazepine	Valproic acid Primidone Topiramate[a] Tiagabine Vigabatrin[b]
Primary generalized Tonic–clonic	Valproic acid Lamotrigine	Carbamazepine	Phenytoin Valproic acid	Phenobarbital Topiramate Tiagabine
Absence	Lamotrigine,[a] ethosuximide	Zonisamide, valproic acid		
Myoclonic atonic	Valproic acid Valproic acid	Clonazepam Clonazepam	Zonisamide	Felbamate[a] (alone or in combination)
Status epilepticus Psychomotor	Diazepam Phenytoin	Phenytoin	Phenobarbital	
Lennox–Gastaut syndrome	Valproic acid felbamate	Lamotrigine Topiramate Rufinamide		

[a]Also indicated for treatment of Lennox–Gastaut syndrome in children.
[b]Also indicated for treatment infantile spasms.

(5) Carbamazepine is metabolized in the liver to 10,11-epoxid, which also has anticonvulsant activity; carbamazepine may induce its own metabolism.

(6) Potential for drug interaction in elderly patients.

(7) **Adverse effects:**

(a) The physician should be notified if any of the following adverse effects occur: jaundice, abdominal pain, pale stool, darkened urine, unusual bruising and bleeding, fever, sore throat, or an ulcer in the mouth. The most common side effects are dizziness, drowsiness, unsteadiness, nausea, and vomiting.

(b) **CNS effects.** These include dizziness, ataxia, and diplopia. If diplopia and ataxia are common and occur after a dose, the schedule could be adjusted to include more frequent administration or a larger proportion of the dose at night. CNS side effects may decrease with chronic administration.

(c) **Gastrointestinal (GI) effects.** These most commonly include nausea, vomiting, and anorexia.

(d) **Metabolic effects.** Hyponatremia occurs after several weeks to months of therapy, and the incidence increases with age. The antidiuretic hormone (ADH) level may be low. Levels of 125 to 135 mEq/L without symptoms should be monitored. Fluid restriction should be instituted when levels decrease to < 125 mEq/L with or without symptoms. Another agent should be used if fluid dose reduction does not help or the seizures recur.

(e) **Hematopoietic effects.** Aplastic anemia is rare. Thrombocytopenia and anemia have a 5% incidence, and they respond to a cessation of drug therapy. Leukopenia is the most common hematopoietic side effect: 10% of cases are transient, and about 2% of patients have persistent leukopenia but do not seem to have increased infections even with white blood cell (WBC) counts of 3000/mL.

Table 37-6   ANTICONVULSIVE DRUG CLASSIFICATION

Barbiturates	Hydantoins	Succinimides	Sulfonamides	Oxazolidinediones	Benzodiazepine	Miscellaneous
Phenobarbital	Phenytoin	Ethosuximide	Zonisamide	Paramethadione	Clonazepam	Lamotrigine
Primidone	Mephenytoin	Methsuximide	Trimethadione	Diazepam	Felbamate	Gabapentin
Mephobarbital	Ethotoin	Phensuximide		Lorazepam	Clorazepate dipotassium	Pregabalin
	Fosphenytoin				Carbamazepine	Oxcarbazepine
					Valproic acid	Lacosamide
					Topiramate	Rufinamide
					Tiagabine	Vigabatrin
					Levetiracetam	

Table 37-7 DOSAGES CHARACTERISTIC OF ANTIEPILEPTIC MEDICATIONS

Drug	Enzyme Inducer	Enzyme Inhibitor	Loading Dose	Usual Adult Dose (mg/day)	Half-life (hr)	Therapeutic Range of Total Plasma Concentration (μg/mL)	Major Mode of Elimination	Protein-Binding Level (%)
Carbamazepine	+/−	−	No	800–1200	11^a–22	4–12	Hepatic	75–80
Phenytoin	+/−	−	Yes	300–700	22–72 / 1–2 (free)	5–20	Hepatic	90
Phenobarbital	+/−	−	Yes	90–300	100	15–40	Hepatic > renal	40–60
Primidone	+/−	−	No	750–3000	15^{a,b}	5–12	Hepatic	20–25
Valproic acid	+/−	+	Yes	1000–3000	15–20	50–150	Hepatic	75–90
Ethosuximide	+/−	−	No	750–1000	30–60^c	40–100	Hepatic > renal	0
Felbamate	+/−	+	No	2400	20–23	30–100	Hepatic > renal	22–25
Gabapentin	−	−	Yes	900–1000	5–7	5–7	Renal	< 3
Lamotrigine	+/−	−	No	200–400	25 / 12.6^d / 70^e	2–6	Hepatic > renal	55
Topiramate	+/−	−	No	200–400	15–23	n/a	Renal > hepatic	9–15
Tiagabine	−	−	No	32–56	6–8	n/a	Hepatic	96
Levetiracetam	−	−	Yes	500–3000	7	n/a	Renal	< 10
Zonisamide	−	−	No	100–600	24–50	n/a	Hepatic	40–60
Oxcarbazepine	+/−	+	No	900–1800	4–9	n/a	Hepatic	40–60
Lacosamide	+/−	−	Yes	200–400	13	n/a	Renal	15
Rufinamide	+/−	−	Yes	3200	6–10	n/a	Renal > liver	34
Lacosamide	+/−	−	Yes	200–400 mg	13	n/a	Renal	15

^{a}The half-life decreases autometabolism after chronic use.
^{b}Metabolized in part to phenobarbital.
^{c}Lower range in children and higher range in adults.
^{d}Receiving other enzyme-inducing drugs.
^{e}Valproic acid slows the metabolism.

        (f) Dermatological effects. Pruritic and erythematous rashes, the Stevens–Johnson syndrome, and lupus erythematosus have been reported.

        (g) Cardiovascular effect such as congestive heart failure, hypertension, syncope, AV block, second- and third-degree heart block.

    (8) REM program

        (a) To inform patients regarding serious dermatological reactions (toxic epidermal necrolysis, Stevens–Johnson syndrome), blood dyscrasias, and suicidal thoughts and behavior that could occur during treatment.

        (b) Medication Guide must be dispensed with this product.

  d. Significant interactions

    (1) Antiepileptic drugs, such as **phenytoin**, **primidone**, and **phenobarbital**, decrease the level of carbamazepine (increase metabolism).

    (2) Valproic acid increases the level of carbamazepine (decreases metabolism).

    (3) Other medications such as **erythromycin**, **isoniazid**, **cimetidine**, **propoxyphene**, **diltiazem**, and **verapamil** increase the level of carbamazepine (decrease metabolism).

    (4) Carbamazepine decreases levels of **calcium-channel blockers**, increasing its own level.

    (5) Carbamazepine decreases the effect of warfarin.

    (6) Antibiotics increase the level of carbamazepine.

    (7) Carbamazepine decreases tricyclic antidepressant levels.

    (8) Carbamazepine an inducer of CYP34A drugs that metabolized within this pathway such as acetaminophen, alprazolam, and levothyroxine would increase plasma concentration of other drugs.

    (9) Grapefruit juice will increase concentration of carbamazepine.

2. Phenytoin (Dilantin)

  a. Mechanism of action

    (1) Phenytoin inhibits the spread of seizures at the motor cortex and blocks posttetanic potentiation by influencing synaptic transmission. There is an alternation of ion fluxes in depolarization, repolarization, and membrane stability phase and alternating calcium uptake in presynaptic terminals.

    (2) Phenytoin is effective for the treatment of generalized tonic–clonic (grand mal) seizures and for partial seizures, both simple and complex. It is not effective for absence seizures.

  b. Administration and dosage (*Table 37-7*)

    (1) The usual daily dose for **adults** is 300 to 700 mg, with adjustments made as needed.

        (a) Regular daily doses above 500 mg are poorly tolerated.

        (b) A loading dose of 900 mg to 1.5 g may be given intravenously (IV). The infusion rate should not exceed 50 mg/min. (Alternatively, an oral loading dose may be given.)

    (2) The usual daily dose for **children** is 4 to 7 mg/kg divided every 12 hrs. An IV loading dose of 15 mg/kg may be given.

    (3) Phenytoin sodium is available as capsules and parenteral solution. Phenytoin is available as tablets and oral suspension.

  c. Precautions and monitoring effects

    (1) IV phenytoin should not be used in patients with sinus bradycardia, sinoatrial block, second- and third-degree atrioventricular (AV) block, or Adams–Stokes syndrome.

    (2) Phenytoin should be used cautiously in patients with myocardial insufficiency and hypotension.

    (3) Elimination of phenytoin converts from first-order elimination (proportional to its concentration) to zero-order elimination (a fixed amount per unit time), usually at high therapeutic levels. The daily dose of phenytoin can be increased 100 mg daily until therapeutic blood levels are attained, after which increases of 30 to 50 mg will avoid twofold to threefold increases in blood levels.

    (4) It is necessary to measure free drug levels or correct the total level when aluminum levels are abnormal or the patient has renal failure.

    (5) Potential for drug interaction in elderly patients.

(6) Lymphadenopathy (local or generalized), including benign lymph node hyperplasia, Hodgkin disease, and lymphoma, has been associated with use of phenytoin.

(7) Phenytoin have been associated with exacerbation of porphyria (an enzyme deficiency that involves skin and CNS).

(8) Adverse effects:

(a) The physician should be notified if any of the following adverse effects occur: swollen or tender gums, skin rash, nausea and vomiting, swollen glands, bleeding, jaundice, fever, or sore throat (i.e., signs of infection or bleeding).

(b) CNS effects include ataxia (limiting side effect), dysarthria, and insomnia. Transient hyperkinesia may follow IV phenytoin infusion. Alcoholic beverages should be avoided while on this medication.

(c) GI effects most commonly include nausea and vomiting. Phenytoin should be taken with food to enhance absorption and decrease GI upset.

(d) Dermatological effects include maculopapular rashes sometimes with fever, Stevens–Johnson syndrome, and lupus erythematosus. Gingival hyperplasia may be reduced by frequent brushing and appropriate oral care.

(e) Connective tissue disorders include a coarsening of the facial features.

(f) Hematopoietic effects include thrombocytopenia, leukopenia, and granulocytopenia.

(g) Miscellaneous effects include hyperglycemia and increased body hair.

d. Significant interactions

(1) Antiepileptic drugs, such as **carbamazepine, valproic acid, clonazepam**, and **phenobarbital**, decrease the level of phenytoin (increase metabolism).

(2) Phenytoin increases the **conversion of primidone to phenobarbital** (increases metabolism).

(3) Other medications such as **disulfiram, isoniazid, chloramphenicol**, and **propoxyphene** increase the level of phenytoin (decrease metabolism).

(4) Drugs whose efficacy is impaired by phenytoin include **corticosteroids, digitoxin, doxycycline, estrogens, furosemide, oral contraceptives, quinidine, rifampin, theophylline, vitamin D**, and **enteral nutritional therapy**.

(5) Coumarin and **warfarin** anticoagulants increase the serum phenytoin levels and prolong the serum half-life of phenytoin by inhibiting its metabolism.

(6) Phenytoin decreases **tricyclic antidepressant** levels.

(7) Phenytoin interacts with **diabetes and arthritis medications**.

3. Fosphenytoin (Cerebyx)

a. Mechanism of action

(1) It is a prodrug of phenytoin.

(2) Water-soluble prodrug of phenytoin. It is converted to phenytoin by the bloodstream phosphatases, with a half-life of about 8 mins in both adults and children.

(3) Fosphenytoin sodium 1.5 mg = 1 mg phenytoin sodium

(4) It is indicated for patients who cannot take oral drugs, and in the acute treatment for status epilepticus.

(5) Administered via IV or intramuscular (IM) injection

(6) A dose conversion table should be used to convert the phenytoin dose to fosphenytoin.

(7) Characteristics similar to phenytoin

(8) Severe cardiovascular reactions such as asystole, ventricular fibrillation, and cardiac arrest. Hypotension could occur with IV administration, which could be controlled by decrease the rate of infusion.

(9) QT prolongation and torsade de pointes when administrated with antiarrhythmic agents such as amiodarone and quinidine

(10) Advantages

(a) Fosphenytoin is an aqueous solution, unlike phenytoin, which is an alkaline solution; therefore, there is no need to add propylene glycol and ethanol to the solution.

(b) Fosphenytoin causes less soft tissue injury at the site of injection. When administered by IM injection, it is completely absorbed and has more predictable serum concentration than IM-injected phenytoin.

4. **Valproic acid (Depakote)**
   a. **Mechanism of action**
      (1) Increases levels of GABA
      (2) Potentiates a postsynaptic GABA response by inhibiting the enzymatic response for the catabolism of GABA.
      (3) Affects the potassium channel, creating a direct membrane-stabilizing effect.
   b. **Administration and dosage** (*Table 37-7*)
      (1) For **adults**, valproic acid is administered orally in a usual dose of 1000 to 3000 mg daily in divided doses.
      (2) For **children**, valproic acid is administered orally in a dose of 15 to 60 mg/kg daily, divided into two or three doses.
      (3) Medication should be taken with food to reduce GI upset.
      (4) Tablets or capsules should be swallowed, not chewed, to avoid irritation of the mouth and throat.
   c. **Precautions and monitoring effects.** There are some reports of hepatotoxicity and increased liver function tests, which are mostly reversible. The severity and incidence of hepatotoxicity increase when the patient is younger than 2 years of age.
   d. **Adverse effects.**
      (1) Contact the physician if abdominal pain, nausea, vomiting, or anoxia occurs; these could be symptoms of pancreatitis.
      (2) **CNS effects** include tremor, ataxia, diplopia, lethargy, drowsiness, behavioral changes, and depression.
      (3) **GI effects** include nausea and increased appetite. Enteric-coated divalproex sodium may reduce these side effects.
      (4) **Dermatological effects** include alopecia and petechiae.
      (5) **Hematopoietic effects** include thrombocytopenia, bruising, hematoma, and bleeding.
      (6) **Hepatic effects** include minor elevations of aspartate aminotransferase (AST), alanine aminotransferase (ALT), and lactate dehydrogenase (LDH).
      (7) **Endocrine effects** include decreased levels of prolactin, resulting in irregular menses and secondary amenorrhea.
      (8) **Pancreatic effects** include acute pancreatitis.
      (9) **Metabolic effects** include hyperammonemia owing to renal origin. Discontinuation may be considered if lethargy develops.
   e. **Significant interactions**
      (1) **Antiepileptic drugs**
         (a) **Primidone** decreases valproic acid clearance (increases metabolism).
         (b) **Phenobarbital** and **phenytoin** displace protein binding, resulting in an increased total phenytoin level and an increase or no change of free phenytoin.
         (c) **Clonazepam** increases CNS toxicity in patients on valproic acid.
      (2) **Other medications**
         (a) **Aspirin** increases the level of valproic acid.
         (b) **Warfarin** inhibits the secondary phase of platelet aggregation.
         (c) **Antacids** increase the level of valproic acid.
      (3) **Laboratory tests**
         (a) False-positive urine ketone tests may result in patients taking valproic acid; thus, patients with diabetes must use caution when using urine tests.
         (b) Thyroid function tests may be altered by antiepileptic drugs.
5. **Phenobarbital (Luminal)**
   a. **Mechanism of action.** Phenobarbital increases the seizure threshold by decreasing postsynaptic excitation by stimulating postsynaptic GABA-A receptor inhibitor responses as a CNS depressant.
   b. **Administration and dosage** (*Table 37-7*)
      (1) For **adults**, phenobarbital is administered orally at 90 to 300 mg daily (in three divided doses or as a single dose at bedtime).
      (2) **Children** typically receive 3 to 6 mg/kg daily in two divided doses. Adjustment is made as needed.

c. **Precautions and monitoring effects**
   (1) Phenobarbital produces respiratory depression, especially with parenteral administration.
   (2) Phenobarbital should be used with caution in patients with hepatic disease who may need dose adjustments.
   (3) Phenobarbital has sedative effects in adults and produces hyperactivity in children.
   (4) Abrupt discontinuation of phenobarbital produces withdrawal convulsions. If the drug must be discontinued, another GABA-A agonist (e.g., benzodiazepine, paraldehyde) should be substituted.
   (5) Potential for drug interaction in elderly patients.
   (6) **Adverse effects.** The physician should be notified if any of the following adverse effects occur: sore throat, mouth sores, easy bruising or bleeding, and any signs of infection.
      (a) **CNS effects** include agitation, confusion, lethargy, and drowsiness. Patients should avoid alcohol and other CNS depressants.
      (b) **Respiratory effects** include hypoventilation and apnea.
      (c) **Cardiovascular effects** include bradycardia and hypotension.
      (d) **GI effects** include nausea, diarrhea, and constipation. If GI upset is experienced, phenobarbital should be taken with food.
      (e) **Hematological effects** include megaloblastic anemia after chronic use (a rare side effect).
      (f) **Miscellaneous effects** include osteomalacia and Stevens–Johnson syndrome, both of which are rare.
d. **Significant interactions**
   (1) **Antiepileptic drugs**, such as **valproic acid** and **phenytoin**, increase the level of phenobarbital (decrease metabolism).
   (2) Other drugs such as **acetazolamide**, **chloramphenicol**, **cimetidine**, and **furosemide** increase the level of phenobarbital (decrease metabolism).
   (3) **Rifampin**, **pyridoxine**, and **ethanol** decrease the level of phenobarbital (increase metabolism).

6. **Primidone (Mysoline)**
   a. **Mechanism of action.** Primidone is a metabolite of phenobarbital and phenylethylmalonamide (PEMA), which has some anticonvulsive effects. It has drug characteristics similar to phenobarbital, with some differences in dose and half-life.
   b. **Administration and dosage** (*Table 37-7*)
      (1) Primidone has a short half-life of 7 hrs, which may require three times daily dosing.
      (2) Primidone is tolerated better if started at 50 mg at night for 3 days until the target daily dose is reached.

7. **Ethosuximide (Zarontin)**
   a. **Mechanism of action**
      (1) Ethosuximide may inhibit the sodium–potassium adenosine triphosphatase (Na^+/K^+ ATPase) system and the reduced form of nicotinamide adenine dinucleotide phosphate (NADPH) linked aldehyde reductase (which is necessary for the formation of γ-hydroxybutyrate, which is associated with the induction of absence seizures).
      (2) Ethosuximide reduces or eliminates the EEG abnormality; however, absence seizures are the only seizures in which the normal EEG has clinical value (i.e., when the EEG abnormality is corrected, the seizures are also controlled).
      (3) Ethosuximide is a relatively benign anticonvulsant with minimum protein binding.
   b. **Administration and dosage** (*Table 37-7*). Ethosuximide is usually given orally in an initial dose of 500 mg daily in **adults and older children** and 250 mg daily in **children ages 3 to 6 years**. The dose may be raised by 250 mg every week to a maximum of 1.5 g daily in adults.
   c. **Precautions and monitoring effects**
      (1) Blood dyscrasias have been reported, making periodic blood counts necessary.
      (2) There have been reports of hepatic and renal toxicity; thus periodic renal and liver function monitoring is necessary.
      (3) Cases of systemic lupus erythematosus have been reported.

   d. Adverse effects
      (1) GI effects include nausea and vomiting. Small doses may lessen these effects. Ethosuximide should be taken with food if GI upset occurs.
      (2) Hematopoietic effects include eosinophilia, granulocytopenia, leukopenia, and lupus.
      (3) CNS effects include drowsiness, blurred vision, fatigue, lethargy, hiccups, and headaches. Alcoholic beverages should be avoided with this medication.
      (4) Psychiatric–psychological effects include confusion and emotional instability.
      (5) Dermatological effects include pruritus, photosensitivity, urticaria, and Stevens–Johnson syndrome.
      (6) Genitourinary effects include increased frequency of urination, vaginal bleeding, renal damage, and hematuria.
      (7) Miscellaneous effects include periorbital edema and muscle weakness. Patients should also be advised of the risks of exposure to sunlight and ultraviolet light.
      (8) REM program
         (a) To inform patients of potential adverse effects, including blood dyscrasias, systemic lupus erythematosus, and suicidal thoughts and behavior, that could occur during treatment.
         (b) Medication Guide must be dispensed with this product.
   e. Significant interactions
      (1) Antiepileptic drugs, such as **carbamazepine**, decrease the level of ethosuximide (increases metabolism).
      (2) Valproic acid increases the level of ethosuximide (decreases metabolism).
8. Clonazepam (Klonopin)
   a. Mechanism of action. Clonazepam is a potent GABA-A agonist, but its efficacy decreases over several months of treatment.
   b. Administration and dosage
      (1) For **adults**, clonazepam is an oral agent that may be given in an initial dose of 1.5 mg daily divided two or three times. The dose may be increased to a maximum of 20 mg daily.
      (2) Children should receive 0.01 to 0.03 mg daily in two or three doses. The dosage may be increased to a maximum of 0.2 mg/kg daily.
   c. Precautions and monitoring effects
      (1) Patients with psychoses, acute narrow-angle glaucoma, and significant liver disease should use this medicine cautiously.
      (2) Adverse effects
         (a) CNS effects include drowsiness, ataxia, and behavior disturbances in children; these may be corrected by dose reduction.
         (b) Respiratory effects include hypersalivation and bronchial hypersecretion.
         (c) Miscellaneous effects include anemia, leukopenia, thrombocytopenia, respiratory depression, anorexia, and weight loss.
      (3) REM program
         (a) To increase awareness of potential risks, including the occurrence of withdrawal symptoms with abrupt discontinuation and suicidal thoughts and behavior, that could occur during treatment.
         (b) Medication Guide must be dispensed with this product.
   d. Significant interactions
      (1) Antiepileptic drugs, such as **phenytoin**, increase the level of clonazepam (decrease metabolism).
      (2) Other drugs. Clonazepam decreases the efficacy of **levodopa** and increases the serum level of **digoxin**.
9. Felbamate (Felbatol)
   a. Mechanism of action. A proposed mechanism of action is that the drug interacts with glycine modulatory site on *N*-methyl-ᴅ-aspartate (NMDA) receptors. Blockade of NMDA may contribute to neuroprotective effects of felbamate. Felbamate is used as monotherapy or adjunctive therapy or without secondary generalization in adults and generalized seizures associated with Lennox–Gastaut syndrome in children. The U.S. Food and Drug

Administration (FDA) recommended that use of felbamate be restricted to only those patients who are refractory to other medications and in whom the risk–benefit relationship warrants its use because of severe hepatotoxicity, aplastic anemia.

b. Administration and dosage (*Table 37-7*)

(1) Adults and children > 14 years of age

(2) Monotherapy, initially 1.2 g in three to four doses daily. The dosage may be increased in 600-mg increments every 2 weeks to 2.4 g daily based on clinical response and, thereafter, 3.6 g daily if necessary.

(3) Adjunctive therapy, 1.2 g in three to four doses daily, with reduction of the dosage of other antiepileptic drugs by 20% to 33%. The dosage of felbamate may be increased in increments of 1.2 g at weekly intervals to a maximum of 3.6 g daily.

(4) Conversion to monotherapy initially 1.2 g daily in three to four doses, with reduction of the dosage of other antiepileptic drugs by 33% at week 3. The felbamate dosage may be increased to 3.6 g daily, and other antiepileptic drugs discontinued or dosage further reduced in stepwise fashion.

(5) Children 2 to 14 years of age with Lennox–Gastaut syndrome, as adjunctive therapy, initially 15 mg/kg daily in three to four doses. The dosage of other antiepileptic drugs is reduced by 20%. The amount of felbamate may be increased in increments of 15 mg/kg at weekly intervals to 45 mg/kg daily. Further reduction in the dosage of other antiepileptic drugs may be necessary.

c. Precaution and monitoring effects. There are two very serious toxic effects, aplastic anemia and liver failure, which lead to death for some patients.

(1) For aplastic anemia, the onset range from 5 to 30 weeks of initiation of therapy. Weekly or biweekly CBCs are recommended initially.

(2) For liver, toxicity time between initiation of treatment and diagnosis of these cases ranges from 2 to 3 weeks after initiation of therapy. It is recommended that liver function tests be performed before initiation of therapy to identify patients who have evidence of preexisting liver damage. Liver function tests should also be performed weekly or biweekly. The FDA recommends that this drug be used only in patients who are refractory to other medications and in whom the risk–benefit relationship warrants its use.

(3) Adverse effects:

(a) Contact the physician if signs of infection (e.g., bleeding or bruising) occur.

(b) This drug has the potential to cause aplastic anemia (bone marrow).

(c) The patient should be monitored for these toxicities by CBCs and liver function tests weekly or biweekly until discontinuation of any sign of these toxicities occurs.

(d) CNS effects are insomnia, headache, anxiety, hyperactivity, and fatigue.

(e) Cardiovascular effects are peripheral edema, vasodilation, hypotension, and hypertension.

(f) Ocular effects are diplopia and blurred vision.

(g) GI effects are anorexia, weight decrease, and nausea.

(h) Hematological effects may include lymphadenopathy, leukopenia, and thrombocytopenia.

(i) Metabolic/nutrition effects may include hypokalemia and hyponatremia.

(j) QT prolongation and torsade de pointes

d. Significant interactions

(1) Felbamate and phenytoin. Felbamate causes an increase in phenytoin plasma concentration. Phenytoin doubles felbamate clearance, resulting in 45% decrease in felbamate levels.

(2) Felbamate and carbamazepine. Felbamate causes a decrease in carbamazepine levels and an increase in carbamazepine metabolites. In addition, carbamazepine causes a 50% increase in felbamate clearance, resulting in a 40% decrease in steady-state trough levels.

(3) Felbamate and valproic acid. Felbamate causes an increase in valproic acid levels, but valproic acid does not affect felbamate levels.

(4) Adverse effects. Signs and symptoms associated with increased plasma level and toxicity are anorexia, nausea, vomiting, insomnia, and headache.

10. **Gabapentin (Neurontin)**
    a. **Mechanism of action.** It is an analog of GABA. It increases GABA turnover, but it does not bind to GABA or any other established neurotransmitter receptor. Its mechanism of action is currently unknown, although it binds to a specific receptor in the brain and inhibits voltage-dependent sodium currents. It has been shown to be effective as an add-on drug in patients with partial seizure with or without secondary generalization.
    b. **Administration and dosage** (*Table 37-7*)
        (1) Patients **> 12 years** receive 900 mg to 1.8 g daily, administered as adjunctive therapy in three divided doses. Titrating to an effective dose normally can be achieved within 3 days by initiating therapy with 300 mg and then increasing the dose in 300-mg increments over the next 2 days to establish a dosage of 900 mg daily in three doses. If necessary, the dosage may be increased to 1.8 g daily. To minimize potential side effects, especially somnolence, dizziness, or fatigue, the first dose on day 1 may be administered at bedtime.
        (2) Patients 3 to 12 years of age should receive 10 to 15 mg/kg/day in three divided doses up to 25 to 50 mg/kg/day.
        (3) The drug is primarily excreted renally; therefore, the dosage should be adjusted for patients who have compromised renal function.
        (4) The drug does not bind to plasma protein. There are no significant pharmacokinetic interactions with other commonly used antiepileptic drugs.
        (5) If gabapentin is discontinued or an alternate anticonvulsant medication is added, it should be done gradually over a minimum of 1 week.
    c. **Precautions and monitoring effects**
        (1) Gabapentin is useful in patients who are taking other medications for epilepsy or other chronic diseases. It may be especially useful for elderly patients.
        (2) Gabapentin is well absorbed orally; it can be taken with or without food. However, patients who have GI problems might have problems with absorption.
        (3) Taper off over at least 1 week; may cause withdrawal symptoms such as anxiety, insomnia, and nausea.
        (4) May cause false-positive result with some urinary protein tests
        (5) **Adverse effects:**
            (a) Common side effects are somnolence, dizziness, ataxia, fatigue, weight gain, and nystagmus.
            (b) **CNS effects** are somnolence, dizziness, ataxia, and fatigue.
            (c) **GI effects** include dyspepsia, dryness of mouth, constipation, and increased appetite.
            (d) **Ocular effects** are diplopia, blurred vision, and nystagmus.
            (e) **Cardiovascular**: congestive heart failure, hypertension/hypotension
            (f) **Dermatologic**: Dry skin, fungal dermatitis, herpes infection, Steven–Johnson syndrome
            (g) **Endocrine:** diabetes melitus
        (6) **REM program**
            (a) To inform patients of the potential risk of suicidal thoughts and behavior that could occur during treatment.
            (b) **Medication Guide** must be dispensed with this product.
    d. **Significant interactions**
        (1) **Antacids and gabapentin.** Antacids reduce the bioavailability of gabapentin by 20%; gabapentin could be taken 2 hrs after antacid use.
        (2) **Cimetidine and gabapentin.** Cimetidine decreases the renal excretion of gabapentin by 14% and consequently increases gabapentin plasma levels (however, this amount is not clinically significant).
        (3) **Oral contraceptives and gabapentin.** Oral contraceptives increase the level of norethindrone by 13%; this amount may not be clinically significant.
11. **Lamotrigine (Lamictal)**
    a. **Mechanism of action.** Its antiepileptic effect is similar to that of phenytoin. Its effect may be the result of inhibition of voltage-dependent sodium currents and reduction of sustained repetitive neuronal activity. It is indicated for the treatment of partial seizures and secondary generalized

tonic–clonic seizures that are not controlled with other drugs. It is also used to treat Lennox–Gastaut syndrome. Lamotrigine is broad spectrum, as well tolerated as monotherapy, and probably the least teratogenic of the first-line agents. It may aggravate severe myoclonic epilepsy.

b. Administration and dosage (*Table 37-7*)

   (1) Adults ($>$ 16 years), initially 50 mg/day in two divided doses (patients taking valproic acid should be given 25 mg every other day), up to 100 mg/day (up to 25 mg daily with valproic acid treatment). Monotherapy: 9 (Adults-12 years) 25 mg daily for 14 days, 50 mg for 14 days, up to 500 mg daily.

   (2) Children 2 to 12 years 0.6 mg/kg/day in two divided doses (0.15 mg/kg/day on valproic acid treatment), up to 1.2 mg/kg/day (up to 0.3 mg/kg/day with valproic acid treatment).

   (3) The smallest available chewable dispersible tablet is 5 mg. Then, after 2 weeks, increase by 0.3 mg/kg/day in one to two divided doses, up to 200 mg/day.

   (4) Swallow chewable dispersible tablet whole, chewed, or in dispersing water or diluted fruit juice. If chewed, consume a small amount of water or diluted fruit juice to aid in swallowing. To disperse, add the chewable dispersible tablet to a small amount of liquid (1 teaspoon or enough to cover the medication). Approximately 1 min later, when the tablet is completely dispersed, swirl the solution and consume the entire quantity immediately.

   (5) For patients taking valproic acid, the initial dose is 50 mg daily for 2 weeks, followed by maintenance doses of 100 to 200 mg daily in two divided doses.

   (6) Reduced clearance in the elderly necessitates dosage reduction.

   (7) Patients with hepatic impairment may require dosage reduction because of reduction in metabolism.

c. Precautions and monitoring effects

   (1) Caution should be used for patients taking this drug. It may adversely affect the patient's metabolism or complicate the elimination of the drug because of renal, hepatic, or cardiac impairment.

   (2) Lamotrigine binds to melanin and can accumulate in melanin-rich tissue over time. Periodic ophthalmological monitoring is recommended.

   (3) Photosensitization (photoallergy and phototoxicity) patients should take protective measures against exposure to ultraviolet light or sunlight.

   (4) Serious rashes requiring hospitalization have been reported. The incidence of rashes, including Stevens–Johnson syndrome, is approximately 1% in patients $<$ 16 years old and 0.3% in adults. Rare cases of toxic epidermal necrolysis or rash-related death have occurred. Most rashes occur within 2 to 8 weeks of initial treatment.

   (5) Adverse effects:

      (a) The most common side effects are dizziness, diplopia, ataxia, blurred vision, nausea, dose-related rash, and vomiting.

      (b) CNS effects are headache, dizziness, and ataxia tics (in children).

      (c) GI effects are nausea, vomiting, diarrhea, and dyspepsia.

      (d) Ocular effects are diplopia, blurred vision, and vision abnormality.

      (e) Dermatological effects are pruritus, and a rash may form similar to that found when using phenytoin and carbamazepine. In many cases, the rash disappears during continued therapy, but 1% to 2% of patients with the rash represent a more serious allergic reaction. Occasionally, patients have developed the Stevens–Johnson syndrome. Concomitant use with valproic acid may increase the likelihood of serious rash. The occurrences of life-threatening rash that were reported developed within 2 to 8 weeks following therapy; other cases of rash have been reported developing up to 6 months after therapy. The incidence of rash is higher in children than in adults.

      (f) Monotherapy during pregnancy found no teratogenic effect.

d. Significant interactions

   (1) Carbamazepine decreases lamotrigine concentration by 70% and increases carbamazepine levels.

   (2) Phenobarbital or primidone decreases lamotrigine concentration by 40%.

   (3) Valproic acid decreases the metabolism of lamotrigine and extends its half-life to 60 hrs, which necessitates a dose reduction.

12. **Topiramate (Topamax)**
    a. **Mechanism of action.** Topiramate is a derivative of fructose. It decreases rapid hippocampal neuronal firing, possibly because of sodium- or calcium-channel inhibition. It is also a weak carbonic anhydrase inhibitor and a sodium-channel blocking agent. Topiramate potentiates the activity of GABA. It has been shown to be effective adjunctive therapy for partial seizure treatment in adults, tonic–clonic seizure, infantile spasms, and Lennox–Gastaut syndrome.
    b. **Administration and dosage** (*Table 37-7*)
       (1) **Adults** 17 years and older, 25 to 50 mg/day, up to 400 mg/day in two divided doses. **Children** 2 to 16 years, 1 to 3 mg/kg/day, up to 5 to 9 mg/kg/day in two divided doses.
       (2) Topiramate is 80% bioavailable, and food does not affect its bioavailability.
       (3) Dose adjustment is necessary for patients with renal or hepatic impairments.
       (4) Enzyme-inducing anticonvulsive drugs can decrease topiramate levels, but topiramate has a significant effect on metabolism of other anticonvulsive drugs.
       (5) Initial treatment is 50 mg daily, followed by titration to an effective dosage. More than 400 mg daily has not been shown to improve response.
    c. **Precaution and monitoring effects**
       (1) Increased incidence of kidney stones (renal calculus) in older patients who received this drug. Patients should be advised to increase intake of fluids while taking topiramate.
       (2) Paresthesia is a common side effect of anhydrase inhibitors.
       (3) Due to effect of topiramate, renal bicarbonate loss and metabolic acidosis could occur.
       (4) Topiramate could cause oligohidrosis and hyperthermia (decrease sweating and increase temperature).
       (5) Acute myopia with secondary angle closure glaucoma could occur, typically occur within 1 month of therapy in which the drug should be discontinued**.**
       (6) **Adverse effects**
          (a) The physician should be notified if any of the following adverse effects occur:
              (i) Breast pain in females
              (ii) Nausea or tremor, which are dose-related side effects.
              (iii) Back pain, chest pain, dyspepsia, or leg pain
          (b) **CNS effects** mostly seen in 600 mg/day dose include psychomotor slowing, difficulty with concentration and speech, somnolence, fatigue, asthenia, weight loss, cognitive disturbances and difficulties, tremors, dizziness, ataxia, and headache.
          (c) **GI effects** include upset, such as nausea, vomiting, and gastroenteritis.
          (d) **Genitourinary effects** polyuria, oliguria and renal calculi.
          (e) **Cardiovascular effects** include chest pain, palpitation, and vasodilation.
          (f) **Ocular effects** include abnormal vision, eye pain, diplopia, and glaucoma.
          (g) **Hematological effects** include anemia, epistaxis, leukopenia, and aplastic anemia.
          (h) **Other**: metabolic acidosis, hypohidrosis (in children)
       (7) **REM program**
          (a) To inform patients of the potential risk for adverse effects, including suicidal thoughts and behavior and teratogenic effects (i.e., cleft lip, cleft palate), that may occur during treatment.
          (b) **Medication Guide** must be dispensed with this product.
    d. **Significant interactions**
       (1) Phenytoin and carbamazepine will increase clearance.
       (2) Topiramate increases the clearance of other drugs that are cleared by cytochrome P450.
13. **Tiagabine (Gabitril)**
    a. **Mechanism of action.** Tiagabine is designed to act on the inhibitory action of GABA by blocking its uptake, thereby prolonging its action after synaptic release. It is indicated as adjunctive therapy for partial seizures.
    b. **Administration and dosage** (*Table 37-7*)
       (1) Starting dose of 4 mg daily for 2 weeks may be increased 4 to 8 mg weekly thereafter, to a maintenance dose of 32 to 56 mg daily.
       (2) Maximum recommended dosage for **children** is 32 mg daily; maximum recommended dosage for **adults** is 56 mg daily.

(3) A high-fat meal decreases the rate of tiagabine absorption but does not affect the extension of absorption. Tiagabine should be taken with food.

c. Precautions and monitoring effects

(1) Moderately severe to severe **generalized weakness** has been reported. It resolves in all cases after reduction in dose or discontinuation of therapy.

(2) **Ophthalmic effects**, as indicated by animal studies, include the possibility for residual binding to retina and melanin binding; this finding, however, has not been confirmed in human studies. Periodic ophthalmological monitoring is necessary.

(3) **Dermatological effects** include the possibility of severe rash to Stevens–Johnson syndrome, as reported in clinical studies.

(4) **Sudden unexpected death** have been reported (as many as 10 cases) among 2531 patients with epilepsy (3831 patient years of exposure).

(5) **EEG abnormalities.** Spike and wave discharges on EEG have been reported to have exacerbations of their EEG abnormalities associated with cognitive/neuropsychiatric events. Patients usually continued tiagabine but required dosage adjustment.

(6) **Adverse effects**

(a) **CNS effects** are confusion, dizziness, and fatigue.

(b) **GI effects** are upset stomach, nausea, mouth ulceration, and anorexia.

(7) **REM program**

(a) To raise awareness of the risk of suicidal thoughts and behavior that could occur during treatment. There have also been case reports of seizures in patients without a history of epilepsy who were receiving **tiagabine** for unapproved indications.

(b) **Medication Guide** must be dispensed with this product.

d. Significant interactions. Phenobarbital, phenytoin, and carbamazepine will increase tiagabine clearance.

14. Zonisamide (Zonegran)

a. Mechanism of action. It is not well known. It may block the sensitive sodium channels and T-type calcium channels. It is indicated for adjunct therapy for partial seizure for adults.

b. Administration and dosage (*Table 37-7*)

(1) **Adults and children** $>$ 16 years of age, 100 mg daily; within 2 weeks, increase to 200 mg/daily in 2-week bases, up to 600 mg daily.

(2) Can be taken with or without food.

c. Precautions and monitoring effects

(1) **Potentially fatal reactions to sulfonamides.** Fatalities have occurred, although rarely, as a result of severe reactions to sulfonamides (a sulfonamide) including Stevens–Johnson syndrome, toxic epidermal necrolysis, fulminant hepatic necrosis, agranulocytosis, aplastic anemia, and other blood dyscrasias.

(2) **Serious hematologic events.** Very rare cases of aplastic anemia and agranulocytosis were reported.

(3) **Cognitive/neuropsychiatric adverse reactions.** The most significant of these can be classified into three general categories: (1) psychiatric symptoms, including depression and psychosis; (2) psychomotor slowing, difficulty with concentration, and speech or language problems, in particular, word-finding difficulties; and (3) somnolence or fatigue.

(4) **Creatine phosphokinase (CPK) elevation and pancreatitis.** Rare adverse events have been observed (less than 1:1000). Severe muscle pain and/or weakness, either in the presence or absence of a fever, markers of muscle damage should be assessed, including serum CPK and aldolase levels, consideration should be given to tapering and/or discontinuation of zonisamide.

(5) **Kidney stones** have been reported in 4% of patients in clinical trials.

(6) May increase mean concentration of serum creatinine and blood, urea, nitrogen; renal function should be monitored periodically.

(7) **Sudden unexplained death in epilepsy.** Nine sudden unexplained deaths occurred among 991 patients with epilepsy (representing 7.7 deaths per 1000 patient years).

(8) Oligohidrosis and hyperthermia have been reported in pediatric patients.

(9) Side effects

    (a) CNS effects are dizziness, headache, somnolence, ataxia, confusion, tremor, and abnormal thinking.

    (b) Cardiovascular effects are palpitation, tachycardia, and vascular insufficiency.

    (c) Dermatologic effects are maculopapular rash, acne, alopecia, and photosensitivity.

    (d) Other effects: nausea, agitation/irritability

(10) REM program

    (a) To communicate the increased risk of suicidal thoughts and behavior associated with treatment.

    (b) Medication Guide must be dispensed with this product.

d. Significant interactions

    (1) Zonisamide induces **liver enzymes** by increasing metabolism and through clearance of zonisamide and decreases half-life.

    (2) Food will delay absorption but will not affect the bioavailability of the drug.

15. Levetiracetam (Keppra)

  a. Mechanism of action. It is a pyrrolidone derivative and is chemically unrelated to other antiepileptic drugs. It displays inhibitory properties in the kindling model in rats. It is used as adjunctive therapy in the treatment of partial seizure, myoclonic, and generalized seizure.

  b. Administration and dosage (*Table 37-7*)

    (1) Adult 16 and older. Starting dose of 1000 mg/day given in two divided doses may be increased every 2 weeks, to a maximum of 3000 mg/day.

    (2) Children 4 to 16 years of age. Initiate therapy with 10 mg/kg twice daily; dose may be increased by 20 mg/kg daily every 2 weeks (maximum, 30 mg/kg twice daily).

  c. Precautions and monitoring effects

    (1) Hematological effects are minor, but there is a statistically significant decrease compared to placebo in total mean RBC count, mean hemoglobin, and mean hematocrit.

    (2) Decrease in WBC count and neutrophil count.

    (3) It also causes drowsiness.

    (4) Adverse effects

      (a) Most commonly reported adverse events are somnolence, weakness (asthenia), hostility, infection, and fatigue.

      (b) CNS effects are somnolence, dizziness, depression, and nervousness.

      (c) Dermatologic: pruritis, skin discoloration, rash, and alopecia

      (d) Respiratory effects are pharyngitis, rhinitis, and increased cough.

  d. Significant interactions. Levetiracetam does not influence the **plasma concentration** of existing antiepileptic drugs, and other **antiepileptic drugs** do not influence the pharmacokinetic effects of levetiracetam.

16. Oxcarbazepine (Trileptal)

  a. Mechanism of action. This drug produces blockade of voltage-sensitive sodium channels, resulting in stabilization of hyperexcited neural membranes, inhibition of repetitive neuronal firing, and diminution of propagation of synaptic impulses. These actions are thought to be important in the prevention of seizure spread in the intact brain. In addition, increased potassium conductance and modulation of high-voltage activated calcium channels may contribute to the anticonvulsant effects of the drug. Indicated for partial seizures in adults and as monotherapy in the treatment of partial seizures in children 4 years of age and older with epilepsy, and as adjunctive therapy in children 2 years of age and older with epilepsy.

  b. Administration and dosage (*Table 37-7*)

    (1) Children 4 to 16 years, 8 to 10 mg/kg/day to 600 mg/day as adjunctive therapy and 8 to 10 mg/kg/day as monotherapy.

    (2) Adults 600 mg/day as adjunctive therapy and 1200 mg/day as monotherapy. A dosage adjustment is needed for patients with renal failure; no dosage adjustment is needed for patients with mild to moderate hepatic impairment.

    (3) Can be taken with or without food.

   c. Precaution and monitoring effects
- **(1)** Clinically significant **hyponatremia** (sodium < 125 mmol/L) can develop during therapy.
- **(2)** **Serious dermatological reactions** including Stevens–Johnson syndrome and toxic epidermal necrolysis have been reported in children and adults.
- **(3)** **Adverse effects**
  - **(a)** **CNS effects** are dizziness, somnolence, headache, ataxia, fatigue, cognitive symptoms (psychomotor slowing, difficult concentrating) and vertigo.
  - **(b)** **GI effects** are vomiting, nausea, and abdominal pain.
  - **(c)** **Neuromuscular and skeletal effects** are abnormal gait and tremor.
  - **(d)** **Ocular effects** are diplopia, nystagmus, and abnormal vision.
  - **(e)** **Endocrine and metabolic effects** common in elderly include hyponatremia (low level of sodium in the blood).
  - **(f)** **Dermatologic:** rash

   d. Significant interactions
- **(1)** Oxcarbazepine inhibits **cytochrome P450 2C19** and induces **cytochrome P450 3A4/5** with potentially important effects on plasma concentrations of other drugs.
- **(2)** Serum concentrations of **phenytoin** and **phenobarbital** are increased.
- **(3)** It decreases **oral contraceptive** effects, benzodiazepine, and calcium-channel blockers.
- **(4)** Cross-sensitivity with **carbamazepine** (25% to 30%).

17. Lacosamide (Vimpat)

   a. Mechanism of action
- **(1)** Enhances the slow inactivation of voltage-gated sodium channels and binding collapsing response mediator protein 2
- **(2)** It is water soluble (20 mg/mL)
- **(3)** Completely orally bioavailable

   b. Administration and dosage
- **(1)** **Adults.** Initially, 50 mg twice daily (100 mg/day). The dose may be increased, at weekly intervals by 100 mg/day given as two divided doses to a daily dose of 200 to 400 mg/day. The safety and effectiveness in children younger than 17 of age have not been established.
- **(2)** **Oral-intravenous replacement therapy.** When switching from oral dose, the initial total daily intravenous dosage should be equivalent to the total daily dosage and frequency of oral dose.

   c. Precaution and monitoring effects
- **(1)** <u>Suicidal behavior and ideation:</u> observed as early as 1 week after starting treatment.
- **(2)** <u>Cardiovascular effects:</u>
  - **(a)** **PR interval prolongation.** Dose-dependent, asymptomatic AV block was observed in 0.4% of patients who received drug.
  - **(b)** Atrial fibrillation and flutter observed in 0.5% of patients who been treated with lacosamide.
- **(3)** <u>Syncope:</u> observed in 1.2% patients who been treated with lacosamide, mostly in patients who received dosage above 400 mg/day.
- **(4)** **Side effects:** dizziness, headache, diplopia, nausea and vomiting, ataxia, vertigo, blurred vision, and rash.
- **(5)** **REM program**
  - **(a)** To inform patients of the potential risk of suicidal thoughts and behavior that could occur during treatment.
  - **(b)** **Medication Guide** must be dispensed with this product.

   d. Significant interactions
- **(1)** Does not effect plasma concentration of concomitant anticonvulsive medications.
- **(2)** Low potential for drug–drug interaction.

18. Rufinamide (Banzel). Does not effect the plasma concentration of other antiseizure drugs.

   a. Mechanism of action
- **(1)** Limits excessive firing of sodium-dependent action potentials, in particular prolongation of the inactive state of the channel.
- **(2)** Its oral bioavailability increases when administrated with food.

    b. **Administration and dosage**
      (1) **Adults.** Initially, 400 to 800 mg every 2 days until the maximum daily dosage of 3200 mg daily (administered in two equally divided doses).
      (2) **Children.** Four years and older, initially 10 mg/kg increments every other day to a target dosage of 45 mg/kg/day or 3200 mg/day (administered in two equally divided doses).
    c. **Precaution and monitoring effects**
      (1) Suicidal behavior and ideation observed as early as 1 week after starting treatment.
      (2) **Cardiovascular effects.** Shortening of the QT interval (up to 20 msec)
      (3) Multiorgan hypersensitivity reactions such as rash and fever.
      (4) **Adverse effects:** dizziness, nausea, diplopia and ataxia, oligomenorrhea, lymphadenopathy, and hematuria.
      (5) **REM program**
        (a) To inform patients of the potential risk of suicidal thoughts and behavior that could occur during treatment.
        (b) **Medication Guide** must be dispensed with this product.
    d. **Significant interactions**
      (1) Does not effect plasma concentration of concomitant anticonvulsive of medications.
      (2) Low potential for drug–drug interaction.
  19. **Vigabatrin (Sabril)**
    a. **Mechanism of action**
      (1) Irreversible inhibition of GABA-transaminase responsible for the catabolism of GABA.
    b. **Administration and dosage**
      (1) **Adults and 16 years of age:** Initially, 1000 mg daily (in two divided dosage); total daily dose could be increased in 500-mg increments at weekly intervals depending on response.
      (2) **16 years of age and older:** same as adult dosage administration
    c. **Precaution and monitoring effects**
      (1) Vision loss and peripheral visual field defect observed in 30% of adult population. In some cases, it could damage the central retina and may decrease visual acuity. A baseline vision testing should be conducted not later than 4 weeks after starting vigabatrin and then followed every 3 months. The onset of vision loss and occurrence of it varies and cannot be predicted. The vision loss is irreversible and may get worse after discontinuation of the therapy. If the patient does not show substantial clinical benefit with 2 to 4 weeks of initiation when used in children and in adult as within 3 months, the drug should be discontinued.
      (2) Abnormal magnetic resonance imaging (MRI) signal changes characterized by increased T2 signal and restricted diffusion in a symmetric pattern involving deep gray matter areas of the brain (thalamus, basal ganglia, brainstem, cerebellum) have been reported in some infants receiving vigabatrin for infantile spasms; these abnormalities are generally transient and resolves upon drug discontinuation.
      (3) Adverse effect: are somnolence, fatigue, light-headedness, peripheral neuropathy, and anemia. Depression developed in 12% of patients. There were no significant cognitive adverse effects.
      (4) **REM program**
        (a) To increase awareness and reduce risks of treatment, including vision loss and suicidal thoughts and behavior.
        (b) The FDA-approved REM program includes a medication guide, communication plan, elements to ensure safe use, and implementation system requiring prescriber and pharmacy certification and patient enrollment.
    d. **Significant interactions**
      (1) Does not effect plasma concentration of concomitant anticonvulsive of medications.
      (2) Suppresses ALT and AST enzyme activity in up to 90% of the patient's which may preclude the use of these tests to detect hepatic injury.
  20. **Less common drugs** are listed in *Table 37-8*.
  21. **Vagus nerve stimulation (VNS)**
    a. It is used as adjunctive therapy for adults and children > 12 years of age whose partial seizures are refractory to antiepileptic medications.

Table 37-8   LESS COMMON DRUGS USED IN PRACTICE

Drug	Labeled Indication	Half-Life (hr)	Total Plasma Concentration (mg/L)	Therapeutic Range of Adult Dose (mg/day)	Usual Mode of Elimination	Major Protein Binding Level
Mephobarbital	• Grand mal • Petit mal • Gets converted to phenobarbital • Indicated when phenobarbital must be decreased because of excessive drowsiness • Hyperexcitability • Mood disturbances	11–67	n/a	400–600	Liver	40–60
Mephenytoin	• Tonic–clonic • Psychomotor • Status epilepticus • Used with phenytoin; together more sedative compared to phenytoin alone	95 (active metabolite)	n/a	200–600	Liver > renal	90
Ethotoin	• Tonic–clonic • Psychomotor • Used as second-line therapy; less toxic and less effective than phenytoin (alone or combined)	3–9[a]	15–50	2000–3000	Liver	n/a
Methsuximide	• Absence • Does not precipitate tonic–clonic (compared to other succinimides)	2–40[b]	n/a	1200	Liver	n/a
Phensuximide	• Absence • Less toxic and less effective compared to other succinimides	8[b]	n/a	1000–3000	Urine, bile	n/a
Paramethadione[c]	• Absence • Useful when other seizures exist with absence seizure • *Note:* Do not use with mephenytoin	n/a	n/a	900–2400	Liver ≥ renal	n/a
Trimethadione[c]	• Absence • Useful when other seizures exist with absence seizure • *Note:* Do not use with mephenytoin	6–13 days	≥ 700	900–2400	Liver	0
Pregabalin	• Simple partial seizure	6	n/a	150–600	Renal	0

[a]At high doses, nonlinear kinetic like phenytoin.
[b]Active metabolite.
[c]Possible fetal malformation if used during pregnancy.

    b. A programmable signal generator that is implanted in the patient's left upper chest has a bipolar VNS lead that connects the generator to the left vagus nerve in the neck, a programming wand that uses radio-frequency signals to communicate noninvasively with the generator, and handheld magnets used by the patient or caregiver to manually turn the stimulator on or off.

    c. The implantation procedure usually lasts 1 hr under general anesthesia. Once programmed, the generator will deliver intermittent stimulation at the desired setting until any additional programming is entered.

C. Surgery. If seizures do not respond to drug therapy, surgery may be performed to remove the epileptogenic brain region. The most common is cortical excision (lobectomy). Between 70% and 80% of patients who have anterior temporal lobectomy have fewer seizures. Between 30% and 40% patients who have frontal lobectomy have fewer seizures.

    1. Indications for surgery are intractable or disabling seizures recurring for 6 to 12 months. Should be considered for patients with medically refractory seizures.

    2. In **stereotaxic surgery**, the surgeon uses three-dimensional coordinates to guide a needle through a hole drilled in the skull, then destroys abnormal pathways via small intracerebral incisions.

    3. Other surgical approaches include temporal lobe resection, removal of the temporal lobe tip, and cerebral hemispherectomy.

III. COMPLICATIONS

A. Convulsive status epilepticus. This disorder is characterized by rapid repetition of generalized tonic–clonic seizures with no recovery of consciousness between seizures. This life-threatening condition may persist for hours or even days; if it lasts longer than 1 hr, severe permanent brain damage may result.

    1. Causes of status epilepticus include poor therapeutic compliance, intracranial infection or neoplasm, alcohol withdrawal, drug overdose, and metabolic imbalance.

    2. Management

        a. A patent airway must be maintained.

        b. If the cause of the condition is unknown, dextrose 50% in water (25 to 30 mL) is given via IV in case hypoglycemia is the cause.

        c. If the seizures persist, **diazepam** (10 mg) is administered via IV at a rate not exceeding 2 mg/min until the seizures stop or 20 mg has been given.

        d. Phenytoin or fosphenytoin is then administered via IV no faster than 50 mg/min to a maximum dose of 11 to 18 mg/kg. Blood pressure is monitored to detect hypotension.

        e. If these measures do not stop the seizures, one of the following drugs is given:

            (1) Diazepam is given as an IV drip of 50 to 100 mg diluted in 500 mL dextrose 5% in water, infused at 40 mL/hr until the seizures stop.

            (2) Phenobarbital is given as an IV infusion of 8 to 20 mg/kg no faster than 100 mg/min.

        f. If seizures continue despite these measures, one of the following steps is then taken:

            (1) Paraldehyde is given via IV in a dosage of 0.10 to 0.15 mL/kg diluted to a 4% solution in normal saline solution.

            (2) Lidocaine is given in an IV loading dose of 50 to 100 mg, followed by an infusion of 1 to 2 mg/min.

            (3) General anesthesia is induced with ventilatory assistance and neuromuscular junction blockade.

B. Nonconvulsive status epilepticus. This condition presents as repeated absence seizures or complex partial seizures. The patient's mental state fluctuates; confusion, impaired responses, and automatisms are prominent. **Initial management** typically involves intravenous diazepam. Complex partial status epilepticus may also necessitate administration of such drugs as phenytoin or phenobarbital.

IV. SEIZURE DISORDER AND PREGNANCY

A. Epidemiology. About 0.5% of all pregnancies occur in women with epilepsy.

B. Preconception counseling. The risks for mother and fetus should be discussed, including the risks of fetal malformation associated with antiepileptic drugs and other genetic factors.

C. **Drug therapy**
1. If the patient is seizure free for at least 2 years, withdrawal of the drug should be considered. If antiepileptic drug therapy is necessary, a switch to monotherapy should be made if possible.
2. Five antiepileptic medications have been used or studied in pregnant patients: carbamazepine, phenobarbital, phenytoin, primidone, and valproic acid. Monotherapy of lamotrigine during pregnancy found no teratogenic effect. Congenital malformations associated with these drugs include craniofacial abnormalities, cardiac defects, and neuronal tube defects. Most of the studies did not consider paternal genetic factors, environmental factors, drug dosing, or combination therapy.
3. Antiepileptic drugs interfere with folate metabolism. Administration of folic acid, 4 mg daily, and multivitamins decreases the risk of malformation, especially of the neuronal tube.
4. Vitamin K, 10 mg/day for the last 1 to 2 months of gestation, will help prevent neonatal hemorrhage, especially in cases of phenytoin or phenobarbital use.
5. **Seizure disorder and oral contraceptives.** Gabapentin, levetiracetam, ethosuximide, valproate, zonisamide, pregabalin, vigabatrin, and tiagabine do not affect the efficacy of oral contraceptives.
6. **Seizure disorder and the elderly population.** The new generation of antiepileptic drugs such as levetiracetam and gabapentin may be more useful owing to low levels of protein binding and safer side effects. Also, the newer agents have less potential for drug interactions than agents eliminated from the liver.

D. **Monitoring**
1. Free serum antiepileptic drug levels should be monitored monthly, immediately before the next dose, and the dose should be adjusted to the lowest dose providing adequate control.
2. Serum α-fetoprotein levels should be checked, and ultrasonography should be performed at 16 weeks of gestation to evaluate for fetal neuronal tube defects. An alternative to these tests is amniocentesis, especially if the mother is taking valproate or carbamazepine.
3. Comprehensive ultrasonography should be performed at 18 and 22 weeks of gestation for patients taking antiepileptic drugs that cause cardiac anomalies.
4. Intrapartum plans should include IV administration of a short-acting benzodiazepine. If there is concern about fetal or maternal respiratory depression, administering IV phenytoin or IM phenobarbital should be considered. Clotting studies should be performed, and 1 mg vitamin K should be given to the infant. Nurses and physicians should be alerted for possible hemorrhage of the infant and apprised that the infant may experience antiepileptic drug withdrawal.

Study Questions

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Phenytoin is effective for the treatment of all of the following types of seizures *except*
   (A) generalized tonic–clonic.
   (B) simple partial.
   (C) complex partial.
   (D) absence.
   (E) grand mal.

2. Which of the following anticonvulsants is contraindicated in patients with a history of hypersensitivity to tricyclic antidepressants?
   (A) phenytoin
   (B) ethosuximide
   (C) acetazolamide
   (D) carbamazepine
   (E) phenobarbital

3. Which anticonvulsive drug requires therapeutic monitoring of phenobarbital serum levels as well as its own serum level?
   (A) phenytoin
   (B) primidone
   (C) clonazepam
   (D) ethotoin
   (E) carbamazepine

4. Which anticonvulsive drug treatment has a higher incidence of kidney stones?

   (A) phenytoin
   (B) carbamazepine
   (C) topiramate
   (D) tiagabine

5. What are the most common adverse effects of anticonvulsive drugs?

   (A) headache and dizziness
   (B) gastrointestinal symptoms
   (C) alternation of cognition and mentation
   (D) adverse effects on appetite and body weight
   (E) all of the above

6. Which antiepileptic drug has the least effect on the efficacy of oral contraceptives?

   (A) phenytoin
   (B) tiagabine
   (C) gabapentin
   (D) lamotrigine
   (E) C and D

7. Which of the following drugs could cause hyponatremia?

   (A) carbamazepine
   (B) phenytoin
   (C) oxcarbazepine
   (D) felbamate
   (E) topiramate
   (F) A, C, and D

Answers and Explanations

1. **The answer is D** *[see II.B.2.a.(2)]*.
   Phenytoin (diphenylhydantoin) is the most commonly prescribed hydantoin for seizure disorders. It is one of the preferred drugs for generalized tonic–clonic (grand mal) seizures and for partial seizures, both simple and complex. However, phenytoin is not effective for absence (petit mal) seizures.

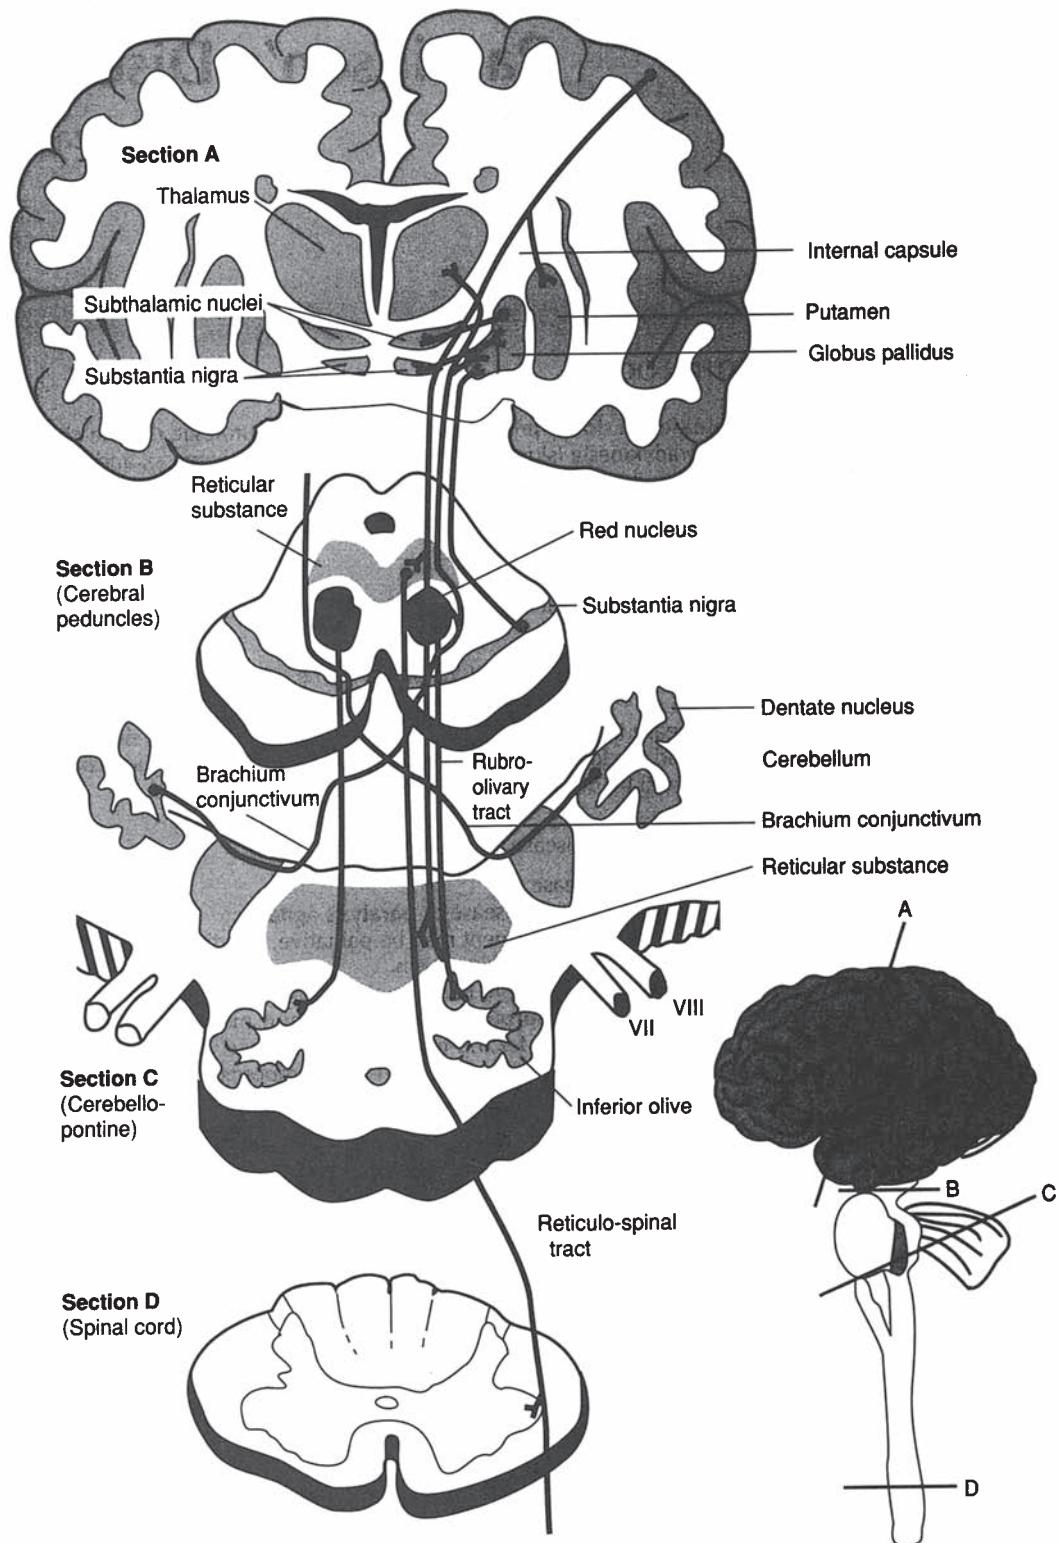
2. **The answer is D** *[see II.B.1.c.(2)]*.
   Carbamazepine is structurally related to the tricyclic antidepressants (e.g., amitriptyline, desipramine, imipramine, nortriptyline, protriptyline) and should not be administered to patients with hypersensitivity to any of the tricyclic antidepressants.

3. **The answer is B** *[see II.B.5–6]*.
   Primidone's antiseizure activity may be partly attributable to phenobarbital. In patients receiving primidone, serum levels of both primidone and phenobarbital should be measured.

4. **The answer is C** *[see II.B.12]*.
   There is a higher incidence of kidney stones (renal calculus) with topiramate administration.

5. **The answer is E** *[see I.B.1–9]*.
   Alternation in cognition and mentation, gastrointestinal symptoms, appetite and body weight, and headache and dizziness are all common adverse effects of anticonvulsive drugs.

6. **The answer is E** *[see IV.C.5]*.
   Gabapentin and lamotrigine do not increase the metabolism of oral contraceptives to a clinically significant level; therefore, they could be used with oral contraceptives.

7. **The answer is F** *[see II.B.1; II.B.9; II.B.16]*.
   Carbamazepine, oxcarbazepine, and felbamate all cause hyponatremia.


Parkinson Disease

AZITA RAZZAGHI

I. DISEASE STATE AND PATHOLOGY

A. **Definition.** Parkinson disease is a slowly progressive degenerative neurological disease characterized by tremor, rigidity, bradykinesia (sluggish neuromuscular responsiveness), and postural instability. Parkinson disease was first described by Dr. James Parkinson in 1817 as "shaking palsy."

B. **Incidence**
   1. It has a prevalence of 1 to 2 per 1000 of the general population and 2 per 100 among people > 65 years.
   2. Onset generally occurs between age 50 and 65; it usually occurs in the 60s.

C. **Pathogenesis.** Parkinson disease is a neurodegenerative disease associated with **depigmentation of the substantia nigra** and the **loss of dopaminergic input to the basal ganglia** (extrapyramidal system); it is characterized by distinctive **motor disability**. The basal ganglia are responsible for initiating, sequencing, and modulating motor activity.
   1. In healthy individuals, dopamine is produced by neurons that project from the substantia nigra to the neostriatum (which includes caudate and putamen) and globus pallidus. In these areas, dopamine acts as an inhibitory neurotransmitter.
   2. Lewy bodies are widespread but occur especially in the basal ganglia, brainstem, spinal cord, and sympathetic ganglia.
   3. In Parkinson disease, the loss of dopamine-producing neurons in the substantia nigra results in an imbalance between dopamine, an inhibitory neurotransmitter, and the excitatory neurotransmitter acetylcholine. Alterations in the concentrations of other neurotransmitters, such as norepinephrine, serotonin, and γ-aminobutyric acid (GABA) are also involved in the pathophysiology of Parkinson disease (*Figure 38-1*).

D. **Cause**. Several forms of Parkinson disease have been recognized.
   1. **Primary (idiopathic) Parkinson disease**
      a. This is also called classic Parkinson disease or **paralysis agitans**.
      b. The cause is unknown; and although treatment may be palliative, the disease is incurable.
      c. Most patients suffer from this type of parkinsonism.
      d. **Hypotheses of neuronal loss** in idiopathic Parkinson disease are as follows:
         (1) **Absorption of highly potent neurotoxins (environmental)**, such as carbon monoxide, manganese, solvents, and *N*-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), which is a product of improper synthesis of a synthetic heroin-like compound. Exposure to these agents, alone or in combination with the neuronal loss of age, may be the cause of Parkinson disease.
         (2) **Exposure to the free radicals**. Normally, dopamine is catabolized by monoamine oxidase (MAO). Hydrogen peroxide and production of free radicals—both toxic to cells—are products of catabolism. Protective mechanisms, enzymes, and free radical scavengers, such as vitamins E and C, protect cells from damage. It is proposed that either a decrease in these protective mechanisms or an increase in the production of dopamine causes a destruction of the neurons by free radicals.
      e. **Genetics factors.** Genes that link to Parkinson disease, such as alpha-synuclein and parkin, are further being studied in treatment and diagnosis of Parkinson disease.

Figure 38-1. Extrapyramidal system involved in Parkinson disease. (Reprinted with permission from Netter F. *Ciba Collection of Medical Illustrations*. West Caldwell, NJ: Ciba Geigy Pharmaceuticals; 1983:69.)

2. Secondary parkinsonism—from a known cause

    a. Only a small percentage of cases are secondary, and many of these are curable.

    b. Secondary parkinsonism may be caused by drugs, including dopamine antagonists, such as the following:

        (1) Phenothiazines (e.g., chlorpromazine, perphenazine)

        (2) Butyrophenones (e.g., haloperidol)

        (3) Reserpine

    c. Poisoning by chemicals or toxins may be the cause; these include

        (1) Carbon monoxide poisoning

        (2) Heavy-metal poisoning, such as that by manganese or mercury

        (3) MPTP, a commercial compound used in organic synthesis and found (as a side product) in an illegal meperidine analog

    d. Infectious causes include

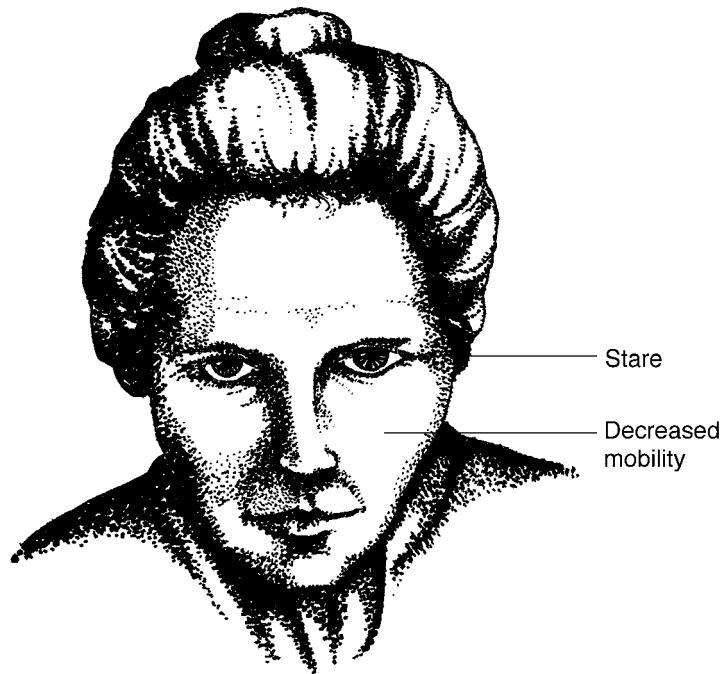
        (1) Encephalitis (viral)

        (2) Syphilis

    e. Other causes include

        (1) Arteriosclerosis

        (2) Degenerative diseases of the central nervous system (CNS), such as progressive supranuclear palsy

        (3) Metabolic disorders such as Wilson disease


E. Signs and symptoms

  1. Tremor

    a. Tremor may be the initial complaint in some patients. It is most evident at rest (**resting tremor**) and with low-frequency movement. When the thumb and forefinger are involved, it is known as the **pill-rolling tremor**. Before pills were made by machine, pharmacists made tablets (pills) by hand, hence the name (*Figure 38-2*).

    b. Some patients experience **action tremor** (most evident during activity), which can exist with or before the resting tremor develops.

  2. Limb rigidity is present in almost all patients. It is detected clinically when the arm responds with a ratchet-like (i.e., cogwheeling) movement when the limb is moved passively. This is owing to a tremor that is superimposed on the rigidity.

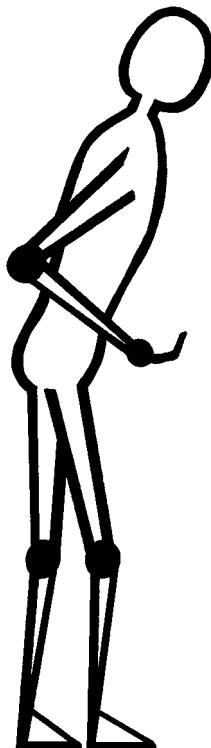
  3. Akinesia or bradykinesia. Akinesia is characterized by difficulty in initiating movements, and bradykinesia is a slowness in performing common voluntary movements, including standing,


Figure 38-2. Resting (or static) tremors. (Adapted from Bates B. *A Guide to Physical Examination and History Taking.* 5th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 1991:197.)

Figure 38-3. Masked face of Parkinson disease. (Adapted from Bates B. *A Guide to Physical Examination and History Taking.* 5th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 1991:197.)

walking, eating, writing, and talking. The lines of the patient's face are smooth, and the expression is fixed (**masked face**) with little evidence of spontaneous emotional responses (*Figure 38-3*).

4. **Gait and postural difficulties.** Characteristically, patients walk with a stooped, flexed posture; a short, shuffling stride; and a diminished arm swing in rhythm with the legs. There may be a tendency to accelerate or festinate (*Figure 38-4*).

5. **Changes in mental status.** Mental status changes, including depression (50%), dementia (25%), and psychosis are associated with the disease and may be precipitated or worsened by drugs.

Figure 38-4. Characteristic walk of patients with Parkinson disease. (Adapted from Bates B. *A Guide to Physical Examination and History Taking.* 5th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 1991:553.)

6. **Unified Parkinson disease rating scale (UPDRS)**
    a. **To evaluate the clinical efficacy** of antiparkinson drugs and **to monitor disease progression**, most investigators have used the UPDRS.
        (1) The disadvantages associated with the use of scales for rating the functional and motor disabilities of patients with Parkinson disease include the potential of interrater variability and imprecision because of the semiquantitative scoring.
        (2) The result of testing depends highly on the stage of the disease, whether the patient is being evaluated during an on or off period, and the relative distribution of the improvement across all the items evaluated.
    b. **Part I** of the UPDRS is an **evaluation of mentation**, **behavior**, and **mood**.
    c. **Part II** is a **self-reported evaluation of the activities of daily living (ADLs)** and includes speech, swallowing, handwriting, ability to cut food, dressing, hygiene, falling, salivating, turning in bed, and walking.
    d. **Part III** is a **clinician-scored motor evaluation**.
        (1) Patients are evaluated for speech, rest-tremor facial expression and mobility, action or postural tremor of hands, rigidity, finger taps, hand movements, rapid alternative pronation–supination movement of hands, leg agility, ease of arising from a chair, posture, postural stability, gait, and bradykinesia.
        (2) Each item is evaluated on a scale of 0 to 4.
            (a) **A rating of 0** on the motor performance evaluation scale indicates **normal performance**.
            (b) **A rating of 4** on the motor performance evaluation scale indicates **severely impaired performance**.
    e. **Part IV** is the **Hoehn and Yahr** staging of severity of Parkinson disease (*Table 38-1*).
    f. **Part V** is the **Schwab and England ADL scale**.
F. **Diagnosis**
    1. Diagnosis depends on clinical findings.
    2. Tests (including imaging) are most often used to rule out an origin of secondary Parkinson disease.
    3. New technologies—for example, positron emission tomography (PET) scan—are used to visualize dopamine uptake in the substantia nigra and basal ganglia. The PET scan measures the extent of neuronal loss in these areas.
    4. A specific form of single photon emission computed tomography (SPECT) can be helpful for diagnosis of parkinsonian syndromes and nonparkinsonian syndromes, particularly essential tremor.
    5. Other diseases that are similar to Parkinson disease are multiple system atrophy (striatonigral degeneration, olivopontocerebellar atrophy, Shy-Drager syndrome), corticobasal ganglionic degeneration, and progressive supranuclear palsy.
    6. **Other investigational diagnostic tools.** (1) transcranial ultrasound, (2) examine deficits in olfaction, and (3) detection of oligometric alpha-synuclein in blood of patients with Parkinson disease.
G. **Treatment** (*Figure 38-5*)
    1. **Nondrug treatment**
        a. **Exercise** is an important adjunctive therapy and is most beneficial. Although exercise does not help with the symptoms of Parkinson disease, regular focused exercise, stretching, and strengthening activities can have a positive effect on mobility and mood.

Table 38-1	STAGES OF PARKINSON DISEASE

Stage	Characteristics
0	No clinical signs evident
I	Unilateral involvement, including the major features of tremor, rigidity, or bradykinesia; minimal functional impairment
II	Bilateral involvement but no postural abnormalities
III	Mild to moderate bilateral disease, mild postural imbalance, but still ability to function independently
IV	Bilateral involvement with postural instability; patient requires substantial assistance
V	Severe disease; patient restricted to bed or wheelchair unless aided

Reprinted with permission from Hoehn MM, Yahr MD. Parkinsonism: onset, progression, and mortality. *Neurology*. 1967;17:427.

Figure 38-5. Management of Parkinson disease.

b. **Nutrition.** Patients with Parkinson disease are at increased risk of poor nutrition, weight loss, and reduced muscle mass. Examples of the beneficial effects of proper nutrition in this group of patients include the following:

(1) Sufficient fiber and fluid intake help prevent constipation associated with Parkinson disease and the medications used to treat the disease.

(2) Calcium supplementation helps maintain the existing bone structure.

(3) Excessive dietary protein in the late stages of the disease causes erratic responses to levodopa therapy.

(4) A large body of literature supports the pathophysiological role of antioxidants as a neuroprotective agent and its role in decreasing progression of Parkinson disease. Products such as α-tocopherol or vitamin, creatine, coenzyme Q10 act as scavengers of free radical which are harmful to cells.

2. **Drug therapy for symptomatic relief.** Treatment is divided into two generalized categories: symptomatic therapies and preventive or protective measures. Neuroprotective strategies are used to slow the development and progression of the disorder.

H. Drug treatment: Neuroprotective treatment

1. MAO-Bs, such as selegiline and tocopherol (vitamin E), act as a scavenger of free radicals.
2. Dopamine agonists serve as scavengers of free radicals and decrease dopamine turnover, which reduces oxidative stress. During early development of the disease, there are increases in oxidative stress. Four classes of drugs are available.
   a. Anticholinergics (for resting tremor)
   b. Precursor of dopamine (e.g., carbidopa/levodopa)
   c. Direct-acting dopamine agonists (e.g., bromocriptine)
   d. Indirect-acting dopamine agonists
      (1) Decrease reuptake (e.g., amantadine)
      (2) Decrease metabolism (e.g., selegiline)

3. **Drug therapy for treating associated symptoms**
   a. **Tricyclic antidepressants** are used to treat **depression**. They exhibit some dopaminergic and anticholinergic effects.
   b. **β-Blockers**, especially **propranolol** with its high lipophilicity, **benzodiazepines**, and **primidone**, are medications used for **action tremor**. Usually, patients show a clinical response in low doses.
   c. **Antihistamines**. Diphenhydramine hydrochloride has some mild anticholinergic effects and is used for symptomatic release of mild tremor; because of its adverse reaction in the CNS, it should be used with caution in the elderly.

4. **General principles of drug therapy**
   a. If a patient does not respond to an agent in one class, another class should be tried. Studies show that some patients respond to one agent when they fail to respond to the other.
   b. Therapy should be started with a low dose and titrated up. Response usually is seen within a few days after starting therapy.
   c. If a second agent is added to the drug therapy, the dose of the first medication should be decreased to minimize side effects.
   d. Drug therapy should never be discontinued suddenly because withdrawal may exacerbate the symptoms.

5. **Definitions concerning drug therapy**
   a. **Dyskinesia/dystonia** typically presents as oral-facial movements, grimacing, or jerky and writhing movements of the trunk and extremities. They are always reversible with antiparkinsonian medications, and they decrease or diminish with dose reduction. Symptoms of Parkinson disease may reappear by reducing the dose, and it is the clinical judgment of the physician or the preference of the patient whether to continue with the drug regimen or tolerate the side effects. There are three types of dyskinesia/dystonia: peak-dose dyskinesia, biphasic dyskinesia, and off-period dystonia. All could benefit from sustained-release preparations.
      (1) Peak-dose dyskinesia
         (a) Could be corrected with sustained-release preparations.
         (b) Decrease l-dopa dose or add catechol-*O*-methyltransferase (COMT) inhibitor.
         (c) Add amantadine.
         (d) Perform surgery.
      (2) Biphasic dyskinesia
         (a) Could be corrected with sustained-release preparations.
         (b) Decrease l-dopa dose and increase dopaminergic dose. If symptoms are still present, a COMT inhibitor should be added.
         (c) Amantadine may be helpful.
      (3) Off-period dystonia
         (a) Decrease l-dopa dose.
         (b) Increase dopaminergic dose.

    b. On–off effect describes oscillations in response (at the receptor site) and sudden changes in mobility from no symptoms to full parkinsonian symptoms in a matter of minutes. No direct relationship between the on–off effect and drug levels has been found. Usually, a second drug is added to the therapy regimen to correct the effect. Reducing the dose of one drug and adding a second drug may also be useful. Could be managed by adding entacapone, dopamine agonist, amantadine, or selegiline.

    c. End-dose effect, known also as the **wearing-off effect**, occurs at a latter part of the dosing interval; it happens after a few years of L-dopa therapy. Reduce the single L-dopa dose and spread the total L-dopa dose over a larger number of single doses. Change to a dopamine agonist and use a sustained-release formulation of L-dopa. Could be managed by adding entacapone, dopamine agonist, amantadine, or selegiline.

    d. Drug holiday. Long-term levodopa use results in down regulation of dopamine receptors. A drug holiday allows striatal nigra dopamine receptors to be resensitized, although controversy exists regarding the consequences and the outcome of this holiday.

6. Physical rehabilitation restores patients' physical function and independence through physical and occupational therapy. Such therapy helps patients with managing big and small muscle groups by focusing on maintaining coordination, dexterity, flexibility, and range of motions.

7. Psychological rehabilitation provides support for patients and their families. Keep in mind that patients with Parkinson disease have a high incidence of depression and that, in later stages of the disease, they develop dementia (*Table 38-2*).

8. Secondary effects of Parkinson disease include

    a. Cardiovascular effects, including orthostatic hypotension and arrhythmia.

    b. Gastrointestinal effects, including constipation and hypersalivation.

    c. Genitourinary effects, including increased urinary frequency and impotence.

    d. Central nervous system effects, including hallucinations, depression, and psychosis. Could be treated with reducing or eliminating amantadine, selegiline, anticholinergics, or dopamine agonists.

9. Late disabilities of Parkinson disease can be divided into two groups.

    a. Levodopa-related disabilities, which include motor fluctuation, dyskinesia, neuropsychiatric toxicity, and reduced response

Table 38-2   OVERVIEW OF PARKINSON DISEASE MANAGEMENT

Stage	Characteristics	Treatment Considerations	
		Physical	**Psychosocial**
Early	Fully functional May have unilateral tremor, rigidity	Preventive exercise program	Education Information
Early middle	Symptoms bilateral, bradykinesia rigidity Mild speech impairment Axial rigidity, stooped posture, stiffness Gait impairment begins	Corrective exercise program	Counseling Support group Monitor for depression
Late middle	All symptoms worse but independent in ADLs May need minor assistance Balance problems	Compensatory and corrective exercise Speech therapy Occupational therapy	Caregiver issues (medications, mobility) Monitor for dementia
Late	Severely disabled, impaired Dependent with ADLs	Compensatory exercise Dietary concerns Skin care Hygiene Pulmonary function	Dementia Depression

ADLs, activities of daily living.
Reprinted with permission from Custin TM. Overview of Parkinson's disease management. *Phys Ther.*1995;75:363–373. This material is copyrighted, and any further reproduction or distribution is prohibited.

    b. Non-levodopa–related disabilities, which include cognitive impairment, instability resulting in more frequent falls, gait disturbance, incontinence, dysphagia, and speech disturbance

    c. Late disabilities management therapies include the following:

      (1) Motor fluctuation. Altering the levodopa dosage and timing, using alternative means of levodopa administration, delivery, and absorption; using direct-acting dopamine agonists or experimental agonists; altering metabolism of dopamine and levodopa parental agonists; using glutamate antagonists; and performing functional neurosurgery

      (2) Miscellaneous late disabilities and management therapies include

        (a) Urinary urgency: oxybutynin

        (b) Urinary retention: apomorphine

        (c) Constipation: fiber, polyethylene glycols

        (d) Tenesmus: clonazepam, apomorphine

        (e) Hypersalivation: antihistamine, anticholinergic

        (f) Dysphagia: liquid levodopa

        (g) Sweating crises: β-blockers, anticholinergic agents

        (h) Daytime sleepiness: selegiline

        (i) Nightmares: amitriptyline, clonazepam

        (j) Panic attacks and depression: liquid levodopa, amitriptyline

        (k) Orthostatic hypotension: domperidone, desmopressin

        (l) Dysphonia: reduce levodopa dosage, speech therapy

        (m) Pain: amitriptyline, fluvoxamine

II. INDIVIDUAL DRUGS

  A. Anticholinergic agents are used for mild symptoms, predominantly tremors.

    1. Mechanism of action. This class of drugs blocks the excitatory neurotransmitter cholinergic influence in the basal ganglia. These drugs are more effective for tremor and rigidity than for bradykinesia and less effective for postural imbalance.

    2. Administration and dosage (*Table 38-3*)

    3. Precautions and monitoring effects

      a. Anticholinergics should be used with caution in patients with obstructed gastrointestinal (GI) or genitourinary (GU) tracts, narrow-angle glaucoma, or severe cardiac disease. Physicians should be notified if a rapid heartbeat or eye pain is experienced. (Frequent ophthalmological visits are recommended.)

      b. The sedative side effects of antihistamines may be beneficial in some patients.

      c. Alcohol and other CNS depressants should be used with caution.

      d. Adverse effects of anticholinergic therapy include the following:

        (1) Peripheral anticholinergic effects include dry mouth (hard candies may be helpful); decreased sweating, resulting in decreased tolerance to heat; urinary retention; constipation (stool softeners may be helpful); increased intraocular tension; and nausea. Because of patients' decreased tolerance to heat, these agents should be used with caution in hot weather. They should also be taken with food to minimize GI upset.

        (2) CNS effects include dizziness, delirium, disorientation, anxiety, agitation, hallucinations, and impaired memory. The incidence of CNS effects increases in elderly individuals.

        (3) Cardiovascular effects include hypotension and orthostatic hypotension.

    4. Significant interactions

      a. Side effects may be potentiated by other drugs with anticholinergic activity, such as **antihistamines**, **antidepressants**, and **phenothiazines**.

      b. Anticholinergic agents increase **digoxin** levels.

      c. When anticholinergic agents are taken with **haloperidol**, the following occurs:

        (1) Schizophrenic symptoms may increase.

        (2) Haloperidol levels may decrease.

        (3) The severity of (not the risk of) tardive dyskinesia may increase.

      d. When **phenothiazines** are taken with anticholinergic drugs, the effects of the phenothiazines decrease and the anticholinergic symptoms increase.

      e. Patients on high doses of anticholinergics combined with **levodopa** should be watched for decreased levodopa activity because of a delayed gastric emptying time.

Table 38-3   DOSAGE RANGE AND CHARACTERISTICS OF DRUG TREATMENT

Drug	Time to Peak Concentration (hr)	Half-Life (hr)	Daily Dosage Range (mg/day)
Anticholinergic agents			
Benztropine	n/a	n/a	1–6
Biperiden	1.0–1.5	18.4–24.3	2–8
Procyclidine	1.1–2.0	11.5–12.6	6–20
Trihexyphenidyl	1.0–1.3	5.6–10.2	2–15
Ethopropazine	n/a	n/a	50–400
Dopamine agents			
Carbidopa/levodopa	1	1.0–1.75	10/100–200/2000
Carbidopa/levodopa, sustained-release	2	> standard treatment	10/400–25/1000, in 2–3 divided doses
Amantadine	4–8	9.7–14.5	100–400
Bromocriptine	1–3	3–8	2.5–40.0
Selegiline	0.5–2.0	2.0–20.5	5–10
Selegiline Oral Disintegrating table*	1	1–3 hrs	0.5–1.0 mg
Rasagiline	1	1.3–3.0 hrs	0.5–1.0 mg
Non-ergot dopamine agents			
Pramipexole	1–2 (3–4[a])	8–12[b]	1.5–4.5, in 3 divided doses
Ropinirole	1–2(3–4[a])	6	3–24, in 3 divided doses
COMT inhibitor	0.5–4.0	70	0.5–6.0
Tolcapone	2	2–3	300–600
Entacapone	1	2–3	200–1600
Rotigotine	15–27	5–7 hrs	2–6 mg
Apomorphine hydrochloride injection (SC)	1	40 mins	2–6 mg

[a]With food.
[b]Older than 65 years of age.
COMT, catechol-*O*-methyltransferase; *n/a*, not available.
*avoids first-pass effect
SC, subcutaneous injection.

B. **Dopamine precursor.** **Levodopa/carbidopa** is the most effective drug for managing Parkinson disease; however, prolonged use decreases its therapeutic effects (there is a decline in efficacy after 3 to 5 years) and increases adverse drug reactions. Dopamine does not cross the blood–brain barrier; therefore, a precursor is used. Peripheral conversion of levodopa to dopamine causes adverse reactions like nausea, vomiting, cardiac arrhythmias, and postural hypotension. To decrease the peripheral conversion and peripheral adverse effects, a peripheral dopa decarboxylase inhibitor (carbidopa) is added to levodopa.

   1. **Mechanism of action**
      a. **Levodopa is converted** to dopamine by the enzyme dopa decarboxylase, which elevates CNS levels of dopamine.
      b. The sustained-release formulation is designed to release the drug over 4 to 6 hrs, thereby inhibiting variation in plasma concentration and decreasing motor fluctuation "off" time or improving overall dose response in patients with advanced disease.
   2. **Administration and dosage** (*Table 38-3*)
      a. It is necessary to give at least 100 mg daily of carbidopa to decrease the incidence of the peripheral conversion of levodopa and GI side effects (e.g., nausea) and increase the bioavailability of levodopa for the CNS.
      b. If carbidopa is given in a separate dosage form, the dose of levodopa can be decreased by 75%.
      c. Carbidopa given separately or in addition permits to lower dose of levodopa with decrease in GI side effect and more rapid dosage titration (max dose 200 mg/day).
      d. Sustained-release preparations are approximately 30% less bioavailable as compared with levodopa/carbidopa. Because of this lower bioavailability, the daily dosage should be higher. If a

patient is receiving a standard preparation and needs to be converted to the sustained-release dose, approximately 10% more levodopa should initially be added to the daily dosage and at least 3 days should pass between increased dosages; then gradually increase the levodopa dose up to 30% of standard preparation.

    e. With the sustained-release preparation, the peak plasma concentration is lower and the trough plasma concentration is higher.

    f. The sustained-release preparation could be divided in half at the scored point only. The tablet should not be chewed or crushed.

    g. When carbidopa is given to patients being treated with levodopa, give the two drugs at the same time, starting with no more than 20% to 25% of the previous daily dosage of levodopa and initiating therapy with carbidopa and levodopa.

    h. Long-term treatment could lead to motor fluctuation and dyskinesias, especially at high doses.

3. Precautions and monitoring effects

    a. Levodopa must be used with caution in patients with narrow-angle glaucoma.

    b. Levodopa may activate a malignant melanoma in patients with suspicious undiagnosed skin lesions or a history of melanoma.

    c. The efficacy of levodopa declines with long-term therapy by desensitizing the receptors or because of the decreased number of receptors, resulting from the progression of the disease.

    d. Adverse drug reactions

        (1) GI effects include anorexia, nausea and vomiting, and abdominal distress. Levodopa should be taken with food to minimize stomach upset.

        (2) Cardiovascular effects include postural hypotension and tachycardia.

        (3) Musculoskeletal effects include dystonia or choreiform muscle movement.

        (4) CNS effects include confusion, memory changes, depression, hallucinations, and psychosis. Physicians should be notified if any of these symptoms occur.

        (5) Hematological effects include hemolytic anemia, leukopenia, and agranulocytosis (rare).

4. Significant interactions

    a. Antacids cause rapid and complete intestinal levodopa absorption (by decreasing gastric emptying time).

    b. Hydantoin decreases the effectiveness of levodopa.

    c. Methionine increases the clinical signs of Parkinson disease.

    d. Metoclopramide increases the bioavailability of levodopa, which decreases the effects of metoclopramide on gastric emptying and on lower esophageal pressure. As a dopamine blocker, it may also precipitate parkinsonian symptoms.

    e. False-positive results are seen with the Coombs test.

    f. The uric acid test increases with the calorimetric method but not with the uricase method.

    g. Hypertensive reactions may occur if levodopa is administered to patients receiving **MAO inhibitors**. MAO inhibitors must be discontinued 2 weeks before starting levodopa.

    h. Administering **papaverine** may decrease the effect of levodopa.

    i. Tricyclic antidepressants decrease the rate and extent of absorption of levodopa; hypertensive episodes have been reported when levodopa is combined with tricyclic antidepressants.

    j. Food decreases the rate and extent of absorption and transport to the CNS across the blood–brain barrier. A **protein-restricted diet** may also help minimize the "fluctuations" (i.e., the decreased response to levodopa) at the end of each day or at various times of the day.

    k. Antihypertensive agents increase risk of postural hypotension.

C. Direct-acting dopamine agonists are classified as ergot derivatives (such as bromocriptine) and nonergolines (such as pramipexole and ropinirole).

    1. These agents mimic dopamine agonist and reduce motor fluctuations.

    2. Drugs in this class have a range of half-lives, and the half-life of any particular drug can vary among patients.

    3. These drugs are not metabolized by the oxidative pathway and do not produce free-radical metabolites.

    4. Dopamine agonists may have a direct antioxidative effect.

    5. They take longer than L-dopa to reach effective doses and require supplementary L-dopa for relief of symptoms after a varying period.

6. Common side effects are nausea and psychiatric side effects similar to L-dopa, such as hallucinations and delusions; dyskinesias are less common.

7. Other adverse effects are headache, nasal congestion, erythromelalgia, pleural and retroperitoneal fibrosis, pulmonary infiltrates, and vasospasm (except with the new, nonergot derivatives such as ropinirole).

8. Annual chest radiographs have been recommended for patients on high-dose therapy with bromocriptine to detect pleuropulmonary changes.

9. New dopaminergic agonists (non-ergot derivatives) cause postural hypotension, sleep disturbances, peripheral edema, constipation, nausea, dyskinesias, and confusion.

10. **Bromocriptine (Parlodel)**
    a. **Mechanism of action**. Bromocriptine is responsible for directly stimulating postsynaptic dopamine receptors; it is most commonly used as an adjunct to levodopa therapy in patients
       (1) with a deteriorating response to levodopa,
       (2) with a limited clinical response to levodopa secondary to an inability to tolerate higher doses, and
       (3) who are experiencing fluctuations in response to levodopa.
    b. **Administration and dosage** (*Table 38-3*)
       (1) Initially, patients are given one-half of a tablet twice daily, which is then increased to one tablet twice daily every 2 to 3 days.
       (2) Patients' responses are extremely variable. Many patients show a dopamine antagonist response at both low and high doses, with the desirable agonist response in the midrange.
       (3) Because postural hypotension may result from the first few doses of bromocriptine, the first dose should be administered with the patient lying down, and sudden changes in posture should be avoided.
    c. **Precautions and monitoring effects**
       (1) Bromocriptine may cause a first-dose phenomenon that can trigger sudden cardiovascular collapse. It should be used with caution in patients with a history of myocardial infarction or arrhythmias.
       (2) Early in therapy, dizziness, drowsiness, and fainting may occur, so patients should be cautious about driving or operating machinery. A physician should be notified if these symptoms appear.
       (3) **Cardiac dysrhythmias**. Patients on bromocriptine were found to have significantly more episodes of atrial premature contractions and sinus tachycardia.
       (4) **Other adverse effects**
          (a) **GI effects**, including anorexia, nausea, vomiting, and abdominal distress, may be decreased by taking bromocriptine with food.
          (b) **Cardiovascular effects** include postural hypotension (to which tolerance develops) and tachycardia. Blood pressure must be monitored, particularly for patients taking antihypertensive medication.
          (c) **Pulmonary effects**, including reversible infiltrations, pleural effusions, and pleural thickening, may develop after long-term treatment, so pulmonary function should be monitored in patients treated longer than 6 months.
          (d) **CNS effects**, including confusion, memory changes, depression, and hallucinations, as well as psychosis, may be exacerbated by bromocriptine; thus, patients with psychiatric illnesses must be monitored.
    d. **Significant interactions**
       (1) A combination of **antihypertensive drugs** and bromocriptine could decrease blood pressure.
       (2) **Dopamine antagonists** increase the effect of bromocriptine.

D. **Indirect-acting dopamine agonists**
   1. **Selegiline (Eldepryl)**
      a. **Mechanism of action**
         (1) MAO catabolizes various catecholamines (e.g., dopamine, norepinephrine, epinephrine), serotonin, and various exogenous amines (e.g., tyramines) found in foods (e.g., aged cheese, beer, wine, smoked meat) and drugs. Lack of MAO in the intestinal tract causes absorption of these amines, creating a hypertensive crisis. MAO type A is predominantly found in the

intestinal tract, and MAO type B in the brain. They differ in their substrate specificity and tissue distribution. This specificity decreases with selegiline as the dose increases. Most patients experience side effects at doses of selegiline higher than 30 to 40 mg/day.

(2) Selegiline is a selective inhibitor of MAO-B, which prevents the breakdown of dopamine selectively in the brain at recommended doses.

(3) Selegiline is most commonly used as an adjunct with levodopa/carbidopa when patients experience a "wearing-off" phenomenon; it decreases the amount of off time and decreases the dose needed of levodopa/carbidopa by 10% to 30%.

(4) Results of some studies show that selegiline delays the time before treatment with a more potent dopaminergic drug like levodopa is needed; the proposed mechanism of action is that an oxidation mechanism contributes to the emergence and progression of Parkinson disease.

b. Administration and dosage (*Table 38-3*). Exceeding the recommended dose of 10 mg/day increases the risk of losing MAO selectivity.

(1) Oral capsule/tablet: 5 mg (maximum of 10 mg/day)

(2) Oral disintegrating tablet: 1.25 mg daily may be increased up to 2.5 mg daily. Disintegrating tablets maximum of 2.5 mg daily.

(3) Transdermal: 6 mg/24 hrs apply upper torso, high on the outer surface of the upper arm, avoid exposure of application site to external heat resources. Excessive heat will increase absorption.

c. Precautions and monitoring effects

(1) Hypertensive crisis. See II.D.1.a.(1).

(2) Levodopa-associated side effects may be increased because the increased amounts of dopamine react with supersensitive postsynaptic receptors. Reducing the dose of levodopa/carbidopa by 10% to 30% may decrease levodopa side effects.

(3) Patients should be educated about foods and drugs containing tyramine and the signs and symptoms of hypertensive reactions.

(4) CNS effects include dizziness, confusion, headache, hallucinations, vivid dreams, dyskinesias, behavioral and mood changes, and depression. Patients who experience insomnia should avoid taking the drug late in the day.

(5) Cardiovascular effects include orthostatic hypotension, hypertension, arrhythmia, palpitations, sinus bradycardia, and syncope.

(6) GI effects include nausea and abdominal pain and **lead to GI bleeding**, weight loss, poor appetite, and dysphagia.

(7) GU effects include slow urination, transient nocturia, and prostatic hypertrophy.

(8) Dermatological effects include increased sweating, diaphoresis, and photosensitivity.

(9) Hepatic effects include mild and transient elevations in liver function tests.

d. CYP2B6 inhibitors may increase level of selegiline. Also, selegiline has active metabolites (n-desmethylselegeline and amphetamine); examples of such significant interactions are

(1) MAO inhibitors are contraindicated with **meperidine** and other opioids. Administration with opioids should be avoided (serotonin syndrome). **Death has occurred after initiation of selegiline shortly after discontinuation of fluoxetine**. At least 5 weeks should elapse between discontinuation of fluoxetine and initiation of selegiline (serotonin syndrome).

(2) Rasagiline: similar to selegiline. The different is 5- to 10-fold greater potency, higher oral absorption. Unlike selegiline, it is not metabolites to amphetamine derivatives (see *Table 38-3*).

2. Amantadine (Symmetrel)

a. Mechanism of action. Amantadine is an antiviral agent (used to prevent influenza).

(1) Amantadine increases dopamine levels at postsynaptic receptor sites by decreasing presynaptic reuptake and enhancing dopamine synthesis and release.

(2) It may also have some anticholinergic effects. It decreases tremor, rigidity, and bradykinesia.

(3) It can be given in combination with levodopa as Parkinson disease progresses.

(4) Clinical effects of amantadine can be seen within the first few weeks of therapy, unlike the other antiparkinsonian medications (e.g., carbidopa/levodopa), which need weeks to months to show their full clinical effects.

b. Administration and dosage (*Table 38-3*)

(1) Amantadine should be started at 100 mg/day. This may be increased to 200 to 300 mg/day as a maintenance dose.

(2) Patients experiencing a decline in response may benefit from the following:

(a) Discontinuing the drug for a few weeks, then restarting it

(b) Using the drug episodically, only when the patient's condition most needs a therapeutic boost

(3) Amantadine is also available in liquid form for patients with dysphagia.

c. Precautions and monitoring effects

(1) Amantadine should be used with caution in patients with renal disease, congestive heart failure (CHF), peripheral edema, history of seizures, and mental status changes. It may be necessary to modify dosages in patients with renal failure.

(2) Tolerance usually develops within 6 to 12 months. If tolerance occurs, another drug from a different class can be added, or the dose may be increased.

(3) Patients should be informed about the side-effect profile.

(a) Peripheral anticholinergic effects include those mentioned in II.A.3.d.(1).

(b) CNS effects include seizures as well as those mentioned in II.A.3.d.(2).

(c) Cardiovascular effects. Patients may develop CHF. Periodic blood pressure monitoring and electrocardiograms (ECGs) are necessary in patients with myocardial infarction or arrhythmias.

(d) Dermatological effects include **livedo reticularis**, a diffuse rose-color mottling of the skin, which is reversible on discontinuation of the drug.

(e) Hematological effects. Periodic complete blood counts (CBCs) should be done for patients with long-term therapy.

(4) Renal function impairment. Dose adjustment is necessary in patients with renal function impairment.

d. Significant interactions

(1) Amantadine increases the anticholinergic effects of **anticholinergic drugs**, requiring a decrease in the dosage of the anticholinergic drug.

(2) Hydrochlorothiazide plus **triamterene** decreases the urinary excretion of amantadine and increases its plasma concentration.

E. Non-ergot dopamine agonists

1. Pramipexole and ropinirole are indicated for both early and advanced stages of Parkinson disease.

2. Both selectively bind to dopamine receptors and activate the D_2-receptor but have little or no affinity to the D_1-receptor. They have greater affinity for the D_3-receptor than for the D_2-receptor. The incidence of adverse events (such as pleuropulmonary fibrosis and retroperitoneal fibrosis, coronary vasoconstriction, erythromelalgia, and Raynaud phenomenon) is low compared to nonselective dopamine agonists.

3. Non-ergot dopamine agonists have a low potential for the development of motor fluctuations and dyskinesia.

a. Pramipexole (Mirapex)

(1) Mechanism of action

(a) D_2 subfamily of dopamine receptors. Pramipexole fully stimulates the dopamine receptors to which it binds. Its action may be related to its capacity to function as an antioxidant and oxygen free-radical scavenger.

(b) Pramipexole also has antidepressant activity in moderate depression, which may be related to its preferential binding to the dopamine D_1-receptor subtype.

(c) Long-acting dopamine agonists appear to have a lower risk of inducing abnormal movements. Their use as initial treatment in early Parkinson disease seems warranted, particularly for those with disease onset at a younger age.

(2) Administration and dosage

(a) Initial treatment: starting dose of 0.375 mg daily given in three divided doses.

(b) Do not increase more frequently than every 5 to 7 days.

(c) Maintenance treatment: 1.5 to 4.5 mg daily in three divided doses with or without levodopa.

(d) When given in combination with levodopa, consider reduction of levodopa dose by an average of 27% from baseline.

(e) Titrate slowly to balance benefits and side effects, such as dyskinesia, hallucinations, somnolence, and dry mouth.

(f) May be taken with food to reduce the occurrence of nausea. Food decreases the rate of absorption but not the extent of absorption.

(g) Dosage adjustment is necessary in patients with renal function impairment.

(h) Weak protein bound 15%

(i) Not extensively metabolized; more than 90% of the dose is excreted unchanged in urine.

(j) Dose needs to be decreased by 25% in the elderly.

(3) Precautions and monitoring effects

(a) Dose reduction necessary in patients > 65 years and in patients with renal function impairment or failure

(b) Symptomatic hypotension

  (i) Dopaminergic agents appear to impair the systemic regulation of blood pressure, which results in orthostatic hypotension.

  (ii) Monitoring and education of the patient is necessary, especially during dose-escalation periods.

(c) Hallucinatory effects are increased in patients > 65 years of age with early or advanced stages of Parkinson disease.

(d) Other effects include nausea, insomnia, constipation, dizziness, somnolence, GI side effects, and visual hallucinations. Sleep attack by falling asleep during activity daily living.

(e) Compulsive behavior related to D_3 activities have been seen without prior history, such as compulsive gambling, hypersexuality, and overreacting.

(f) Falling asleep during activities of daily living

(4) Significant interactions

(a) Cimetidine reduces renal clearance of pramipexole.

(b) No interaction with selegiline, probenecid, or domperidone.

(c) When combined with levodopa, the dosage of levodopa must be decreased by 27%.

b. Ropinirole (Requip)

(1) Mechanism of action is similar to pramipexole.

(2) Administration and dosage

(a) Initial treatment: 0.25 mg three times daily

(b) Titrate weekly increments

(c) After week 4, if necessary, daily dosage may be increased by 1.5 mg/day on a weekly basis up to 9 mg/day, to a total of 24 mg/day.

(d) Discontinue gradually over a 7-day period. Decrease the frequency of administration from three times to two times daily for 4 days and then once daily for the remainder of the week.

(e) When given in combination with levodopa, consider reduction of levodopa dose.

(f) May be taken with food to reduce the occurrence of nausea. Food decreases the rate of absorption but not the extent of absorption.

(g) Metabolized by the liver (cytochrome P450 1A2) and first-pass effect

(h) Smoking induces the liver metabolism.

(i) Between 30% and 40% protein bound

(3) Precautions and monitoring effects

(a) Syncope. Bradycardia is observed in patients treated with ropinirole. Most cases occur within the first 4 weeks of therapy and are usually associated with a recent increase of dose.

(b) Binds to melanin-containing tissues like the eyes and skin

(c) Symptomatic hypotension

  (i) Dopaminergic agents appear to impair the systemic regulation of blood pressure, which results in orthostatic hypotension.

  (ii) Monitoring and education of the patient is necessary, especially during dose-escalation periods.

    (d) Hallucinatory effects are increased in patients > 65 years of age with early or advanced stages of Parkinson disease.

    (e) Other side effects include nausea, dizziness, somnolence, headache, fatigue, and abnormal vision. Sleep attack, by falling asleep during activity daily living.

   (4) Significant interactions

    (a) Smoking induces the liver metabolism, but the effect of smoking on clearance of ropinirole has not been studied.

    (b) There is no interaction between levodopa, theophylline, digoxin, or domperidone.

    (c) Estrogens decrease the clearance of ropinirole by approximately 36%.

    (d) Ciprofloxacin increases ropinirole area under the curve (AUC) by 84% and maximum plasma concentration by 60%.

  c. Apomorphine Hydrochloride Injection SC (Apokyn)

   (1) Mechanism of action

    (a) Stimulating of postsynaptic dopamine D_2-type receptors within caudate and putamen in brain.

    (b) Subcutaneous injection is indicated for acute intermittent treatment if hypomobility "off" episodes (end of dose wearing, unpredictable on/off episodes).

   (2) Administration and dosage

    (a) Doses more than 6 mg is not recommended.

    (b) Dose should be started at 2 mg increase to maximum of 6 mg.

    (c) It should be administrated at "off" state and should begin test dose at 2 mg where blood pressure can be monitored. Blood pressure should be monitored predose and at 20, 40, and 60 mins postdose standing up.

    (d) If patient developed orthostatic hypotension, patient should not received apomorphine.

    (e) Patients who have a significant interruption in therapy (more than a week) should be restarted on a 0.2 mL (2 mg) dose and gradually titrated to effect.

   (3) Precautions and monitoring

    (a) Profound hypotension and loss of consciousness when given with 5-HT$_3$-antagonist **class (including ondansetron, granisetron)**

    (b) QT prolongation and potential proarrhythmia effect. Patient should be monitored for palpitation syncopy and signs for episode of torsades de pointes.

    (c) Sleep attack, falling asleep during daily activities.

    (d) Hallucination

    (e) **Sulfite sensitivity**: contains a sulfite that may cause allergic-type reactions, including anaphylactic symptoms and life-threatening or less severe asthmatic episodes in certain susceptible people

   (4) Drug interactions

    (a) 5-HT$_3$-antagonist such as ondansetron, granisetron, dolasetron, palonosetron results in hypotension.

    (b) Antihypertensive medications and vasodilators may result in hypotension.

    (c) Contraindicated when used with other drugs that have potential to prolong QT, QTC interval. It increases risk of life-threatening arrhythmias.

 4. COMT inhibitors

  a. Tolcapone (Tasmar)

   (1) Mechanism of action

    (a) Tolcapone is a selective and reversible inhibitor of COMT and is used as an adjunct to levodopa/carbidopa therapy.

    (b) Tolcapone inhibits COMT both peripheral and centrally.

    (c) COMT is the main enzyme responsible for peripheral and central metabolism of catecholamines, including levodopa. Addition of a COMT inhibitor results in the doubling of the elimination half-life of levodopa and in increased oral bioavailability of levodopa by 40% to 50%.

    (d) Tolcapone is indicated as an adjunct therapy to carbidopa/levodopa therapy.

   (2) Administration and dosage

    (a) Starting dose of 100 to 200 mg three times daily

    (b) Usual daily dose of 200 mg three times daily

(c) If patient fails to show expected benefit after 3 weeks of treatment, discontinue drug because of associated risk of liver failure. Rapid withdrawal or abrupt reduction dose could lead to hyperpyrexia and confusion symptoms such as high fever and severe rigidity similar to those in neuroleptic malignant syndrome.

(3) Precautions and monitoring

(a) Liver toxicity. High risk of fatal liver failure has been reported with tolcapone. Discontinue use if substantial benefit is not seen within 3 weeks of commencement of therapy.

(b) Do not use in patients with liver disease or in patients who have two alanine aminotransferase (ALT) or aspartate aminotransferase (AST) values greater than the upper limit of normal.

(c) Advise patient regarding self-monitoring for liver disease (i.e., clay-colored stool, jaundice, fatigue, appetite loss, or lethargy).

(d) Monitor AST and ALT every 2 weeks for the first year, then every 4 weeks for the next 6 months and every 8 weeks thereafter.

(e) MAO and COMT are two major enzyme systems involved in the metabolism of catecholamines; combination of tolcapone with a nonselective MAO inhibitor will result in inhibition of the pathway responsible for normal catecholamine metabolism.

(f) Tolcapone can be taken concomitantly with a selective MAO-B inhibitor, such as selegiline in recommended dose of less or equal to 10 mg/day.

(g) Fibrolic complications, such as retroperitoneal fibrosis, pulmonary infiltrates or effusion, or pleural thickening.

(4) Other side effects

(a) Orthostatic hypotension. Tolcapone enhances levodopa bioavailability and, therefore, may increase the occurrence of orthostatic hypotension.

(b) Diarrhea usually manifests within 6 to 12 weeks after administration of tolcapone but can develop as early as 2 weeks after administration. Diarrhea normally resolves after discontinuation of the drug.

(c) Hallucinations are sometimes accompanied by confusion, insomnia, and excessive dreaming. Hallucinatory effects usually occur after initiation of tolcapone and are usually resolved by decreasing the dose of levodopa.

(d) Tolcapone may potentiate the dopaminergic side effect of levodopa and may cause or exacerbate preexisting dyskinesia. Decreased doses of levodopa may or may not alleviate the symptoms.

(e) Severe cases of rhabdomyolysis have been reported, which present as fever, alternation of consciousness, and muscular rigidity.

(f) Others. Dyspepsia, abdominal cramping, mild paresthesia of the legs, and temporary discoloration of urine have also been noted but are not considered clinically important.

(g) Drug interactions. Although no drug interaction studies have been conducted, concurrent use of tolcapone and drugs that are metabolized by the COMT system (i.e., methyldopa, dobutamine, apomorphine) should be monitored. Tolcapone also has affinity for the cytochrome P450 2C9 isoenzyme, similar to warfarin. Coagulation parameters should be monitored when tolcapone is administered with warfarin.

b. Entacapone (Comtan)

(1) Mechanism of action

(a) Entacapone is a selective and reversible inhibitor of COMT and permits additional levodopa to reach the brain. It does not have any anti-Parkinson effect of its own.

(b) It acts only peripherally by inhibiting COMT.

(c) It improves the duration of on time and decreases the duration of off time.

(d) It is indicated as an adjunct to those on levodopa/carbidopa therapy who experience the signs and symptoms of end-of-dose wearing-off.

(2) Administration and dosage

(a) Dosage: 200 mg with each dose of L-dopa up to eight times daily with a maximum dose of 1600 mg daily.

   (b) Rapid withdrawal could lead to emergency signs and symptoms of Parkinson disease, such as hyperpyrexia and confusion (symptoms resembling neuroleptic malignant syndrome).

   (c) Levodopa + carbidopa and entacapone: Available in four strengths, each in a 1:4 ratio of carbidopa to levodopa and combined with entacapone 200 mg in a standard-release formulation, 50, 100, 150, and 200 mg of levodopa.

  (3) Precautions and monitoring effects

   (a) MAO. COMT and MAO are two major enzymes in the metabolism of catecholamines. Do not use together.

   (b) Drugs metabolized by COMT. Drugs that are metabolized by this pathway, such as isoproterenol, epinephrine, norepinephrine, dopamine, and dobutamine, as well as methyldopa, may interact and may result in increased heart rate, arrhythmias, and an excessive increase in blood pressure.

   (c) Hepatic function impairment. The majority of the drug is metabolized by the liver; therefore, use caution in patients who have liver function abnormalities.

   (d) Fibrotic complication. Cases of retroperitoneal fibrosis, pulmonary infiltrates, pleural effusion, and pleural thickening have been reported. These complications may resolve when the drug is discontinued, but complete resolution may not always occur.

   (e) Biliary excretion. Entacapone is excreted by bile; therefore, use caution with drugs known to interfere with biliary excretion, such as probenecid, erythromycin, and ampicillin.

   (f) Patients may be at increased risk for cardiovascular events such as myocardial infarction, stroke, and cardiovascular death.

   (g) Patients may be at increased risk of developing prostate cancer.

  (4) Other side effects. Dyskinesia/hyperkinesia, nausea, urine discoloration (brownish orange), diarrhea, and abdominal pain

  (5) Drug interactions

   (a) May interact with drugs that are metabolized by the liver cytochrome P450.

   (b) Iron salts and digoxin reduces bioavailability of carbidopa/levodopa/entacapone.

   (c) After ingestion of carbidopa/levodopa/entacapone, the saliva, sweat, or urine may appear dark (red, brown, or black). This is clinically insignificant, garments may become discolored.

III. SURGICAL TREATMENT.
All surgeries require needle insertion into the brain, which in turn increases the risk of hemorrhage.

 A. Globus pallidus internus (Gpi) pallidotomy

  1. Definition. A pallidotomy entails the surgical resection of parts of the globus pallidus.

  2. Advantages. Improves contralateral dyskinesia.

  3. Disadvantages. Increased risk of damage to other parts of the brain, including optic nerve and internal capsule, and risk of emotional, behavioral, and cognitive deficits.

 B. Deep-brain stimulation

  1. Definition. High-frequency stimulation that induces functional inhibition of target regions of the brain by implanting an electrode into a target site and connecting the lead to a subcutaneously placed pacemaker.

  2. Advantages. No destructive lesion is formed. Stimulation parameters can be readjusted at any time to improve efficacy or decrease adverse events.

  3. Disadvantages. Side effects associated with equipment (such as lead breaks, infection, skin erosion, mechanical malfunction, and need for battery replacement). Other side effects include paresthesia, limb dystonia, ataxia, intracerebral hemorrhage, seizure, and confusion.

 C. Fetal nigral transplantation

  1. Definition. Implantation of embryonic dopaminergic cells into the denervated striatum to replace degenerated neuronal cells.

  2. Advantages. Implanted cells all survive, and innervation of the striatum is accomplished in an organotypic manner. Does not necessitate making a destructive lesion.

3. **Disadvantages.** Optimal transplant variables and target site not defined. Also, clinical studies showed development atypical dyskinesias during off period.

D. Use of genetically engineered viruses (adeno-associated virus, AAV) to carry levodopa-dopamine converting enzyme aromatic L-amino decarboxylase (AADC) to increase effectiveness of levodopa; as a result, decrease doses of levodopa and subsequently decrease dyskinesia and other side effects associated with levodopa.

E. Neuronal regeneration: delivering either growth factors or stem cells to produce dopamine-producing neurons.

Study Questions

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following drugs is a catechol-*O*-methyltransferase (COMT) inhibitor and has reports of fatal liver toxicity with it?

   (A) tolcapone
   (B) entacapone
   (C) rasagiline
   (D) selegiline

2. Levodopa is associated with which of the following problems?

   (A) Gastrointestinal side effects
   (B) Involuntary movements
   (C) Decline in efficacy after 3 to 5 years
   (D) All of the above

3. Amantadine has which of the following advantages over levodopa?

   (A) More rapid relief of symptoms
   (B) Higher success rate
   (C) Better long-term effects

4. Which drug is a non-ergot dopamine agonist and has a side-effect profile different from the rest of the dopaminergic agents?

   (A) entacapone
   (B) levodopa/carbidopa
   (C) ropinirole
   (D) selegiline

5. Which of the following medications is indicated as an adjunct to carbidopa/levodopa therapy?

   (A) pramipexole
   (B) bromocriptine
   (C) amantadine
   (D) tolcapone

Answers and Explanations

1. **The answer is A** *[see II.E.4.a.(3).(a)–(c)]*.
   High risk of fatal liver failure use with caution with patients with liver abscess. Patients should be monitored and instructed to look for signs of liver disease such as clay-colored stool, jaundice, fatigue, loss of appetite, and lethargy.

2. **The answer is D** *[see II.B.3.c–d]*.
   Levodopa can cause GI side effects such as nausea and vomiting, particularly when starting treatment. Bowel irregularity and gastrointestinal bleeding can also occur. With long-term levodopa therapy, involuntary choreiform movements can develop, and the efficacy of the drug declines. Other unwanted effects of levodopa include tachycardia and cardiac arrhythmias, postural hypotension, and psychiatric disturbances such as confusion or depression.

3. **The answer is A** *[see II.D.2.a.(4); II.D.2.c–d]*.
   Amantadine is most efficacious within the first few weeks, whereas benefits from levodopa may not be seen for weeks to months. Amantadine is more beneficial than the anticholinergics but is less effective than levodopa. Unfortunately, the efficacy of amantadine declines after 6 to 12 months of therapy. The efficacy of levodopa declines after 3 to 5 years of therapy.

4. The answer is C *[see II.E.3.a–b]*.

Non-ergot dopamine agonists such as ropinirole are indicated for both early and advanced stages of Parkinson disease. These drugs selectively bind to dopamine receptors and activate the D_2-receptor but have little or no affinity for the D_1-receptor. They have a greater affinity for the D_3-receptor than for the D_2-receptor. The incidence of adverse events (e.g., pleuropulmonary fibrosis and retroperitoneal fibrosis, coronary vasoconstriction, erythromelalgia, and Raynaud phenomenon) is low compared to nonselective dopamine agonists. Non-ergot dopamine agonists have a low potential for the devolvement of motor fluctuations and dyskinesia.

5. The answer is D *[see II.E.4.a.(1).(d)]*.

Tolcapone is an inhibitor of COMT enzyme used to metabolize catecholamines, including levodopa. It is indicated as an adjunct therapy to carbidopa/levodopa therapy.

Schizophrenia

REBEKAH R. ARTHUR GRUBE, ANDREW J. MUZYK

I. INTRODUCTION

    A. Schizophrenia is a major psychiatric disorder affecting approximately 1% to 2% of the world population. This complex condition was first described in the late 1800s and exists as a constellation of symptoms that includes hallucinations, delusions, decreased affect, disorganized behavior, and impaired functioning.

II. DIAGNOSIS AND CLINICAL FEATURES

    A. Schizophrenia is **diagnosed** based on *Diagnostic and Statistical Manual of Mental Disorders*, 4th ed. (*DSM-IV-TR*) criteria.

        1. A patient must have at least two of the following symptoms: delusions, hallucinations, disorganized speech, disorganized or catatonic behavior, and negative symptoms.

        2. The symptoms should be present for at least 1 month, with at least 6 months of continuous prodromal or residual symptoms.

        3. At least one area of the patient's social or occupational functioning should be significantly affected.

        4. Other conditions causing similar symptoms such as schizoaffective disorder, mood disorders, substance abuse, and general medical conditions should be ruled out.

    B. Five **types** of schizophrenia exist (*Table 39-1*).

    C. The clinical features of schizophrenia are categorized as **positive**, **negative**, or **disorganized** symptoms (*Table 39-2*). The most common symptoms are **hallucinations** and **delusions**.

        1. A **hallucination** is a perception disturbance in sensory experiences of the environment. Hallucinations can be auditory, visual, olfactory, or tactile. Auditory hallucinations are most common.

Table 39-1 TYPES OF SCHIZOPHRENIA

Type	Presentation
Catatonic	Motor symptoms are most notable. The patient may either demonstrate rigid immobility or excessive purposeless movement. The patient may be silent and withdrawn or may become loud and shout. Bizarre voluntary movements such as posturing may also occur. The patient may fluctuate between the two extremes.
Disorganized	The patient tends to have disorganized speech and behavior with a flat affect. Hallucinations and delusions are not well formed and fragmented. The patient may also have bizarre mannerisms and grimacing.
Paranoid	The most common type of schizophrenia. Patients are usually preoccupied with paranoid delusions or auditory hallucinations. Cognitive function is usually preserved; if thought disorder is present, it does not prevent description of delusions or hallucinations.
Residual	The patient does not have acute psychosis, but some symptoms of schizophrenia remain. Largely negative symptoms are seen, such as flat affect, social withdrawal, and loose associations. Prominent delusions or hallucinations are not present.
Undifferentiated	The patient meets the criteria for a diagnosis of schizophrenia but does not meet the criteria for a specific type, or the patient may meet the criteria for multiple types of schizophrenia. No one type appears to be dominant.

Table 39-2   SYMPTOMS OF SCHIZOPHRENIA

Positive Symptoms	Negative Symptoms	Disorganized Symptoms
Delusions	Affective flattening	Disorganized speech
Hallucinations	Alogia	Thought disorder
Combativeness	Anhedonia	Disorganized behavior
Insomnia	Amotivation	Poor attention
	Apathy	
	Asocial behavior	

2. A **delusion** is an incorrect or false belief. Delusions can be religious, paranoid/persecutory, grandiose, somatic, influential, or sexual. Persecutory or paranoid delusions are the most common.

III. TREATMENT GOALS AND OBJECTIVES.
There is currently no known cure for schizophrenia. Treatment options include **psychotherapy** as well as **pharmacotherapy**. The goals and objectives of treatment are as follows:

A. Minimize symptoms of schizophrenia
B. Improve quality of life and social/occupational functioning
C. Prevent relapse and hospitalization
D. Minimize adverse effects of medications
E. Prevent suicide attempts or self-harm

IV. PHARMACOTHERAPY: ANTIPSYCHOTIC MEDICATIONS

A. Two generations of antipsychotic medications are available for treatment: **first-generation (typical antipsychotics)** and **second-generation (atypical antipsychotics)**.
   1. The choice of an appropriate antipsychotic agent depends on the patient's previous experiences with antipsychotic medications, adverse effects, the patient's concomitant medical conditions, medication interactions, and the patient's preference.
   2. Current American Psychiatric Association (APA) guidelines recommend using an atypical antipsychotic first, owing to less risk for extrapyramidal symptoms (EPS). Patients who prefer or have a history of response to typical antipsychotics may first use typical antipsychotics.
   3. Response to medications is not immediate, and maximal treatment response may take 6 months or longer to be seen.
   4. After a treatment response is seen, patients should be maintained on the current therapy for a minimum of 6 months. Most patients will require chronic therapy, because 80% of first-episode patients who do not receive antipsychotic treatment will relapse within 5 years.
B. **Typical antipsychotic medications** (*Table 39-3*)
   1. **Mechanism of action.** The antipsychotic effect of these medications is primarily mediated through the blockade of dopamine type 2 (D2) receptors. Agents within this medication class vary in their activity at histamine, muscarinic, and α-receptors, although these receptors are not responsible for desired therapeutic activity.
   2. **Potency.** Typical antipsychotic agents are classified by their potency for the dopamine receptor into high-, moderate-, and low-potency antipsychotics. High-potency agents have a higher affinity for the dopamine receptor and are associated with higher risk for the development of EPS. Low-potency agents have less affinity for dopamine receptors; and although they have less risk for causing EPS, they are associated with more adverse effects from their activity at histamine, muscarinic, and α-receptors.
   3. **Efficacy.** When dosed in equivalent doses, the various typical antipsychotics have similar efficacy. Equivalent doses are described using **chlorpromazine (CPZ) equivalents** (*Table 39-3*). Typical antipsychotics are thought to be as effective as atypical antipsychotics for positive symptoms but are less effective for negative symptoms.
   4. **Adverse effects.** Typical antipsychotics are associated with several adverse effects (*Tables 39-3 and 39-4*).

| Table 39-3 | PROPERTIES OF TYPICAL ANTIPSYCHOTICS |

Agent	CPZ[a] Equivalent	Dose Range[a] (mg/day)	Sedation	EPS	Anticholinergic Side Effects	Orthostatic Hypotension
Chlorpromazine (Thorazine)	100	300–1000	+++	++	++	+++
Trifluoperazine (Stelazine)	5	5–15	+	+++	+	+
Thioridazine (Mellaril)	100	300–800	+++	+	+++	+++
Perphenazine (Trilafon)	10	16–64	++	++	+	+
Fluphenazine (Prolixin)	2	5–20	+	+++	+	+
Thiothixene (Navane)	5	15–50	+	+++	+	++
Haloperidol (Haldol)	2	5–20	+	+++	+	+
Molindone (Moban)	10	30–100	++	++	+	+
Loxapine (Loxitane)	10	30–100	+	++	+	+

[a]Data from Lehman AF, Lieberman JA, Dixon LB, et al. Practice guideline for treatment of patients with schizophrenia. 2nd ed. *Am J Psych.* 2004;161:1–56.
CPZ, chlorpromazine; *EPS*, extrapyramidal symptoms; + + +, high; + +, moderate; +, low.

| Table 39-4 | GENERAL ADVERSE EFFECTS OF ANTIPSYCHOTICS |

Typical Antipsychotics	Atypical Antipsychotics
Sedation	Sedation
Anticholinergic effects	Anticholinergic effects (clozapine, olanzapine)
Blurred vision	Orthostatic hypotension
Constipation	Moderate to severe weight gain
Dry mouth	Diabetes mellitus
Urinary retention	Hypercholesterolemia
Extrapyramidal symptoms	Hyperprolactinemia (risperidone)
Lowered seizure threshold	Lowered seizure threshold
Orthostatic hypotension	QT prolongation
Hyperprolactinemia	Neuroleptic malignant syndrome
Moderate weight gain	Extrapyramidal symptoms
QT prolongation	Sexual dysfunction
Photosensitivity	
Temperature dysregulation	
Neuroleptic malignant syndrome	
Sexual dysfunction	
Elevated liver enzymes	

Table 39-5	ADVERSE EFFECTS BY RECEPTOR AFFINITIES

Receptor Antagonized	Adverse Effects
Histamine	Sedation
	Weight gain
Dopamine	Extrapyramidal symptoms
	Hyperprolactinemia
Muscarinic	Anticholinergic adverse effects
	Cognitive impairment
	Tachycardia
Alpha	Orthostatic hypotension
	Reflex tachycardia
Serotonin	Weight gain

a. The activity of the various typical antipsychotics at the dopamine, α-, muscarinic, and histamine receptors is responsible for many of the adverse effects of these medications (*Table 39-5*).

b. **Extrapyramidal side effects** can occur with all the typical antipsychotics, especially with high-potency typical antipsychotics. Four types of extrapyramidal side effects have been described: acute dystonia, akathisia, pseudoparkinsonism, and tardive dyskinesia.

   (1) **Acute dystonia** describes sudden muscle spasms that primarily occur in the eye, neck, face, and throat muscles. An acute dystonic reaction can be a medical emergency; therefore, use of an intravenous or intramuscular treatment may be warranted for quick symptom resolution.

      (a) Acute dystonias can occur within hours of initiating the medication or increasing the dose. This is most common in young men and in patients using high doses of high-potency typical antipsychotics.

      (b) Management includes the use of anticholinergic agents like benztropine and diphenhydramine; if ineffective, benzodiazepines can also be used. Prevention of future reactions may be achieved by decreasing the dose of antipsychotic, using oral anticholinergics, or changing therapy to an atypical antipsychotic.

   (2) **Akathisia** is described as inner restlessness associated with feelings of having to move.

      (a) Patients with akathisia may pace or be unable to sit still. This may occur within days to a few months after the initiation of therapy or increase in dose.

      (b) Treatment of akathisia includes dose reduction of the antipsychotic, lipophilic β-blockers or benzodiazepines. Therapy may also be changed to an atypical antipsychotic. Anticholinergic agents may not be useful in the treatment of akathisia.

   (3) **Pseudoparkinsonism** clinically appears similar to idiopathic Parkinson disease and includes symptoms like shuffling gait, masklike face, cogwheel rigidity, and resting or pill-rolling tremor.

      (a) This can occur within 1 to 3 months after starting therapy or increasing the dose of the antipsychotic agent.

      (b) This is treated by changing to an atypical antipsychotic, decreasing the dose, and/or adding an anticholinergic agent.

   (4) **Tardive dyskinesia (TD)** usually does not occur until the patient has been taking antipsychotics for a year or more. It is a movement disorder that can occur in various locations of the body, including the face, tongue, hips, and extremities.

      (a) Movements can be dystonic (fixed) or choreoathetoid (rhythmic). Common movement disorders include tongue chewing, lip smacking, and rhythmic movements of the trunk.

       (b) TD may be irreversible, so patients taking antipsychotics should be monitored closely for the appearance of any movement disorders.

       (c) A tool such as the Abnormal Involuntary Movement Scale (AIMS) is available to assist in monitoring TD.

       (d) Vigilant monitoring for signs of TD is the best way to prevent it from occurring. Stopping the causative agent (if possible) and switching to an atypical antipsychotic may be the best treatment for preventing irreversible TD. Multiple treatments have been used to attempt to treat TD, although none have been definitively proven to be effective. These include vitamin E, benzodiazepines, baclofen, and reserpine.

    c. **Neuroleptic malignant syndrome (NMS)** is an uncommon but potentially fatal adverse effect of antipsychotics. Signs and symptoms include fever, severe rigidity, altered mental status, unstable blood pressure, tachycardia, incontinence, elevated creatine kinase, and increased white blood count.

       (1) NMS has a sudden onset, and should prompt immediate discontinuation of all antipsychotics. Antipsychotics are recommended not to be restarted for at least 2 weeks following the resolution of NMS. It is also recommended to restart antipsychotic therapy with a different medication.

       (2) Treatment includes supportive care and the use of bromocriptine and/or dantrolene.

C. **Atypical antipsychotic medications** (*Table 39-6*)

    1. Ten atypical antipsychotics are currently on the U.S. market: clozapine (Clozaril), risperidone (Risperdal), olanzapine (Zyprexa), quetiapine (Seroquel), ziprasidone (Geodon), aripiprazole (Abilify), paliperidone (Invega), asenapine (Saphris), iloperidone (Fanapt), and lurasidone (Latuda).

    2. The **mechanism of action** for atypical antipsychotics is different from that of the typical antipsychotics. With the exception of aripiprazole, the atypical antipsychotics are dopamine antagonists but also potently block 5-HT_{2A}-receptors. They block 5-HT to a greater extent than dopamine. Aripiprazole is a partial dopamine and 5-HT_{1A}-agonist and a 5-HT_{2A}-antagonist. Asenapine has a high affinity for 5-HT, dopamine, alpha, and histaminergic receptors with low affinity for muscarinic receptors. Iloperidone acts at numerous 5-HT and dopamine receptors and has high affinity for alpha-1 receptors. Lurasidone is a partial agonist 5-HT_{1A}-receptor with no affinity for muscarinic or histaminergic receptors.

    3. **Receptor affinity** differs for the various atypical antipsychotics. All atypical antipsychotics have activity at the 5-HT_{2A}-receptor and dopamine receptor. Different agents have different activity for histamine, α-, and muscarinic receptors (*Table 39-6*).

    4. Atypical antipsychotics may have increased efficacy for negative symptoms compared to typical antipsychotics. Clozapine has demonstrated efficacy for treatment-refractory schizophrenia.

    5. **Adverse effects.** Atypical antipsychotics differ from typical antipsychotics in their adverse effect profile (*Table 39-4*). Owing to their higher affinity for 5-HT_2-receptors compared to dopamine receptors, they are associated with less EPS and hyperprolactinemia than typical antipsychotics. However, they have problematic adverse effects, which limit their use (*Table 39-6*).

      a. Atypical antipsychotics have been linked with weight gain, hyperlipidemia, and hyperglycemia. The risk for the development of these metabolic adverse effects differs among agents.

    6. Clozapine was the first atypical antipsychotic to be marketed in the United States, is the only antipsychotic with no risk of EPS or TD and is the only antipsychotic with proven efficacy for treatment-refractory schizophrenia. Clozapine has also been shown to reduce suicidal behavior. However, clozapine is indicated only in patients who have failed at least two previous antipsychotics (including typical and atypical antipsychotics) because of its risk of agranulocytosis. Complete blood count (CBC) must be monitored at baseline, every week for the first 6 months of therapy, every other week for the next 6 months, and then every month thereafter. Clozapine may also lower seizure threshold in patients, especially with higher doses. Clozapine should be used with caution in patients at risk for seizures or with a history of a seizure disorder. Clozapine can cause numerous other side effects, especially early in therapy, therefore additional reading is required for a better understanding of its benefits and risks.

Table 39-6 PROPERTIES OF ATYPICAL ANTIPSYCHOTICS

Medication	Dose Range[a] (mg/day)	Receptor Affinity[a]	Sedation	EPS	Anticholinergic Effects	Orthostatic Hypotension	Weight Gain
Clozapine	150–600	D, 5-HT, M, H$_1$, α	+++	0	+++	+++	+++
Risperidone	2–8	D, 5-HT, H$_1$, α	+	+ to ++	0	+	++
Olanzapine	10–30	D, 5-HT, M, H$_1$, α	++	+	++	+	+++
Quetiapine	300–800	D, 5-HT, H$_1$, α	++	+	0	++	++
Ziprasidone	120–200	D, 5-HT, H$_1$, α	0	+	0	0	0
Aripiprazole	10–30	D, 5-HT, H$_1$, α	+	+	0	0	0
Paliperidone[b]	3–12	D, 5-HT, H$_1$, α	+	+ to ++	0	+	unknown

[b]Data from Invega package insert, 2007. Titusville, NJ: Janssen, L.P.
5-HT, 5-hydroxytryptamine (serotonin); α, alpha; *D,* dopamine; *EPS,* extrapyramidal symptoms; *H$_1$,* histamine; *M,* muscarinic; +++, high; ++, moderate; +, low.

7. Unique formulations of atypical antipsychotics are available for patients.
    a. **Orally disintegrating tablets.** Risperidone, olanzapine, aripiprazole, and asenapine are available as orally disintegrating tablets. Asenapine must be given sublingually to increase its absorption. If the tablet is swallowed, its bioavailability significantly decreases from 35% to less than 2%.
    b. **Intramuscular formulations.** Ziprasidone, olanzapine, and aripiprazole are available in intramuscular formulations for use in acutely agitated patients with schizophrenia.
        (1) Ziprasidone may be given as 10 or 20 mg. The 10 mg dose may be repeated in 2 hrs, and the 20 mg dose may be repeated in 4 hrs. The maximum daily dose is 40 mg.
        (2) Olanzapine may be given as 10 mg. The 10 mg dose may be repeated every 2 hrs up to a maximum of 30 mg daily.
        (3) **Aripiprazole may be given as 9.75 mg. The 9.75 mg dose may be repeated every 2 hrs up to a maximum of 30 mg daily.**
D. **Noncompliant patients.** Those patients with a history of noncompliance or who have frequent hospitalizations secondary to noncompliance may be candidates for a long-acting intramuscular formulation of antipsychotic. Currently five options exist: haloperidol decanoate, fluphenazine decanoate, long-acting risperidone (Risperdal Consta), paliperidone palmitate (Invega Sustenna), and olanzapine pamoate (Zyprexa Relprevv).
    1. **Haloperidol decanoate** is given intramuscularly every 3 to 4 weeks. The starting dose should be 10 to 15 times the total daily dose of oral haloperidol. Oral overlap should continue for 1 month. Loading a patient with 20 times the total daily dose of oral haloperidol is another strategy and it does not require oral overlap. Doses should be administered as 100 or 200 mg subsequent doses every 3 to 7 days until the full dose is given. Follow-up intramuscular doses are then decreased by 25% after this initial loading dose has been given.
    2. **Fluphenazine decanoate** is administered intramuscularly every 2 to 3 weeks. The starting dose is 1.2 to 1.6 times the total daily dose of oral fluphenazine. Oral overlap is recommended for 1 week. The maximum dose of fluphenazine decanoate is 100 mg at any one time. The lowest effective dose of this formulation should be used.
    3. **Long-acting risperidone** is administered intramuscularly every 2 weeks. An effective dose of oral risperidone should first be identified before changing to the long-acting formulation. Patients should be started at 25 mg every 2 weeks and covered with oral medications for 3 weeks after initiation. Doses may be increased to a maximum of 50 mg every 2 weeks.
    4. Paliperidone palmitate is administered intramuscularly in the deltoid or gluteal muscle. Therapy is initiated with a loading dose of 234 mg followed by a second injection of 156 mg 1 week later. Subsequent doses are given every 4 weeks and range from 39 to 234 mg.
    5. Olanzapine pamoate is administered intramuscularly at a dose of 210 mg or 300 mg every 2 weeks or 405 mg every 4 weeks during the first 8 weeks of therapy. After 8 weeks, doses can range from 150 mg to 300 mg every 2 weeks or 300 mg to 405 mg every 8 weeks. Olanzapine pamoate can only be administered at a registered health care facility and patients must be monitored for at least 3 hours following injection. This monitoring is required due to delirium/sedation syndrome.
E. **Antipsychotic agents** may be switched for several reasons, such as lack of efficacy and adverse effects. When switching antipsychotic agents, the original agent should be titrated down while the new agent is titrated up. If changing from a typical antipsychotic to an atypical antipsychotic secondary to EPS, anticholinergic agents may be continued until the typical agent is completely discontinued.
F. **Adjunctive therapy.** In patients with partial or no response to therapy after an adequate trial, approximately 4 weeks, of an antipsychotic, a second antipsychotic should be tried. After the failure of two to three antipsychotics, the patient meets the criteria for clozapine, and its use should be considered. Augmentation is an option for those patients unable to take clozapine or with partial/no response. Clozapine has been studied in combination with typical and atypical antipsychotics. Other options for augmentation include mood stabilizers, such as lithium, valproic acid, and carbamazepine. Antidepressants have also been used in patients suffering from depressive symptoms. Electroconvulsive therapy (ECT) has also been used as an adjunctive therapy in patients with partial or no response to antipsychotics.

Study Questions

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by one of the suggested answers or phrases. Choose the best answer.

For questions 1–5: DG is a 23-year-old female committed to the inpatient psychiatric ward by her parents. They state that she has recently been under a large amount of stress from college, and they have noticed over the past year that she has become more withdrawn from her friends and social activities. They also state that she angers more easily than she used to as a child, and this morning they found her with a knife trying to slit her wrists. DG states that the voices keep telling her she is bad and that she should kill herself. She does not admit to any visual hallucinations but describes multiple voices (male and female) talking to her continuously telling her that she should harm herself or that people are out to get her. She keeps telling you that her parents are trying to get rid of her, and she wants to leave. She appears to be a healthy young woman although noticeably agitated. Her medical history is significant only for smoking one pack/day since age 16. DG is diagnosed with schizophrenia.

1. Which type of schizophrenia is DG likely experiencing based upon her presenting signs and symptoms?

   (A) catatonic
   (B) disorganized
   (C) paranoid
   (D) residual

2. Which of the following of DG's symptoms is best described as a negative symptom of schizophrenia?

   (A) social withdrawal
   (B) auditory hallucinations
   (C) delusions
   (D) agitation

3. The medical team decides to initiate treatment for DG. Which of the following antipsychotic medications is the best initial treatment for this patient?

   (A) haloperidol
   (B) risperidone
   (C) thioridazine
   (D) clozapine

4. Which of the following is *not* a potential adverse effect of the medication selected for DG in question 3?

   (A) weight gain
   (B) pseudoparkinsonism
   (C) sedation
   (D) urinary retention

5. DG is stabilized on the medication prescribed and is discharged home. DG is readmitted into the psychiatric ward 1 year later for auditory and visual hallucinations secondary to noncompliance on her current treatment regimen. Which of the following treatment options is most appropriate for DG at this time?

   (A) haloperidol decanoate
   (B) long-acting risperidone
   (C) clozapine monotherapy
   (D) adjunctive clozapine with haloperidol

For questions 6–8: TW is a 52-year-old female with a history of schizophrenia and diabetes mellitus type 2. She has been treated for many years with haloperidol with good response; however, she has recently developed lip smacking and tongue chewing.

6. What type of adverse effect is TW experiencing?

   (A) akathisia
   (B) acute dystonia
   (C) pseudoparkinsonism
   (D) tardive dyskinesia

7. Which of the following medications has been used to treat the adverse effect described in question 6?

   (A) vitamin E
   (B) propranolol
   (C) diphenhydramine
   (D) amantadine

8. Now that TW is experiencing this reaction, her health care providers want to change her therapy to a different antipsychotic. Which of the following antipsychotics is the best treatment option for her?

   (A) olanzapine
   (B) risperidone
   (C) quetiapine
   (D) fluphenazine

9. Which of the following atypical antipsychotics would be the least likely to cause weight gain?

    (A) risperidone
    (B) olanzapine
    (C) quetiapine
    (D) aripiprazole

10. Which of the following statements does not describe a way in which atypical antipsychotics differ from typical antipsychotics?

    (A) Atypical antipsychotics have a higher affinity for serotonin receptors than dopamine receptors.
    (B) Atypical antipsychotics are more efficacious for positive symptoms than typical antipsychotics.
    (C) Atypical antipsychotics are more likely to cause weight gain and hyperlipidemia than typical antipsychotics.
    (D) Atypical antipsychotics are less likely to cause extrapyramidal symptoms (EPS) than typical antipsychotics.

11. Which of the following long-acting injectable antipsychotics requires a 3-week overlap with oral antipsychotic medication following the first injection?

    (A) paliperidone
    (B) olanzapine
    (C) haloperidol
    (D) risperidone

12. Which of the following antipsychotics is the only agent shown to produce benefit in WELL-DEFINED treatment-resistant schizophrenia?

    (A) risperidone
    (B) clozapine
    (C) olanzapine
    (D) chlorpromazine

13. Which of the following antipsychotics is most likely to cause anticholinergic side effects?

    (A) aripiprazole
    (B) olanzapine
    (C) paliperidone
    (D) risperidone

14. XY is currently being treated for schizophrenia and was recently started on haloperidol (Haldol) 20 mg daily 1 week ago. You notice that he is pacing the unit floors; and upon talking to him, he confesses being unable to sit still. He says he feels like he has a motor running inside him that is relieved only by walking. Your team thinks he is agitated from his hallucinations and wants to increase the haloperidol to 30 mg. You recommend which of the following?

    (A) Disagree with the team, he is experiencing a manic episode and needs to have valproic acid added to his treatment regimen.
    (B) Disagree with the team, he is experiencing a dystonic reaction related to the haloperidol dose. Recommend decreasing the dose and starting an IV anticholinergic medication
    (C) Disagree with the team, he is experiencing akathisia related to the haloperidol dose. Recommend decreasing the dose and starting a benzodiazepine.
    (D) Disagree with the team, he is experiencing tardive dyskinesia related to the haloperidol dose. Recommend decreasing the dose and stating an anticholinergic medication

15. Which of the following antipsychotics acts as a partial agonist at $5\text{-}HT_{1A}$ receptors?

    (A) aripiprazole
    (B) olanzapine
    (C) haloperidol
    (D) risperidone

Answers and Explanations

1. **The answer is C** [see Table 39-1].
   DG's prominent symptoms include well-formed hallucinations and delusions. These hallucinations and delusions are characteristics of paranoid schizophrenia. DG also does not meet the criteria for any other type of schizophrenia.

2. **The answer is A** [see Table 39-2].
   Social withdrawal or asocial behavior is a negative symptom of schizophrenia. Hallucinations, delusions, and agitation are all positive symptoms of schizophrenia.

3. **The answer is B** [see IV.A.2; IV.C.1; IV.C.6].
   The American Psychiatric Association currently recommends using atypical antipsychotics first over typical antipsychotics, unless the patient has a preference. Haloperidol and thioridazine are typical antipsychotics. Clozapine should be used only for treatment refractory patients because of its adverse effect profile.

4. **The answer is D** [see Table 39-4; Table 39-6].
   Risperidone has been associated with moderate weight gain, low to moderate risk of EPS, and low risk of sedation. It has not been associated with anticholinergic effects such as urinary retention.

5. **The answer is B** *[see IV.D.3]*.
   DG has a history of response with risperidone; however, she is experiencing a relapse of symptoms owing to noncompliance. A long-acting formulation is indicated to assist with medication compliance. As she has not failed multiple antipsychotics, DG is not a candidate for clozapine or adjunctive clozapine. Long-acting risperidone is preferred in this patient over haloperidol decanoate owing to the patient's response history and its preferable adverse effect profile.

6. **The answer is D** *[see IV.B.4.b.(1)–(4)]*.
   TW is experiencing lip smacking and tongue chewing of a late onset, which is best described as tardive dyskinesia.

7. **The answer is A** *[see IV.B.4.b.(4).(d)]*.
   Vitamin E, benzodiazepines, baclofen, and reserpine have all been used in the treatment of tardive dyskinesia, although none has been definitively proven to be effective.

8. **The answer is C** *[see Table 39-3; Table 39-6]*.
   Because TW is experiencing tardive dyskinesia, her therapy should be changed to an atypical antipsychotic. Her medical history is significant for type 2 diabetes mellitus. Olanzapine is associated with a high risk of causing weight gain, and other metabolic symptoms and should not be used in this patient. Risperidone has a low to moderate risk of EPS. Other atypical antipsychotics, such as quetiapine, that carry a lower risk of EPS would be preferable.

9. **The answer is D** *[see Table 39-6]*.
   Olanzapine has a high risk of causing weight gain. Risperidone and quetiapine have a moderate risk of causing weight gain. Aripiprazole is associated with a low risk of weight gain.

10. **The answer is B** *[see IV.C.2–5.a; Table 39-4]*.
    Atypical antipsychotics have a higher affinity for serotonin receptors than dopamine receptors, whereas typical antipsychotics have no activity at serotonin receptors. Atypical and typical antipsychotics have similar efficacy for positive symptoms of schizophrenia; however, atypical antipsychotics have increased efficacy against negative symptoms. Atypical antipsychotics are more likely to cause significant weight gain and hyperlipidemia and less likely to cause EPS than typical antipsychotics.

11. **The answer is D** *[see IV.D.3]*.
    Risperdal Consta is the only injectable that requires a 3-week overlap with oral risperidone following the first injection. The other injectables either do not require an oral overlap or it is less/greater than 3 weeks.

12. **The answer is B** *[see IV.C.6]*.
    Clozapine is the only antipsychotic to be effective in treatment-resistant schizophrenics.

13. **The answer is B** *[see Table 39-6]*.
    Olanzapine is the only antipsychotic listed that is a strong antagonist of cholinergic receptors. The other three agents have no to minimal blockage of the cholinergic receptors.

14. **The answer is C** *[see IV.B.4.b.(2)]*.
    The patient is experiencing akathisia from too high of a haloperidol dose. The haloperidol dose should be decreased and a benzodiazepine should be started. Akathisia is described as an inner restlessness coupled with an inability to sit still or a need to move.

15. **The answer is A** *[see IV.C.2]*.
    Aripiprazole is the only antipsychotic listed that in addition its blocking of 5-HT and dopamine receptors, it also acts as an agonist at 5-HT1A receptors.

Mood Disorders, Anxiety Spectrum Disorders, Attention-Deficit Hyperactivity Disorder (ADHD), and Insomnia

REBEKAH R. ARTHUR GRUBE, ANDREW J. MUZYK

I. TREATMENT OF MAJOR DEPRESSIVE DISORDER. Major depressive disorder is defined as a mood disorder in which the patient has one or more episodes of major depression but has no history of mania, mixed, or hypomania episodes. Major depressive episodes are described in II.D.

A. Diagnosis and clinical features
   1. Major depressive episodes are diagnosed using the *Diagnostic and Statistical Manual of Mental Disorders*, 4th ed. (*DSM-IV-TR*) criteria. To meet the criteria for a major depressive episode, patients should experience at least five or more persistent symptoms for at least 2 weeks. These symptoms include depressed mood, loss of interest or pleasure in activities, change in appetite, unintentional weight gain or loss, insomnia or excess sedation, psychomotor agitation or retardation, decreased energy or fatigue, feelings of worthlessness or inappropriate guilt, decreased ability to concentrate, and recurrent thoughts of suicide, death, or suicide attempt.[1]
   2. Symptoms should impair social or occupational functioning and should not be related to a general medical condition or substance abuse.
B. Treatment options. Three treatment options exist for the treatment of depression: **pharmacotherapy**, **psychotherapy**, and **electroconvulsive therapy (ECT)**. Complementary or alternative treatments used in major depression include St. John's wort, S-adenosyl methionine, omega-3 fatty acids, and folate.
   1. **Pharmacotherapy options (antidepressants).** Pharmacotherapy can be used for mild to severe major depression and produces a response in 50% to 75% of patients. Some evidence suggests antidepressants are more effective in patients with moderate to severe depression. Antidepressants have similar efficacy; however, they differ in adverse effects, mechanism of action, drug–drug interactions, and cost. Therefore, selection of an antidepressant should take these factors into consideration. Patients with a history of response to a particular agent may restart that agent if desired.
      a. **Monoamine oxidase inhibitors (MAOIs)** (*Table 40-1*)
         (1) **Indications.** MOAIs have numerous adverse effects and medication interactions and are indicated only in patients refractory to other antidepressants. These agents also have

803

Table 40-1   MONOAMINE OXIDASE INHIBITORS

Agent	Starting Dose (mg/day)	Usual Dose^a (mg/day)	Anticholinergic Effects	Sedation	Weight Gain
Phenelzine (Nardil)	15	45–90	++	++	+++
Isocarboxazid (Marplan)	10–20	30–60	++	++	++
Tranylcypromine (Parnate)	10	30–60	++	+	++
Selegiline (Emsam) patch	6	6–12	++	0	+

^{a}For normal adults. Doses may need to be adjusted for elderly patients or those with impaired renal or hepatic function.
+++, high; ++, moderate; +, slight.

a role in patients presenting with atypical depression. Recently, the FDA approved a transdermal patch formulation of selegiline (Emsam), which may be useful in patients unable to take oral antidepressants.

(2) **Mechanism of action.** MAOIs inhibit monoamine oxidase, which is responsible for the breakdown of neurotransmitters such as dopamine (DA), serotonin (5-HT), and norepinephrine (NE).

(3) **Adverse effects** include hypertensive crises, serotonin syndrome, orthostatic hypotension, peripheral edema, weight gain, and sexual dysfunction.

(a) **Hypertensive crises** can occur when increased levels of sympathetic amines, such as NE, build up in the body, which can be the result of ingestion of tyramine-containing foods like wine and cheese or the administration of sympathomimetic agents (e.g., decongestants). Patients should be counseled regarding the risk for drug and food interactions when taking MAOIs. A tyramine-restricted diet is not required with the 6 mg/day selegiline patch, however at doses of 9 mg/day or greater it is recommended.

(b) **Serotonin syndrome.** MAOIs in combination with selective serotonin reuptake inhibitors, tricyclic amines, serotonin and norepinephrine reuptake inhibitors, and any other agent with serotonergic activity can lead to serotonin syndrome. The clinical manifestations of serotonin syndrome are given in *Table 40-2*.

(c) Other common side effects include orthostatic hypotension, sexual dysfunction (anorgasmia, decreased libido, and erectile/ejaculatory dysfunction), and insomnia.

(4) **Medication interactions**

(a) MAOIs are substrates of various cytochrome P450 (CYP450) enzymes and levels can be affected by enzyme inhibitors and inducers.

b. Many tricyclic amines (TCAs) can be classified as tertiary and secondary (*Table 40-3*). Tertiary and secondary amines have pharmacological differences, although this mainly influences their adverse effect profile.

(1) **Indications.** Owing to their numerous adverse effects, TCAs are not usually indicated first line for the treatment of depression.

Table 40-2   SIGNS AND SYMPTOMS OF SEROTONIN SYNDROME

Cognitive-Behavioral Dysfunction	Autonomic Nervous System Dysfunction	Neuromuscular Dysfunction
Confusion	Diarrhea	Myoclonus
Hypomania	Shivering	Hyperreflexia
Agitation	Fever	Tremor
	Diaphoresis	Seizure
	Change in blood pressure	Death
	Nausea and vomiting	

| Table 40-3 | TRICYCLIC AMINES |

Agent	Usual Dose[a] (mg/day)	Anticholinergic Effects	Sedation	Orthostatic Hypotension	Cardiac Effects	Weight Gain
Tertiary amine						
Amitriptyline (Elavil)	100–300	++++	++++	++++	+++	++++
Doxepin (Sinequan)	100–300	+++	++++	++	++	++++
Imipramine (Tofranil)	100–300	+++	+++	++++	+++	++++
Trimipramine (Surmontil)	75–300	++++	++++	+++	+++	++++
Secondary amine						
Nortriptyline (Pamelor)	50–200	++	++	+	++	+
Desipramine (Norpramin)	100–300	+	++	++	++	+
Protriptyline (Vivactil)	20–60	++	+	++	+++	+

[a]For normal adults. Doses may need to be adjusted for elderly patients or those with impaired renal or hepatic function.
++++, very high; +++, high; ++, moderate; +, slight.

    (a) TCAs may be considered for patients with a history of response to TCAs, patients refractory to other medications, or patients with comorbidities that might benefit from TCAs, such as neuropathic pain and migraines.

    (b) TCAs can be lethal in overdose and should not be used in patients with suicidal ideations. Additionally, TCAs should be avoided or used with caution in patients with cardiovascular conditions, closed-angle glaucoma, urinary retention, or severe prostate hypertrophy.

(2) Mechanism of action. TCAs produce their antidepressant effect by inhibiting the reuptake of 5-HT and NE. TCAs also have effect at α-adrenergic, histamine, and cholinergic receptors. Tertiary and secondary amines have equal potency in blocking NE reuptake. Tertiary amines possess greater potency for blocking 5-HT reuptake and greater affinity for these other receptors.

(3) Adverse effects. Several adverse effects exist for TCAs and may differ between agents, depending on their affinity for α-adrenergic, cholinergic, and histamine receptors (*Table 40-3*).

    (a) Tertiary amine TCAs have been associated with a higher risk of causing anticholinergic adverse effects (blurred vision, constipation, urinary retention, dry mouth), sedation, weight gain, and orthostatic hypotension than secondary amine TCAs. Elderly patients may experience memory impairment and confusion due to anticholinergic effects of this medication class. Anticholinergic-induced delirium may be seen in overdose.

    (b) Additional adverse effects include tachycardia, orthostatic hypotension, arrhythmias (especially in overdose), cardiac conduction abnormalities, decreased seizure threshold, sedation, falls, and sexual dysfunction. Nortriptyline may be the least likely to cause orthostatic blood pressure changes.

    (c) Owing to their activity on serotonin, TCAs have the potential for causing serotonin syndrome when used in combination with other serotonergic agents.

(4) Medication interactions. TCAs are substrates of various cytochrome P450 (CYP450) enzymes, and levels can be affected by enzyme inhibitors and inducers. Drug–drug interactions occurring at CYP3A4 and CYP2D6 are most common with TCAs.

Table 40-4 SELECTIVE SEROTONIN REUPTAKE INHIBITORS AND SEROTONIN AND NOREPINEPHRINE REUPTAKE INHIBITORS

Agent	Starting Dose (mg/day)	Usual Dose (mg/day)	Half-Life	CYP450 Isoenzyme Inhibition
Fluoxetine (Prozac)	10–20	20–60; 80 mg weekly[a]	7–9 days[b]	2D6, 2C9/19 (potent); 3A4 (mild)
Paroxetine (Paxil)	10–20	20–60	21 hrs	2D6 (potent)
Sertraline (Zoloft)	25–50	50–200	24 hrs	2D6 (mild)
Citalopram (Celexa)	10–20	20–60	35 hrs	2D6 (mild)
Escitalopram (Lexapro)	5–10	10–20	27–32 hrs	2D6 (mild)
Venlafaxine (Effexor)	75	75–375	11 hrs	2D6 (mild)
Desvenlafaxine (Pristiq)	50	50	10 hrs	34A (mild)
Duloxetine (Cymbalta)	40	60–120	9–19 hrs	2D6 (moderate)

[a]Fluoxetine can be given in a once-weekly formulation in patients stabilized on fluoxetine 20 mg daily; should be started 1 week after the last dose of fluoxetine.
[b]Norfluoxetine is an active metabolite of fluoxetine and has a half-life of 7–9 days. The half-life of fluoxetine alone is 2–3 days.
CYP450, cytochrome P450.

    c. Selective serotonin reuptake inhibitors (SSRIs). Five SSRIs are currently available in the United States for the treatment of depression (*Table 40-4*). SSRIs are considered to be first-line antidepressants for the treatment of depression and many are also indicated for other comorbid psychiatric disorders.

       (1) Mechanism of action. SSRIs exert their antidepressant effect by blocking the reuptake of serotonin. SSRIs due differ in the pharmacological actions (such as fluoxetine blocking NE reuptake and paroxetine blocking cholinergic receptors).

       (2) Adverse effects

          (a) SSRIs have been associated with nausea, vomiting, insomnia, sedation, sexual dysfunction, headache, falls, osteopenia, akathisia, agitation, and tremor.

          (b) Paroxetine has also been associated with anticholinergic adverse effects.

          (c) These agents have been associated with serotonin syndrome when used in combination with other serotonergic agents.

          (d) Abrupt discontinuation of SSRIs can cause withdrawal symptoms, such as nightmares, vivid dreams, tremor, anxiety, and nausea. Fluoxetine is the least likely to cause withdrawal, while paroxetine causes the greatest discontinuation syndrome. SSRIs should be slowly tapered when discontinued to prevent this syndrome.

       (3) Medication interactions

          (a) SSRIs are metabolized by the liver mainly by CYP3A4 and CYP2D6 enzymes. Fluoxetine and paroxetine are strong inhibitors of CYP2D6.

          (b) SSRIs alone and in combination with NSAIDs have been associated with gastrointestinal bleeding.

    d. Serotonin and norepinephrine reuptake inhibitors (SNRIs) (*Table 40-4*). Three SNRIs are currently available for the treatment of depression: venlafaxine (Effexor), desvenlafaxine (Pristiq), and duloxetine (Cymbalta). Data have shown these medications to have efficacy for the treatment not only of depression but also for peripheral neuropathies. Duloxetine carries an FDA-approved indication for the treatment of pain in diabetic neuropathy and fibromyalgia.

       (1) Mechanism of action. SNRIs inhibit the reuptake of 5-HT and NE, thereby increasing their levels. These medications differ from TCAs in that they have little activity for α-adrenergic, cholinergic, or histamine receptors. Duloxetine is a potent inhibitor of 5-HT and NE at clinical doses, whereas venlafaxine requires higher doses (> 150 mg/day) to affect both 5-HT and NE.

Table 40-5	MISCELLANEOUS ANTIDEPRESSANTS		
Agent	**Starting Dose (mg/day)**	**Usual Dose (mg/day)**	**Cytochrome P450 Isoenzyme Inhibition**
Bupropion (Wellbutrin)	75–150	300–450	2D6
Mirtazapine (Remeron)	15	15–45	Does not inhibit
Trazodone (Desyrel)	50–100	150–600	Does not inhibit

    (2) Adverse effects. SNRIs have an adverse effect profile similar to that of the SSRIs. Venlafaxine has been associated with elevations of diastolic blood pressure, particularly with the immediate release formulation and at higher doses. Abrupt discontinuation of SNRIs can lead to withdrawal symptoms, particularly with immediate-release venlafaxine.

    (3) Medication interactions. Venlafaxine and duloxetine are both mainly substrates for the CYP2D6 liver enzymes. Duloxetine is a moderate inhibitor of CYP2D6 (*Table 40-4*). SNRIs should not be used with MAOIs or other serotonergic agents owing to risk of serotonin syndrome.

  e. Bupropion (Wellbutrin) (*Table 40-5*). In addition to its indication for major depression, bupropion is also FDA approved for smoking cessation.

    (1) The mechanism of action for bupropion is not completely understood. Bupropion is known to inhibit the reuptake of NE and dopamine.

    (2) Common adverse effects associated with the use of bupropion include nausea, vomiting, headaches, activation, agitation, hypertension, and insomnia.

      (a) Bupropion has been associated with less sexual dysfunction than other antidepressant medications.

      (b) Bupropion has been associated with an increased risk for seizures and is contraindicated in patients at risk for seizures. This includes patients with the following medical disorders: seizure disorder, history of anorexia or bulimia, or using or withdrawing from medications such as alcohol or benzodiazepines. Doses > 450 mg should not be used, and dose increases should be gradual.

    (3) Medication interactions. Bupropion is a substrate of CYP2B6 liver enzymes and is a strong inhibitor of CYP2D6.

  f. Mirtazapine (Remeron) (*Table 40-5*)

    (1) Mirtazapine antagonizes α-adrenergic and 5-HT$_2$- and 5-HT$_3$-receptors, causing an increase in NE and 5-HT. In addition, mirtazapine has activity at histamine (H) receptors.

    (2) Adverse effects for mirtazapine include sedation, weight gain, constipation, dry mouth, and increased appetite. Sedation, increased appetite, and weight gain can be problematic, particularly at lower doses. Mirtazapine has a lower risk for causing sexual dysfunction compared to SSRIs.

    (3) Medication interactions. Mirtazapine is a substrate of CYP3A4 and CYP2D6 liver enzymes. Mirtazapine is a weak inhibitor of CYP1A2 and CYP3A4 enzymes.

  g. Trazodone (Desyrel) (*Table 40-5*). Trazodone is indicated for the treatment of depression. It is more frequently used in low doses as adjunctive treatment for insomnia in depressed patients.

    (1) The mechanism of action for trazodone is not completely understood, but is mainly thought to block 5-HT reuptake, increase in 5-HT neurotransmission, and block 5-HT$_2$-postsynaptic receptors.

    (2) The most common adverse effects of trazodone include sedation, nausea, sexual dysfunction, and orthostatic hypotension. Trazodone has rarely been associated with priapism and QT prolongation.

    (3) Medication interactions. Trazodone is metabolized mainly by CYP3A4, whereas active metabolite *m*-chlorophenylpiperazine (mCCP) is metabolized by CYP2D6.

    h. Nefazodone (Serzone). Nefazodone is a medication structurally similar to trazodone. It was considered to be first line for treatment of depression; however, recent reports of hepatotoxicity have limited its use and led to a black box warning for possible liver failure leading to death.

      (1) Mechanism of action. Nefazodone has a mechanism of action similar to trazodone.

      (2) Adverse effects. Common adverse effects for nefazodone include dry mouth, nausea, constipation, visual alterations, orthostatic hypotension, and sedation. The most severe adverse effect associated with nefazodone is hepatic failure.

        (a) Reported rates by the FDA estimate one case of liver failure resulting in death or transplant per 250,000 to 350,000 patient-years. Liver function enzymes should be monitored routinely.

        (b) The generic product is still available, although brand name nefazodone was withdrawn from the U.S. market in 2004.

      (3) Medication interactions. Nefazodone is highly protein bound and is an inhibitor of CYP3A4.

  i. Atypical antipsychotics have recently been the subject of multiple studies in the treatment of major depression. For information regarding dosing, adverse effects, and mechanism of action see Chapter 39. Olanzapine is available in a formulation with fluoxetine (Symbyax) and is FDA approved for treatment-resistant depression. Quetiapine and aripiprazole are FDA approved for adjunct therapy to antidepressants.

      (1) Duration of treatment. Treatment is divided into three phases: acute phase, continuation phase, and maintenance phase.

        (a) The acute phase begins with the initiation of therapy until remission is reached, typically lasting between 6 and 12 weeks.

        (b) The continuation phase begins after remission is reached and typically lasts between 4 and 9 months. Medication from the acute phase is continued during this phase to prevent relapse of depression.

        (c) A maintenance phase is used in patients with a high risk of recurrence of depression, such as those with a history of multiple episodes of depression, history of suicidal thoughts, and severe depression. These patients should receive maintenance treatment for 2 to 3 years, and many may receive lifelong therapy.

      (2) Administration and dosage

        (a) Antidepressants are usually started at low doses and slowly titrated up to reach target doses over a period of a few weeks to prevent adverse reactions. Clinical response determines if the dose should be further titrated. Although full effects may not be seen for 4 to 6 weeks, often some signs and symptoms of depression such as insomnia may resolve within 1 to 2 weeks of starting an antidepressant. Patients must receive maximum tolerated doses for 4 to 8 weeks without response to be classified as ineffective.

        (b) If patients receive only a partial or no response, other antidepressants may be considered. When changing to another antidepressant agent, caution should be used to prevent serotonin syndrome.

      (3) Augmentation of therapy. When patients fail to fully or partially respond to two or more medications, augmentation of antidepressant therapy with another agent may be considered.

        (a) Lithium and thyroid hormone have been used for augmentation of antidepressant medications.

        (b) Dual antidepressant augmentation has also been used. Agents that have been used include bupropion, TCAs, and mirtazapine.

      (4) Suicide risk. The FDA has now issued a black box warning for all antidepressants that an increase in suicidal thoughts and actions may occur with therapy and that adolescents and children receiving this therapy should be closely monitored.

      (5) Treatment options in pregnancy

        (a) Benefit needs to be weighed against risk of teratogenicity.

        (b) SSRIs and ECT are recommended treatment options.

        (c) Paroxetine is pregnancy category D due to cardiac malformations.

(d) Bupropion is pregnancy category B.

(e) Antidepressants are considered compatible with breastfeeding, but mothers should be warned of possible risks to their newborn.

II. TREATMENT OF BIPOLAR DISORDER

A. **Definition.** Bipolar disorder is a syndrome in which patients suffer from episodes of mania and depression.

B. **Diagnosis.** Bipolar disorder is diagnosed using *DSM-IV-TR* criteria. The symptoms should impair social or occupational functioning and should not be related to a general medical condition or use of a substance.

1. Mania is described as at least a 1-week period of a continuously elevated or irritable mood, although shorter durations of symptoms are acceptable if the patient is hospitalized. In addition to elevated mood, the patient should experience at least three of the following symptoms: elevated self-esteem or grandiose ideations, reduced need for sleep, pressured speech, racing thoughts or flight of ideas, easily distracted, psychomotor agitation, and excessive involvement in high-risk activities.

2. Major depressive episode is diagnosed using the same diagnostic criteria in patients presenting with unipolar depression (see previous section titled Major Depressive Disorder). Depressive episodes are more frequent, last longer, and occur more in bipolar II disorder.

3. Hypomania has similar symptoms to that of mania; however, symptoms are not as severe. Hypomania is diagnosed by an elevated mood present for at least 4 days, with at least three of the same symptoms as described for mania. These symptoms should not interfere with social or occupational functioning and should not cause hospitalization.

4. A mixed disorder is diagnosed when the criteria for both mania and a major depressive episode are met every day for nearly 1 week, affects social and occupational functioning, and is not caused by a general medical condition or substance.

5. Bipolar disorder may be classified into bipolar I disorder, bipolar II disorder, cyclothymia, and rapid cycling.

   a. **Bipolar I disorder.** Patients are classified with bipolar I disorder with a history of at least one mixed or manic episode and at least one major depressive episode.

   b. **Bipolar II disorder.** Patients are classified with bipolar II disorder with a history of at least one episode of hypomania and one major depressive episode but have never experienced mania or a mixed episode.

   c. **Cyclothymic disorder.** Patients are classified with cyclothymic disorder with at least a 2-year history of multiple episodes of hypomania and depressive symptoms. These patients have never met full criteria for a major depressive or manic episode.

   d. **Rapid cycling.** Patients that experience at least four depressive, manic, hypomanic, or mixed episodes within a 12-month period are described as rapid cycling.

C. **Clinical course.** The course of bipolar disorder is lifelong, episodic, and patient specific.

1. Patients usually experience episodes of depression initially. Men are more likely to initially present with mania, but both men and women are more likely to have a first episode of depression. Approximately 95% of bipolar patients will experience a depressive episode during their lifetime.

2. Episodes vary in length and severity; however, they may last from days to months if untreated.

3. The duration of time between episodes varies. Commonly, 4 years or more may separate the first and second episode but subsequent episodes are more frequent.

4. The management of this disorder can be complicated by mixed episodes, rapid cycling, and substance abuse. It is imperative to screen patients for substance use disorders, medical illnesses, medications, and risk-taking behavior as possible causes for acute mood changes. Substance abuse occurs in approximately 45% of patients.

5. Suicide rates are high in bipolar disorder. Approximately 50% of bipolar patients attempt suicide with completed suicide rates of 10% to 15%. Suicide is more likely to be attempted in patients experiencing a depressive or mixed episode.

D. **Treatment options**

1. **Pharmacotherapeutic options.** Mood stabilizers have historically been the mainstays of therapy for bipolar disorder. Agents include lithium, valproic acid and its derivatives (divalproex sodium), and carbamazepine. Recent literature has supported the use of atypical antipsychotics as

| Table 40-6 | ALGORITHMS FOR TREATMENT OF BIPOLAR I DISORDER |

Type of Episode	Monotherapy Options First-Line	Monotherapy Options Second-Line
Acute mania	Lithium, VPA, aripiprazole, quetiapine, risperidone, ziprasidone	Olanzapine, CBZ
Acute mixed	VPA, aripiprazole, quetiapine, risperidone, ziprasidone	Olanzapine, CBZ
Acute depressive	Lamotrigine or lamotrigine plus antimanic	Quetiapine, olanzapinefluoxetine
Maintenance mania or mixed	Lithium, VPA, or lamotrigine	Olanzapine
Depression	Lamotrigine plus antimanic or lamotrigine	

CBZ, carbamazepine; *VPA*, valproic acid.
Adapted from Suppes T, Dennehy EB, Hirschfeld RM, et al. The Texas implementation of medication algorithms: update to the algorithm for treatment of bipolar I disorder. *J Clin Psychiatry*. 2005;66:870–886.

monotherapy or adjunctive treatments in bipolar mania. Agents for the treatment of depressive episodes in patients with bipolar remains more limited, with data supporting the use of lithium, lamotrigine, quetiapine, and olanzapine-fluoxetine. The 2005 Texas Implementation of Medication Algorithms update for the treatment of bipolar I disorder is summarized in *Table 40-6*.

a. Lithium is indicated for the acute and chronic treatment of mania. Lithium may also be effective in the treatment of mixed episodes and depressive episodes.

  (1) Lithium carbonate is available as immediate-release (Eskalith), controlled-release (Eskalith CR), or extended-release (Lithobid) tablets, and lithium citrate (Lithonate) is available as syrup.

  (2) **Pharmacokinetics**

  (a) Between 60% and 100% of lithium is absorbed from the gastrointestinal tract. The extent of absorption is not affected by food. The rate of absorption varies depending on the formulation.

  (b) Lithium is not highly protein bound.

  (c) Lithium is eliminated primarily through the kidneys. Changes in renal function can significantly affect the clearance of lithium.

  (3) The mechanism of action for lithium is currently unknown, although several theories exist.

  (a) Lithium is thought to help correct desynchronized biological rhythms in patients with bipolar disorder.

  (b) Lithium may affect membrane stabilization.

  (c) Lithium may augment homeostasis by enhancing the function of secondary messenger systems, especially cyclic adenosine monophosphate (cAMP), cyclic guanosine monophosphate (cGMP), and phosphatidylinositol.

  (d) Lithium can inhibit NE release and accelerate its metabolism.

  (e) Lithium may decrease receptor sensitivity and increase presynaptic reuptake of NE and 5-HT.

  (4) Lithium has a narrow therapeutic index, with a therapeutic range of 0.5 to 1.0 mEq/L. Toxicity is associated with levels > 1.5 mEq/L. Patients presenting with acute mania generally require levels in the higher end of the therapeutic range than those on maintenance therapy. Patients treated for bipolar depression require a level ≥ 0.8 mEq/L. Maintenance lithium levels can be as low as 0.6 mEq/L if patients are clinically stable.

  (a) Patients are generally started on 300 mg two to three times daily of lithium and titrated up by 300 mg increments as needed to achieve therapeutic effects and minimize toxicity. Patients can be switch to a long-acting formulation once a patient is stabilized on treatment.

  (b) Patient-specific factors such as age, weight, and renal function should be considered.

Table 40-7	ADVERSE EFFECTS OF LITHIUM	
Early Onset	**Long-Term Use**	**Toxicity**
Gastrointestinal upset	Morphological kidney changes	Severe drowsiness
Nausea	EKG changes	Coarse hand tremor
Polydipsia	Bradycardia	Muscle twitching
Nocturia	Weight gain	Seizures
Dry mouth	Decreased libido	Choreoathetosis
Hand tremor	Hypothyroidism	Vomiting
Leukocytosis	Rash	Confusion
Polyuria	Acne	Vertigo

(c) Serum concentrations may be monitored 5 days after initiation therapy or changing doses. A level can be checked after 3 days of treatment in patients with suspected toxicity or decreased renal function. Levels should be obtained 12 hrs after the dose, usually in the morning before the first dose of the day. Patients' prescribed extended-release lithium may have a 12-hr trough level that is 12% to 33% higher than regular release lithium.

(d) Once a patient is stabilized, follow-up lithium levels can occur less frequently (every 6 to 12 months) and can be dictated by the clinical status of a patient.

(e) Prior to starting lithium, baseline monitoring should include a medical history, medication history, physical examination, basic metabolic panel, renal function panel, pregnancy test, thyroid panel, complete blood count, and ECG (if risk factors merit ECG).

(f) Follow-up labs should include renal function panel, basic metabolic panel, complete blood count, and a thyroid function panel. These labs can occur less frequently (every 6 to 12 months) in stabilized patients.

(5) **Clinical response.** Clinical response may be seen within 1 to 2 weeks after lithium initiation for the treatment of acute mania. When used in depression, responses may not occur for 6 to 8 weeks. Lithium has been shown to produce an 8- to 10-fold decrease in suicide rates.

(6) **Precautions and adverse effects**

(a) Lithium has an absolute contraindication in patients experiencing acute renal failure or women in their first trimester of pregnancy.

(b) Lithium has the following relative contraindications: renal impairment, cardiovascular disease, dehydration, pregnancy, seizure disorder, and thyroid disease.

(c) Lithium has numerous adverse effects (*Table 40-7*). Adverse effects (especially those seen early in therapy) can be related to too high peak levels. Doses should be decreased to minimize these peak-related adverse effects. Certain adverse effects indicate toxicity. If toxicity occurs, lithium should be immediately discontinued, the patient should be properly hydrated, stomach contents should be emptied with gastric lavage, and if severe toxicity occurs (level ≥ 3 mEq/L), hemodialysis may be indicated.

(7) Many medications and disease states may affect lithium levels in the body (*Table 40-8*).

(a) Use of lithium with antipsychotics or benzodiazepines may increase the risk for CNS toxicity.

(b) Use of lithium with medications that can increase 5-HT may cause serotonin syndrome.

b. Valproic acid (VPA) is indicated in the acute and chronic treatment of mania. VPA may also be effective in the treatment of hypomania, mixed disorders, and rapid cycling (*Table 40-6*).

(1) **Mechanism of action.** The mechanism of action for VPA is not entirely known. Efficacy for VPA is thought to be related to its ability to increase levels of GABA.

Table 40-8	FACTORS THAT CHANGE LITHIUM CONCENTRATIONS[a]

Increase Lithium Levels	Decrease Lithium Levels
Angiotensin-converting enzyme inhibitors	Acetazolamide
Angiotensin II receptor blockers	Methylxanthines (e.g.,
Nonsteroidal anti-inflammatory drugs	theophylline, caffeine)
Thiazides	Osmotic diuretics
Dehydration	Pregnancy (third trimester)
Renal dysfunction	Sodium supplements
Sodium loss	Urine alkalinizers (ex.
Fluoxetine	sodium bicarbonate)

[a]Not an all-inclusive list.

(2) Many formulations exist for VPA. VPA is formulated as valproic acid (Depakene) in capsules and syrup, as divalproex sodium in delayed-release tablets (Depakote) and extended-release tablets (Depakote ER), and as valproate in intravenous solution (Depacon).

(3) VPA is generally initiated at doses of 20 to 30 mg/kg/day given in divided doses for inpatients and 250 mg three times daily for outpatients. The current therapeutic range (50 to 125 μg/mL) was originally described for the treatment of seizure disorders and has not been established for efficacy in bipolar disorder. The extended-release formulation has a 15% to 25% decreased bioavailability there requiring a 25% dose increase when switching from an immediate-release formulation.

    (a) Levels may be first obtained after 3 to 5 days of therapy. These values should be trough values and obtained 12 hrs following a dose. The monitoring of VPA levels can occur less frequently (every 6 to 12 months) in clinical stable patients.

    (b) Patients that are treated for 4 to 6 weeks with VPA concentrations of 80 to 120 μg/mL without clinical response may be classified as failures of VPA therapy.

(4) Adverse effects. Common adverse effects of VPA include nausea, vomiting, dyspepsia, sedation, elevated liver enzymes, hair loss, and tremor. Less frequent adverse effects include thrombocytopenia, leukopenia, pancreatitis, weight gain, and liver failure. VPA has also been associated with polycystic ovarian syndrome in women of child-bearing age.

    (a) Gastrointestinal adverse effects may be minimized by lowering the dose or by using divalproex formulations instead of valproic acid or sodium valproate.

    (b) Liver function tests and complete blood counts should be monitored at baseline, every month for the first 2 months of therapy, and then every 6 to 12 months thereafter.

    (c) VPA has a wide therapeutic index making a lethal overdose less likely to occur.

(5) Medication interactions. VPA has the potential for multiple drug interactions. VPA is highly protein bound in the body; thus, levels can increase in the presence of another medication that is highly protein bound. VPA is also a substrate and inhibitor of the cytochrome P450 isoenzyme 2C9 and can potentially elevate levels of other medications that are metabolized via this isoenzyme.

c. Carbamazepine (CBZ) is indicated in the acute treatment of mania, but is considered to be a second-line agent owing to its numerous adverse effects and medication interactions (*Table 40-6*).

(1) The mechanism of action for CBZ is not completely known; however, its efficacy in bipolar disorder is thought to be the result of its effects on GABA and G protein-linked second messenger systems, such as cAMP.

(2) CBZ should be initiated at doses of 200 to 600 mg/day given in divided doses and increased by 200 mg/day to usual doses of 800 to 1000 mg/day.

    (a) A therapeutic range of 4 to 12 μg/mL has been described for seizure disorders. Although correlation between this range and efficacy has not been fully established for bipolar disorder, it is used to minimize adverse effects.

        (b) Levels may be obtained 5 to 7 days after initiating therapy. Levels should continued to be obtained in the following few weeks because CBZ concentrations will decrease in the body once autoinduction occurs.

        (c) Patients who are treated for 4 to 6 weeks with CBZ concentrations of 6 to 12 μg/mL without clinical response may be classified as failures of CBZ therapy.

    (3) Adverse effects. CBZ is associated with numerous adverse effects, many of which are dose related.

        (a) Frequent adverse effects include dizziness, drowsiness, ataxia, fatigue, blurred vision, diplopia, nystagmus, confusion, headache, nausea, vomiting, diarrhea, and dyspepsia. The gastrointestinal adverse effects of CBZ are often dose related.

        (b) Additional adverse effects include rash, leukopenia, thrombocytopenia, hyponatremia, elevation in liver enzymes, and weight gain.

        (c) Severe idiosyncratic reactions may also occur, including agranulocytosis, aplastic anemia, severe thrombocytopenia, liver failure, Stevens–Johnson syndrome, and pancreatitis.

        (d) Complete blood counts, liver function tests, thyroid tests, and electrolytes should be monitored at baseline and every 3 to 6 months.

        (e) Carbamazepine can be lethal with ingestions over $\geq$ 6 g.

    (4) Medication interactions. CBZ is an inducer of many hepatic enzymes responsible for metabolism of medications and, therefore, has numerous medication interactions. Oral contraceptive levels in the body can be decreased in patients taking CBZ. Alternative forms of contraception should be used in patients taking CBZ. CBZ can also induce its own metabolism (autoinduction). Decreases in CBZ levels in the body may be seen after 3 to 30 days of therapy. CBZ levels should be monitored and adjusted accordingly.

d. Lamotrigine is indicated in the maintenance treatment of bipolar disorder with benefit in preventing depressive episode relapse. Lamotrigine may be effective in rapid cycling bipolar patients (*Table 40-6*). Lamotrigine has mixed evidence regarding its use in acute depressive episodes.

    (1) The mechanism of action for lamotrigine is not completely understood. It is currently thought to be related to its ability to decrease release of glutamate and aspartate by blocking sodium channels.

    (2) Owing to the risk of rash, lamotrigine should be initiated at low doses (25 mg/day) and slowly increased by 25 mg every 1 to 2 weeks. Lamotrigine should be administered twice daily in doses > 50 mg. Usual dose range is 50 to 300 mg/d. Patients who are taking lamotrigine with VPA should decrease the dose by half owing to a significant medication interaction. Patients taking lamotrigine with carbamazepine should start at 50 mg/d, because carbamazepine increases the clearance of lamotrigine from the body.

    (3) Common adverse effects include dizziness, diplopia, nausea, vomiting, rash, photosensitivity, ataxia, headache, and blurred vision. Rashes may be severe and life-threatening such as Stevens–Johnson rash, and patients should immediately discontinue the medication if a rash appears.

e. Atypical antipsychotics have recently been the subject of multiple studies in the treatment of bipolar disorder. All atypical antipsychotics except clozapine, iloperidone, and lurasidone are approved for the treatment of bipolar disorder (*Table 40-6*). For information regarding dosing, adverse effects, and mechanism of action, see Chapter 39. Olanzapine and quetiapine are approved for maintenance treatment in bipolar. Olanzapine is available in a formulation with fluoxetine (Symbyax), and quetiapine is approved for depressive episodes. Olanzapine and aripiprazole are available in intramuscular injections approved for treatment of agitation associated with bipolar mania.

f. Additional anticonvulsants

    (1) Oxcarbazepine is a medication structurally similar to carbamazepine but with fewer adverse effects. It is postulated to have similar therapeutic effects in bipolar disorder to carbamazepine; however, studies demonstrating its efficacy are limited. It currently is recommended only in combination with other mood stabilizers.

g. Antidepressants should be used cautiously in patients with bipolar disorder because of the risk of inducing mania. When possible, patients should be receiving mood stabilizers at goal doses before initiating antidepressants and should be cautiously monitored. Bupropion and paroxetine have been associated with less risk of inducing mania than other antidepressants and may be preferable.

       h. Benzodiazepines may be useful adjuncts to a primary treatment in reducing agitation, anxiety, and insomnia. Benzodiazepines should be discontinued once the primary treatment is stabilized because benzodiazepines are ineffective in treating bipolar disorder. Lorazepam is available in an intramuscular formulation, which may be useful in acute agitation.

2. Treatment duration/phases. The treatment of bipolar disorder is structured similarly to that of depression with acute, continuation, and maintenance phases. Maintenance treatment is strongly recommended for all patients with bipolar disorder, especially those with a family history.

3. Treatment augmentation

    a. Patients with no or partial response to monotherapy may receive combination therapy with two agents. Agents that can be combined include lithium, VPA, and the atypical antipsychotics. Atypical antipsychotics, if used, should be combined with either VPA or lithium and not combined with another atypical antipsychotic.

    b. For depressive episodes, lamotrigine may be combined with another mood stabilizer as first-line therapy, and the olanzapine–fluoxetine combination product is a second-line option.

4. Treatment options in pregnancy

    a. Multiple agents used in the treatment of bipolar disorder have been associated with birth defects.

       (1) Lithium, VPA, and CBZ are pregnancy category D medications.

       (2) Lithium has been associated with birth defects, primarily in the first trimester.

       (3) VPA and CBZ should be used during pregnancy only if the benefits outweigh the risks. If the decision is made to use these medications during pregnancy, folic acid should be given to minimize the risk of defects.

       (4) Lamotrigine and oxcarbazepine are pregnancy category C medications.

III. TREATMENT OF ANXIETY SPECTRUM DISORDERS. Generalized anxiety disorder, panic disorder, and social anxiety disorder

  A. Introduction. Anxiety is a natural response to a real or perceived danger; however, when it causes significant distress or impairment in an individual's life, then it becomes an anxiety disorder. Anxiety disorders are the most commonly encountered psychiatric disorders in health care.

  B. Diagnosis/clinical presentation

    1. Generalized anxiety disorder (GAD) is diagnosed when an individual experiences unrealistic or excessive anxiety and worry for a period of at least 6 months. Additionally, the individual must have difficult in controlling that anxiety or worry. Accompanying the anxiety or worry more days than not over the 6 month period are 3 or more of following symptoms: feeling tense or restless, easily fatigued or worn-out, difficulty concentrating, irritability, and difficulty with sleep. Lastly, GAD must cause significant distress or impairment and not be accounted for by another medical, psychiatric, or substance use disorder.

    2. A patient is diagnosed with a panic disorder when that individual experiences repeated unexpected panic attacks and these attacks are followed by a 1-month period of one or more: persistent concern over future attacks, worry about the consequences of future attacks, and a significant change in behavior related to the attacks. Lastly, panic disorder must cause significant distress or impairment and not be accounted for by another medical, psychiatric, or substance use disorder.

      a. A panic attack usually peaks in 10 mins and lasts no longer than 30 mins. Common symptoms experienced during an attack include sweating, chest pain, dizziness, tachycardia, palpitations, and abdominal distress. During an attack an individual will often feel like they are losing control or dying.

    3. Social anxiety disorder (SAD) is diagnosed when a person has an intense persistent fear of social situations where an individual may be exposed to unfamiliar people or to scrutiny by others. Exposure to the situation produces anxiety that the individual recognizes is unreasonable or excessive. Usually feared situations are avoided or endured with distress. Lastly, SAD symptoms must cause significant distress or impairment and not be accounted for by another medical, psychiatric, or substance use disorder.

      a. Feared situations include public speaking, talking with strangers, and eating or writing in front of others. Common physical symptoms include blushing (cardinal symptom), diarrhea, sweating, and tachycardia.

C. Treatment

1. The mainstay of treatment for GAD, panic disorder, and SAD is the antidepressants. There is emerging evidence with other classes of medications, such as the atypical antipsychotics; however, treatment with antidepressants is still considered first-line treatment. Of the antidepressants, SSRIs and venlafaxine are the first-line treatment options. Nonpharmacological treatments focus on cognitive behavioral therapies (CBT) and are recommended for mild symptoms of these disorders or in combination with pharmacological treatment. The effect of CBT may take weeks to months.

2. The goals of treatment should be a reduction in the frequency and severity of symptoms and relief of a patient's distress and impairment. Full symptom remission should be a realistic goal with treatment.

D. Treatment options

1. **Antidepressants**
    a. **GAD**
        (1) Of the antidepressants, paroxetine, escitalopram, venlafaxine XR, and duloxetine are FDA approved for GAD. The anti-anxiety effect from antidepressants occurs in 2 to 4 weeks. Imipramine (Tofranil), a TCA antidepressant, may be a useful second-line treatment.
    b. **Panic**
        (1) SSRIs are the first-line treatment of panic disorder. Sertraline, paroxetine, and venlafaxine XR are FDA approved. Imipramine has also been shown to be highly effective; however, its use is limited to its adverse effect profile. Treatment effect usually takes at least 4 weeks; however, patients may not respond until 8 to 12 weeks. Initial antidepressant dosing in panic disorder is usually half the initial starting dose used in the treatment of depression.
    c. **SAD**
        (1) Antidepressants are first-line treatment of SAD. Paroxetine, sertraline, venlafaxine XR, and fluvoxamine XR (Luvox XR) are FDA approved. Mirtazapine (Remeron) and phenelzine may be good second-line antidepressants. TCAs are not effective in SAD. Onset of effect may take 4 to 6 weeks with some patients not achieving maximal benefit until 12 weeks. Initial antidepressant dosing in SAD is usually half the initial starting dose used in the treatment of depression.

2. **Other treatment options**
    a. **GAD**
        (1) Benzodiazepines are effective medications due to their anxiolytic properties and may provide rapid symptom relief. All benzodiazepines are considered equally effective and as a class may be most beneficial for somatic and autonomic symptoms. Benzodiazepines may be most useful when used early in treatment in combination with an antidepressant.
        (2) Buspirone (Buspar) is a nonbenzodiazepine anxiolytic useful in the treatment of GAD. Buspirone is a second-line treatment option and may be most useful in patients unable to take benzodiazepines. The anxiolytic properties of buspirone may be due to partial agonism of 5-HT$_{1A}$-receptors. The effectiveness of buspirone may take up to 4 weeks. Side effects are mild and include dizziness, nausea, and headaches.
        (3) Other treatment options include hydroxyzine (Vistaril), pregabalin, and atypical antipsychotics.
    b. **Panic**
        (1) Benzodiazepines—alprazolam (Xanax) and clonazepam (Klonopin) are FDA approved. Diazepam (Valium) and lorazepam (Ativan) may also be effective. Benzodiazepines provide rapid symptom relief and may be most useful when used early in treatment in combination with an antidepressant.
        (2) Phenelzine (Nardil), an MAOI, may be an alternative treatment option for treatment-resistant patients.
    c. **SAD**
        (1) Benzodiazepines, gabapentin (Neurontin), buspirone (Buspar), pregabalin (Lyrica), and atypical antipsychotics may be useful in SAD.

E. **Evaluation of treatment**
1. **GAD**
   a. Treatment response should occur within 4 weeks of starting an antidepressant and much more quickly with benzodiazepines.
   b. Treatment should continue for a 1-year period following treatment response.
   c. Treatment should be slowly tapered over several months regardless of the medication chosen. Benzodiazepines require a slow gradual dose reduction due to concerns of withdrawal such as seizures and rebound symptoms.
2. **Panic**
   a. Treatment response should occur within 6 to 8 weeks following antidepressant initiation. Patients receiving antidepressants may need up to 12 weeks of treatment before receiving a full response. Adequate treatment with a benzodiazepine is considered 4 weeks.
   b. Treatment should continue for a period of 12 to 24 months following treatment response.
   c. Treatment should be slowly tapered over several months regardless of the medication chosen.
3. **SAD**
   a. An adequate antidepressant trial is 8 to 12 weeks.
   b. Treatment should continue for a period of 12 to 24 months following treatment response.
   c. Treatment should be slowly tapered over several months regardless of the medication chosen.

IV. OBSESSIVE COMPULSIVE DISORDER (OCD)

A. **Introduction.** OCD is a psychiatric disorder characterized by intrusive obsessive thoughts and ritualistic behaviors performed to reduce anxiety.

B. **Diagnosis**
1. *DSM-IV* diagnostic criteria for OCD diagnosis include the following: recurrent obsession or compulsions which are severe enough to be time consuming (> 1 hr/day) or cause marked distress or significant impairment; realizations that obsessions/compulsions are excessive or unreasonable; condition is not the direct result of a psychiatric, medical, or substance abuse disorder.
   a. An obsession is a recurrent, persistent idea, thought, impulse, or image that is experienced as intrusive and inappropriate and causes anxiety or distress.
      (1) Obsessions can have many themes including aggressive impulses, contamination, order, religion, doubts, and sexual imagery.
   b. A compulsion is a repetitive act or mental ritual designed to counteract the anxiety caused by obsessions.
      (1) Common compulsions include hand washing, checking, ordering, need to confess, counting, and repeating.

C. **Clinical presentation**
1. Patients with OCD will most often present to a nonpsychiatric doctor with physical complaints such as chapped hands from repeated washings or gum bruising from repeated tooth brushing. Irritable bowel syndrome is also commonly seen in patients with OCD.

D. **Treatment**
1. The mainstay of OCD treatment is the SSRIs. There is emerging evidence with other classes of medications, such as the atypical antipsychotics; however, the SSRIs are still considered first-line treatment. Nonpharmacological treatments focus on cognitive behavioral therapies (CBT) and are recommended for mild symptoms of OCD or in combination with pharmacological treatment. The effect of CBT may take weeks to months.
2. The goal of treatment should be a reduction in the frequency and severity of symptoms. Even a partial resolution of symptoms may provide a remarkable relief to a patient's distress and impairment.
3. **Treatment options**
   a. **Serotonergic antidepressants**
      (1) All SSRIs are used in the treatment of OCD; however, only four are FDA approved for this indication; fluoxetine (Prozac), fluvoxamine (Luvox), paroxetine (Paxil), and sertraline (Zoloft). Fluoxetine (Prozac), fluvoxamine (Luvox), and sertraline (Zoloft) are FDA approved for children with OCD.

       (2) Clomipramine (Anafranil) is a tricyclic antidepressant with strong serotonergic properties. Clomipramine has been shown to be as equal efficacious as SSRIs; however, its use is limited by side effects. Clomipramine is FDA approved for OCD in both children and adults.

       (3) Clomipramine is started at 25 mg/day and increased to a maximum dose of 250 mg/day.

    b. Other antidepressants

       (1) Mixed evidence exists for venlafaxine (Effexor), mirtazapine (Remeron), and phenelzine (Nardil).

    c. Atypical antipsychotics

       (1) Augmentation with an atypical antipsychotic has been shown to produce a response rate around 50%. Olanzapine (Zyprexa), quetiapine (Seroquel), and risperidone (Risperdal) have the most evidence supporting their use. See Chapter 39 for specific information on atypical antipsychotics.

       (2) Augmentation with an atypical antipsychotic is recommended only after a 3-month trial of a maximal dosed antidepressant.

       (3) Atypical antipsychotics may be particularly useful for the treatment of tics.

  4. Evaluation of treatment

    a. Full symptom remission is rare and an unrealistic expectation. Approximately 70% of patients will have some degree of symptom improvement following antidepressant treatment.

    b. An adequate trial of an antidepressant is 8 to 12 weeks. Antidepressant medications should be dosed to their maximum tolerated dose for a period of at least 4 to 6 weeks.

    c. Treatment should be continued for a period of 1 to 2 years with a slow gradual taper over the course of months to a year.

    d. A patient should fail two to three trials with different SSRIs before moving to clomipramine (Anafranil).

    e. Combination treatment, SSRI + clomipramine or augmentation of an antidepressant with an atypical antipsychotic, can be tried in patients with treatment-resistant OCD.

    f. Lifelong treatment is for patients with two to four severe relapses or three to four mild relapses.

V. POSTTRAUMATIC STRESS DISORDER

  A. Introduction. PTSD is a psychiatric disorder with severely debilitating symptoms. Largely recognized as a combat-related phenomenon, PTSD is now widely recognized in civilians as well.

  B. Diagnosis/clinical presentation

    1. Exposure to a traumatic event is required for a patient to have PTSD. The traumatic event must cause anxiety or impairment that interferes with an individual's ability to function. Lastly, the symptoms cannot be caused by another psychiatric, medical, or substance abuse disorder.

    2. Three symptoms domains of PTSD are re-experiencing, avoidance, and increased arousal. For diagnosis, at least one symptom from the re-experiencing domain is required, three symptoms from the avoidance domain are required, and two symptoms from the increased arousal are required.

    3. These symptoms must be present for greater than a 1-month period and must cause significant impairment in an individual's life.

    4. Common symptoms include: Re-experiencing domain: recurring bad memories, distressing nightmares, flashbacks, and intense fear/anxiety with remembering event; Avoidance domain: Avoidance of people, places, activities, thoughts, feelings associated with traumatic event, restricted affect, sense of doom, and diminished pleasure. Increased arousal domain: insomnia, irritability, anger, and hypervigilance.

    5. Subsets of PTSD

      a. Acute stress disorder occurs within 2 days of experiencing a traumatic event, but symptoms resolve within 1 month after the event.

      b. Acute PTSD is defined as PTSD lasting less than 3 months.

      c. Chronic PTSD is defined as PTSD lasting 3 months or more.

  C. Treatment

    1. The mainstay of treatment is the SSRIs. There is emerging evidence with other classes of medications, such as other antidepressants, atypical antipsychotics, and alpha-1 antagonists; however, the SSRIs are still considered first-line treatment. Nonpharmacological treatments focus on cognitive behavioral therapies (CBT), eye movement desensitization and reprocessing, and stress

management. These nonpharmacological treatments are recommended for mild symptoms of OCD or in combination with pharmacological treatment. The effect of CBT may be most useful if initiated within days to weeks following the traumatic event.

2. The goal of treatment should be a reduction in the frequency and severity of symptoms in the three symptom domains. With symptom remission, patients should also have improvement in impairments and quality of life.

3. **Treatment options**

   a. **Antidepressants**

      (1) All antidepressant medications are used in the treatment of PTSD. However, only the SSRIs and venlafaxine (Effexor) are considered first-line treatment options for PTSD. Older TCAs and MAOIs are effective but limited in their use due to their side effect burden. TCAs may be a good second-line treatment option. Mirtazapine (Remeron) may also be a good second-line treatment option due to studies showing benefit in global symptom reduction. MAOIs should be reserved as a third-line treatment option.

      (2) Paroxetine (Paxil) and sertraline (Zoloft) are FDA approved for acute treatment. Sertraline is also FDA approved for long-term treatment.

      (3) Antidepressants may work best on the symptom domains of avoidance and increased arousal. Benefit may also be seen in re-experiencing. Phenelzine (Nardil) may be useful in reducing nightmares, flashbacks, and insomnia.

   b. **Alternative treatment options**

      (1) Atypical antipsychotics, alpha-1 antagonists, anticonvulsants, and β-blockers may be useful augmenting agents.

      (2) Atypical antipsychotics and anticonvulsants may help reduce irritability, impulsivity, and violent behaviors. Atypical antipsychotics have been shown to effectively reduce the core symptoms as well. See Chapter 39 for specific information on atypical antipsychotics.

      (3) The alpha-1 antagonist prazosin (Minipress) dosed between 1 mg and 4 mg may reduce nightmares and insomnia.

      (4) Benzodiazepines have not been shown to be effective. Their use is discouraged use due to their potential for abuse and to cause dissociation.

4. **Evaluation of treatment**

   a. Full symptom remission should be the goal of treatment.

      (1) Full remission is defined as a 70% or greater reduction in symptoms.

      (2) Fifty percent symptom reduction is considered an adequate response.

      (3) Twenty-five percent to 50% symptom reduction is a partial treatment response.

   b. An adequate trial of an antidepressant is 6 to 12 weeks. Antidepressant medications should be dosed to their maximum tolerated dose for a period of at least 4 to 6 weeks.

   c. Treatment should be continued for a period of at least 1 year with a slow gradual taper over the course of months to a year.

VI. TREATMENT OF ATTENTION-DEFICIT HYPERACTIVITY DISORDER (ADHD)

A. **Introduction.** ADHD is a condition characterized by the inability to maintain and sustain attention and control behavior and impulses. ADHD was the first psychiatric disorder to be diagnosed and treated in children rather than in adults. There is increasing recognition that symptoms and impairments of ADHD may persist beyond childhood and into adulthood.

B. **Diagnosis**

1. Symptoms must be present before the age of 7 years old and be present in two or more settings. Symptoms must not result from another psychiatric, developmental, or medical disorder.

2. Six or more symptoms (symptom list in the following text) must be present for a period of at least 6 months. Diagnosis requires evidence of inattention or hyperactivity and impulsivity or both. Evidence of symptoms comes from reports from the child, parents, and teachers. Symptoms include:

   a. **Inattention**

      (1) Often fails to give close attention to details and makes careless mistakes, has difficult sustaining attention, does not seem to listen, does not seem to follow through, has difficulty

organizing tasks, avoids tasks that require sustained attention, loses things necessary for activities, is easily distracted, is forgetful.

  b. Hyperactivity and impulsivity

   (1) Often fidgets, leaves seat, runs about or climbs excessively, has difficulty with quiet leisure activities, is "on the go" or "driven by motor," talks excessively, blurts out answers, has difficulty awaiting turn, interrupts, or intrudes.

 3. These diagnostic criteria are the same for both children and adults. The use of these criteria for adults may present problems since most adults may not remember being diagnosed before the age of 7, some symptoms may not be age appropriate, and the minimal requirement of six criteria may result in underdiagnosis.

C. Clinical presentation

 1. Eighty percent of children will present with a combination of symptoms of inattention plus hyperactivity/impulsivity. Ten percent to 15% will have only with symptoms inattention, while 5% will only demonstrate symptoms of hyperactivity/impulsivity.

 2. Approximately two-thirds of children with ADHD will have impairing levels of symptoms persisting into adulthood.

 3. Children with ADHD may also have a comorbid condition; however, children with ADHD have a lower prevalence of comorbid conditions compared to adults.

  a. Most common comorbid conditions in children include: learning and language disorder, oppositional defiant disorder, mood and anxiety disorders, tic, and posttraumatic stress disorder.

 4. Adults seek treatment mainly due to the negative impact of ADHD on their own lives, family, and work.

  a. Medical and psychiatric comorbidities are more prevalent in adults and should be included in the differential diagnosis for ADHD symptoms and taken into consideration when patients are being treated with stimulants or nonstimulants.

   (1) Medical conditions include thyroid disorders, head trauma, poisoning, substance intoxication, and seizure disorders.

   (2) Psychiatric conditions include mood disorders, anxiety, substance use, and borderline and antisocial personality disorders.

D. Treatment

 1. The mainstay of ADHD treatment is pharmacological treatment. Both stimulant and nonstimulant medications are effective in ADHD. Stimulant medications are recommended as first-line treatment because approximately 70% to 90% of patients will have a symptom response. Stimulants have a larger effect size and a lower number needed to treat compared to nonstimulants. Nonstimulants, such as atomoxetine and extended-release guanfacine, are second-line treatment options. Nonpharmacological treatment, mainly behavioral modification, may have the best benefit when used in combination with medication.

 2. Stimulant medications (for doses, durations of effect, adverse effects, and contraindications see *Table 40-9*)

  a. This medication class consists of both methylphenidate and amphetamine containing agents. All stimulants mainly work by blocking the reuptake of both dopamine and norepinephrine. The effect of stimulants on ADHD symptoms should occur within days to 1 week. There has little evidence to support any major differences in efficacy, adverse effects, or response rates between stimulants.

  b. Treatment with stimulants is started at the lowest possible dose and titrated slowly up to the maximal tolerated dose. Initiation of therapy usually starts with an immediate-release stimulant and then changes to an extended-release agent to minimize the number of doses per day. Extended-release formulations may improve compliance, decrease the potential for abuse, and remove the stigma associated with taking medication during the school/work day.

  c. If a patient does not have a response to one stimulant, another stimulant should be tried before changing to a nonstimulant medication. It is recommended that a patient try both a methylphenidate and amphetamine containing agent because there are slight differences between these agents that may affect patient response.

Table 40-9 STIMULANT MEDICATIONS USED IN THE TREATMENT OF ADHD

	Usual Dosage (mg)	Duration of Effect (hr)	Adverse Effects	Contraindications
Methylphenidate-based			Growth/appetite suppression, headaches, insomnia, irritability, jitteriness, mild increase in blood pressure and heart rate	Seizures, tics, marked tension, anxiety, aggression glaucoma, MAOIs
Short-acting				
Ritalin, Methylin	10–20	3–5		
Intermediate-acting				
Ritalin SR	20–40	3–8		
Metadate ER	10–20	3–8		
Methylin ER	10–20	3–8		
Long-acting				
Ritalin LA	20–40	6–8		
Concerta	27–54	10–12		
Metadate CD	10–20	4–8		
Daytrana patch	10–30	9–12		
Dexmethylphenidate				
Focalin	5–10	3–5		
Focalin XR	5–20	8–12		
Amphetamine-based			Growth/appetite suppression, headaches, insomnia, irritability, jitteriness, mild increase in blood pressure and heart rate	Cardiovascular disease, hypertension, hyperthyroidism glaucoma, MAOIs
Adderall	5–30	4–6		
Adderall XR	10–30	8–12		
Dextrostat	5–20	3–5		
Dexedrine spansule	5–15	5–8		
Vyvanse	20–70	8–12		

MAOIs, monoamine oxidase inhibitors.

    d. Methylphenidate patch (Daytrana) is the only transdermal formulation of a stimulant medication. It is to be worn for a maximum of 9 hrs. The patch should be placed on the hip; alternating placement sites with each use.

    e. Pemoline has been withdrawn from the market due to concerns of hepatotoxicity.

    f. Special consideration of adverse effects and precautions should be taken before starting an adult on a stimulant medication.

  3. Nonstimulant medications (for doses, durations of effect, adverse effects, and contraindications, see *Table 40-10*)

    a. Atomoxetine and extended-release guanfacine are the only FDA approved nonstimulant medications for ADHD and are recommended as second-line treatment options. Atomoxetine is also FDA approved for adult ADHD. Nonstimulant medications may be useful in patients unable to tolerate stimulants or their adverse effects, if a contraindication exists for stimulant use, as an adjunctive treatment to stimulants for ADHD symptoms, as treatment of adverse effects from stimulants, or in patients with a comorbid substance use disorder or psychiatric illness (such as a mood disorder or anxiety).

    b. Atomoxetine is a selective norepinephrine reuptake inhibitor and its effect on ADHD symptoms may take several weeks. Atomoxetine has no abuse potential and may have less effect on growth and sleep compared to stimulants. Atomoxetine's labeling contains a bolded warning about the potential for severe liver injury and patients should be monitored for signs and symptoms of hepatotoxicity.

Table 40-10	COMMON NONSTIMULANT MEDICATIONS USED IN THE TREATMENT OF ADHD			
	Usual Dosage (mg)	**Duration of Effect (hr)**	**Adverse Effects**	**Contraindications**
Atomoxetine (Strattera)	18–60	24	Nausea, vomiting, mild increases in blood pressure and heart rate, suicidality, liver injury	Clinical/laboratory evidence of liver injury, MAOIs, glaucoma
Guanfacine ER (Intuniv)	1–4	24	Mild sedation, dizziness, constipation, hypotension	Hypersensitivity to guanfacine
Bupropion (Wellbutrin SR, XL)	50–300	24	Weight loss, insomnia, agitation, seizure at high doses	Seizure, eating disorders MAOIs, BZ or alcohol use abuse (withdrawal)

MAOIs, monoamine oxidase inhibitors; *BZ*, benzodiasepine.

    c. Extended-release guanfacine works by inhibiting central release of norepinephrine and by increasing blood flow to the prefrontal cortex. Benefit in disruptive behavior, aggression, and sleep may also be experienced with this medication.

    d. Bupropion is an antidepressant that is a weak dopamine and norepinephrine reuptake inhibitor. Overall, bupropion has shown modest efficacy. In small sample size studies in children, bupropion has demonstrated greater benefit compared to placebo and equal efficacy compared to methylphenidate. Bupropion may cause less appetite suppression compared to methylphenidate.

    e. Other nonstimulant agents include clonidine, modafinil, tricyclic antidepressants, anticonvulsants, and antipsychotics. Clonidine may be a useful adjunct to stimulants for symptoms of hyperactivity, impulsivity, aggression, or insomnia. Anticonvulsants and antipsychotics may be most useful in patients with comorbid bipolar disorder, conduct disorder, or aggression.

4. Evaluation of treatment

    a. Stimulants are first-line treatment

        (1) Stimulants produce an effect on symptoms within days to 1 week.

        (2) An adequate trial of a stimulant is considered weeks to 1 month.

        (3) A trial of two stimulants (one methylphenidate and one amphetamine) is recommended as a first-line treatment.

    b. Nonstimulants are second-line treatment options

        (1) Atomoxetine and extended-release guanfacine are FDA-approved treatments. Atomoxetine is FDA approved in adults.

        (2) An adequate trial of atomoxetine is 6 weeks; an adequate trial of extended-release guanfacine is 1 to 2 months.

    c. Patients prescribed either medication class should be assessed periodically to ensure medication benefit and to monitor for adverse effects.

        (1) Height, weight, and eating and sleeping patterns should be assessed at baseline and every 3 months for children prescribed stimulants.

        (2) Adults should be appropriately monitored for any changes in their health, for any changes in their comorbid conditions, and for any adverse effects from ADHD medications.

5. Pregnancy and lactation

    a. All stimulants and nonstimulants (except bupropion) are pregnancy category C. Bupropion is pregnancy category B.

    b. The American Academy of Pediatrics does not recommend the use of methylphenidate and amphetamine in breastfeeding mothers. The effects of nonstimulants in breastfeeding are unknown.

VII. TREATMENT OF INSOMNIA

A. Introduction. Insomnia can refer to a disorder or to a symptom. Insomnia commonly occurs as a symptom experienced in many medical and psychiatric conditions and, as such, is defined as difficulty falling and/or staying asleep or poor quality of sleep. As a disorder, insomnia in addition to these symptoms causes a significant amount of impairment and distress in a person's life.

B. Diagnosis

1. Using the criteria listed by the International Classification of Sleep Disorder, 2nd edition, general criteria for insomnia are the following:
   a. Difficult initiating or maintaining sleep, waking up too early, or sleep that is chronically non-restorative or poor in quality.
   b. Insomnia occurs despite adequate opportunity and circumstances for sleep.
   c. At least one of the following daytime impairments related to sleep difficulty:
   (1) Fatigue or malaise
   (2) Impairment in attention, memory, or concentration
   (3) Social, work, school performance impairment
   (4) Mood disturbance or irritability
   (5) Daytime sleepiness
   (6) Motivation or energy reduction
   (7) Proneness for errors or accidents
   (8) Tension, headaches, or GI symptoms related to sleep loss
   (9) Concerns or worries about sleep

C. Treatment

1. Treatment of insomnia includes both nonpharmacological and pharmacological treatment options. Nonpharmacological treatment may be a good first-line treatment option or can be useful in combination with medication. Pharmacological treatment options include prescription, OTC medications, and natural remedies. Benzodiazepines and benzodiazepine-receptor agonists are the mainstay of treatment although two new agents, ramelteon (Rozerem) and doxepin (Silenor), have been recently FDA approved. These two agents act through pathways different from the benzodiazepines.

2. **Nonpharmacological treatment**
   a. A number of cognitive behavioral therapies exist including sleep hygiene education, stimulus-control therapy, relaxation therapy, and sleep-restriction therapy.
   b. Sleep hygiene includes maintaining a regular sleep schedule; avoiding vigorous activity, alcohol, and nicotine before bedtime; creating a comfortable bedroom environment; and minimizing negative thoughts or focus on sleep.
   c. Stimulus-control and relaxation therapies are meant to minimize hyperarousal before bedtime and to promote a calm environment used for only for sleep.
   d. Studies have demonstrated the effectiveness of nonpharmacological treatment especially in reducing time to sleep onset, total sleep time, and the number and duration of night awakenings.

3. **Pharmacological treatment**
   a. Prescription medication for insomnia centers on the benzodiazepines and benzodiazepine-receptor agonists. Other medications used for insomnia include ramelton, doxepin, sedating antidepressants and antipsychotics, and miscellaneous medications including barbiturates, chloral hydrate, and ethchlorvynol. The use of barbiturates, chloral hydrate, and ethchlorvynol has largely fallen out favor due to concern over adverse effects. Avoid giving these medications with food as it delays their onset of effect. See *Table 40-11* for doses, onset, half-lives, adverse effects, and contraindications for selected medications.
   b. Benzodiazepines and benzodiazepine-receptor agonists—although all benzodiazepines are used in the treatment of insomnia, only nine agents are FDA approved for this indication.
   (1) Benzodiazepines work by binding nonselectively to benzodiazepine receptors linked to the GABA$_A$ receptor. Nonselective benzodiazepines bind to three different types of benzodiazepine receptors; however, only the benzodiazepine type 1 (BZ type 1) receptor confers sedation.
   (2) Benzodiazepine-receptor agonists only selectively bind to the BZ type 1 receptor and therefore cause sedation without producing an anticonvulsant effect or skeletal muscle relaxation.

Table 40-11	COMMON MEDICATIONS USED IN THE TREATMENT OF INSOMNIA				
	Usual Dosage (mg)	Onset (min)	Maximal Half-lives (hr)	Adverse Effects	Contraindications
Benzodiazepines				Drowsiness, dizziness, ataxia, anterograde amnesia, rebound insomnia	None Avoid triazolam with drugs that induce CYP3A4.
Quazepam (Doral)	7.5–15.0	20–45	84		
Temazepam (Restoril)	7.5–30.0	30–60	15		
Triazolam (Halcion)	0.125–0.250	15–30	5		
Estazolam (Prosom)	0.5–2.0	60	24		
Flurazepam (Dalmane)	15–30	15–30	100		
Benzodiazepine-receptor agonists				Same as above. Eszopiclone has an unpleasant taste.	None Avoid with drugs that induce CYP3A4.
Eszopiclone (Lunesta)	1–3	30	7		
Zaleplon (Sonata)	5–20	20	1		
Zolpidem (Ambien)	5–10	30	3		
Extended-release Zolpidem (Ambien XR)	6.25–12.5	30	5.5		
Other medications					
Ramelteon (Rozerem)	8	30–60	5	Drowsiness, dizziness, increased prolactin	Hepatic failure Avoid with drugs that induce CYP1A2.
Doxepin (Silenor)	3–6	30	30	Anticholinergic, dizziness, hypotension, somnolence	MAOIs, glaucoma, severe urinary retention

(3) These medications have been shown to improve sleep latency, total sleep time, number of awakenings, and sleep quality.
  (a) Shorter acting agents may have a better effect on reducing time to sleep.
  (b) Longer acting agents may have a better effect on total sleep time.
(4) Benzodiazepine-receptor agonists may have less rebound insomnia, potential for abuse and dependence, hangover effect, and rebound insomnia upon drug discontinuation compared to nonselective benzodiazepines. Zolpidem has been associated with parasomnias including sleepwalking, eating, and driving.
(5) Eszopiclone and extended-release zolpidem are not limited to short-term use.
(6) All of these agents should be slowly titrated over the course of weeks to a month.
(7) All of these agents are schedule IV medications.
c. **Ramelteon**
  (1) Ramelteon is a melatonin-receptor agonist selectively targeting the melatonin receptors MT1 and MT2 located in the hypothalamus. Stimulating these receptors is thought to affect the sleep–wake cycle and promote sleep. This is the first and only agent in this medication class.
  (2) This medication does not bind to GABA receptors.
  (3) Ramelteon has been shown to reduce time to sleep onset and improve total sleep time.
  (4) Ramelteon is not limited to short-term use.
  (5) Ramelteon is a noncontrolled medication. It is metabolized by CYP1A2 hepatic enzymes. Do not take with a high-fat meal or use in a patient with severe hepatic impairment.
d. **Sedating antidepressants and antipsychotics**
  (1) Doxepin is FDA approved for the treatment of insomnia. Doxepin is a tricyclic antidepressant that produces its effects through histamine blockade.

(2) Tricyclic antidepressants have limited data supporting their use. This medication class may be most effective in patients with insomnia who have a comorbid depression or substance use disorder or in patients who have a contraindication or a poor response to benzodiazepine agents. See Chapter 38 for side effects of this medication class.

(3) The use of antipsychotics may best most effective in insomnia patients with a comorbid psychiatric disorder. See Chapter 37 for side effects of this medication class.

   e. **OTC medications and natural remedies**

     (1) Antihistamines such as diphenhydramine and doxylamine are found in nonprescription sleeping aids. There is a paucity of data supporting their use.

       (a) Adverse effects include a hangover effect, dizziness, dry mouth, and constipation. Tolerance to these agents develops quickly.

     (2) **Natural remedies**

       (a) Melatonin and valerian are two commonly used natural remedies. There is minimal data to support the use of these two products for insomnia. The FDA does not strictly regulate nutritional supplements and herbal products therefore ingredients are not standardized.

  D. **Evaluation of treatment**

    1. Choice of a sleep agent should be based on a number of patient-specific factors including age, length of treatment, sleep complaint, substance use history, and cost. Pharmacological treatment may be most appropriate for patients with significant impairment and distress.

    2. Treatment should focus on both quantitative and qualitative aspects of patient's sleep and daytime function.

    3. Short half-life agents may work best in reducing sleep latency, whereas long-acting agents work may work best in improving total sleep time.

    4. Ramelteon and doxepin may be best for patients with insomnia and a comorbid substance use disorder.

    5. Sedating antidepressants and antipsychotics may work best for patients with insomnia and a comorbid psychiatric disorder.

    6. Antihistamines may work best for patients with infrequent symptoms.

  E. **Pregnancy**

    1. Benzodiazepines FDA approved for insomnia are all pregnancy category X.

    2. Benzodiazepine-receptor agonists are all pregnancy category C.

    3. Ramelteon and doxepin are both pregnancy category C.

    4. See Chapters 37 and 38 for the pregnancy category ratings for sedating antidepressants and antipsychotics.

Study Questions

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following is correct regarding the *DSM-IV* diagnosis of major depressive disorder?

  (A) Patients must have 10 or more symptoms.

  (B) Symptoms must be present for at least 2 weeks.

  (C) Symptoms do not cause significant social or occupational impairment.

  (D) Diagnosis requires a history of mania.

2. A patient with major depression should receive antidepressant therapy for at least

  (A) 2 weeks.

  (B) 6 weeks.

  (C) 2 months.

  (D) 6 months.

For questions 3–4: A 36-year-old woman presents with a 2-month history of depressed mood, anhedonia, increased appetite, weight gain, hypersomnolence, and suicidal ideation. This is the patient's first episode of major depression.

3. Which of the following antidepressants would be most appropriate in the treatment of this patient?

    (A) amitriptyline
    (B) sertraline
    (C) phenelzine
    (D) mirtazapine

4. Which of the following is *not* a potential adverse effect of the medication selected for the patient in question 3?

    (A) sexual dysfunction
    (B) nausea
    (C) urinary retention
    (D) insomnia

5. Which of the following medications would most likely exacerbate a preexisting seizure disorder?

    (A) venlafaxine
    (B) trazodone
    (C) bupropion
    (D) paroxetine

6. A patient who has received citalopram 40 mg/day for 2 weeks for the treatment of major depression complains that the medication is not working and would like to be switched to another agent. What is the appropriate recommendation?

    (A) Provide the patient with some information on monoamine oxidase inhibitors (MAOIs) and call the physician to recommend switching the patient to phenelzine.
    (B) Encourage the patient to continue with the current regimen and inform him or her that it may take 4 to 6 weeks before the full response is evident.
    (C) Recommend adding lithium to augment the current regimen.
    (D) Recommend switching to mirtazapine because of therapeutic failure with citalopram.

7. A patient diagnosed with depression was unsuccessfully treated with fluoxetine. Fluoxetine was discontinued, and 14 days later, the patient started therapy with phenelzine. Then, 3 days after phenelzine was started, the patient presented with hyperreflexia, fever, elevated blood pressure, confusion, and diarrhea. What is the most likely cause of this clinical presentation?

    (A) serotonin syndrome
    (B) serotonin withdrawal syndrome
    (C) hypertensive crisis
    (D) neuroleptic malignant syndrome

8. A patient presents with pressured speech, inability to sleep for 72 hrs, bizarre dress, inappropriate makeup, and grandiose delusions that interfere with social functioning. Which of the following is the most likely diagnosis?

    (A) depression
    (B) euthymia
    (C) hypomania
    (D) mania

9. Which of the following medications would be considered first-line monotherapy for an acute episode of mania?

    (A) gabapentin
    (B) lithium
    (C) lamotrigine
    (D) haloperidol

10. Which of the following is the appropriate therapeutic range for lithium in the treatment of mania?

    (A) 0.4 to 0.6 mEq/L
    (B) 0.6 to 1.5 mEq/L
    (C) 1.0 to 2.0 mEq/L
    (D) 0.5 to 1.2 mEq/L

11. Which of the following mood stabilizers would be most appropriate in a patient with liver disease?

    (A) lithium
    (B) valproic acid
    (C) carbamazepine
    (D) none of the above

12. A 32-year-old, 70-kg man diagnosed with bipolar I disorder is being treated with valproic acid (VPA). Which of the following is a reasonable loading dose for VPA in this patient?

    (A) 250 mg twice a day
    (B) 500 mg twice a day
    (C) 250 mg three times a day
    (D) 500 mg three times a day

13. Which of the following factors may increase lithium concentration?

    (A) caffeine
    (B) osmotic diuretics
    (C) increased fluid intake
    (D) nonsteroidal anti-inflammatory drugs

14. Which of the following is a late adverse effect of lithium?

    (A) nausea
    (B) hand tremor
    (C) seizures
    (D) hypothyroidism

15. Which of the following antidepressants is a potent inhibitor of CYP2D6 liver enzyme?

    (A) citalopram (Celexa)
    (B) paroxetine (Paxil)
    (C) trazodone (Desyrel)
    (D) venlafaxine (Effexor)

16. The dosage range for selegiline (Emsam) patch is which of the following?

    (A) 6 to 12 mg
    (B) 12 to 15 mg
    (C) 3 to 6 mg
    (D) 20 to 40 mg

17. Which of the following tricyclic amine antidepressants (TCAs) causes the most anticholinergic side effects?

    (A) nortriptyline (Pamelor)
    (B) desipramine (Norpramin)
    (C) amitriptyline (Elavil)
    (D) protriptyline (Vivactil)

18. Which of the following medications for bipolar disorder is recommended as maintenance treatment?

    (A) aripiprazole (Abilify)
    (B) carbamazepine (Tegretol)
    (C) lamotrigine (Lamictal)
    (D) iloperidone (Fanapt)

19. Which of the following medications would have the quickest onset of symptom relief in a patient presenting with generalized anxiety disorder (GAD)?

    (A) fluoxetine (Prozac)
    (B) buspirone (Buspar)
    (C) lorazepam (Ativan)
    (D) venlafaxine XR (Effexor XR)

20. Buspirone (Buspar) mechanism of action can best be described as which of the following?

    (A) Norepinephrine reuptake inhibitor
    (B) 5-HT_2-receptor antagonist
    (C) D_2-receptor antagonist
    (D) Partial agonist at 5-HT_{1A}-receptors

21. Duration of treatment for panic disorder should be continued for a period of how long after symptom remission?

    (A) 3 months
    (B) 6 months
    (C) 12 months
    (D) 12 to 24 months

22. Which of the following medication classes is considered a first-line treatment option for social anxiety disorder?

    (A) Atypical antipsychotics
    (B) Anticonvulsants
    (C) Selective serotonin reuptake inhibitors (SSRIs)
    (D) Tricyclic antidepressants

23. Which benzodiazepine is FDA approved for the treatment of panic disorder?

    (A) diazepam (Valium)
    (B) clonazepam (Klonopin)
    (C) lorazepam (Ativan)
    (D) chlordiazepoxide (Librium)

Answers and Explanations

1. **The answer is D** *[see I.A.1]*.
   The *DSM-IV-TR* criteria provide the diagnostic guidelines for MDD require a patient have five or more symptoms present for a period of at least 2 weeks. These symptoms must cause significant social and occupational impairment. If a patient had a history of mania as part of his or her symptoms presentation, this patient would be diagnosed as bipolar rather than as unipolar MDD.

2. **The answer is D** *[see I.B.1]*.
   Patients should receive antidepressant therapy through the continuation phase, which is generally 6 to 9 months.

3. **The answer is B** *[see I.B.1.c]*.
   Sertraline, an SSRI, is a good first-line agent, particularly in patients who would benefit from the stimulatory side effects. Amitriptyline and mirtazapine would not be good alternatives because of this patient's hypersomnolence and weight gain. In addition, a TCA (amitriptyline) is not recommended in patients at risk for suicide. Although some aspects of this patient's depression may be considered atypical, an MAOI would not be selected as first-line therapy, given that it is the patient's first episode of depression.

4. The answer is C *[see I.B.1.c]*.
Sertraline has been associated with nausea, sexual dysfunction, and insomnia. Sertraline does not express anticholinergic activity and would, therefore, not cause urinary retention. Of the SSRIs, only paroxetine has been associated with causing anticholinergic adverse effects.

5. The answer is C *[see I.B.1.e]*.
Although all antidepressants can lower the seizure threshold, bupropion is contraindicated in patients with seizure disorder. Bupropion is specifically contraindicated in patients with a seizure disorder. Paroxetine was associated with a 0.1% incidence of seizures during clinical trials. Seizure associated with venlafaxine occurs infrequently (1/100 to 1/1000 patients). The overdosage of trazodone may be associated with seizures; but at normal doses, trazodone is not thought to alter the seizure threshold.

6. The answer is B *[see I.B.1.i]*.
An antidepressant must be given at the maximum tolerated dose for 4 to 6 weeks before it is considered a therapeutic failure; therefore, the best recommendation is to continue with the current regimen for at least 2 more weeks. MAOIs are reserved for refractory depressed patients and are not indicated in this patient scenario. Lithium is an appropriate augmentative agent but is not indicated until the patient has failed two or three different antidepressant trials.

7. The answer is A *[see Table 40-2]*.
Serotonin syndrome may result when starting an MAOI immediately after another agent that increases serotonin levels. Generally, a 2-week washout period is recommended; however, fluoxetine requires a 5-week washout period because of norfluoxetine (active metabolite).

8. The answer is D *[see II.B.1]*.
The clinical presentation described is consistent with mania. Hypomania generally does not impair functioning. Euthymia implies normal mood, whereas depression typically involves more neurovegetative symptoms.

9. The answer is B *[see Table 40-6]*.
Lithium is considered to be first-line monotherapy for euphoric mania. Gabapentin has demonstrated utility as a mood stabilizer but is considered only an adjunctive therapy. Lamotrigine is an anticonvulsant that currently has data supporting its use in depressive episodes of bipolar disorder but not as first-line monotherapy for mania. Haloperidol is a traditional antipsychotic that may be used parenterally to manage acute agitation but is not appropriate as first-line monotherapy.

10. The answer is D *[see II.D.1.a.(4)]*.
The therapeutic range of lithium is 0.5 to 1.2 mEq/L. When using lithium in the treatment of acute mania, the upper end of the therapeutic range is typically used.

11. The answer is A *[see II.D.1.a.(2)]*.
Lithium is not known to cause hepatic dysfunction, nor is it metabolized via the liver. However, both valproic acid and carbamazepine can impair liver function.

12. The answer is D *[see II.D.3]*.
The appropriate loading dose for VPA in acute mania is 20 mg/kg/day; therefore, in this patient, the appropriate loading dose is 1400 mg/day. This equation approximates the need for the patient, and it is appropriate to round up to available dosage forms.

13. The answer is D *[see Table 40-8]*.
Caffeine, osmotic diuretics, and increased fluid intake all decrease lithium concentrations. Nonsteroidal anti-inflammatory drugs decrease renal blood flow and decrease lithium clearance, resulting in increased lithium concentrations.

14. The answer is D *[see Table 40-7]*.
Hypothyroidism is a late side effect of lithium therapy usually occurring after 18 months of treatment. Thyroid function panel should be checked at baseline and on follow-up to monitor for this adverse effect.

15. The answer is B *[see Table 40-4]*.
Paroxetine is a potent inhibitor of CYP2D6. The other antidepressants listed are only mildly potent inhibitors of CYP2D6.

16. The answer is A *[see Table 40-1]*.
The recommended dosage range for selegiline patch is 6 to 12 mg/day. Patients should be started on 6 mg and slowly titrated up in dose to a maximum dose of 12 mg/day.

17. The answer is C *[see Table 40-3]*.
Tertiary amine TCAs cause more anticholinergic adverse effects than secondary amine TCAs. Of the antidepressants listed, only amitriptyline is a tertiary amine TCA.

18. The answer is C *[see Table 40-6]*.
Lamotrigine has been shown to be an effective agent in the preventing relapse into both mania and depression. Therefore, lamotrigine is FDA approved for maintenance treatment of bipolar disorder.

19. The answer is C *[see III.E.1]*.
Lorazepam is a benzodiazepine and these agents produce symptom relief in GAD within days to 1 week of treatment. All other medications listed require a period of at least up to 2 weeks or longer for GAD symptom relief.

20. The answer is D *[see III.D.2.a]*.
Buspirone main mechanism of action is through partial agonism of 5-HT_{1A}-receptors. Buspirone does not act at all by the other mechanisms of action listed.

21. The answer is D *[see III.E.2]*.
Treatment of panic disorder should be continued for a period of 12 to 24 months in order to ensure patients do not have a relapse of symptoms.

22. The answer is C *[see III.D.1.c]*.
SSRIs are the first-line treatment option for SAD. These other treatments listed may be used as possible second-line treatments.

23. The answer is B *[see III.D.2.b]*.
Clonazepam and alprazolam XR (Xanax XR) are the only benzodiazepines FDA approved for the treatment of panic disorder.

Asthma and Chronic Obstructive Pulmonary Disease

ROY A. PLEASANTS II

I. ASTHMA

- **A. Definition.** Asthma is a chronic inflammatory disorder of the airways. It involves complex interactions between many cells (e.g., eosinophils, mast cells, macrophages) and inflammatory mediators (e.g., interleukins, leukotrienes) that result in inflammation, obstruction (partially or completely reversible after treatment or resolves spontaneously), increased airway responsiveness (i.e., hyperresponsiveness), and episodic asthma symptoms (see I.G.1). Neutrophils may play an important role in some asthma exacerbations.

- **B. Classification.** Asthma severity classifications according to the 2007 expert panel report of the National Heart, Lung, and Blood Institute (NHLBI) include **mild intermittent asthma** in addition to **mild, moderate,** and **severe persistent asthma** (*Table 41-1*). The asthma guidelines highlight that disease severity is used to initiate therapy and asthma control should be used to monitor therapy. The 2007 guidelines have also been modified to incorporate domains of both disease risk and impairment to determine disease severity. The guidelines define impairment as the frequency and intensity of symptoms and functional limitations the patient is currently experiencing or has recently experienced. Risk is defined as the likelihood of asthma exacerbations, progressive decline in lung function (or for children lung growth), or adverse effects from medications. A patient's severity classification plays an important role in determining the most appropriate pharmacotherapeutic approach and is determined by
  - **1.** symptoms (short-acting β-agonist use, nocturnal symptoms),
  - **2.** interference with normal daily activity,
  - **3.** lung function (spirometry to determine FEV_1 and FVC), and
  - **4.** frequency of exacerbations.

- **C. Incidence.** In 2002, according to CDC data, approximately 31 million Americans had ever been told they had asthma during their lifetime. In 2002, 20 million people in the United States had asthma (~7% of population).
  - **1.** It has been estimated that 8.3 million children age 18 years and younger have asthma.
  - **2.** Asthma improves in many children as they age; 50% appear to have "outgrown" asthma by their midteens. However, it is incorrect to consider that these individuals no longer have asthma because many eventually have a return of symptoms.
  - **3.** Sixty percent of asthmatics have at least one asthma flare each year.
  - **4.** Although death from asthma remains uncommon, death rates had been increasing in recent years but appear to have reached a plateau. In 2007, there were 3447 deaths attributed to asthma; this represents a significant decline since 2000. The most common cause of death is believed to be inadequate assessment of the severity of airway obstruction by either practitioner or patient, leading to suboptimal therapy.
  - **5.** The cost to society of asthma is substantial. In 2000 alone, it is estimated that direct costs related to asthma exceeded $8.1 billion. These costs include $2.4 billion for medications and $3.5 billion for

Table 41-1 CLASSIFICATION OF ASTHMA SEVERITY

Components of Severity		Classification of Asthma Severity ≥ 12 Years of Age			
		Intermittent	Persistent		
			Mild	Moderate	Severe
Impairment Normal FEV₁/FVC: 8–19 yrs 85% 20–39 yrs 80% 40–59 yrs 75% 60–80 yrs 70%	Symptoms	≤ 2 days/week	> 2 days/week but not daily	Daily	Throughout the day
	Nighttime awakenings	≤ 2×/month	3–4×/month	≥ 1×/week but not nightly	Often 7×/week
	Short-acting β₂-agonist use for symptom control (not prevention of EIB)	≤ 2 days/week	> 2 days/week but not daily, and not more than 1× on any day	Daily	Several times per day
	Interference with normal activity	None	Minor limitation	Some limitation	Extremely limited
	Lung function	• Normal FEV₁ between exacerbations • FEV₁ > 80% predicted • FEV₁/FVC normal	• FEV₁ > 80% predicted • FEV₁/FVC normal	• FEV₁ > 60% but < 80% predicted • FEV₁/FVC reduced 5%	• FEV₁ < 60% predicted • FEV₁/FVC reduced > 5%
Risk	Exacerbations requiring oral systemic corticosteroids	0–1/year (see note)	≥ 2/year (see note) ⟶		
		Consider severity and interval since last exacerbation. Frequency and severity may fluctuate over time for patients in any severity category. Relative annual risk of exacerbations may be related to FEV₁.			
Recommended Step for Initiating Treatment		Step 1	Step 2	Step 3	Step 4 or 5
				and consider short course of oral systemic corticosteroids	
		In 2–6 weeks, evaluate level of asthma control that is achieved and adjust therapy accordingly.			

EIB, exercise-induced bronchospasm; *FEV₁*, forced expiratory volume 1 sec; *FVC*, forced vital capacity.
Adapted from Expert Panel Report 3: guidelines for the diagnosis and management of asthma. Available online at http://www.nblbi.nih.gov/guidelines/asthma/epr3/index.htm; last accessed April 10, 2008.

hospitalizations. Indirect costs of asthma are estimated at $4.6 billion. Acute care visits (e.g., hospitalizations) account for the majority of health care costs for asthma.

D. Cause. Precipitating factors of an acute asthma exacerbation may include the following:
  1. Allergens (e.g., pollen, house dust mite, animal dander, mold, cockroaches, food)
    a. Concurrent predisposition to allergy is highly prevalent in patients with asthma, especially children.
    b. For example, allergic rhinitis is reported in 45% of patients with asthma compared to 20% of the general population.
  2. Occupational exposures (e.g., chemical irritants, flour, wood, textile dusts)
  3. Viral respiratory tract infections
  4. Exercise
  5. Emotions (e.g., anxiety, stress, hard laughter, crying)

6. Exposure to irritants (e.g., strong odors, chemicals, fumes)

7. Environmental exposures (e.g., weather changes, cold air, sulfur dioxide, cigarette smoke)

8. Drugs

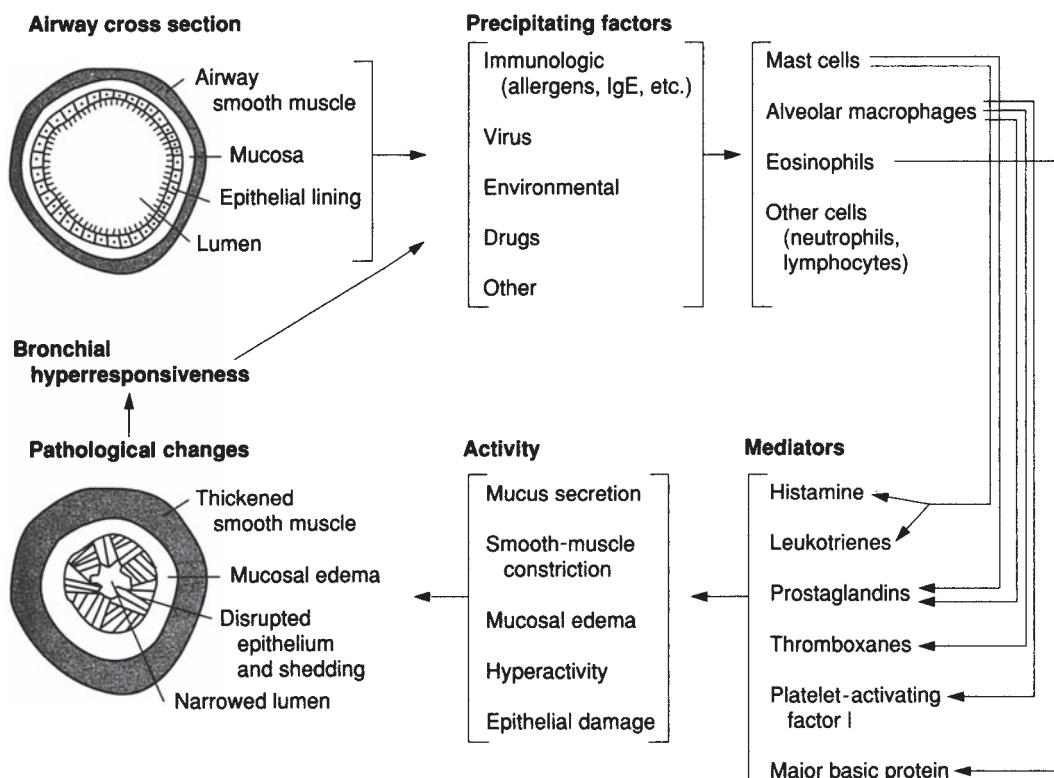
    a. Reactions to drugs may occur as a result of hypersensitivity or as an extension of the pharmacological effect.

    b. Problematic drugs include

        (1) aspirin and other nonsteroidal anti-inflammatory drugs such as ibuprofen (note: cyclooxygenase 2 inhibitors are not recommended for use in aspirin-sensitive asthma patients)

        (2) antiadrenergic and cholinergic drugs (e.g., β-adrenergic blockers, bethanechol)

        (3) medications (or foods) that contain tartrazine, sulfites, benzalkonium chloride, and other preservatives

        (4) excipients in inhaled drugs that are derivatives of legumes (soybeans) in peanut allergic patients (e.g., oleic acid).


E. Pathology. On postmortem examination of patients with asthma, the following characteristics have been identified:

1. Hypertrophy of smooth muscle

2. Airways containing plugs consisting of inflammatory cells and their debris, proteins, and mucus

3. Inflammatory cellular infiltrate with vasodilation, denuded airway epithelium, and microvascular leakage

4. Vasodilation of the vasculature

5. Denuded airway epithelium

6. Microvascular leakage

7. Collagen deposition in basement membranes

F. Pathophysiology (*Figure 41-1*)

1. Major contributing processes

    a. Inflammatory cells (i.e., mast cells, eosinophils, activated T cells, macrophages, and epithelial cells) secrete mediators and influence the airways directly or via neural mechanisms.

Figure 41-1. The pathophysiology of asthma.

   b. Airway obstruction is responsible for many of the clinical manifestations of asthma.

      (1) Severity of obstruction is variable and believed to be a result of bronchoconstriction, airway wall edema, mucus plug formation, airway remodeling, smooth muscle hypertrophy, and hyperplasia.

      (2) Airway obstruction reduces ventilation to some lung regions, which causes a ventilation/perfusion (V/Q) imbalance that leads to hypoxemia. This is reflected by a reduction in the partial pressure of arterial oxygen (Pao_2) observed in moderate-to-severe exacerbations.

   c. Hyperresponsiveness, an exaggerated response to certain stimuli, is an important feature of asthma and appears to correlate with clinical severity and medication requirements. Increased levels of inflammatory mediators and infiltration by inflammatory cells are thought to be the primary mechanisms responsible for airway hyperresponsiveness.

   d. Airway inflammation is crucial to development of asthma and contributes to airway hyperresponsiveness, airflow obstruction, respiratory symptoms, and disease chronicity. Inflammatory cells and their mediators are responsible for altered mucociliary function, epithelial disruption ranging from minor ciliary loss to severely denuded epithelium, increased airway permeability (to inhaled allergens, irritants, and inflammatory mediators), and reduced clearance of inflammatory mediators.

      (1) Acute inflammation is associated with early recruitment of cells to the airway.

      (2) Subacute inflammation is associated with recruited and resident cell activation, resulting in more persistent inflammation.

      (3) Chronic inflammation is associated with persistent cell damage and ongoing repair, resulting in airway abnormalities that may become permanent.

   e. Alteration in **autonomic neural control** also contributes to obstruction.

      (1) Elevated parasympathetic tone and reflex bronchoconstriction may occur as a result of increased cholinergic sensitivity or a change in muscarinic receptor function.

      (2) Increased smooth muscle responsiveness may be the result of smooth muscle hypertrophy. Exposure of the nerve endings, caused by inflammation, may also contribute.

   f. Airway remodeling can result from persistent inflammation to chronic asthma. The resulting damage can yield permanent airway abnormalities because of subbasement membrane collagen deposition and fibrosis. Hypertrophy of the airway smooth muscle is another form of tissue remodeling in asthma. These events may occur even in the face of mild disease, but airway remodeling does not necessarily occur in all asthma patients.

  2. Sequencing of events in asthma

   a. Triggering. In an allergic asthma patient, after exposure to an allergic trigger, the antigen binds to immunoglobulin E (IgE), which is attached to activated mast cells. Nonallergic factors (e.g., aspirin, viral infections) may also function as triggers. Viral infections serve as an important cause of worsened asthma.

   b. Early and late responses

      (1) The **early asthmatic response** begins within 30 mins of trigger exposure (usually only several minutes after exposure) and resolves within 2 hrs. This results in constriction of the airway smooth muscles, bronchospasm, and subsequently asthma symptoms. This response can be blocked by the administration of short-acting β-agonists (albuterol [Proair, Ventolin, Proventil], pirbuterol [Maxair], or levalbuterol [Xopenex]).

      (2) The **late asthmatic response** involves a second decline in lung function, typically 4 to 8 hrs after the initial trigger exposure. The early asthma response does not necessarily progress into the late asthmatic response. The late asthmatic response, principally an inflammatory response, is characterized by persistent airflow obstruction, airway inflammation, and bronchial hyperresponsiveness. The response may last several days, and bronchial hyperreactivity may persist for several weeks. This response can be blocked by the administration of corticosteroids—inhaled steroids such as budesonide (Pulmicort) and leukotriene modifiers such as montelukast (Singulair) or cromones (i.e., nedocromil [Tilade]).

G. Clinical evaluation

  1. Physical findings

   a. In asymptomatic patients, physical findings of asthma are often not present.

   b. Physical findings depend on the severity of the underlying disease and the severity of the exacerbation. Regardless of the underlying disease severity, patients can have mild, moderate, or severe exacerbations (*Table 41-2*).

Table 41-2	STAGES OF SEVERITY OF AN ACUTE ASTHMATIC ATTACK				
Stage	**Symptoms**	**FEV_1 or FVC**	**Arterial pH**	**PaO_2**	**$PaCO_2$**
I Mild	Breathlesness while walking, speaks in sentences, moderate wheezing	> 70% of normal	Normal or ↑	Normal or ↓	Normal or ↓
II Moderate	Dyspnea while at rest, in phrases, loud wheezing throughout expiration	40%–69% of normal	↑	> 60 mm Hg	< 42 mm Hg
III Severe	Breathlessness while at rest, speaks in words loud wheezing, coughing difficulty speaking, accessory chest muscle use, and chest hyperinflation	< 40% of normal	Normal or ↓	< 60 mm Hg	> 42 mm Hg
IV Respiratory failure	Severe respiratory distress, confusion lethargy, cyanosis disappearance of breath sounds, and pulsus paradoxus > 12 mm Hg	< 25% of normal	↓↓	↓	↑↑

FEV_1, forced expiratory volume in 1 sec; *FVC*, forced vital capacity; *PaO_2*, partial pressure of arterial oxygen; *$PaCO_2$*, partial pressure of arterial carbon dioxide; ↑, increased; ↓, decreased; ↑↑, markedly increased; ↓↓, markedly decreased.

   c. Patients with **chronic**, **poorly controlled**, **severe asthma** may have evidence of chronic hyperinflation, including barrel chest and decreased diaphragmatic excursion, similar to chronic obstructive pulmonary disease.

   d. **Acute exacerbations** may have a sudden or gradual onset. Symptoms are frequently nocturnal or occur in the early morning hours.

      (1) Common findings in an acute exacerbation include

         (a) Shortness of breath

         (b) Wheezing (usually occurs at the end of exhalation but may be heard throughout inspiration and exhalation in more severe asthma)

         (c) Chest tightness

         (d) Cough

         (e) Tachypnea and tachycardia (moderate-to-severe exacerbations)

         (f) Pulsus paradoxus (severe exacerbations)

      (2) Between acute asthma exacerbations, the patient may be asymptomatic.

2. **Diagnostic test results**

   a. **Pulmonary function tests** determine the degree of airway obstruction and may be normal between exacerbations. The 2007 NHLBI asthma guidelines recommend spirometry in all asthma patients > 5 years old to determine that airway obstruction is at least partially reversible. Breathing tests include spirometry and peak flow meter testing.

      (1) **Forced expiratory volume in 1 second (FEV_1)** and forced vital capacity (FVC) both decrease during an acute exacerbation. The spirometer is used to generate the FEV_1 and FVC.

      (2) Residual volume (RV) and total lung capacity (TLC) may increase in asthma because of **air trapping** and subsequent **lung hyperinflation**.

      (3) **Peak expiratory flow rate (PEFR)**, obtained through the patient forcefully breathing out into a **peak flow meter**, correlates well with FEV_1. However, PEFR measurement is not used in making the diagnosis of asthma. PEFR measurement can be used to monitor control of asthma.

         (a) Uses of PEFR monitoring at home include assessment of therapy, trigger identification, and assessment of the need for referral to emergency care.
   (b) PEFR monitoring at home is recommended for patients who have had severe exacerbations, who are poor perceivers of asthma symptoms, and who have moderate-to-severe disease.

   (c) PEFR is best measured in early morning, before medication administration. More frequent monitoring over a few weeks may also be indicated to identify specific patterns and to identify a patient's personal best PEFR measurement. In this case, measurements are taken before medications are taken in the morning (i.e., on awakening).

  (4) **Provocation testing** with **histamine or methacholine challenge** may be performed to assess hyperresponsiveness and to rule out asthma in a patient who has had normal pulmonary function test results but in whom asthma is still suspected.

 b. **Blood analysis**, **although not typically undertaken in asthma**, typically shows a slightly increased white blood cell (WBC) count during an acute exacerbation; eosinophilia also may be present. Leukocytosis may be present because of WBC demargination that occurs when patients receive systemic corticosteroids.

 c. **Pulse oximetry** is a noninvasive means of assessing the degree of hypoxemia during an acute exacerbation. The oximeter measures oxygen saturation in arterial blood (Sao_2) and pulse.

 d. **Arterial blood gas measurements** may be required to help gauge the severity of the asthma exacerbation (*Table 41-2*).

  (1) In the early stages of an asthma exacerbation, **hyperventilation** results in a decrease in the partial pressure of arterial carbon dioxide ($Paco_2$). If the exacerbation progresses and the airways remain narrowed, respiratory muscles may fatigue and the $Paco_2$ level increases.

  (2) **Respiratory acidosis** is a poor prognostic sign. It develops if hypoxemia worsens and the patient's respiratory rate is not maintained owing to respiratory fatigue. This results in a rising $Paco_2$ level.

 e. An **electrocardiogram (ECG)** may show sinus tachycardia. An ECG may be particularly useful in an older patient.

 f. A **chest radiograph** may be normal or could detect accompanying pneumothorax, atelectasis, or pneumonia. Evidence of hyperinflation may be present in acute asthma and in chronic, poorly controlled asthma. A chest radiograph may also be needed to exclude other causes of the patient's symptoms.

3. **Signs of respiratory distress** include

 a. use of accessory muscles,

 b. inability to speak in sentences or ambulate owing to dyspnea,

 c. declining mental status,

 d. PEFR < 50% of predicted (or personal best),

 e. cyanosis,

 f. suprasternal retractions,

 g. absence of respiratory sounds,

 h. increasing $Paco_2$, and

 i. unable to sleep for extended time because of shortness of breath.

4. Patients with **potentially fatal asthma** should be quickly identified and aggressively managed. These patients have the following characteristics:

 a. History of severe exacerbations, particularly exacerbations that develop suddenly

 b. Poor self-perception of asthma symptoms and severity

 c. History of intubation or intensive care unit (ICU) admission for asthma

 d. Two or more hospitalizations, or three or more visits to the emergency department for asthma within 1 year

 e. Hospitalization or treatment in the emergency department for asthma within the last month

 f. Frequent β-agonist use (i.e., more than two canisters per month), current systemic steroid treatment, or recent systemic steroid withdrawal

 g. Concurrent conditions (e.g., cardiovascular or psychiatric disease, substance abuse, low socioeconomic status, particularly in urban areas)

H. **Therapy**

1. **Treatment objectives**
 a. The goal of therapy is to provide symptomatic control with normalization of lifestyle and to return pulmonary function as close to normal as possible.

    b. The treatment goals listed in the 2007 NHLBI's expert panel update report include the following:

        (1) Reduce impairment

            (a) Prevent chronic and troublesome symptoms day or night.

            (b) Maintain normal pulmonary function.

            (c) Maintain normal activity levels, including exercise and attendance at work or school.

            (d) Minimal use of short-acting inhaled β_2-agonist (less than two times per week) for quick relief of symptoms (not including use prior to exercise).

            (e) Meet patient and family expectations.

        (2) Reduce risk

            (a) Prevent recurrent exacerbations and minimize need for ED visits or hospitalizations.

            (b) Prevent loss of lung function.

            (c) Provide optimal pharmacotherapy and with minimal or no adverse effects from medications.

2. Management of acute asthma exacerbations

    a. **Home-based** treatment of an acute asthma exacerbation (*Figure 41-2*)

    b. Treatment of an acute asthma exacerbation in the **hospital or emergency department** (*Figure 41-3*)

3. Management of persistent asthma

    a. A stepwise approach to pharmacological therapy is recommended to gain and maintain control of asthma in both the impairment and risk domains (*Table 41-3*). The type, amount, and scheduling of medication is dictated by asthma severity for initiating therapy and the level of asthma control for adjusting therapy.

    b. At each step, patients should control their environment to avoid or control factors, when possible, that make their asthma worse (e.g., allergens, irritants). This requires specific diagnosis and education.

    c. Inhaled steroids are considered to be first-line anti-inflammatory agents in asthma.

    d. Combination products for asthma are formoterol/budesonide (Symbicort), fluticasone/salmeterol (Advair), and mometasone/formoterol (Dulera). These products are indicated for moderate or severe persistent asthma. The 2007 NHLBI asthma guidelines give equal weight to increasing the dose of the inhaled steroid compared to adding a long-acting β_2-agonist to the inhaled steroid in uncontrolled chronic asthma. In the United States, Advair is available as metered dose inhalers (MDIs) and dry-powder inhalers (DPIs) (Diskus); Symbicort is available as an MDI.

    e. Inhaled β-agonists such as albuterol and levalbuterol are used as needed for acute symptoms for all levels of severity.

        (1) Daily or increasing use of a short-acting inhaled β_2-agonist suggests the need for additional long-term controller (i.e., anti-inflammatory) therapy.

        (2) Pretreatment with either an inhaled β-agonist, montelukast, or nedocromil may be used before exercise or allergen exposure.

    f. A rescue course of systemic corticosteroid (e.g., prednisone) may be needed at any time and at any step.

4. Prevention and treatment of exercise-induced bronchospasm (EIB)

    a. Steps to prevent EIB should be implemented in all patients with asthma.

    b. Patients should be advised that a warm-up period might be helpful in preventing EIB.

    c. EIB can usually be prevented with one of the following options:

        (1) Short-acting β-agonists (e.g., albuterol) should be administered 15 mins before exercise. These are considered the drug of choice for EIB.

        (2) Long-acting β-agonists—salmeterol (Serevent) and formoterol (Foradil)—should be administered 30 to 60 mins before exercise. When salmeterol is used chronically for EIB, some patients may lose protection toward the end of the 12-hr dosing interval. Because of its rapid onset, formoterol may be dosed 15 mins before exercise. Generally, short-acting agents are preferred over long-acting β-agonists.

        (3) Nedocromil may be used to prevent EIB and exacerbations related to exposure to other asthma triggers. Nedocromil should be administered no more than 1 hr before exercise or exposure.

        (4) Leukotriene modifiers given daily help with EIB but should not be used on an as-needed basis just before exercise.

Figure 41-2. The NIH treatment algorithm for the home-based management of asthma exacerbations. (National Institutes of Health, U.S. Department of Health and Human Services. *NIH Highlights of the Expert Panel Report 3; Guidelines for the Diagnosis and Management of Asthma.* 2007. Figure 5-4. NIH Publication 80-4051.)

      d. Regardless of the prophylactic approach, all patients who experience EIB should have a short-acting β-agonist available for treatment of breakthrough symptoms.

    5. Concurrent diseases

      a. Allergic rhinitis, sinusitis, and gastroesophageal reflux disease (GERD) frequently coexist with asthma. Other notable comorbidities in asthma include vocal cord dysfunction (VCD) and obstructive sleep apnea.

      b. GERD is frequent in persons with obstructive lung disease. Management of GERD with proton pump inhibitors (PPIs), such as pantoprazole (Protonix), can improve asthma symptoms and, in some patients, breathing tests. H_2 antagonists, such as ranitidine (Zantac), are less effective than PPIs in this situation.

      c. Asthma control has been shown to improve if these conditions are adequately controlled.

Figure 41-3. NIH treatment algorithm for management of asthma exacerbations in the emergency department and hospital. FEV_1, forced expiratory volume in 1 sec; *PEF*, peak expiratory flow; PCO_2, partial pressure of carbon dioxide. (From National Institutes of Health, US Department of Health and Human Services. *NIH Highlights of the Expert Panel Report 3: Guidelines for the Diagnosis and Management of Asthma.* 2007. Figure 5-6. NIH Publication 08-4051.)

Table 41-3 MEDICATIONS RECOMMENDED FOR LONG-TERM CONTROL OF ASTHMA

Step	Age 0–4 Years[a]	Age 5–11 Years[a]	Age ≥ 12 Years[b]
1 (intermittent asthma)	Short-acting inhaled β₂-agonist taken as needed to treat symptoms	Short-acting inhaled β₂-agonist taken as needed to treat symptoms	Short-acting inhaled β₂-agonist taken as needed to treat symptoms; short-acting inhaled β2-agonist, cromolyn, or nedocromil taken shortly before exercise in patients known to have exercise-induced bronchospasm
2 (persistent asthma)	Inhaled corticosteroid (low dose) daily; cromolyn or montelukast is an alternative (but not preferred)	Inhaled corticosteroid (low dose) daily; cromolyn, leukotriene-receptor antagonist, nedocromil, or theophylline is an alternative	Inhaled corticosteroid (low dose) daily; cromolyn, leukotriene-receptor antagonist, nedocromil, or sustained-release theophylline is an alternative (but not preferred)
3 (persistent asthma)	Inhaled corticosteroid (medium dosage)	Inhaled corticosteroid (low dosage) plus long-acting β₂-agonist, leukotriene-receptor antagonist, or theophylline; or inhaled corticosteroid (medium dosage)	Inhaled corticosteroid (low dosage) and long-acting β₂-agonist; or inhaled corticosteroid (medium dosage); inhaled corticosteroid (low dosage) plus either leukotriene-receptor antagonist, theophylline, or zileuton is an alternative (but not preferred)
4 (persistent asthma)	Inhaled corticosteroid (medium dosage) plus either long-acting β₂-agonist or montelukast	Inhaled corticosteroid (medium dosage) and long-acting β₂-agonist; inhaled corticosteroid (medium dosage) plus either leukotriene-receptor antagonist or theophylline is an alternative (but not preferred)	Inhaled corticosteroid (medium dosage) and long-acting β₂-agonist; inhaled corticosteroid (medium dosage) plus leukotriene-receptor antagonist, theophylline, or zileuton is an alternative (but not preferred)
5 (persistent asthma)	Inhaled corticosteroid (high dosage) plus either long-acting β₂-agonist or montelukast	Inhaled corticosteroid (high dosage) and long-acting β₂-agonist; inhaled corticosteroid (high dosage) plus either leukotriene-receptor antagonist or theophylline is an alternative (but not preferred)	Inhaled corticosteroid (high dosage) and long-acting β₂-agonist; omalizumab may be considered for patients with sensitivity to relevant perennial allergens
6 (persistent asthma)	Inhaled corticosteroid (high dosage) and oral systemic corticosteroid plus either long-acting β₂-agonist or montelukast	Inhaled corticosteroid (high dosage), oral systemic corticosteroid, and long-acting β₂-agonist; inhaled corticosteroid (high dosage) and oral systemic corticosteroid plus either leukotriene-receptor antagonist or theophylline is an alternative (but not preferred)	Inhaled corticosteroid (high dosage), oral systemic corticosteroid, and long-acting β₂-agonist; omalizumab may be considered for patients with sensitivity to relevant perennial allergens

[a]For all six steps, a short-acting β₂-agonist should be used as needed to relieve symptoms of asthma.
[b]For all six steps, a short-acting β₂-agonist—up to three treatments at 20-min intervals—should be used as needed to relieve symptoms of asthma. Short-course therapy with an oral systemic corticosteroid may be needed.
Adapted from Expert Panel Report 3: guidelines for the diagnosis and management of asthma. Available online at http://www.nhlbi.nih.gov/guidelines/asthma/epr3/index.htm; last accessed April 10, 2008.

I. **Therapeutic agents**
   1. **β-Agonists**—albuterol, formoterol, arformoterol, levalbuterol, metaproterenol (Metaprel), pirbuterol, salmeterol
      a. Short-acting β-agonists (albuterol, levalbuterol, pirbuterol, metaproterenol) are best reserved for worsening symptoms, treatment of acute exacerbations, and prophylaxis for EIB. Assessing the frequency of short-acting β-agonist use for rescue therapy can help determine the patient's level of asthma control. Those requiring regular use (e.g., every day), of short-acting β-agonists have uncontrolled disease and should receive more aggressive controller therapy.
      b. **Indications for long-acting β-agonists**
         (1) Maintenance treatment of moderate and severe persistent asthma in combination with inhaled corticosteroids, particularly for patients with frequent nocturnal symptoms.
            (a) Long-acting β_2-agonists (salmeterol, formoterol, arformoterol) should not be used as sole therapy for an acute asthma exacerbation in lieu of short-acting agents.
            (b) Research indicates that rather than increasing the dose of the inhaled corticosteroid in uncontrolled chronic asthma, adding a long-acting β-agonist results in a greater improvement in symptoms and breathing tests.
            (c) Recent warnings have been placed in the package inserts for long-acting β_2-agonists regarding an increased risk of asthma death. This has led to the 2007 NIH asthma guidelines giving higher priority to increasing the dose of inhaled steroids as compared to adding a long-acting β_2-agonist to current inhaled steroid dose to manage uncontrolled chronic asthma. There are boxed warnings in the package insert for these drugs.
         (2) **Prophylaxis of EIB**
         (3) Patients with asthma and concurrent chronic obstructive pulmonary disease (COPD)
      c. **Therapeutic effects.** These sympathomimetic agents relieve bronchoconstriction during acute asthma exacerbations as well as during chronic therapy and prevent exacerbations from occurring during exercise.
      d. **Mechanism of action**
         (1) β_2-Agonists stimulate β_2-receptors, activating adenyl cyclase, which increases intracellular production of cyclic adenosine monophosphate (cAMP).
            (a) Increased intracellular cAMP and activation of cAMP results in bronchodilation, improved mucociliary clearance, and reduced inflammatory cell mediator release.
            (b) Stimulation of β_2-receptors in skeletal muscle accounts for tremor.
         (2) β-Agonists differ in their affinity for the β_1- and β_2-receptors. Agents with greater β_1-receptor affinity are more likely to cause cardiac effects.
      e. **Administration and dosage**
         (1) Whenever possible, agents should be administered via **inhalation** to minimize systemic exposure and adverse reactions. **Systemic** administration should be reserved for patients who cannot use inhalation therapy.
         (2) Regimens with long-acting β_2-agonists should also include a concurrent inhaled corticosteroid, unless it is being used only to prevent EIB. All regimens containing long-acting agents should also include a short-acting agent for treatment of acute symptoms.
         (3) Dosage information is provided in *Table 41-4*.
      f. **Precautions and monitoring effects**
         (1) Common adverse effects of β-agonists include tremor, palpitation, tachycardia, nervousness, and headache. Leg cramps may occur with high doses owing to hypokalemia.
         (2) Nonselective β-agonists (e.g., isoproterenol [Isuprel]) may induce myocardial ischemia, myocardial necrosis, and arrhythmias because of excessive cardiac stimulation. Use of β_2-selective agents (e.g., albuterol, bitolterol) is preferred.
         (3) **Tachyphylaxis** (form of tolerance) can occur with regular use of inhaled or oral β-agonists. Suggested mechanisms include
            (a) A decrease in the number of active β-receptors owing to movement of receptors from the cell surface into the cell (**down regulation**)
            (b) A decreased sensitivity in the β-receptors to stimuli, making them unable to activate adenyl cyclase
               (i) The clinical significance of this effect is unclear with normal doses of β-agonists.
               (ii) This effect may be lessened by adding corticosteroids to the regimen.

Table 41-4 β-ADRENERGIC AGONISTS USED IN THE TREATMENT OF ASTHMA OR COPD

Agent	Severe Acute		Chronic		Site of Action	Duration of Action	Comments
	Pediatric	Adult	Pediatric	Adult			
Albuterol							
NEB: 0.5% (5 µg/mL)	ET: 0.15 mg/kg (minimum 2.5 mg) q20 mins × 3 doses, then 0.15–0.30 mg/kg up to 10 mg q1–4 hrs p.r.n. or 0.5 mg/kg/hr continuously QR: 0.05 mg/kg (minimum 1.25 mg; maximum 2.5 mg) in 2–3 mL saline q4–6 hrs	ET: 2.5–5.0 mg q20 mins × 3 doses, then 2.5–10.0 mg q1–4 hrs p.r.n. or 10–15 mg/hr continuously QR: 1.25–5.00 mg in 2–3 mL saline q4–8 hrs	Not currently recommended	Not currently recommended	β₁-receptors + β₂-receptors + + +	3–8 hrs inhalation 4–8 hrs oral	May mix with cromolyn or ipratropium NEB. May double dose for mild exacerbations.
MDI: 0.09 mg/puff	ET: 4–8 puffs q20 mins × 3 doses, then q1–4 hrs with spacer QR: 2 puffs t.i.d. q.i.d. p.r.n. PT: 1–2 puffs 5 mins before exercise	ET: 4–8 puffs q20 mins up to 4 hrs, then q1–4 hrs p.r.n. QR: 2 puffs t.i.d. q.i.d. p.r.n. PT: 2 puffs 5 mins before exercise	Not currently recommended	Not currently recommended			
Oral: 4-mg sustained-release	Not currently recommended	Not currently recommended	0.3–0.6 mg/kg/ day (maximum 8 mg/day)	4 mg q12 hrs			
Biolterol							
NEB: 0.2% (2 mg/mL)	ET: 0.15 mg/kg (minimum 2.5 mg) q20 mins × 3 doses, then 0.15–0.30 mg/kg up to 10 mg q1–4 hrs p.r.n. or 0.5 mg/kg/hr continuously	ET: 2.5–5.0 mg q20 mins × 3 doses, then 2.5–10.0 mg q1–4 hrs p.r.n. or 10–15 mg/hr continuously QR: 0.5–3.5 mg in 2–3 mL saline q4–8 hrs	Not currently recommended	Not currently recommended	β₁-receptors + β₂-receptors + + +	6–8 hrs	Dilute NEB with 2–3 mL normal saline. Do not mix NEB with other NEB solutions. Thought to be about half as potent as albuterol on a milligram basis.

Medication					Receptor Selectivity	Duration	Comments
MDI: 0.37 mg/puff	ET: 4–8 puffs q20 mins × 3 doses, then q1–4 hrs with spacer QR: 2 puffs t.i.d. q.i.d. p.r.n. Adapted from National Institutes of Health, National Heart, Lung, and Blood Institute, National Asthma Education and Prevention Program expert panel report 2: Guidelines for the diagnosis and management of asthma [NIH Publication 97-4051] July 1997:91, Figure 3–5d (NIH ERR-2, Fig. 35d).

(4) Hypokalemia may occur in some patients, particularly those receiving concurrent medications that cause hypokalemia (e.g., diuretics, amphotericin) and high doses, including inhaled agents.

(5) Paradoxical bronchoconstriction found with β-agonists may be the result of a "cold freon effect" or the use of additives such as benzalkonium chloride in the formulation.

(6) Unlike albuterol, which is a racemic mixture of albuterol's R- and S-isomers, levalbuterol HCl (Xopenex) is composed of the active *R*-enantiomer.

(7) Systemic adverse reactions when the recommended starting dose of levalbuterol is used appear to be similar to or *slightly less frequent* than the effects of albuterol. When the dose of levalbuterol is increased to 1.25 mg, however, the incidence of adverse reactions is similar to the corresponding dose of albuterol.

(8) It is important to be aware of **significant drug–drug interactions.**

    (a) Concomitant use of systemic β-agonists with **monoamine oxidase inhibitors**, **tricyclic antidepressants**, or **methyldopa** may infrequently lead to severe hypertension. The risk with aerosolized agents may be smaller.

    (b) β-Adrenergic blockers (especially nonselective agents as propranolol and carvedilol [Coreg]) precipitate bronchospasm and increase the dose of β-agonist necessary to achieve bronchodilation. The risk of bronchospasm should be weighed against the potential benefits of β-blockers. β_1-Selective agents such as metoprolol (Toprol XL) may be used carefully (e.g., in the hospital) in asthma patients when the risk–benefit ratio indicates such, as in an acute myocardial infarction.

    (c) β-Agonists should not be combined with other sympathomimetic agents because of additive cardiovascular effects. Vasoconstrictor and vasopressor effects of epinephrine are antagonized by β-**adrenergic blocking agents** (e.g., phentolamine).

(9) The effects of β-agonists should be closely monitored in the elderly and in patients with a history of hyperthyroidism, diabetes, seizures, arrhythmias, and coronary artery disease.

2. Corticosteroids

  a. Therapeutic effects. Corticosteroids suppress the inflammatory response and decrease airway hyperresponsiveness.

  b. Mechanism of action. Corticosteroids bind to glucocorticoid receptors on the cytoplasm of cells. The activated receptor **regulates transcription** of target genes.

    (1) Corticosteroids reduce inflammation via

      (a) inhibition of transcription and release of inflammatory genes

      (b) increased transcription of anti-inflammatory genes that produce proteins that participate in or suppress the inflammatory process

    (2) Clinical effects include

      (a) reduced production of inflammatory mediators

      (b) enhanced β-adrenergic receptor expression (thus making the β_2-agonist work better)

      (c) decreased mucus production

      (d) prevention of endothelial and vascular leakage

      (e) partial reversal of tissue-remodeling

  c. Administration and dosage

    (1) There is no significant difference in the clinical efficacy of the corticosteroid agents currently available. The **route of administration** is determined by the condition of the patient.

    (2) Systemic corticosteroids are used for rapid response during an exacerbation. Improvement in pulmonary function may begin within 1 to 3 hrs; however, the maximum effect is not achieved until 6 to 9 hrs or longer after administration. Supplemental doses should be administered to patients who are already taking systemic corticosteroids when they experience an exacerbation, even if the exacerbation is mild.

    (3) Intravenous corticosteroids (e.g., methylprednisolone [Solu-Medrol]) are administered to patients who are unable to take oral medications in severe exacerbations. Large doses (e.g., methylprednisolone 60 mg or 125 mg intravenously [IV]) can be quickly administered; however, patients can usually be switched to oral therapy as soon as they show clinical improvement and can tolerate oral medication.

(4) Oral corticosteroids are acceptable as emergency treatment if the patient can tolerate the oral route and is not believed to be in imminent danger of respiratory arrest. **Prednisone** and **prednisolone (Prelone)** are the most frequently used oral corticosteroids.

(a) Prednisone and prednisolone are frequently administered in short "bursts" over 3 to 10 days [see I.I.2.c.(4).(b)] to treat acute exacerbations in the outpatient setting and in the emergency department. This type of regimen may also be used to rapidly achieve asthma control.

(b) During burst therapy, these agents may be administered for 3 to 10 days in one or two daily doses and then discontinued. When used in this fashion, tapering is not usually necessary but is often done by physicians. However, if a patient's condition appears to worsen after the last dose has been administered, it is reasonable to reinstitute the corticosteroid and then begin a tapering regimen.

(5) Because **inhaled corticosteroids** are least likely to produce adverse reactions, the inhaled route should be used whenever possible for chronic treatment.

(a) Inhaled corticosteroids should not be used alone to treat serious acute exacerbations.

(b) **Inhaled steroids are the preferred anti-inflammatory therapy for chronic asthma.**

(c) In milder outpatient flares, doses of the inhaled steroids may be increased temporarily (although this is controversial and should not be done if in a combination inhaler of ICS/LABA).

(d) The number of corticosteroids available for inhalation therapy is increasing. The most recent additions are mometasone (Asmanex) and ciclesonide (Alvesco).

(e) Dosages of inhaled corticosteroids are provided in *Table 41-5*. When asthma control is achieved, attempts should be made to use the lowest effective dose to maintain

Table 41-5 ESTIMATED COMPARATIVE DAILY DOSAGES FOR INHALED CORTICOSTEROIDS[a]

Drug	Low Daily Dose		Medium Daily Dose		High Daily Dose	
	Adult	Child	Adult	Child	Adult	Child
Beclomethasone						
CFC: 42 or 84 μg/puff	168–504 μg	84–336 μg	504–840 μg	336–672 μg	> 840 μg	> 672 μg
HFA: 40 or 80 μg/puff	80–240 μg	80–160 μg	240–480 μg	160–320 μg	> 480 μg	> 320 μg
Budesonide

Triamcinolone						
100 μg/puff	400–1000 μg	400–800 μg	1000–2000 μg	800–1200 μg	> 2000 μg	> 1200 μg

[a]In all cases, the lowest dose to maintain control should be used. Some doses are outside package labeling.
[b]MDI doses are actuator doses (i.e., amount leaving actuator).
CFC, chlorofluorocarbons; *DPI*, dry-powder inhaler; *HFA*, hydrofluoroalkanes; *MDI*, metered dose inhaler.
Modified from National Asthma Education and Prevention Program expert panel report guidelines for the diagnosis and management of asthma—NHLBI Asthma Guidelines 2007. August 2007.

control (step-down therapy). Side effects of inhaled steroids (and systemic steroids) are dose-dependent.

(f) Inhaled corticosteroids are considered first-line anti-inflammatory therapy for mild-to-severe persistent asthma in both adults and children.

(6) Treatment of asthma exacerbation in adults

(a) For treatment of a severe exacerbation, prednisone may be given at a dose of 2 mg/kg (maximum of 60 mg/day). For intravenous treatment, methylprednisolone is given at a dosage of 120 to 180 mg/day in three or four divided doses for 48 hrs or until the patient can tolerate oral medications. The dosage is then reduced to 60 to 80 mg/day until PEFR reaches 70% predicted (or personal best).

(b) For outpatient burst therapy, the dosage of prednisone is 1 to 2 mg/kg/day (maximum of 60 mg/day) in one or two divided doses for 3 to 10 days.

(7) Treatment of asthma exacerbation in children

(a) For inpatient treatment of a severe exacerbation, prednisone, methylprednisolone, or prednisolone is given at a dosage of 1 mg/kg every 6 hrs for 48 hrs. The dosage is then reduced to 1 to 2 mg/kg/day (maximum of 60 mg/day) in two divided doses until PEFR is 70% predicted (or personal best).

(b) For outpatient burst therapy, the dosage of prednisone is 1 to 2 mg/kg/day (maximum of 60 mg/day) in one or two divided doses for 3 to 10 days.

d. Precautions and monitoring effects

(1) Systemic corticosteroids

(a) Careful monitoring is necessary in patients with diabetes (steroids commonly increase blood sugar), hypertension, adrenal suppression, congestive heart failure (fluid retention owing to mineralocorticoid effects), peptic ulcer disease, candidiasis, immunosuppression, osteoporosis, chronic infections, cataracts, glaucoma, myasthenia gravis, and psychiatric diseases (e.g., depression, psychosis). Some of these side effects begin shortly after beginning systemic steroids (e.g., hyperglycemia), whereas others (e.g., osteoporosis) only occur with long-term use.

(b) If a prolonged course of systemic therapy is necessary to maintain asthma control, interference with the hypothalamic-pituitary-adrenal axis is lessened by a single morning dose (i.e., 6 to 8 A.M.) or alternate-day therapy. For alternate-day therapy, the dose is twice that of the single morning dose.

(c) Patients on regular systemic therapy should be closely monitored and should receive regular ophthalmological evaluations and osteoporosis screening, and preventative therapy (e.g., calcium, vitamin D, bisphosphonates) if indicated.

(2) Inhaled corticosteroids

(a) Local effects associated with inhaled corticosteroids include hoarseness (dysphonia) and fungal infection (candidiasis) of the mouth and throat. Local side effects can be lessened through mouth rinsing, use of a spacer, and use of certain inhaled steroid products.

(b) The U.S. Food and Drug Administration (FDA) includes warning labels on inhaled corticosteroid products to include dose related slowing of growth velocity in children (approximately one-third in. per year). Shortly after the labeling was revised, two major publications demonstrated short-term growth suppression of approximately 1 cm in the first year of budesonide treatment but without long-term effects on final adult height. However, children should be treated with the lowest effective dose and should be reminded that poorly controlled asthma also slows growth.

(c) Large doses of inhaled corticosteroids may result in systemic effects, such as reduced bone density, changes in adrenal function, skin changes, adrenal suppression, and cataract formation. Further study is needed to fully understand these effects and to determine their clinical significance. However, patients receiving high doses of inhaled corticosteroids should be closely monitored and should receive regular ophthalmological evaluations and osteoporosis screening and treatment (e.g., calcium, vitamin D) if indicated.

(d) Spacers (e.g., AeroChamber) are generally prescribed for patients who receive moderate-to-high doses of inhaled corticosteroids via MDIs. Patients should also

gargle, rinse their mouth and throat, and expectorate after administration. Both of these interventions minimize oropharyngeal drug deposition, local adverse reactions, and gastrointestinal absorption.

(i) Steroids in dry-powder inhalers (Pulmicort Flexhaler) generally have a lower incidence of local side effects due to smaller particle size and less oropharyngeal deposition.

(ii) A new form of beclomethasone (Qvar) MDI also has a low incidence of local side effects due to relatively low oropharyngeal deposition.

(3) Significant interactions

(a) Concurrent use of **hepatic microsomal enzyme inducers** (e.g., rifampin, barbiturates, hydantoins) causes enhanced corticosteroid metabolism, reducing therapeutic efficacy.

(b) Concurrent use of **estrogens**, **oral contraceptives**, **itraconazole (Sporanox)**, or **macrolide antibiotics** (e.g., erythromycin, clarithromycin [Biaxin]) may decrease corticosteroid clearance.

(c) **Cyclosporine** may increase the plasma concentration of corticosteroids.

(d) Administration of **potassium-depleting diuretics** (e.g., thiazides, furosemide) or other potassium-depleting drugs (e.g., amphotericin) with corticosteroids causes enhanced hypokalemia. Serum potassium should be closely monitored, especially in patients on **digitalis glycosides**.

3. **Leukotriene modifiers** are the newest agents with anti-inflammatory properties to be approved for use in asthma. Leukotrienes are important participants in asthma pathophysiology. Cellular effects of leukotrienes include enhanced migration of eosinophils and neutrophils, increased adhesion of leukocytes, and increased monocyte and neutrophil aggregation. Leukotrienes also increase capillary permeability and cause smooth muscle contraction.

a. **Leukotriene modifiers** currently available in the United States include montelukast, zafirlukast (Accolate), and zileuton (Zyflo).

(1) Therapeutic effects

(a) Leukotriene modifiers have anti-inflammatory and bronchodilator activity. They may allow reduction in corticosteroid doses in some patients.

(b) Because they may be less effective anti-inflammatory agents than inhaled corticosteroids, they are considered second-line agents.

(c) In children, for whom administration of inhaled drugs is challenging, oral leukotriene receptor antagonists may be particularly useful.

(d) They may be useful in patients with concurrent allergic rhinitis and asthma.

(2) Mechanism of action. The leukotriene receptor antagonists are selective cysteinyl leukotriene 1 (cys-LT-1) receptor antagonists; therefore, they prevent leukotrienes from interacting with their receptors. Zileuton, a leukotriene modifier, blocks the effects of 5-lipo-oxygenase and ultimately blocks leukotriene production.

(3) Administration and dosage

(a) The dosage of **zafirlukast** in children > 12 years and adults is 20 mg twice daily. Food reduces bioavailability, so zafirlukast should be taken at least 1 hr before or 2 hrs after meals. Children 5 to 11 years of age should receive 10 mg twice daily.

(b) The dosage of **montelukast** in adolescents 15 years of age or older and adults is one 10-mg tablet once every evening. The dosage for children 6 to 14 years of age is one 5-mg chewable tablet once every evening. Children ages 2 to 5 should receive one 4-mg chewable tablet once every evening. Food does not appear to change bioavailability.

(4) Precautions and monitoring effects

(a) Adverse reactions to montelukast are uncommon and include headache, dizziness, and dyspepsia.

(b) Adverse reactions associated with zafirlukast include headache, dizziness, nausea, and diarrhea.

(c) **Churg–Strauss syndrome**, a form of eosinophilic vasculitis, has rarely been associated with zafirlukast, montelukast, and pranlukast (available in Japan). It has usually, but not always, occurred in patients whose chronic steroid regimens were tapered and discontinued. At-risk patients should be monitored for vasculitic rash; eosinophilia; and increasing pulmonary, cardiac, and neuropathic symptoms.

       (d) Significant drug–drug interactions may occur.
- **(i) Aspirin** increases zafirlukast levels.
- **(ii) Erythromycin, theophylline**, and **terfenadine** decrease zafirlukast concentrations.
- **(iii)** Zafirlukast may increase the anticoagulant effect of **warfarin** and levels of dofetilide.
- **(iv)** Drug interactions appear to be less significant with montelukast. Patients who are receiving montelukast with **hepatic enzyme inducers** (e.g., rifampin, phenobarbital) should be monitored closely.
- **(v)** The chewable forms of montelukast (4- and 5-mg tablets) contain aspartame and should be avoided in patients with **phenylketonuria**.

b. The only **lipoxygenase inhibitor** approved by the FDA is **zileuton (Zyflo)**. Zileuton may allow reduction in corticosteroid doses in some patients.

(1) Therapeutic effects. Lipoxygenase inhibitors have anti-inflammatory and bronchodilator activity.

(2) Mechanism of action. Lipoxygenase inhibitors prevent the formation of leukotrienes. Zileuton blocks 5-lipoxygenase, the enzyme responsible for leukotriene formation.

(3) Administration and dosage. In adults and children 12 years of age and older, the dosage of zileuton is 600 mg four times daily. It may be taken without regard to meals. A new formulation, Zileuton CR, may be dosed twice daily.

(4) Precautions and monitoring effects
- **(a)** Zileuton is contraindicated in patients with hepatic function impairment and should be monitored closely in patients who drink large quantities of alcohol.
- **(b)** Adverse effects include headache, abdominal pain, asthenia, nausea, dyspepsia, and myalgia. Drug therapy was discontinued in almost 10% of patients owing to side effects, although this was similar to placebo.
- **(c) Significant drug–drug interactions** may occur.
  - **(i)** Zileuton increases concentrations of **propranolol, terfenadine**, and **theophylline.**
  - **(ii)** The anticoagulant effect of **warfarin** is increased by zileuton.
- **(d)** Hepatic enzymes (e.g., alanine aminotransferase [ALT]) may become elevated during therapy, with most occurrences during the first several months of therapy. Symptomatic hepatitis has been reported. Therefore, the manufacturer recommends that serum ALT be checked before initiation of treatment, monthly for 3 months, and every 2 to 3 months for the rest of the first year. ALT should be checked periodically thereafter.
  - **(i)** Patients should be monitored closely for signs or symptoms of liver dysfunction (e.g., right upper quadrant abdominal pain, flu-like symptoms, fatigue, nausea, lethargy, itching, jaundice).
  - **(ii)** If ALT increases to more than five times the upper limit of normal, therapy should be discontinued and the patient should be monitored until enzymes normalize.

4. Cromolyn

a. Therapeutic effects. Cromolyn is currently only available as a nebulized solution for the treatment of asthma. Nedocromil and cromolyn MDIs have been removed from the market. Cromolyn is less effective in its anti-inflammatory properties than the inhaled steroids, however, because of its excellent safety profile is sometimes still used in children.

(1) When used prophylactically, cromolyn prevents the early and late response of asthma.

(2) When used as maintenance therapy for asthma, this medication suppresses nonspecific airway reactivity.

b. Mechanism of action. Cromolyn is believed to act locally by stabilizing mast cells and thereby inhibiting mast cell degranulation.

c. Administration and dosage

(1) Cromolyn is available as a nebulized solution in 2 ml ampules containing 20 mg and is administered as often as four times a day.

(2) When used as prophylaxis of EIB, it should be used 30 minutes prior to exercise.

(3) After administration, initial improvement is seen within 1 to 2 weeks; however, the maximum effect may take longer.

   d. **Precautions and monitoring effects**
      (1) Cromolyn is **not effective during an acute asthma exacerbation.** It should be used only for maintenance therapy of persistent asthma or for prevention of EIB.
      (2) It is well tolerated, although paradoxical bronchospasm, wheezing, coughing, nasal congestion, and irritation or dryness of the throat may occur.
5. **Theophylline compounds (methylxanthines)**
   a. **Indications**
      (1) Theophylline compounds may be considered if β-agonists and corticosteroids fail to control an acute asthma exacerbation.
      (2) Theophylline is an alternative to long-acting β-agonists in the treatment of persistent asthma.
      (3) Theophylline is most beneficial as an adjuvant to inhaled corticosteroids in patients with nocturnal or early morning symptoms.
   b. **Therapeutic effects**
      (1) Theophylline compounds produce bronchodilation to a lesser extent than β-agonists.
      (2) Nonbronchodilator effects include reduced mucus secretion, enhanced mucociliary transport, improved diaphragmatic contractility, and possibly reduced fatigability.
      (3) There may also be notable degree of anti-inflammatory activity.
   c. **Mechanism of action.** Theophylline-induced phosphodiesterase inhibition results in increased levels of cAMP.
   d. **Administration and dosage**
      (1) Oral therapy (e.g., sustained-release theophyllines) allows for a longer dosing interval and improves compliance. Compliance to oral theophylline also may be better than that of inhaled bronchodilators and corticosteroids.
         (a) Because theophylline does not distribute well into fatty tissue, dosages should be calculated using lean body weight.
         (b) The initial dose of theophylline for adults and children > age 1 is 10 mg/kg/day (maximum of 300 mg/day) given in divided doses. Usual dosage should be adjusted to achieve serum theophylline concentration of 5 to 15 μg/mL (5 to 10 μg/mL acceptable).
         (c) The dosage can be titrated slowly upward and the serum level monitored until a therapeutic level is obtained.
         (d) The usual maximal daily dose in adults is 800 mg/day.
         (e) The maximum recommended dosage in children < age 1 is 0.2 × (age in weeks) + 5 = mg/kg/day and in children ≥ 1 year is 16 mg/kg/day, given in divided doses.
         (f) Ultra-sustained release theophylline formulations (Theo-24 and Uniphyl) may be dosed once daily.
         (g) In addition to theophylline, other methylxanthine compounds are available (e.g., oxtriphylline, dyphylline) but infrequently used. Dosing of these compounds is based on theophylline content (*Table 41-6*).
      (2) Intravenous therapy. Although frequently used in the past, IV administration is now uncommon. IV administration is generally used only in hospitalized patients for whom oral therapy is not possible (e.g., vomiting, nothing by mouth).
         (a) The usual **loading dose** for adults and children not previously receiving a methylxanthine is 5 mg/kg of theophylline administered over 20 to 30 mins at a rate not exceeding 25 mg/min.

Table 41-6   THEOPHYLLINE CONTENT OF THEOPHYLLINE-CONTAINING PRODUCTS

Preparation	Theophylline Content (%)	Equivalent Dose (mg)
Theophylline anhydrous (most oral solids)	100	100
Theophylline monohydrate (oral solutions)	91	110
Aminophylline anhydrous	86	116
Aminophylline hydrous	79	127
Oxtriphylline	64	156

Table 41-7	FACTORS THAT ALTER THEOPHYLLINE CLEARANCE

Factors that increase theophylline clearance (decrease levels)

Age 1–9 yrs
Drugs
  Carbamazepine
  Phenobarbital
  Phenytoin
  Rifampin
Fever
Food (may delay or reduce absorption of some sustained-release products)
High-protein diet
Smoking (marijuana and tobacco)

Factors that decrease theophylline clearance (increase levels)

Age
  Elderly
  Premature neonates
  Term infants < 6 months
Cor pulmonale
Congestive heart failure, decompensated
Drugs
  Allopurinol
  β-Blockers (nonselective)
  Calcium-channel blockers
  Cimetidine
  Fluoroquinolones (ciprofloxacin)
  Influenza virus vaccine
  Macrolides (clarithromycin, erythromycin)
  Oral contraceptives
  Ticlopidine
  Zafirlukast
Fever/viral illness
Fatty foods (may increase rate of absorption of some products)
High-carbohydrate diet
Liver dysfunction (e.g., cirrhosis)

     (b) The usual **maintenance infusion** rate of theophylline in healthy nonsmoking adults on no interacting drugs is 0.4 mg/kg/hr. This rate should be adjusted for factors that affect theophylline metabolism and serum levels (see *Table 41-7*).

  e. Precautions and monitoring effects

    (1) Theophyllines are contraindicated in patients with hypersensitivity to xanthine compounds and should be used cautiously in patients with a history of peptic ulcer or untreated seizure disorder.

    (2) Adverse effects include nausea, vomiting, diarrhea, anorexia, palpitations, dizziness, restlessness, nervousness, insomnia, seizures, reduced lower esophageal sphincter tone, and reduced control of gastroesophageal reflux disease. Patients who experience adverse gastrointestinal effects should be evaluated to rule out theophylline toxicity versus local gastrointestinal effect.

    (3) Theophylline clearance can be altered by several factors and drug interactions (*Table 41-7*). Close drug-level monitoring is required for patients with factors that alter theophylline clearance.

    (4) Careful monitoring is required in patients with hepatic disease, hypoxemia, hypertension, congestive heart failure, alcoholism, and in the elderly. Because of developmental

changes in the neonate and child, dosing must be carefully established and monitored in these populations as well.

    (5) Therapeutic drug monitoring of serum levels, adverse reactions, and concomitant drug use is essential for long-term therapy owing to theophylline's age- and condition-specific clearance.

        (a) Therapeutic effect is achieved and toxicity minimized by keeping drug concentrations at 5 to 15 μg/mL.

        (b) Drug levels should be assessed at steady state (typical half-life 8 hrs, up to 24 hrs in severe heart and liver failure).

        (c) During oral therapy, trough drug levels should be obtained at steady state.

        (d) Dyphylline serum levels should be monitored during therapy because serum theophylline levels will not measure dyphylline. The minimal effective therapeutic concentration of dyphylline is 12 μg/mL.

6. Anticholinergics. Bronchodilation occurs when these drugs block postganglionic muscarinic receptors in the airway. Response to anticholinergics is most pronounced in patients with fixed airway obstruction (e.g., COPD) but may have a role in combination with β-agonists.

    a. Ipratropium bromide (**Atrovent**) is a quaternary ammonium compound.

        (1) Indications

            (a) Ipratropium bromide is recommended for use in combination with β-agonists for the treatment of an acute asthma exacerbation in the emergency department or hospital settings. However, benefits in the chronic management of asthma have not been established.

            (b) Ipratropium bromide may be particularly useful in older patients and patients with coexisting COPD.

            (c) Ipratropium should not be used alone to treat an asthma exacerbation.

            (d) Ipratropium bromide is an alternative bronchodilator in some patients who cannot tolerate β-agonists and in patients who present with bronchospasm induced by a β-blocker.

        (2) Administration and dosage

            (a) Closed-mouth MDI technique or the use of a spacer is recommended for patients receiving anticholinergic therapy via MDI.

            (b) The starting dose of the MDI is two inhalations four times a day. When administered via nebulizer, the dose is 500 μg (2.5 mL) four times a day.

        (3) Precautions and monitoring effects

            (a) If the anticholinergic spray contacts the eye, intraocular pressure may increase.

            (b) The onset of action (approximately 15 mins) and peak effect (1 to 2 hrs) are more delayed than for β-agonists.

    b. Aerosolized **atropine** is used rarely now that ipratropium bromide nebulization solution is available owing to atropine's high incidence of systemic adverse effects.

7. Antihistamines are useful for patients with coexisting allergic rhinitis; however, their role in the treatment of asthma remains unclear. Antihistamines compete with histamine for H_1-receptor sites on effector cells and thus help prevent the histamine-mediated responses that influence asthma.

8. Antibiotics are generally not used for the treatment of asthma, unless other signs of infection are present.

9. Magnesium sulfate, administered intravenously, may be useful in some patients because of its modest ability to cause bronchodilation. When administered intravenously, it also improves respiratory muscle strength in hypomagnesemic patients. Research has suggested that magnesium may reduce admission rate and improve FEV_1 in severe, acute asthma exacerbations and in stable, chronic asthma.

10. Immunotherapy (allergy shots) improves asthma control in some patients and is ineffective in others. A recent meta-analysis demonstrated that immunotherapy may improve lung function, reduce symptoms, and decrease medication requirements in a significant number of patients.

11. Mucus may contribute to airway obstruction in asthma. However, because some inhaled mucolytics such as acetylcysteine may precipitate bronchospasm, they should not be used for the treatment of patients with asthma.

12. Omalizumab (Xolair) is an anti-IgE compound used for severe asthma and concurrent allergies. It is usually administered twice monthly as an injection in a specialty physician's office. Life-threatening anaphylaxis has rarely been reported with this medication.

J. **Drug delivery options**
1. **MDIs**
   a. When administered with good technique and a spacer, the efficacy of MDIs is similar to that of nebulizers, despite the lower doses administered with an MDI and spacer. The only MDI that comes with a built-in spacer is the Azmacort (triamcinolone) inhaler.
   b. For small children to be able to use an MDI, a spacer with a face mask must be used.
   c. MDIs can be difficult to use. Steps for properly using an MDI are outlined in *Table 41-8*.
   d. MDIs can be administered to patients on mechanical ventilation with the use of an attachment device designed for the mechanical ventilator circuit. Higher doses of the β_2-agonist are often used in this setting.
   e. Breath-actuated MDIs (e.g., Maxair Autohaler) require the patient to use a closed-mouth technique. When inhalation has begun, the medication is released automatically. This type of inhaler is useful for a patient who is having problems coordinating actuation and inhalation.
2. **Spacers and holding chambers** (e.g., AeroChamber, AeroVent, Ellipse, InspirEase, OptiChamber)
   a. Spacers and holding chambers reduce the amount of drug deposited in the oral cavity.
   b. The use of spacers and holding chambers may minimize local and systemic adverse reactions.
   c. Addition of a spacer in a patient with poor MDI technique may improve pulmonary delivery of the agent.
   d. Spacers should be considered in all patients who are receiving medium-to-high doses of inhaled corticosteroids.
   e. They are especially beneficial for patients with poor hand–lung coordination, such as very young and old.
   f. Devices vary in construction and efficacy. The presence of a one-way mouthpiece valve, inhalation rate whistle, size, and durability are all factors that should be considered when selecting a particular spacer for a patient. Some new spacers have antistatic interiors to minimize adherence of aerosol particles to the interior of the spacer.
3. **Nebulizers**
   a. Compared to MDI and spacer administration, nebulizers require less patient coordination during administration of multiple inhalations.
   b. Disadvantages of nebulizers include cost, preparation and administration time, size of the device, and drug delivery inconsistencies among devices.
   c. Despite the disadvantages, nebulization is recommended for delivery of high-dose β-agonists and anticholinergics in severe exacerbations.
4. **Dry-powder inhalers**
   a. Dry-powder inhalers (DPIs) are coming to the market as a result of the international move to avoid the use of chlorofluorocarbon (CFC) propellants. They are also being used more frequently because many patients find them easier to use than an MDI.

Table 41-8	PROCEDURE FOR THE PROPER USE OF METERED DOSE INHALERS (MDIs)

Assemble MDI, if necessary.
Remove cap and inspect mouthpiece for foreign objects.
Attach MDI to spacer (if applicable).
Shake MDI (with spacer).
Tilt head back slightly and exhale fully.
Position inhaler:
   Wrap lips around spacer mouthpiece.
   Position inhaler 1–2 in. from open mouth.
   Wrap lips around inhaler mouthpiece.
Just as you begin to inhale, depress canister once to release medication.
Continue inhaling slowly (over 3–5 secs) until lungs are full.
Hold breath for 5–10 secs.
Wait 1 min before repeating steps to deliver additional puffs.
Rinse mouth out after use of inhaled steroids.

    b. Dry-powder inhalers require the user to
- **(1)** first load the dose into the delivery chamber
- **(2)** exhale fully
- **(3)** inhale rapidly or slowly, depending on the device (versus only slow inhalation required for MDI administration)
- **(4)** use the closed-mouth technique
- **(5)** avoid exhaling into the mouthpiece before inhalation

    c. Spacers are not used with DPIs.

    d. Patients should be advised to keep these devices away from moisture.

K. Nonpharmacological treatment

    1. Humidified oxygen is administered to all patients with severe, acute asthma to reverse hypoxemia. Although the fraction of inspired oxygen (FIO_2) administered is based on the patient's arterial blood gas status, 1 to 3 L/min is generally given via face mask or nasal cannula. The goal is to keep the $SaO_2 > 90\%$ ($> 95\%$ if the patient is pregnant or has heart disease).

    2. Heliox is a mixture of helium and oxygen that has a lower density than air. Because of its decreased airflow resistance, heliox may increase ventilation during acute asthma exacerbations. Because conflicting information has been published in studies using heliox, its role in asthma is unclear.

    3. Intravenous fluids and electrolytes may be required if the patient is volume depleted.

    4. Environmental control and allergen avoidance are important in the management of a patient with asthma.

        a. Available data suggest that avoidance of known allergens can improve asthma control.

        b. Some measures include use of allergen-resistant mattress and pillow encasements, use of high-filtration vacuum cleaners, removal of carpets and draperies, and avoidance of furry pets.

    5. Vaccines (e.g., influenza virus, polyvalent pneumococcals) are recommended to prevent infection, which may precipitate an exacerbation.

II. CHRONIC OBSTRUCTIVE PULMONARY DISEASE

A. Definitions. The National Heart, Lung, and Blood Institute/World Health Organization (NHLBI/WHO) Global Initiative for Chronic Obstructive Lung Disease (GOLD) definition of COPD is "a disease state characterized by airflow limitation that is not fully reversible. The airflow limitation is usually both progressive and associated with an abnormal inflammatory response of the lungs to noxious particles or gases." The American Thoracic Society definition is similar: A disease state characterized by the presence of airflow limitation owing to chronic bronchitis or emphysema; the airflow obstruction is generally progressive, may be accompanied by airway hyperreactivity, and may be partially reversible. The two major forms of COPD—**chronic bronchitis** and **emphysema**—frequently coexist. COPD also coexists with asthma. These guidelines have been updated annually.

    1. Chronic bronchitis is characterized by excessive mucus production by the tracheobronchial tree, which results in airway obstruction as a result of edema and bronchial inflammation. Bronchitis is considered chronic when the patient has a cough producing more than 30 mL of sputum in 24 hrs for at least 3 months of the year for 2 consecutive years and other causes of chronic cough have been excluded.

    2. Emphysema is marked by permanent alveolar enlargement distal to the terminal bronchioles and destructive changes of the alveolar walls. There is a lack of uniformity in airspace enlargement, resulting in loss of alveolar surface area. The collapse of these small airways results in airflow limitation that is independent of exertion.

B. Incidence. Approximately 17 million Americans have COPD. COPD is the third leading cause of death in the United States and the leading cause of hospitalization in the older population. It is most commonly diagnosed in older men; however, the incidence is increasing in women owing to an increasing population of women smokers. Women may be more likely to have more rapidly progressive COPD than men. Asthma is a common comorbidity.

C. Cause. Various factors have been implicated in the development of COPD, including the following:

    1. Cigarette smoking is the primary causal factor for the development of COPD, present in $> 90\%$ of patients.

        a. One mechanism suggests that pulmonary hyperreactivity secondary to smoking results in persistent airway obstruction.

    b. There is also an increased risk of COPD in people who have α_1-antitrypsin (AAT) deficiency. One in three people with genetic AAT deficiency develop emphysema, usually as young adults.

        (1) AAT is a serine protease inhibitor, and it is also an acute-phase reactive protein. The major physiological function of AAT is inhibition of neutrophil elastase.

        (2) AAT deficiency should be suspected when emphysema develops early in the absence of a significant smoking history.

  2. Exposure to irritants such as sulfur dioxide (as in polluted air), noxious gases, and organic or inorganic dusts or combustible fuels in the home.

  3. A history of respiratory infections or bronchial hyperreactivity

  4. Social, economic, and hereditary factors

D. Pathophysiology

  1. Chronic bronchitis

    a. **Respiratory tissue inflammation** results in vasodilation, congestion, mucosal edema, and goblet cell hypertrophy. These events trigger goblet cells to produce excessive amounts of mucus.

    b. **Changes in tissue** include increased smooth muscle, cartilage atrophy, infiltration of neutrophils and other cells, and impairment of cilia.

    c. Airways become blocked by thick, tenacious mucous secretions, which trigger a productive cough.

    d. Normally, sterile airways can become colonized with *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis*, *Staphylococcus aureus*, and *Pseudomonas aeruginosa* species. Recurrent lung infections (viral and bacterial) reduce ciliary and phagocytic activity, increase mucus accumulation, weaken the body's defenses, and further destroy small bronchioles.

    e. As the **airways degenerate**, overall gas exchange is impaired, causing **exertional dyspnea**.

    f. Hypoxemia results from a V/Q imbalance and is reflected in an increasing arterial carbon dioxide tension (i.e., increasing Pa_{CO_2}).

    g. Sustained hypercapnia (increased Pa_{CO_2}) desensitizes the brain's respiratory control center and central chemoreceptors. As a result, compensatory action to correct hypoxemia and hypercapnia (i.e., a respiratory rate or depth increase) does not occur. Instead, hypoxemia serves as the stimulus for breathing. Use of narcotics or benzodiazepines, especially in combination, should be done cautiously in these patients to avoid respiratory failure.

  2. Emphysema

    a. **Anatomical changes** are the result of loss of tissue elasticity.

        (1) **Inflammation** and **excessive mucus secretion** (as from long-standing chronic bronchitis) cause air trapping in the alveoli. This contributes to breakdown of the bronchioles, alveolar walls, and connective tissue.

        (2) As clusters of alveoli merge, the number of alveoli diminishes, leading to increased space available for air trapping.

        (3) Destruction of alveolar walls causes collapse of small airways on exhalation and disruption of the pulmonary capillary beds.

        (4) These changes result in V/Q abnormalities; blood is shunted away from destroyed areas to maintain a constant V/Q ratio, unlike the case in chronic bronchitis.

        (5) Hypercapnia and respiratory acidosis are uncommon in emphysema because V/Q imbalance is compensated for by an increased respiratory rate.

    b. There are **specific regions of the lung** in which characteristic anatomical changes of emphysema occur.

        (1) In **centrilobular** (centriacinar) emphysema associated with cigarette smoking, destruction is central, selectively involving respiratory bronchioles. Typically, bronchioles and alveolar ducts become dilated and merge.

        (2) In **panlobular** (panacinar) emphysema, all lung segments are involved. The alveoli enlarge and atrophy, and the pulmonary vascular bed is destroyed. This form of emphysema is associated with AAT deficiency.

        (3) In **paraseptal** emphysema, the lung periphery adjacent to fibrotic regions is the site of alveolar distention and alveolar wall destruction. This is associated with spontaneous pneumothorax.

E. **Clinical evaluation**

1. **Physical findings**

a. **Predominant chronic bronchitis** typically has an insidious onset after age 45.

(1) A **chronic productive cough** is the hallmark of chronic bronchitis. It occurs first in winter, then progresses to year-round. It is usually worse in the morning. Smoking cessation can help lessen the productive cough.

(2) **Exertional dyspnea**, the most common presenting symptom, is progressive. However, the severity of this symptom may not reflect the severity of the disease.

(3) Other common findings include obesity, rhonchi and wheezes on auscultation, prolonged expiration, and a normal respiratory rate. As the disease progresses, right ventricular failure is common, which presents as jugular venous distention, peripheral edema, hepatomegaly, and cardiomegaly. Because patients tend to develop cyanosis, the term *blue bloater* is sometimes used to describe patients with chronic bronchitis.

b. **Predominant emphysema** has an insidious onset, and symptoms occur after age 55.

(1) The **cough** is chronic but less productive than in chronic bronchitis.

(2) **Exertional dyspnea** is progressive, constant, severe, more characteristic of emphysema than chronic bronchitis.

(3) Other common findings include weight loss, tachypnea, pursed-lip breathing, prolonged expiration, accessory chest muscle use, hyperresonance on percussion, diaphragmatic excursion, and diminished breath sounds. Because patients are able to maintain reasonably good oxygenation because of their tachypnea, the term *pink puffer* is sometimes used to describe patients with emphysema. Note however, that the pink puffer and blue bloater presentations are not specific for the respective diseases.

c. Patients may have elements and physical findings from each of these diseases simultaneously. Comorbidities such as CHF, CAD, stroke, DM, and depression are common in COPD patients.

2. **Diagnostic test results**

a. **COPD** patients with characteristic symptoms of cough, dyspnea, sputum production, and/or exposure to known risk factors (e.g., smoking) should be evaluated for a COPD diagnosis. If the patient has $FEV_1/FVC < 70\%$ and a postbronchodilator $FEV_1 < 80\%$ predicted, he or she has airflow limitation that is not fully reversible. Patients with a smoking history (e.g., > 20 pack/year history and > 45 years old) should be considered for the diagnosis. Spirometry can be used to help make the diagnosis.

b. **Chronic bronchitis**

(1) Blood analysis may reveal polycythemia as a result of to erythropoiesis secondary to hypoxemia. With bacterial infection, the WBC count may be increased.

(2) Sputum inspection reveals thick purulent or mucopurulent sputum tinged yellow, white, green, or gray; an acute change in color and/or quantity suggests infection.

(3) Arterial blood gas studies may show a markedly decreased Pao_2 level (45 to 60 mm Hg), reflecting hypoxemia, and a $Paco_2$ level that is normal or elevated (50 to 60 mm Hg), reflecting hypercapnia.

(4) Pulmonary function tests may be normal in the early disease stages. Later, they show a reduced FEV_1/FVC ratio, increased residual lung volume, a decreased vital capacity, and a decreased FEV_1. Unlike emphysema, chronic bronchitis patients tend to have normal diffusing capacity, normal static lung compliance, and normal TLC.

(5) Chest radiograph typically identifies lung hyperinflation, a barrel chest, and increased bronchovascular markings.

(6) An ECG may reveal right ventricular hypertrophy and changes consistent with cor pulmonale.

c. **Emphysema**

(1) Sputum inspection reveals scanty sputum that is clear or mucoid. Infections are less frequent than in chronic bronchitis.

(2) Arterial blood gas studies typically indicate a reduced or normal Pao_2 level (65 to 75 mm Hg) and, in late disease stages, an increased $Paco_2$ level (50 to 60 mm Hg).

(3) Pulmonary function tests show a reduced FEV_1/FVC ratio, normal or increased static lung compliance, reduced FEV_1 and diffusing capacity, and increased TLC and RV.

  (4) Chest radiograph usually reveals bullae, blebs, a flattened diaphragm, lung hyperinflation, vertical heart, enlarged anteroposterior chest diameter, decreased vascular markings in the lung periphery, and a large retrosternal air space.

F. Treatment objectives endorsed by GOLD include the following:
 1. Prevent disease progression (smoking cessation)
 2. Relieve symptoms and improve exercise tolerance (enable the patient to perform normal daily activities)
 3. Improve health status
 4. Prevent and treat exacerbations
 5. Prevent and treat complications
 6. Reduce mortality

G. Therapy
 1. Pharmacological treatment. Therapy is based on disease staging, which is determined by spirometry (*Table 41-9*).

  a. Short-acting anticholinergics and β-agonists, alone or in combination, are the most commonly used initial agents. Long-acting bronchodilators, such as salmeterol, formoterol, tiotropium (Spiriva), and theophylline are added to the short-acting agents. Methylxanthines are usually added when the response to other agents is inadequate. In addition to bronchodilation, these agents can decrease dyspnea, improve exercise capacity, improve quality of life, and decrease the frequency and severity of exacerbations, especially tiotropium. A new agent was recently approved, roflumilast (Daliresp), in the United States. It is a selective PDE4 inhibitor that is indicated to decrease COPD exacerbations in certain patients.

  b. Bronchodilators are the most important therapy for symptoms in COPD. *Figure 41-4* indicates a strategy of use.

  c. Inhaled corticosteroids, such as fluticasone and budesonide, have shown small benefits in FEV_1; the majority of their benefit occurs in reducing the severity of exacerbations, not the number of exacerbations.

  d. Anticholinergics (e.g., ipratropium bromide, tiotropium bromide, atropine)

   (1) Indications. Anticholinergics may be used as first-line bronchodilators or in conjunction with β-agonists in the treatment of COPD because these agents are the most potent bronchodilators for the condition.

   (2) Mechanism of action. Ipratropium bromide, tiotropium bromide, and atropine produce bronchodilation by competitively inhibiting cholinergic responses. Ipratropium bromide and tiotropium bromide also reduce sputum volume without altering viscosity. Some studies have shown an increased response to these agents in COPD when they are combined with β-agonists. Tiotropium has greater affinity for cholinergic receptors than ipratropium.

   (3) Administration and dosage

    (a) Ipratropium bromide is three to five times more potent and has significantly fewer side effects than atropine, which is rarely used today since the development of nebulized ipratropium.

    (b) Initial MDI dosing of ipratropium bromide is two inhalations (40 μg) four times daily, but dosing can be increased to six inhalations four times daily without significant risk. These higher doses are often required to achieve therapeutic benefit. Administration should be via MDI with spacer or MDI alone using a closed-mouth technique.

    (c) Dosing of ipratropium bromide solution is 500 μg/2.5 mL (1 unit dose vial) or more via nebulizer four times daily.

    (d) Tiotropium bromide capsules contain 22.5 μg tiotropium bromide monohydrate, equivalent to 18 μg tiotropium.

     (i) Tiotropium is an inhalation powder contained in a hard capsule. It should be administered once daily only via a HandiHaler device, which delivers 10 μg tiotropium.
     (ii) Patients should generally not be placed on both ipratropium and tiotropium because of the increased risk of anticholinergic side effects, and no additional bronchodilation is likely achieved by adding ipratropium. For example, if a COPD patient is currently on ipratropium/albuterol (Combivent, DuoNeb), and tiotropium is started, the albuterol should be continued as the short-acting bronchodilator and ipratropium discontinued.

Table 41-9   THERAPY AT EACH STAGE OF COPD

	0: At Risk	I: Mild	II: Moderate IIA	IIB	III: Severe
Old	0: At Risk	I: Mild	II: Moderate	IIB	III: Severe
New	0: At Risk	I: Mild	II: Moderate	II: Severe	IV: Very Severe
Characteristics	Chronic symptoms Exposure to risk factors Normal spirometry	$FEV_1/FVC < 70\%$ $FEV_1 \geq 80\%$ With or without symptoms	$FEV_1/FVC < 70\%$ $50\% \leq FEV_1 < 50\%$ With or without symptoms	$FEV_1/FVC < 70\%$ $30\% \leq FEV_1 < 50\%$ With or without symptoms	$FEV_1/FVC < 70\%$ $FEV_1 < 30\%$ or $FEV_1 < 50\%$ predicted plus chronic respiratory failure
		Avoidance of risk factor(s); influenza vaccination			
			Add short-acting bronchodilator when needed		
			Add regular treatment with one or more long-acting bronchodilators		
			Add rehabilitation		
				Add inhaled glucocorticosteroids if repeated exacerbations	
					Add long-term oxygen if chronic respiratory failure
					Consider surgical treatments

FEV_1, forced expiratory volume in 1 sec; FEV, forced vital capacity.

Figure 41-4. Stepped care approach to bronchodilators in COPD. *AC*, anticholinergic; *LA*, long acting; *PDE*, phosphodiesterase; *SA*, short acting.

e. **β-Agonists** (see I.I.1; *Table 41-4*)

(1) **Indications.** β_2-Agonists may be used as first-line bronchodilators or in conjunction with anticholinergic agents in the maintenance treatment of COPD. Short-acting agents are used regularly or on an as-needed basis for symptoms. Some patients may respond clinically to the prolonged treatment with β_2-agonists even after demonstrating lack of acute reversibility (spirometry testing showing $< 12\%$ or < 200-mL increase in FEV_1) to short-acting agents.

(2) **Mechanism of action.** β_2-Agonists relieve dyspnea caused by airway obstruction, although the response is usually not as significant as in patients with asthma. These agents may also increase mucociliary clearance by stimulating ciliary activity (helps patients expectorate sputum).

(3) **Administration and dosage**

(a) β_2-Agonists are administered via inhalation (e.g., DPI, nebulizer, MDI with or without a spacer), unless the patient cannot use the drug properly; then an oral agent is used cautiously.

(b) β_2-Agonists of the same duration should not be used in combination because an adequate dose of a single agent provides peak bronchodilation. However, it is reasonable to administer a long-acting product (e.g., salmeterol, formoterol) on a regular basis with a short-acting agent reserved for as-needed or rescue therapy.

(c) Salmeterol, formoterol, arformoterol (long-acting β-agonist) are administered twice daily. Indacterol (Arcapta®) is a recently marketed long-acting β-agonist that is administered once daily as a dry powder inhaler. They may also be used in combination with ipratropium bromide or tiotropium. Neither agent is used on an as-needed basis for rescue therapy, although formoterol does have a rapid onset of action.

(d) Inhaler devices that require a rapid inspiratory rate may result in suboptimal lung deposition in the COPD patient with limited inspiratory capacity. An MDI or nebulizer may be more optimal in this type of patient.

f. **Theophylline** (see I.I.5)

(1) **Indications.** Theophylline compounds typically are added to the drug regimen after an unsuccessful trial of ipratropium bromide and β-adrenergics. Theophylline appears to have a greater clinical role in COPD than in asthma. Other similar agents (phosphodiesterase inhibitors) are in development.

(2) Mechanism of action. In COPD, theophylline compounds are used because they increase mucociliary clearance, stimulate the respiratory drive, enhance diaphragmatic contractility, improve the ventricular ejection fraction, and stimulate renal diuresis. Their bronchodilator properties are modest, at best. Theophylline may be used in lieu of other long-acting bronchodilators or in combination.

(3) Administration and dosage. A trial of 1 to 2 months with the serum drug level maintained at 5 to 12 μg/mL and maximized.

    (a) Because of the nonbronchodilator effects of methylxanthines, they may be continued in the face of a clinical response, even in the absence of improved FEV_1.

    (b) If no change occurs in the patient's clinical condition and/or FEV_1, theophylline therapy should be discontinued owing to the potential for side effects.

(4) Precautions and monitoring effects. Serum drug levels should be closely monitored in all patients, especially those with signs of toxicity (tachycardia, nausea, vomiting) as well as with liver impairment, congestive heart failure and/or cor pulmonale as a result of reduced theophylline metabolism. Potential drug interactions (e.g., with ciprofloxacin) may warrant blood testing.

g. Roflumilast (Daliresp)

(1) Indication. Roflumilast is indicated as a treatment to reduce the risk of COPD exacerbations in patients with severe COPD associated with chronic bronchitis.

(2) Mechanism of action. Roflumilast is a long-acting selective PDE4 inhibitor that provides anti-inflammatory effects and mild bronchodilator effects.

(3) Administration and dosage. The dose of roflumilast is 500 mcg once daily, with or without food.

(4) Precautions and monitoring. The primary side effects of roflumilast are GI intolerance (diarrhea, nausea). Weight loss, averaging 5 lb, was seen in clinical trials. The PI warns that suicidality was reported in a small number of patients; the relationship with roflumilast is unclear. Drug interactions through CYP450 may occur, analogous to those seen with theophylline.

h. Corticosteroids (see I.I.2; *Table 41-5*)

(1) Indications

    (a) Systemic corticosteroids (preferably oral) are indicated in the treatment of acute COPD exacerbations and chronically in some severe patients.

    (b) Inhaled corticosteroids play a less prominent role in COPD than in asthma.

    (c) Candidates for prolonged use of inhaled corticosteroid therapy should

        (i) be symptomatic and have a documented spirometric response (i.e., an increase in FEV_1 of at least 15% and 200 mL after 6 weeks to 3 months of use).

        (ii) have an $FEV_1 < 50\%$ predicted, with a history of repeated exacerbations requiring systemic corticosteroids or antibiotics.

    (d) Long-term use of systemic steroids should be avoided if possible. Osteoporosis of the spine and ribs is especially common in COPD patients receiving frequent or maintenance systemic steroids. It has been recently recognized that inhaled steroids increase the risk of bacterial pneumonia in COPD patients.

(2) Administration and dosage

    (a) For oral use in outpatient management of acute exacerbations, prednisone or prednisolone is administered at a dosage of 40 mg/day for 10 days.

    (b) The dose of oral (e.g., prednisolone) or intravenous corticosteroids (e.g., methylprednisolone) for hospital management of acute COPD exacerbations is not established. However, doses and duration of therapy should be limited (e.g., 30 to 40 mg/day of prednisolone for 10 to 14 days) to avoid significant adverse effects.

    (c) In COPD, inhaled steroids are not as efficacious as in asthma patients.

    (d) In appropriate patients, corticosteroids may be administered via DPI or MDI with spacer.

    (e) Response to oral corticosteroids does not predict response to inhaled corticosteroids.

    (f) Medium doses of inhaled corticosteroids are recommended for COPD (e.g., Flovent 110 μg two puffs twice a day or the combination of Advair 250 μg one puff twice a day).

    (g) Inhaler devices that require a rapid inspiratory rate (e.g., Pulmicort Flexhaler) are generally not desirable in COPD patients.

    i. **Antibiotics**

      (1) Indications

         (a) Antibiotics are used to treat exacerbations with suspected infection as evidenced by an increase in volume or change in color or viscosity of the sputum, along with dyspnea.

         (b) Prevention of infection with chronic antibiotic therapy is controversial and should be considered only in patients with multiple exacerbations annually (i.e., more than two per year).

      (2) Antibiotic therapy

         (a) Ambulatory antibiotic treatment of exacerbations in patients with COPD is recommended when there is evidence of worsening dyspnea and cough with purulent sputum and increased sputum volume.

           (i) Hospital or laboratory antibiograms should be reviewed when selecting an appropriate agent for *S. pneumoniae*, *M. catarrhalis*, and *H. influenzae*.

           (ii) Agents may include either a second-generation cephalosporin (e.g., cefuroxime, cefaclor), trimethoprim-sulfamethoxazole, a β-lactam with or without a β-lactamase inhibitor (e.g., amoxicillin, amoxicillin-clavulanate), macrolides (azithromycin [Zithromax]), or an oral fluoroquinolone (ciprofloxacin [Cipro], levofloxacin [Levaquin]). (Note that recent evidence indicates chronic macrolides may have a role to decrease COPD exacerbations).

          (iii) If infection with *M. pneumoniae* or *Legionella pneumophila* is a concern, although uncommon in COPD flares, a macrolide or fluoroquinolone may be added.

         (b) Antibiotic treatment of pneumonia in hospitalized patients with COPD includes either a second- or third-generation cephalosporin (e.g., cefuroxime, ceftriaxone, cefotaxime) or a β-lactam with or without a β-lactamase inhibitor (e.g., amoxicillin-clavulanate [Augmentin], piperacillin-tazobactam [Zosyn]), a macrolide, or fluoroquinolone.

         (c) COPD exacerbations are treated for 3 to 10 days, depending on the agent used (e.g., moxifloxacin 400 mg for 5 days) and the patient.

    j. **Mucolytics** (e.g., oral *N*-acetylcysteine) may improve sputum clearance and disrupt mucus plugs.

    k. **Expectorants** (e.g., guaifenesin) may be used. Potassium iodide should be avoided because of side effects associated with iodine therapy.

    l. **Antioxidants** (e.g., oral *N*-acetylcysteine) may reduce exacerbation frequency.

    m. **Influenza virus vaccine** is recommended because of its ability to reduce death and serious illness by almost 50%.

2. **Nonpharmacological therapy**

    a. **Vaccinations**

      (1) Influenza vaccination administered each fall/winter. **Polyvalent pneumococcal** vaccine is recommended by the American Thoracic Society.

    b. **Oxygen therapy**

      (1) Recommended for hypoxemia chronically or during exacerbations. Currently recommended to administer oxygen at least 15 hr/day.

      (2) Reverses hypoxemia (particularly at night and during exercise).

      (3) Indications for home oxygen treatment include

         (a) $Pao_2 < 55$ mm Hg or $Sao_2 < 88\%$

         (b) Pao_2 of 55 to 60 mm Hg or $Sao_2 < 89\%$ with evidence of cor pulmonale, pulmonary hypertension, or polycythemia (hematocrit $> 55\%$).

      (4) Patients hospitalized for COPD exacerbations should receive controlled oxygen to keep $Pao_2 > 60$ mm Hg or $Sao_2 > 90\%$. Arterial blood gas (ABG) tests may be performed 30 mins after placing the patient on oxygen to identify and minimize CO_2 retention.

    c. **Chest physiotherapy** loosens secretions, helps reexpand the lungs, and increases the efficacy of respiratory muscle use. Techniques include postural drainage, chest percussion and vibration, coughing, and deep breathing. These efforts may help patients with lobar atelectasis or who produce large quantities (i.e., > 25 mL/day) of sputum.

d. **Physical rehabilitation** improves the patient's exercise tolerance and quality of life. A pulmonary rehabilitation program usually includes physical conditioning and social, psychological, and nutritional interventions. This can be an effective intervention.

e. **Smoking cessation** and avoidance of other irritants has been shown to slow the rate of decline in FEV_1 in COPD patients. It is obviously one of the most important interventions. Nicotine gum, patches, inhalers, lozenges, bupropion, varenicline (Chantix), and clonidine may be useful in smoking cessation. Behavior intervention significantly enhances the effectiveness of pharmacological therapy in smoking cessation.

f. **Surgery.** There is a growing body of evidence that lung volume reduction surgery may be beneficial to patients with severe emphysema. Clinical trials have now delineated proper patient selection for this type of surgery. Lung transplantation is also performed in selected patients.

H. Complications of COPD

1. **Pulmonary hypertension.** With decreased pulmonary vascular bed space (owing to lung congestion), pulmonary arterial pressure increases. In some cases, pressure increases enough to cause **cor pulmonale** (right ventricular hypertrophy) with consequent heart failure.

2. **Acute respiratory failure.** In advanced stages of COPD, the brain's respiratory center may become seriously compromised, leading to poor cerebral oxygenation and an increased $Paco_2$ level. Hypoxia and respiratory acidosis may ensue. If the condition progresses, respiratory failure occurs.

3. **Infection.** In chronic bronchitis, trapping of excessive mucus, air, and bacteria in the tracheobronchial tree sets the stage for infection. In addition, impairment of coughing and deep breathing, which normally cleanses the lungs, leads to destruction of respiratory cilia. Once an infection sets in, reinfection can easily occur.

4. **Polycythemia.** An increase in red blood cells infrequently can lead to hypercoagulable states, embolism, and stroke. This happens uncommonly today due to the widespread use of supplemental oxygen in COPD patients.

Study Questions

Directions for questions 1–7: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The symptoms of allergen-mediated asthma result from which of the following?

   (A) Increased release of mediators from mast cells
   (B) Increased adrenergic responsiveness of the airways
   (C) Increased vascular permeability of bronchial tissue
   (D) Decreased calcium influx into the mast cells
   (E) Decreased prostaglandin production

2. Acute exacerbations of asthma can be triggered by all of the following *except*

   (A) bacterial or viral pneumonia.
   (B) hypersensitivity reaction to penicillin.
   (C) discontinuation of asthma medication.
   (D) hot, dry weather.
   (E) stressful emotional events.

3. A 45-year-old male with a history of asthma has a peak expiratory flow rate (PEFR) of 65%, nocturnal wheezing once a month, and daytime wheezing usually less than twice a week. According to the National Institutes of Health (NIH) guidelines for the treatment of asthma, he has which type?

   (A) Mild intermittent
   (B) Mild persistent
   (C) Moderate persistent
   (D) Severe persistent

4. The patient in question 3 should be treated with which *two* agents?

   (A) Inhaled steroid and ipratropium
   (B) Inhaled steroid and albuterol MDI (as needed)
   (C) Inhaled steroid and aspirin

5. A 15-year-old female is brought to the emergency department. She is breathing 30 times per minute, is unable to speak in full sentences, and has a peak expiratory flow rate (PEFR) $< 50\%$ predicted. The preferred first-line therapy for her asthma exacerbation is

(A) theophylline.
(B) β-agonist.
(C) corticosteroid.
(D) cromolyn sodium.
(E) A and B
(F) B and C

6. The primary goals of asthma therapy in an adult patient include all of the following *except*

(A) maintain normal activity levels.
(B) maintain control of symptoms.
(C) avoid adverse effects of asthma medications.
(D) prevent acute exacerbations and chronic symptoms.
(E) prevent destruction of lung tissue.

7. Which of the following tests is used at home to assess therapy and determine if a patient with asthma should seek emergency care?

(A) Forced expiratory volume in 1 sec (FEV_1)
(B) Forced vital capacity (FVC)
(C) Total lung capacity (TLC)
(D) Peak expiratory flow rate (PEFR)
(E) Residual volume (RV)

Directions for question 8: The incomplete statement in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

(A) if **I only** is correct
(B) if **III only** is correct
(C) if **I and II** are correct
(D) if **II and III** are correct
(E) if **I, II, and III** are correct

8. The disease process of chronic bronchitis is characterized by

   I. the destruction of central and peripheral portions of the acinus.
  II. an increased number of mucous glands and goblet cells.
 III. edema and inflammation of the bronchioles.

Directions for questions 9–11: Each description in this section is most closely associated with **one** of the following agents. The agents may be used more than once or not at all. Choose the **best** answer, **A–E**.

(A) cimetidine
(B) albuterol
(C) ipratropium bromide
(D) epinephrine
(E) atropine

9. Decreases theophylline clearance

10. Has anticholinergic activity with few side effects

11. Has high β_2-adrenergic selectivity

Answers and Explanations

1. **The answer is A** *[see I.F; Figure 41-1].*
In asthma, airborne antigen binds to the mast cell, activating the IgE-mediated process. Mediators (e.g., histamine, leukotrienes, prostaglandins) are then released, causing bronchoconstriction and tissue edema.

2. **The answer is D** *[see I.D; Figure 41-1].*
Exacerbations of asthma can be triggered by allergens, respiratory infections, occupational stimuli (e.g., fumes from gasoline or paint), emotions, and environmental factors. Studies have shown that cold air can cause release of mast cell mediators by an undetermined mechanism. Hot, dry air does not cause this release.

3. **The answer is C** *[see Table 41-3].*
The patient has moderate persistent asthma. All three parameters are consistent with mild persistent asthma. If any one of the three parameters indicated moderate persistent asthma, then the patient would be classified as moderate asthma (PEFR = 65%).

4. **The answer is B** *[see Figure 41-3].*
Inhaled steroids are the anti-inflammatory drug of choice owing to proven efficacy. All patients should be prescribed a short-acting β_2-agonist to use as rescue therapy for worsening symptoms. If chronic symptoms worsen, a long-acting β_2-agonist can be added (e.g., Advair). Remember that increasing the dose of the inhaled steroid may not improve symptoms, a long-acting bronchodilator is more likely to do so.

5. **The answer is F** *[see Figure 41-3].*
   Patient is obviously in respiratory distress. Aggressive treatment with oxygen, systemic steroids, and short-acting bronchodilators is indicated. Ipratropium could also be added to the albuterol in the acute setting.

6. **The answer is E** *[see I.F; I.H.1; II.D].*
   Asthma is characterized by reversible airway obstruction in response to specific stimuli. Mast cells release mediators, which trigger bronchoconstriction. After an acute attack, in most cases symptoms are minimal and pathological changes are not permanent. Unlike asthma, COPD does cause progressive airway destruction, chronic bronchitis by excessive mucus production and other changes, and emphysema by destruction of the acinus.

7. **The answer is D** *[see I.G.2.a.(3)].*
   For home monitoring, PEFR is the best test for assessment of therapy, trigger identification, and the need for referral to emergency care. It is recommended for patients who have had severe exacerbations of asthma, who are poor perceivers of asthma symptoms, and those with moderate-to-severe disease.

8. **The answer is D (II, III)** *[see II.D.1–2].*
   Chronic bronchitis is characterized by an increase in the number of mucous and goblet cells owing to bronchial irritation. This results in increased mucus production. Other changes include edema and in-flammation of the bronchioles and changes in smooth muscle and cartilage. Emphysema is a permanent destruction of the central and peripheral portions of the acinus distal to the bronchioles. In this disease, adequate oxygen reaches the alveolar duct, owing to increased rate of breathing, but perfusion is abnormal.

9. **The answer is A** *[see Table 41-8].*

10. **The answer is C** *[see II.G.1.a].*

11. **The answer is B** *[see Table 41-4].*
    Cimetidine, an H_2-receptor antagonist, decreases theophylline clearance by inhibiting hepatic microsomal mixed-function oxidase metabolism, thus increasing serum theophylline concentrations. Theophylline clearance can be decreased by 40% during the first 24 hrs of concurrent therapy. Anticholinergic agents such as atropine and ipratropium bromide produce bronchodilation by competitively inhibiting cholinergic receptors. The disadvantages of atropine include dry mouth, tachycardia, and urinary retention. Ipratropium bromide is three to five times more potent than atropine and does not have these side effects. Albuterol is one of the most β_2-selective adrenergic agents available. Other such agents include terbutaline, bitolterol, and pirbuterol. Agents with β_2-selectivity dilate bronchioles without causing side effects related to β_1-stimulation (e.g., increased heart rate).

Osteoarthritis and Rheumatoid Arthritis

<div style="text-align:right">42</div>

TINA HARRISON THORNHILL

I. DEFINITION AND CAUSE

A. **Osteoarthritis (OA)** is a common chronic condition of articular cartilage degeneration. Secondary changes can occur in the bone, leading to pain, decreased functioning, and even disability. OA affects nearly 21 million middle-aged and elderly Americans. It is the most common form of arthritis. Although not always symptomatic, most people older than the age of 55 years have radiological evidence of the disease. Until age 55 years, OA affects men more frequently than women, but after age 55, women are more likely to have the disease.

B. **Rheumatoid arthritis (RA)** is a chronic, systemic autoimmune disease that involves inflammation in the membrane lining of the joints and often affects internal organs. Most patients exhibit a chronic fluctuating course of disease that can result in progressive joint destruction, deformity, and disability. RA affects between 1 and 2 million Americans. It occurs three times more often in women, and peaks at age 35 to 50 years.

II. NORMAL JOINT ANATOMY AND PHYSIOLOGY

A. The **synovial joint** consists of two bone ends covered by articular cartilage. The roles of articular cartilage include
   1. Enabling frictionless movement of the joint.
   2. Distributing the load across the joint (shock absorber), to prevent damage.
   3. Promoting stability during use.

B. **Cartilage** is avascular and aneural. It is metabolically active and undergoes continual internal remodeling. It is composed primarily of water but is also made from chondrocytes and extracellular matrix.

C. **Chondrocytes** control the synthesis and degradation of the matrix. They produce proteoglycans and collagen in the extracellular matrix to maintain the integrity of the matrix in healthy cartilage.

D. The **joint capsule** is a fibrous outer layer that encapsulates the joint. The joint capsule is lined by **synovium**, a membrane that produces a viscous fluid that lubricates the joint.

E. The **synovial fluid** is composed, in part, of hyaluronic acid. Glucosamine is a component of hyaluronic acid. The role of hyaluronic acid is to maintain functional and structural characteristics of the extracellular matrix.

F. **Bursae** are small sacs that are lined with synovial membrane and filled with fluid to provide cushioning and lubrication for the movement of the joint.

III. OSTEOARTHRITIS

A. **Pathophysiology.** Many age-related changes contribute to the development of OA.
   1. The strength of tendons, ligaments, and muscles declines with advancing age and may contribute to the development of the disease.
   2. The number of chondrocytes declines owing to apoptosis (cell death), decreased proliferation, or both.

3. The synthesis of normal proteoglycans is reduced.
4. Chondrocytes lose the ability to promote healing and cartilage remodeling, resulting in cartilage matrix degradation. Proteoglycans are depleted.
5. Matrix metalloproteinases (MMPs) and proinflammatory cytokines promote cartilage degradation.
6. Interleukin 1 (IL-1) has several roles in the development of OA
    a. Induction of chondrocytes and synovial cells to synthesize MMPs
    b. Inhibits the synthesis of type II collagen and proteoglycans, preventing collagen from repairing itself
    c. Enhances nitric oxide production and induces chondrocyte apoptosis
7. Pain occurs as a result of
    a. Osteophytes (spurs of cartilage and bone at the joint)
    b. Synovitis
    c. Bursitis
    d. Tendonitis
B. **Risk factors** for OA include advanced age, female gender, muscle weakness, obesity, joint trauma, heredity, congenital or developmental anatomical defects, and repetitive stress.
C. **Clinical presentation.** OA is characterized by a deep, localized ache in a joint. Pain and stiffness usually occurs with rest or immobility and lasts < 30 mins. Inflammation, if present, is mild. Patients will often complain of crepitus, a popping or cracking noise heard in the joint upon moving. OA most commonly affects the hips, knees, spine, feet, and hands.
D. **Diagnosis**
1. **Physical examination.** Joint tenderness, diminished range of motion, crepitus, and misshaped joints.
2. **Laboratory tests.** No specific lab tests are diagnostic for OA; however, if arthrocentesis is performed, synovial fluid will reveal mild leukocytosis with predominance of mononuclear lymphocytes.
3. **Radiography.** Narrowing of joint space (owing to loss of cartilage), subchondral sclerosis, and osteophytes are seen.
4. The American College of Rheumatology (ACR) has defined **criteria for OA of the hip**, **knee**, **and hand**:
    a. OA of the hip is characterized by hip pain and at least two of the following:
        (1) Erythrocyte sedimentation rate (ESR) < 20 mm/hr
        (2) Radiographic evidence of femoral or acetabular osteophytes
        (3) Radiographic evidence of joint space narrowing
    b. OA of the knee is characterized by knee pain, radiographic evidence of osteophytes, and at least one of the following:
        (1) Age > 50 years
        (2) Morning stiffness that lasts < 30 mins
        (3) Articular crepitus on motion
    c. OA of the hand is characterized by hand pain, aching, or stiffness and at least three of the following:
        (1) Hard tissue enlargement of ≥ 2 distal interphalangeal (DIP) joints.
        (2) Hard tissue enlargement of ≥ 2 selected joints (second and third DIP and/or proximal interphalangeal [PIP], and the first carpometacarpal joints of both hands).
        (3) Fewer than three swollen metacarpophalangeal (MCP) joints.
        (4) Deformity of at least one of ten selected joints.
E. **Treatment**
1. **Goals**
    a. Control pain and other symptoms
    b. Maintain or improve joint mobility
    c. Correct or minimize functional limitations and disability
2. **Nonpharmacological treatments.** The mainstay of OA therapy should focus on these nondrug therapies.
    a. **Patient education** may include tips on joint protection and exercise programs.
    b. **Weight loss** (if overweight) can decrease pain and OA symptoms.

c. **Aerobic exercise programs** to increase muscle strength.

d. **Physical therapy** for range-of-motion exercises and strengthening.

e. **Assistive devices** (e.g., canes, walkers) may help decrease joint load.

f. **Acupuncture** leads to improvements in pain and function after 26 weeks, compared to placebo or arthritis education in patients with mild knee OA.

g. **Wedge insoles** can help reduce mechanical stress in persons with medial knee OA.

h. **Thermal therapy** (e.g., hot shower or tub, ice pack) may be of benefit for some patients with OA.

3. **Pharmacological treatment**

a. **Acetaminophen** (APAP) is considered first-line therapy by the ACR for OA. It has excellent analgesic and antipyretic activity, but no anti-inflammatory effects.

(1) A dose of $\leq$ 4 g/day is recommended to avoid toxicity. Concomitant use of other medications with acetaminophen should be evaluated closely to avoid overdose.

(2) Hepatotoxicity can occur in patients taking $>$ 4 g APAP a day. Symptoms can include nausea, vomiting, abdominal pain, malaise, and diaphoresis.

(3) Because there is little, if any, inflammation in the OA joint, APAP has been shown to be equally efficacious as ibuprofen and naproxen in patients with mild to moderate OA pain.

(4) Studies have shown either APAP immediate-release or extended-release is effective in treating mild to moderately severe OA pain.

b. **Nonsteroidal anti-inflammatory drugs (NSAIDs)** and **cyclooxygenase 2 (COX-2) specific inhibitors** are indicated in OA treatment when the response to APAP is inadequate (*Table 42-1*).

(1) **Mechanism of action.** NSAIDs are nonselective inhibitors of COX-1 and COX-2 as well as thromboxane synthetase.

(2) **Analgesia** is seen with short treatment duration and at lower doses (e.g., ibuprofen $\leq$ 1200 mg/day).

(3) **Anti-inflammatory** response is seen with higher doses and usually requires several days of therapy to achieve anti-inflammatory effect.

(4) **Adverse effects.** The FDA mandates that a published NSAID Medication Guide be issued with all NSAID prescriptions informing patients about the potential adverse effects.

(a) **Gastrointestinal** (GI) toxicity is caused by direct mucosal injury and inhibition of prostaglandins. Symptoms include dyspepsia, ulceration, and bleeding.

(i) COX-2 inhibitors may be an option for patients with a history of peptic ulcer disease; however, the GI safety of these agents has not been demonstrated long term.

(ii) People at risk for GI toxicity include the elderly and those with a history of peptic ulcer disease, chronic alcohol use, high-dose or multiple NSAID use, and concomitant corticosteroid use.

| Table 42-1 | SELECTED ANTI-INFLAMMATORY DRUGS |

Generic (Brand)	Initial Daily Dose	Maximum Daily Dose
Nonacetylated salicylates		
Salsalate (Disalcid)	1000 mg twice a day	3000 mg
Nonsteroidal anti-inflammatory drugs		
Aspirin (various)	650 mg every 4 hrs	4000 mg
Diclofenac (Voltaren)	75 mg twice a day	200 mg
Ibuprofen (Motrin, Advil)	400 mg three times a day	3200 mg
Naproxen (Naprosyn, Aleve)	500 mg twice a day	1100 mg
Nabumetone (Relafen)	1000 mg once a day	2000 mg
Sulindac (Clinoril)	150 mg twice a day	400 mg
Tolmetin (Tolectin)	400 mg three times a day	1800 mg
Cyclooxygenase 2 inhibitor		
Celecoxib (Celebrex)	100 mg twice a day	400 mg

(b) Renal toxicity results from the inhibition of prostaglandins. Although the risks are low (~5%), it does not appear to be dose dependent and is usually reversible.

  (i) Effects can include hyperkalemia, hyponatremia, increased serum creatinine, sodium and water retention, and acute renal failure.

  (ii) People at risk for renal toxicity include the elderly and those with preexisting renal disease, hypertension, diabetes mellitus, congestive heart failure, cirrhosis, and volume depletion (e.g., hemorrhage, sepsis, diuretics, and diarrhea).

(c) Hematological effects are the result of decreased platelet aggregation.

(d) Hepatic toxicity, although not common, can include elevated liver enzymes. Patients at risk include those with a history of hepatitis, alcoholism, and heart failure.

(e) Central nervous system effects can include sedation, confusion, and mental status changes and are primarily seen in the elderly.

(f) Allergic reactions, such as asthma, urticaria, and photosensitivity, may be seen. Cross-sensitivity has been seen in patients allergic to aspirin.

(g) Cardiovascular (CV) effects (e.g., myocardial infarction, stroke, hypertension, and heart failure) have been reported. Studies of celecoxib have shown a dose-related increase in CV events in patients with a history of colorectal neoplasia who were at risk of recurrent adenomatous polyps. The U.S. Food and Drug Administration (FDA) recommends using celecoxib at the lowest possible dose for the least time possible.

c. Other oral analgesics

(1) Tramadol (Ultram). Considered a good choice when the patient's pain is unrelieved by NSAIDs, when the patient cannot take NSAIDs, or when the patient experiences breakthrough pain while taking NSAIDs.

  (a) Mechanism of action. Centrally acting analgesic that inhibits the reuptake of norepinephrine and serotonin and mildly binds to the μ-receptor.

  (b) Dose. 50 to 100 mg every 4 to 6 hrs, not to exceed 400 mg/day; and 300 mg/day in the elderly. In patients with impaired renal function (creatinine clearance [CrCl] < 30 mL/min), the dosage interval should be every 12 hrs, with a maximum dose of 200 mg. The extended-release formulation is dosed 100 mg daily with a maximum dose of 300 mg/day.

  (c) Adverse effects. Although it is not an opioid analgesic, its side effects are similar: nausea, constipation, rash, dizziness, somnolence, and orthostatic hypotension.

  (d) Drug interactions. Concomitant use with selective serotonin reuptake inhibitors (SSRIs; e.g., citalopram, sertraline, fluoxetine) may cause serotonin syndrome. Tramadol is metabolized by CYP3A4.

(2) Opiate analgesics (e.g., codeine, oxycodone) are usually reserved for patients who fail single- or multiple-analgesic therapy. They may also be useful for acute exacerbations of pain. Side effects can include constipation, sedation, nausea, confusion, and respiratory depression.

(3) Topical analgesics are effective in relieving OA pain in some patients. Topical therapy can be used as monotherapy or in conjunction with oral therapy.

  (a) Capsaicin (e.g., Zostrix) is derived from hot chili peppers and with chronic use (> 2 weeks) works by depleting stores of substance P. Patients should be counseled to wash hands thoroughly after application to avoid contact with other skin to avoid burning and stinging.

  (b) Diclofenac (e.g., Voltaren Gel) is a topical NSAID approved for OA of the knee (4 gm QID) and hands (2 gm QID). The max daily dose is 32 gm/day. The same adverse effects as oral NSAIDs are possible, but studies show that they are rare.

(4) Intra-articular injections

  (a) Corticosteroids may be useful in knee OA when inflammation is present, but are not routinely recommended in hip OA owing to administration difficulties. Duration of action is up to 4 weeks. Because of adverse effects on the bone, injections should be limited to three or four per year. Long-term benefits and safety have not been established definitively.

(b) **Hyaluronic acid derivatives** are intended to improve elasticity and viscosity of synovial fluid. They are indicated for the treatment of knee OA when treatment failure to other therapies occurs. **Sodium hyaluronate (Hyalgan**; 20 mg weekly for 5 weeks) and **hylan polymers (Synvisc**; 16 mg weekly for 3 weeks) are two agents currently available. Most benefits are seen after the last dose; effects are superior to placebo. These agents should be used with caution in patients with allergies to avian proteins, feathers, and egg products.

(5) **Adjunctive treatments.** These agents are widely used by patients; however, efficacy has not been consistently demonstrated in controlled trials.

   (a) **Glucosamine** acts as a substrate for and promotes the synthesis of the glycosaminoglycans.

      (i) The dose is 500 mg three times a day.

      (ii) **Side effects** may include GI discomfort, fatigue, and skin rash.

   (b) **Chondroitin** helps protect against the breakdown of collagen and proteoglycans. It is usually found in combination with glucosamine, but the added benefits are not clear.

      (i) The dose is 1200 mg/day.

      (ii) **Side effects** can include prolonged bleeding time and nausea.

(6) **Surgical interventions** (e.g., arthroscopy, joint replacement) are considered when pain is severe and not responding to medical treatment or when disability interferes with daily activities.

IV. RHEUMATOID ARTHRITIS

A. **Etiology and pathogenesis.** The cause of RA is not fully understood but appears to be multifactorial. It is considered an autoimmune disease in which the body loses its ability to distinguish between synovial and foreign tissue. Other factors involved in RA are as follows:

1. **Environmental influences**, such as infections or trauma, are thought to trigger the development of RA.

2. **Genetic markers**, such as human leukocyte antigen DR4 (HLA-DR4), have been associated with triggering the inflammatory process in RA. Such markers, however, are not considered diagnostic because ~30% of people with HLA-DR4 never develop RA.

3. Antigen-dependent activation of **T lymphocytes** leads to proliferation of the synovial lining, activation of proinflammatory cells from the bone marrow, cytokine and protease secretion, and autoantibody production.

4. **Anticitrullinated proteins** and peptides are high specific for RA.

5. **Tumor necrosis factor** α (TNF-α), **IL-1**, **IL-6**, **IL-8**, and **growth factors** propagate the inflammatory process, and agents found to alter these cytokines show promise in reducing pain and deformity.

6. **Inflamed synovium** is a hallmark of the pathophysiology of RA. Synovium proliferates abnormally, growing into the joint space and into the bone, forming a pannus. The pannus migrates to the articular cartilage and into the subchondral bone leading to destruction of cartilage, bone, tendons, and blood vessels.

B. **Clinical manifestations**

1. The onset of RA is insidious. In early disease, symptoms include malaise and anorexia, accompanied by symmetrically tender and swollen joints. Pain in the joints is common and aggravated by movement.

2. Most commonly, the joints first affected by RA include the MCP and PIP joints of the hands, the metatarsophalangeal (MTP) joints, and the wrists. Other areas affected by RA include the spine, shoulder, ankle, and hip.

C. **Clinical course.** The severity of the disease is variable.

1. Within 4 months of diagnosis, irreversible joint damage is detectable on radiographic images. The rate at which joint damage occurs is greatest during the first year.

2. Extra-articular manifestations can include rheumatoid nodules, anemia, peripheral neuropathy, kidney disease, CV effects, and pulmonary disease.

3. Causes of mortality in RA are cardiovascular disease, infection, respiratory disease, and malignancy.

D. **Laboratory assessment**

1. **Rheumatoid factor (RF)** is found in > 60% of patients with RA; however, as many as 5% of healthy individuals will have elevated titers of RF. If initially negative, the test can be repeated in 6 to 12 months. RF is not an accurate measure of disease progression.

2. **Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)** are markers of inflammation and are usually elevated in patients with RA. They can also help indicate the activity of the disease, but they do not indicate disease severity.

3. **Anticyclic citrullinated peptide antibodies** (ACPA) are found in most patients with RA and are useful in predicting erosive disease.

E. **Diagnosis and clinical evaluation.** In 2010, the ACR and EULAR (European League Against Rheumatism) established a score-based algorithm criteria aimed at diagnoses before joint damage occurs. Providing the patient has at least one joint with active synovitis (swelling) than cannot be explained by another diagnosis. Definitive RA is defined as a score $\geq$ 6/10 based on four domains:

1. **Joint involvement** (e.g., number and location of involved joints)
2. **Serology** (e.g., RF, ACPA)
3. **Acute phase reactants** (e.g., CRP, ESR)
4. **Duration of symptoms**

F. **Radiographic examination** can reveal the extent of bone erosion and cartilage loss. An MRI can detect proliferative pannus.

G. **Treatment objectives.** The goals in the management of RA are

1. To prevent or control joint damage
2. To prevent loss of function
3. To decrease pain
4. To maintain the patient's quality of life
5. To avoid or minimize adverse effects of treatment

H. **Prognosis.** Poor prognostic factors include active disease with multiple tender and swollen joints, evidence of erosions seen on radiographs, elevated RF and/or ACPA, and elevated ESR and/or CRP. Additionally, worse outcomes, including disability and morbidity, are associated with female gender, advancing age, cigarette smoking, and genotype.

I. **Therapy.** The ACR published updated treatment recommendations in 2008 on nonbiological and biological disease modifying drugs. Nonpharmacological therapy (e.g., exercise, joint protection, physical therapy) and NSAIDs (*Table 42-1*) were not included in the report as these do nothing to alter the course of the disease or prevent joint destruction. Consideration, however, may be made to include these as adjuvant therapy for mild to moderate pain relief.

1. **Corticosteroids.** Low-dose systemic corticosteroids (e.g., prednisone, methylprednisolone) have excellent anti-inflammatory activity and are immunosuppressant. The lowest effective dose should be used because of adverse effects (e.g., hyperglycemia, GI toxicity, osteoporosis). These agents have shown to slow joint damage; however, they are often used as "bridge" therapy as patients start on disease-modifying antirheumatic drugs (DMARDs) or during an acute RA flare.

2. **Nonbiological disease-modifying antirheumatic drugs (NBDMARDs)** (*Table 42-2*) are used to reduce or prevent joint damage and preserve joint function and should be considered within 3 months of diagnosis. NOTE—the 2008 recommendations only assessed the use of methotrexate (MTX), leflunomide, sulfasalazine, hydroxychloroquine, and minocycline. Other NBDMARDs were not mentioned because of lack of clinical efficacy, side effects, or both.

   a. **Methotrexate (MTX; Rheumatrex)** works by inhibiting dihydrofolate reductase and is considered standard therapy for RA. MTX is recommended for all patients with RA (as monotherapy or with other DMARDs) regardless of disease duration, disease burden, or prognostic factors. Concomitant use with folic acid may reduce side effects.

   b. **Leflunomide (Arava)** inhibits pyrimidine synthesis and is recommended for all patients with RA (as monotherapy or with other DMARDs) regardless of disease duration, disease burden, or prognostic factors. Because of its long elimination half-life, cholestyramine is recommended as a binding agent if serious toxicities occur or if the patient wishes to become pregnant.

   c. **Sulfasalazine** is cleaved by bacteria in the colon into sulfapyridine and 5-aminosalicylic acid. It is recommended for all disease durations and degrees of illness without poor prognosis.

   d. **Hydroxychloroquine's** mechanism of action for RA is unknown. It is recommended for those without poor prognosis and low disease activity of $\leq$ 2 years.

3. **Biological DMARDs (BDMARDs)** (*Table 42-2*) can reduce or prevent joint damage, preserve joint integrity and function in patient with moderate to severe RA. They are used primarily in those failing an adequate trial of one or more NBDMARDs or in patients with high disease

Table 42-2 DISEASE-MODIFYING ANTIRHEUMATIC DRUGS (DMARDs)

Agent (Brand)	Time to Effect (months)	Starting Dose	Adverse Effects	Monitoring Parameters	Some Drug Interactions
Traditional DMARDs					
Methotrexate (Rheumatrex)	0.5–6.0	7.5–15.0 mg PO weekly	Nausea, diarrhea, mouth ulcers, hepatotoxicity, pulmonary toxicity, myelosuppression	LFTs, SrCr, CBC, chest x-ray Hepatitis B and C serology	Penicillin, cyclosporine, NSAIDs
Sulfasalazine (Azulfidine)	1–3	500 mg PO b.i.d.; gradually increase to 2–3 g/day in 2–4 divided doses	Nausea, diarrhea, rash, photosensitivity	CBC, LFTs, SrCr	Iron, digoxin, warfarin
Hydroxychloroquine (Plaquenil)	2–6	200–300 mg PO b.i.d.	Ocular toxicity, rash, nausea, myopathy	Eye exam, SrCr, CBC, LFTs	Cimetidine
Minocycline (Dynacin)	n/d	100 mg PO b.i.d.	GI, rash	CBC, LFTs	Calcium, magnesium, aluminum, iron
Biologicals					
Leflunomide (Arava)	1–4	100 mg/day PO × 3 days (load), then 10–20 mg/day	Diarrhea, nausea, infection, rash, HTN, alopecia, liver toxicity	LFTs, CBC, SrCr, PPD, hepatitis B and C serology	MTX, rifampin, warfarin
Etanercept (Enbrel)	0.25–3.00	50 mg SC weekly	Abdominal pain, HA, injection site reactions, infections	PPD, CBC, LFTs, SrCr	Cyclophosphamide
Infliximab (Remicade)	0.5	3 mg/kg IV over 2 hrs at weeks 0, 2, and 6; then every 8 weeks	Nausea, HA, abdominal pain, dizziness, hepatic, hematologic, infections	PPD, CBC, LFTs, SrCr	None known
Adalimumab (Humira)	0.25–1.00	40 mg SC every 2 wks	Injection site reactions, infection, rash, HA	PPD, CBC, LFTs, SrCr	None known

Table 42-2 Continued

Agent (Brand)	Time to Effect (months)	Starting Dose	Adverse Effects	Monitoring Parameters	Some Drug Interactions
Anakinra (Kineret)	0.25–1.00	100 mg/day SQ	HA, injection site reactions, infection	CBC with neutrophil counts, LFTs, SrCr	Entanercept, thalidomide
Abatacept (Orencia)	n/d	10 mg/kg IV at day 0; then 2 weeks, 4 weeks, and continuing every 4 weeks	Injection site reactions, infections, HA, nausea, HTN, nasopharyngitis	PPD, CBC, LFTs, SrCr	Anakinra, TNF-antagonists
Rituximab (Rituxan)	n/d	1000 mg IV at days 0 and 14	Injection site reactions, HTN, infections, nausea, arthralgia	Hepatitis B serology, CBC, LFTs, SrCr	Cisplatin
Less Frequently Used DMARDs					
Gold Salts (Aurolate)	3–6	25–50 mg IM every 2–4 weeks	Itching, rash, stomatitis, proteinuria, conjunctivitis	CBC with differential, SrCr, urinalysis	Penicillamine
D-penicillamine (Cuprimine)	3–6	125–250 mg PO daily; increase gradually to 250 mg t.i.d.	Nausea, rash, photosensitivity, myelosuppression	CBC, SrCr	Gold, iron, zinc, antacids, digoxin, antimalarials
Azathioprine (Imuran)	2–3	50–150 mg/day	Chills, fever, N/V, diarrhea, leucopenia	CBC, LFTs	Allopurinol
Cyclosporine (Neoral)	2–4	3–10 mg/kg/day	HTN, HA, nausea, paresthesia, leukopenia	BP, SrCr, LTFs, serum drug levels	CYP450 3A/4 inhibitors, MTX, digoxin, allopurinol, glucocorticoids

BP, blood pressure; *CBC*, complete blood count; *HA*, headache; *HTN*, hypertension; *IM*, intramuscularly; *IV*, intravenously; *LFTs*, liver function tests; *MTX*, methotrexate; *n/d*, no data available; *N/V*, nausea and vomiting, *NSAIDs*, nonsteroidal anti-inflammatory drugs; *PO*, by mouth; *PPD*, tuberculosis skin test; *SC*, subcutaneously; *SrCr*, serum creatinine; *TNF*, tumor necrosis factor; including 2008 recommendations by the ACR.

activity and poor prognosis. *Note*: the only BDMARDs included in the 2008 guidelines are abatacept, adalimumab, etanercept, infliximab, and rituximab. The remaining BDMARDs were not included either because they were not FDA approved at the time of the publication or because of very infrequent use, high incidence of side effects, or both.

   a. **TNF-α blockers** (e.g., etanercept [Enbrel], infliximab [Remicade], adalimumab [Humira], golimumab [Simponi], and certolizumab pegol [Cimzia]) inhibit the inflammatory response mediated in immune cells. Etanercept, adalimumab, and certolizumab can be used as monotherapy or in conjunction with MTX. Infliximab and golimumab is only FDA approved for use with MTX in RA. These drugs are recommended if high disease activity is present early in the course of the illness (< 3 months) with poor prognosis. These drugs are usually considered when patients do not achieve an acceptable response to MTX or other NBDMARDs.

   b. **Abatacept (Orencia)** is the first T-cell costimulation blocker. It is used as monotherapy or NBDMARDs. Abatacept is recommended with MTX + NBDMARD does not work in the presence of moderate disease with poor prognosis.

   c. **Rituximab (Rituxan)** is an anti-CD20 monoclonal antibody. Depletion of the CD20+ B cells appears to affect the autoimmune response and helps with the chronic synovitis associated with RA. It is used when the patient fails MTX and/or multiple DMARDs and has high disease burden and poor prognosis. Severe, even fatal, infusion reactions have been reported.

   d. **Anakinra (Kineret)** is an IL-1 receptor antagonist. It is used as monotherapy or in conjunction with any DMARD except a TNF-blocker.

   e. **Tocilizumab (Actemra)** is an IL-6 receptor monoclonal antibody. It is indicated for moderate-to-severe RA in adults who have not achieved response with one or more TNF-antagonists. It can be used as monotherapy or with MTX or other NBDMARDs.

4. **Combination therapy.** Concurrent use of several NBDMARDs has been studied. The 2008 guidelines support the following combinations: MTX + HCQ, MTX + sulfasalazine, MTX + leflunomide, and sulfasalazine + HCQ + MTX. Some patients currently receiving DMARD therapy with new or worsening symptoms have benefited from combination therapy. Combination therapy with multiple biological DMARDs were not recommended in the 2008 guidelines because of increased side effects and/or lack of efficacy.

5. **Treatment recommendations** are published by the ACR and are available at http://www.rheumatology.org.

6. **Surgical treatment** (e.g., carpal tunnel release, total joint arthroplasty, joint fusion) may be considered when pain is severe, range of motion is lost, or joint function is poor.

Study Questions

1. Which of the following statements best characterizes osteoarthritis (OA)?

   (A) OA is a common disorder characterized by diffuse inflammation leading to increased disability.

   (B) OA is a systemic disorder characterized by degenerative changes in the joint(s) and typically exhibits extra-articular involvement.

   (C) OA is a common disorder that affects the normal synthesis and degradation of cartilage.

   (D) OA is a common disorder that adversely affects bone density and leads to falls and fractures.

   (E) OA is a systemic disorder frequently associated with localized inflammation and pannus formation.

2. Which of the following agents is recommended as first-line drug therapy by the American College of Rheumatology for patients with mild to moderate osteoarthritis?

   (A) Ibuprofen (Motrin)

   (B) Celecoxib (Celebrex)

   (C) Diclofenac gel (Voltaren Gel)

   (D) Tramadol (Ultram)

   (E) Acetaminophen (Tylenol)

3. When consideration is given to diagnosing osteoarthritis, which of the following statements is FALSE?

   (A) Joint tenderness, diminished range of motion, and/or articular crepitus can be assessed
   (B) Radiographical evidence will show joint space narrowing
   (C) Common patient complaints include a deep, localized ache in a joint
   (D) Laboratory evidence reveals a high sedimentation rate, positive rheumatoid factor, and anti-cyclic citrullinated peptide antibody
   (E) Morning stiffness lasts < 30 mins

4. Which of the following disease modifying anti-rheumatic drugs are recommended by the American College of Rheumatology for all patients with rheumatoid arthritis regardless of disease duration and degrees of disease activity?

   (A) Methotrexate and sulfasalazine
   (B) Methotrexate and hydroxychloroquine
   (C) Methotrexate and etanercept
   (D) Methotrexate and leflunomide
   (E) Methotrexate and minocycline

5. In order to reduce toxicity with methotrexate, concomitant administration with what vitamin is recommended?

   (A) Folic acid
   (B) Thiamine
   (C) Ascorbic acid
   (D) Pyridoxine
   (E) Riboflavin

6. All of the following statements are true about the use of hyaluronic acid derivatives in osteoarthritis (OA) *except*:

   (A) Should be considered in those not responding to simple analgesics
   (B) Should be considered for the treatment of knee OA
   (C) Should be considered as disease-modifying agents
   (D) Should be considered if no allergies exist to feathers or egg products
   (E) Should be considered to improve elasticity of synovial fluid

7. Which of the following agents used for osteoarthritis or rheumatoid arthritis require dosage adjustment in patients with renal impairment?

   (A) Prednisone
   (B) Acetaminophen
   (C) Oxycodone
   (D) Glucosamine
   (E) Tramadol

8. Which of the following disease modifying antirheumatic drugs can be administered orally?

   (A) Certolizumab (Cimzia)
   (B) Anakinra (Kineret)
   (C) Abatacept (Orencia)
   (D) Leflunomide (Arava)
   (E) Etanercept (Enbrel)

9. What is the recommended starting dose of methotrexate when used for rheumatoid arthritis?

   (A) 2.5 mg PO daily
   (B) 2.5 mg PO weekly
   (C) 7.5 mg PO daily
   (D) 7.5 mg PO weekly
   (E) 25 mg PO weekly

10. Ocular toxicity is associated with

   (A) leflunomide (Arava)
   (B) methotrexate (Rheumatrex)
   (C) hydroxychloroquine (Plaquenil)
   (D) infliximab (Remicade)
   (E) adalimumab (Humira)

11. A baseline PPD is recommended to rule-out latent tuberculosis before initiating:

   (A) leflunomide, etanercept, infliximab
   (B) methotrexate, sulfasalazine, hydroxychloroquine
   (C) leflunomide, methotrexate, etanercept
   (D) methotrexate, infliximab, anakinra
   (E) abatacept, leflunomide, sulfasalazine

12. Before initiating therapy with a nonsteroidal anti-inflammatory drug, it is important to evaluate:

   (A) hematocrit, sodium, triglycerides
   (B) serum creatinine, hematocrit, blood pressure
   (C) blood pressure, serum folate, potassium
   (D) liver function tests, serum creatinine, and serum folate
   (E) sodium, hematocrit, respiration

13. All of the following statements are true about disease modifying antirheumatic drugs *except*:

   (A) Should be started within 3 to 4 months of diagnosis of RA
   (B) Can reduce or prevent joint damage
   (C) Shown to work within 1 to 2 days of starting therapy
   (D) Classified as nonbiological or biological
   (E) Can preserve joint function

Answers and Explanations

1. **The answer is C** *[see III.C]*.
   Inflammation is generally not present in osteoarthritis. It is a localized (not systemic) disorder that affects the cartilage and can eventually affect the underlying bone causing severe pain and disability.

2. **The answer is E** *[see III.E.3.a]*.
   The ACR recommends acetaminophen ($\leq$ 4 gm/day) as the first drug treatment option in patients with mild to moderate OA pain.

3. **The answer is D** *[see III.D.2]*.
   No specific lab tests are diagnostic for OA.

4. **The answer is D** *[see IV.I.2.a & b]*.
   Based on the ACR's 2008 RA Treatment Guidelines, both MTX and leflunomide are recommended for all patients with RA regardless of disease duration, disease burden, or prognostic factors.

5. **The answer is A** *[see IV.I.2.a]*.
   MTX inhibits dihydrofolate reductase. Research has shown supplemental doses of folic acid (e.g., 1 mg/day) can reduce side effects.

6. **The answer is C** *[see III.E.3.c.(4)(b)]*.
   To date, no drug treatment (including hyaluronic acid derivatives) has demonstrated

7. **The answer is E** *[see III.E.3]*.
   Tramadol's maximum daily dose is 200 mg and should be given every 12 hrs if creatinine clearance is $\leq$ 30 mL/min.

8. **The answer is D** *[see Table 42-2]*.
   Leflunomide is available for oral administration. The other agents must be given SC or IV.

9. **The answer is D** *[see Table 42-2]*.
   The initial starting dose of MTX when treating RA is 7.5 mg PO weekly.

10. **The answer is C** *[see Table 42-2]*.
    An ophthalmic exam is recommended when patients are receiving hydroxychloroquine.

11. **The answer is A** *[see Table 42-2]*.
    Some biological DMARDs have been linked with re-activating latent TB; therefore, before starting therapy with leflunomide, etanercept, or infliximab, patients should have a PPD placed.

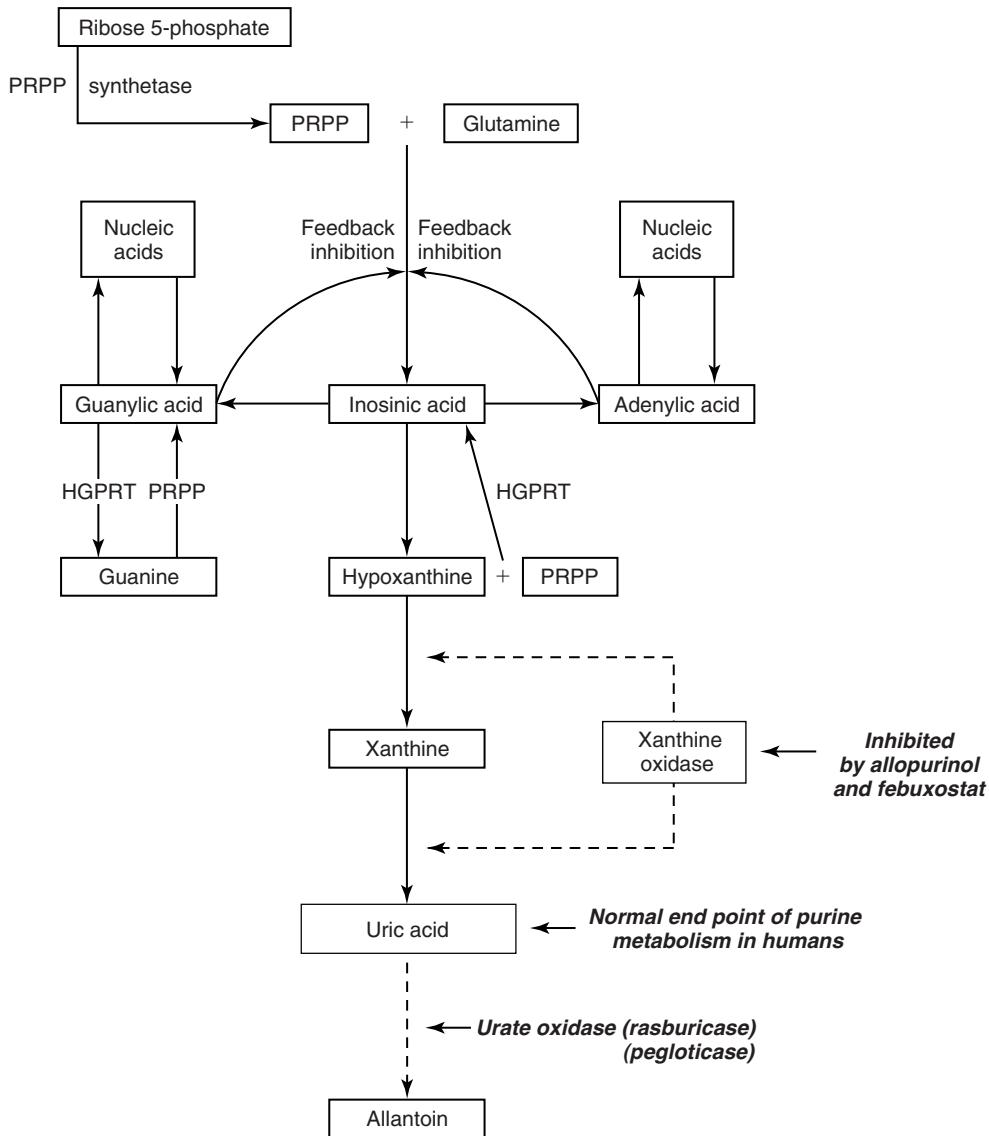
12. **The answer is B** *[see III.E.3.b.(4)]*.
    Common side effects of NSAIDs include GI toxicity (e.g., bleeding), acute renal failure, and fluid retention (leading to hypertension).

13. **The answer is C** *[see IV.I.3; Table 42-2]*.
    The main disadvantage to DMARD therapy is the time it takes for the medication to work. In general, nonbiological agents can take 3 to 4 months for affect; whereas biological agents can take 1 to 2 months (or more).

Hyperuricemia and Gout

LARRY N. SWANSON

I. INTRODUCTION

A. Definitions


1. **Hyperuricemia** refers to a serum uric acid level that is elevated more than two standard deviations above the population mean. In most laboratories, the upper limit of normal is 7 mg/dL (uricase method). However, the level varies with the laboratory method used; the upper limit of normal is about 1 mg/dL lower for women than for men.

2. **Gout** is a disease that is characterized by recurrent **painful acute attacks** of urate crystal-induced arthritis. It may include **tophi**—deposits of monosodium urate—in and around the joints and cartilage and in the kidneys, as well as uric acid nephrolithiasis.

B. General information

1. The prevalence of gout is believed to be between 3 and 5 million individuals in the United States.

2. Most gout victims are men (7 to 9 times more often than women); most women with the disease are postmenopausal.

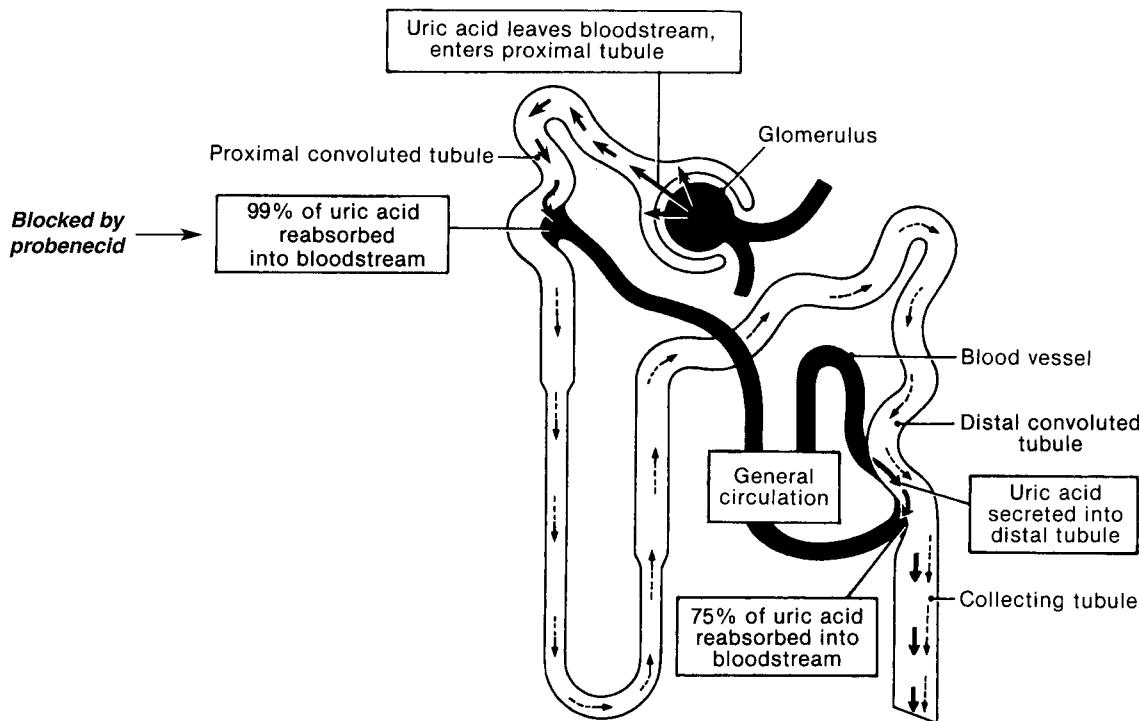
3. The mean age at disease onset is 47 years.

4. The risk of developing gout increases as the serum uric acid level rises. Virtually all gout patients have a serum uric acid level > 7 mg/dL.

5. Research shows that among patients with a serum uric acid level above 9 mg/dL, the cumulative incidence of gout reached 22% after 5 years.

6. Gout has a familial tendency; 10% to 60% of cases occur in family members of patients with the disease.

7. Obesity, hypertension, hyperlipidemia, atherosclerosis, diabetes, and alcohol abuse are often associated with hyperuricemia and gout. Certain nutritional approaches (i.e., achieving ideal body weight or limitation of alcohol intake) can treat both the hyperuricemia and the associated conditions.

C. Uric acid production and excretion


1. Uric acid, an end product of **purine metabolism**, is produced from both dietary and endogenous sources. Its formation results from the conversion of adenine and guanine moieties of nucleoproteins and nucleotides (*Figure 43-1*).

2. **Xanthine oxidase** catalyzes the reaction that occurs as the final step in the degradation of purines to uric acid.

3. The body ultimately excretes uric acid via the kidneys (300–600 mg/day; two-thirds of total uric acid) and via the gastrointestinal (GI) tract (100–300 mg/day; one-third of the total uric acid).

4. Uric acid has no known biological function.

5. The body has a total uric acid content of 1.0 to 1.2 g; the daily turnover rate is 600 to 800 mg.

6. At a pH of 4.0 to 5.0 (i.e., in urine), uric acid exists as a poorly soluble free acid; at physiological pH, it exists primarily as **monosodium urate salt**.

7. Uric acid filtration, reabsorption, and secretion sites are shown in *Figure 43-2*.

Figure 43-1. Uric acid formation. *HGPRT*, hypoxanthine–guanine phosphoribosyltransferase; *PRPP*, phosphoribosyl-1-pyrophosphate. (Adapted with permission from DiPiro J, Talbert R, Yee G, et al. *Pharmacotherapy—A Pathophysiologic Approach*. 8th ed. New York, NY: McGraw-Hill; 2011:1622.)

D. **Cause.** Hyperuricemia and gout may be primary or secondary.
   1. **Primary hyperuricemia** and **gout** apparently result from an innate **defect in purine metabolism** or **uric acid excretion**. The exact cause of the defect usually is unknown.
      a. Hyperuricemia may result from **uric acid overproduction**, **impaired renal clearance of uric acid**, or a **combination** of these.
      b. Some patients with primary hyperuricemia and gout have a known enzymatic defect, such as hypoxanthine–guanine phosphoribosyltransferase (HGPRT) deficiency or phosphoribosyl-1-pyrophosphate (PRPP) synthetase excess (*Figure 43-1*).
      c. Principally for therapeutic purposes, patients with primary hyperuricemia and gout can be classified as **overproducers** or **underexcretors** of uric acid.
         (1) **Overproducers** (about 10% of patients) synthesize abnormally large amounts of uric acid and excrete excessive amounts: > 800 to 1000 mg daily on an unrestricted diet or > 600 mg daily on a purine-restricted diet. These individuals generally have a markedly increased miscible urate pool (> 2.5 g).

Figure 43-2. Uric acid filtration, reabsorption, and secretion sites. At the glomerulus, uric acid is filtered and enters the proximal tubule. There, approximately 99% of uric acid is reabsorbed into the bloodstream. At the distal tubule, uric acid is secreted; subsequently, about 75% of the amount secreted is reabsorbed. Therefore, almost all urinary uric acid is excreted at the distal tubule.

    (2) Underexcretors (about 90% of patients) generally produce normal or nearly normal amounts of uric acid but excrete < 600 mg daily on a purine-restricted diet. They generally have only a slightly increased miscible urate pool. Some underexcretors are also overproducers.

  2. Secondary hyperuricemia and **gout** develop during the course of another disease or as a result of drug therapy.

    a. Hematological causes of hyperuricemia and gout (associated with increased nucleic acid turnover and breakdown to uric acid)

      (1) Lymphoproliferative disorders

      (2) Myeloproliferative disorders

      (3) Certain hemolytic anemias and hemoglobinopathies

    b. Chronic renal failure. In this condition, reduced renal clearance of uric acid can lead to hyperuricemia.

    c. Drug-induced disease

      (1) Aspirin and **other salicylates** inhibit tubular secretion of uric acid when given in low doses (e.g., < 2 g/day of aspirin). At high doses, these agents frequently cause uricosuria.

      (2) Cytotoxic drugs increase uric acid concentrations by enhancing nucleic acid turnover and excretion.

      (3) Diuretics (except spironolactone) may cause hyperuricemia; most likely, this occurs either via volume depletion, which, in turn, increases proximal tubular reabsorption, or via impaired tubular secretion of uric acid.

      (4) Ethambutol and **nicotinic acid** increase uric acid concentrations by competing with urate for tubular secretion sites, thereby decreasing uric acid excretion.

      (5) Cyclosporine decreases renal urate clearance, as do **pyrazinamide** and **levodopa**.

      (6) Ethanol alters uric acid metabolism both by **increasing uric acid production** through an increase in adenine nucleotide catabolism and by **suppressing renal uric acid excretion** as a result of lactate inhibition of renal tubular uric acid secretion.

      d. Miscellaneous disorders. Diabetic ketoacidosis, psoriasis, and chronic lead poisoning are examples of conditions that may cause hyperuricemia.

E. Pathophysiology

1. Gouty arthritis develops when **monosodium urate crystals** are deposited in the synovium of involved joints.

2. An **inflammatory response** to monosodium urate crystals leads to an attack of acute gouty arthritis; painful joint swelling is characterized by **redness**, **warmth**, **and tenderness**. A systemic reaction may accompany joint symptoms.

3. If gout progresses untreated, **tophi**, or **tophaceous deposits** (deposits of monosodium urate crystals) may be noted (**nodules on ears, fingers, elbow, etc.**, **which usually are not painful**) and can eventually lead to joint deformity and disability; kidney involvement may lead to renal impairment. However, these developments are uncommon in the general gout population and represent late complications of hyperuricemia.

4. **Renal complications** of hyperuricemia and gout may have serious consequences.

    a. Acute tubular obstruction

      (1) This complication may develop secondary to uric acid precipitation in the collecting tubules and ureters, with subsequent blockage and renal failure. It is most common in patients with gout secondary to myeloproliferative or lymphoproliferative disorders, particularly after chemotherapy when allopurinol is omitted.

      (2) Another agent, **urate oxidase** (rasburicase), may be used in the prophylaxis and treatment of hyperuricemia in pediatric patients with leukemia, lymphoma, and solid-tumor malignancies who are receiving anticancer therapy. This agent works by converting uric acid into allantoin, which is five times more soluble in urine than uric acid.

    b. Urolithiasis. This condition is characterized by formation of uric acid stones in the urinary tract. Low urine pH seems to be a contributing factor. The risk of urolithiasis rises as serum and urinary uric acid levels increase. This condition is seen more often in patients who produce significant amount of urinary uric acid ($>$ 1100 mg/day).

    c. Chronic urate nephropathy. In this complication, urate deposits arise in the renal interstitium. It is generally agreed, however, that chronic hyperuricemia rarely, if ever, leads to clinically significant nephropathy. The presence of additional disease (e.g., diabetes mellitus, hypertension) may explain the finding of nephropathy in gout patients.

F. Clinical presentation. Clinical evaluation and the need for intervention depend on the clinical presentation.

1. **Asymptomatic hyperuricemia**
2. **Acute gouty arthritis**
3. **Intercritical gout**
4. **Chronic tophaceous gout**

II. ASYMPTOMATIC HYPERURICEMIA is characterized by an elevated serum uric acid level but has no signs or symptoms of urate deposition disease (arthritis, tophi, or urolithiasis).

A. Clinical presentation. Hyperuricemia in and of itself is not believed to be a disease. There also has to be evidence of deposition of urate in the joints, soft tissues, or kidney to routinely warrant drug therapy intervention. Certainly, the risk of symptom development and complications increases as the serum uric acid level rises. However, as many as two-thirds of patients with elevated serum uric acid levels will continue to remain symptom-free. It is difficult to predict which patients who have asymptomatic hyperuricemia will eventually develop hyperuricemia-related issues. Although hyperuricemia often occurs concurrently in patients with cardiovascular disease, diabetes, and hypertension, it has not been proven to be a causal factor for any of these conditions. Serum urate levels of up to 13 mg/dL in men and 10 mg/L in women have not been shown to cause deterioration in renal function.

B. Therapy. Therefore, urate lowering **drug treatment for most patients is not required, General interventions** such as encouraging maintenance of good urine output (to prevent uric acid stone formation), avoidance of high purine meats and fish, and regular medical exams to get serum urate levels and to check for clinical evidence of gout related signs.

III. ACUTE GOUTY ARTHRITIS. This clinical presentation of gout is characterized by **painful arthritic attacks** of sudden onset.

A. **Pathogenesis.** Monosodium urate crystals form in articular tissues; this process sets off an inflammatory reaction. **Trauma**, **exposure to cold**, **dietary overindulgence**, **or another triggering event** may be involved in the development of the acute attack.

B. **Signs and symptoms**

1. The **initial attack** is abrupt, usually **occurring at night** or in the early morning as synovial fluid is reabsorbed. This severe arthritic pain progressively worsens and generally involves only one or a few joints.

   a. The **affected joints** typically become hot, swollen, and extremely tender. Seventeenth-century British physician Thomas Sydenham described his personal experience with gout this way: "Now it is a violent stretching and tearing of the ligaments—now, it is a gnawing pain and now a pressure and tightening. So exquisite and lively . . . is the feeling of the part affected, that it cannot bear the weight of bedclothes nor the jar of a person walking in the room."

   b. The **most common site** of the initial attack is the **first metatarsophalangeal joint**; an attack there is known as **podagra**. Other sites that may be affected include the instep, ankle, heel, knee, wrist, elbow, and fingers.

2. The first few untreated attacks typically last 3 to 14 days. The **joint pain and inflammation completely resolves**, even when not treated and is a hallmark of the condition. Later attacks may affect more joints and take several weeks to resolve.

3. During recovery, as edema subsides, local desquamation and pruritus may occur.

4. **Systemic symptoms** during an acute attack may include fever, chills, and malaise.

C. **Diagnostic criteria**

1. **Definitive diagnosis** of gouty arthritis can be made by demonstration of **monosodium urate crystals** in the synovial fluid of affected joints. These needle-shaped crystals are termed **negatively birefringent** when viewed through a polarized light microscope.

2. **Serum analysis** usually reveals an above-normal uric acid level: however, this finding is not specific for acute gout. Other common serum findings include **leukocytosis** and a moderately **elevated erythrocyte sedimentation rate**.

3. A **dramatic therapeutic response to colchicine** may be helpful in establishing the diagnosis, but this is not absolute because other causes of acute arthritis may respond as well.

4. When fluid cannot be aspirated from the affected joint, a **diagnosis of gout is supported by**:

   a. A prior **history of acute monoarticular arthritis** (especially of the **big toe**) followed by a **symptom-free period**

   b. The presence of **hyperuricemia**

   c. Rapid **resolution of symptoms after colchicine** therapy

5. **Other conditions** that may **mimic** gout include pseudogout (calcium pyrophosphate dihydrate crystal disease) or septic arthritis.

D. **Treatment goals**

1. To relieve pain and inflammation

2. To terminate the acute attack

3. To restore normal function to the affected joints

E. **Therapy**

1. **General therapeutic principles**

   a. The affected joint (or joints) should be immobilized.

   b. **Anti-inflammatory drug therapy** should begin **immediately**. For maximal therapeutic effectiveness, these drugs should be kept on hand so that the patient may begin therapy as soon as a subsequent attack begins.

   c. **Urate-lowering drugs should <u>not</u> be given until the acute attack is controlled**, as these drugs **may prolong the attack** by causing a change in uric acid equilibrium. Urate-lowering agents can begin within 1 to 2 weeks after the resolution of the attack.

2. **Specific drugs.** Any of the following agents may be used:

   a. **Nonsteroidal anti-inflammatory drugs (NSAIDs)**

      (1) **Indications.** Most physicians consider these drugs the agents of choice, especially the newer NSAIDs. These drugs may be preferred when treatment is delayed significantly after

symptom onset or when the patient cannot tolerate the adverse GI effects of colchicine. Begin with high doses for 2 to 3 days, then taper the dose rapidly over the next several days.

   (a) **Indomethacin** (Indocin) is usually given in a dose of **50 mg three times daily** initially then the dose is tapered. Significant pain relief is achieved within a few hours. Tenderness and warmth usually decreases over the next day and a half with swelling disappearing within a few days.

   (b) **Specific NSAIDs**—such as **naproxen** (Naprosyn) 750 mg followed by 250 mg every 8 hrs until the attack subsides or **sulindac** (Clinoril) 200 mg twice a day to start, reducing the dose with satisfactory response (7 days of therapy are usually adequate)—are specifically approved for this indication, but many other NSAIDs have been used successfully. There is no evidence that any particular NSAID is more effective than others in the treatment of an acute gouty attack. Some have also used selective cyclooxygenase 2 (COX-2) inhibitors for these attacks.

(2) **Precautions and monitoring effects**

   (a) **Adverse effects of indomethacin** are usually dose related. These effects occur in 10% to 60% of patients and may require that the drug be stopped. They primarily include GI complaints of nausea and abdominal discomfort and central nervous system (CNS) effects of headaches and dizziness. Because of these CNS effects, it should be avoided in the elderly. Indomethacin should be taken with food or milk to minimize gastric mucosal irritation.

   (b) **Precautions.** NSAIDs, in general, require cautious use in patients with a history of hypertension, congestive heart failure (CHF), peptic ulcer disease, or mild to moderate renal failure.

b. **Colchicine.** The traditional drug for relieving pain and inflammation and ending the acute attack, colchicine is most effective when started within 24 hrs after symptoms begin (the period of maximal leukocyte migration). Some would use this agent only if the patient is intolerant to NSAIDs or for those patients who have used colchicine successfully in the past. Colchicine has been available on the market for many years as non-FDA approved medication. The "standard" dosage regimen had not been carefully studied for effectiveness and safety. In August 2009, Colcrys (brand of colchicine) was approved for the treatment of gout in a new, lower dosage regimen.

(1) **Mechanism of action.** Colchicine apparently **impairs leukocyte migration** to inflamed areas and disrupts urate deposition and the subsequent inflammatory response. **It has no effect on serum urate levels**.

(2) **Dosage and administration**

   (a) **Oral regimen**

   (i) The **new dosing regimen** approved for Colcrys is as follows: **1.2 mg at the first sign of an acute attack; then give 0.6 mg 1 hr later (maximum of 1.8 mg within 1 hr)**. In the AGREE trial, this dose (1.8 mg total) had similar efficacy to high dose (4.8 mg total), but with less gastrointestinal adverse events (23% vs. 77%).

   (ii) Previous older dosing regimens were as follows: 0.6 mg to 1.2 mg initially, followed by 0.6 mg every 1 to 2 hrs until pain relief occurred or abdominal discomfort or diarrhea developed or a total dose of 6 mg had been administered. The effective dose of colchicine in patients with acute gout was considered to be very close to which caused adverse GI symptoms.

   (b) **Intravenous (IV) regimen.** In February 2008, the FDA asked that IV preparations of this agent should no longer be manufactured or shipped in the United States because of significant toxicity and fatalities.

(3) **Precautions and monitoring effects**

   (a) **GI distress** (e.g., nausea, vomiting, abdominal cramps, diarrhea) has occurred in 50% to 80% of patients receiving oral colchicine in a dose-dependent manner. With the new dosage regimen, these side effects should be lower. Oral colchicine should be avoided in patients with peptic ulcer disease and other GI disorders.

   (b) In the process that led to the approval of the marketing of Colcrys, fatal colchicine toxicity was noted in patients on standard therapeutic doses of colchicine taken with

certain other drugs such as **clarithromycin**. **Important drug interactions** can occur in patients taking colchicine with **P-glycoprotein** (P-gp) (amiodarone, cyclosporine, tacrolimus, quinidine, erythromycin) and **cytochrome P450** (**CYP3A4**) inhibitors (azole antifungals, macrolide antibiotics, protease inhibitors).

    (c) **Chronic colchicine therapy** (see IV.C.2) may result in **neuromyopathy** (patient notes numbness, paresthesias, and/or weakness), which is more likely in patients with decreased kidney function. It is best to limit colchicine therapy to 6 months duration (after goal serum uric acid is achieved.)

  c. Corticosteroids

    (1) Corticosteroid intra-articular injections are particularly effective in patients with acute single-joint gout. The actual act of **aspiration of the joint fluid alone can sometimes greatly reduce the extent of the pain of gout**. Specific doses of these agents corticosteroids is related to joint size. An intra-articular dose of **triamcinolone** 8 mg in smaller joints (10 mg in the knee), **methylprednisolone acetate** (5 to 25 mg per joint), or **betamethasone** 3 to 6 mg can be used.

    (2) Systemic corticosteroid therapy is another option, especially when either NSAIDs or colchicine cannot be given or have not been effective. As an example, **oral prednisone** (20 to 60 mg/day initially, with the dose tapered during a period of 5 to 7 days) can be useful without producing a rebound effect. **IM betamethasone** (7 mg) or **IV methyl-prednisolone** 125 mg are examples of other potential agents. **IM ACTH** 40 units (reduces inflammation by stimulating corticosteroid production by the patient's adrenal gland plus it activates melanocortin type 3 receptors) may also be used. This agent may not be preferred because of the short duration of action.

IV. INTERCRITICAL GOUT is the symptom-free period after the first attack. This phase may be interrupted by the recurrence of acute attacks.

  A. Onset of subsequent attacks varies. In most untreated patients, the second attack occurs within 2 years of the first, but in some it may be delayed for 5 to 10 years. A small percentage of patients never experience a second attack. If hyperuricemia is insufficiently treated, subsequent attacks may become progressively longer and more severe and may involve more than one joint.

  B. Treatment goals

    1. To reduce the frequency and severity of recurrent attacks

    2. To minimize urate deposition in body tissues, thereby preventing progression to chronic tophaceous gout.

  C. Therapy

    1. Nondrug urate-reducing measures. The following reversible factors can raise the serum uric acid level and should be addressed: avoid selected **high-purine content foods** (e.g., **primarily meats [including organ-rich foods like liver, sweetbreads, etc.] and seafood**), treat obesity, avoid alcohol consumption, or alter drug therapy that may increase the serum uric acid (i.e., change from a thiazide diuretic to a drug like Losartan). [See IV.C.3.b.(5)]. The purine content of the diet does not usually contribute more than 1.0 mg/dL to the serum urate concentration. Weight reduction sometimes reduces the serum uric acid level slightly; however, crash diets should be avoided. Drinking two or more beers increased the risk of gout by 2.5-fold in one study versus a 1.6-fold increase for other alcohol spirits. Wine intake was *not* associated with an increased risk of gout. High purine content vegetables don't appear to increase the risk of gouty attacks. Increasing low fat dairy products in the diet, however, may lower serum urate.

    2. Prophylaxis against a future gout flare after resolution of an acute gouty attack may consist of **low-dose colchicine**, 0.6 mg once or twice daily in the patient with normal renal function.

      a. Adverse effects from colchicine at these doses are usually uncommon. In patients, particularly the elderly, who develop loose or diarrheal stools, 0.6 mg every other day might work.

      b. Low-dose NSAIDs may also be used alternatively (naproxen 250 mg twice daily or indomethacin 25 mg twice daily).

      c. Generally, begin prophylactic drug treatment 2 to 3 weeks before urate lowering drug therapy is begun and administer until the desired serum uric acid level is achieved. Prolonged use of

these agents may prevent recurrent episodes of gouty arthritis, but they do not prevent the development of silent bony erosions and tophi deposits.

    d. If the patient develops signs and symptoms of an impending gouty arthritis attack, he can increase the dose to 1.2 mg followed by an additional dose of 0.6 mg 1 hr later.

3. Urate-reducing drug therapy. The goal for gouty attack prevention is to reduce the serum urate concentrations to values < 6.0 mg/dL. A reduction to < 5.0 mg/dL may be required for the resorption of tophi. **The decision to begin drug therapy should be carefully considered, as urate-lowering drug treatment should be lifelong.** Urate-reducing drugs include the xanthine oxidase inhibitors, **allopurinol** (Zyloprim) and **febuxostat** (Uloric), which reduce uric acid production and the **uricosuric** agent **probenecid** (Benemid), which increases renal uric acid excretion. Uric acid lowering therapy **should *not* be initiated during an acute gout attack as this action may prolong the attack** by changing the equilibrium of body urate. During the first 6 to 12 months of therapy, these drugs may increase the frequency, severity, and duration of acute attacks. Therefore, some clinicians administer prophylactic colchicine concomitantly during the early months of uricosuric therapy (see IV.C.2.).

    a. Indications for therapy with a drug that lowers serum urate concentrations should be considered when **all** of the following criteria are met:

        (1) The cause of the hyperuricemia cannot be corrected or, if corrected, does not lower the serum urate concentration to < 7.0 mg/dL.

        (2) The patient has had two or three definite attacks of gout or has tophi.

        (3) The patient is convinced of the need to take medication regularly and permanently.

    b. Specific agents

        (1) Allopurinol (Zyloprim)

            (a) Mechanism of action. Allopurinol and its long-acting metabolite, **oxypurinol, block the final steps in uric acid synthesis by inhibiting xanthine oxidase, an enzyme that converts xanthine to uric acid** (*Figure 43-1*). Thus, the drug reduces the serum uric acid level although increasing the renal excretion of the more soluble oxypurine precursors; this decreases the risk of uric acid stones and nephropathy.

            (b) Indications. Allopurinol is considered by many to be **the drug of choice for lowering uric acid levels** because of its effectiveness in both underexcretors and overproducers, but it is specifically the preferred urate-reducing agent for patients in the following categories:

              (i) Patients who are clearly overproducers (overexcretors) of uric acid

              (ii) Patients with recurrent tophaceous deposits or uric acid stones

              (iii) Patients with renal impairment (but dose needs to be decreased)

            (c) Dosage and administration. It is recommended by the experts that allopurinol be given initially in a daily dose of 100 mg, then increased by 100 mg/day once every 1 to 4 weeks, if needed. Typically, the uric acid level starts to fall after 2 days with maximal effect for a given dose in about 1 to 2 weeks. **300 mg once daily is the most commonly prescribed dose, but this may be an inadequate dose.** A dose of **up to 800 mg/day** (in two to three divided doses) may be needed to achieve the desired 6 mg/dL serum uric acid level. The drug should be given daily without interruption. The dose should be decreased in patients with impaired renal function: 200 mg/day maximum for the patient with a creatinine clearance (CrCl) of $10-20$ mL/min, to 100 mg/day for a patient with a CrCl of less than 10 mL/min, and the dosage interval lengthened if less than 3 mL/min.

            (d) Precautions and monitoring effects. Allopurinol is generally well tolerated.

              (i) Side effects occurring in 3% to 5% of patients include rash, diarrhea, drug fever, leukopenia or thrombocytopenia. About 2% of patients will develop a **rash**; **some** are **mild** and can be treated by stopping the agent, **others** are more **severe** (**Steven Johnsons or toxic epidermal necrolysis** [**TEN**]). Approximately 20% of patients given both allopurinol and ampicillin together develop a rash.

              (ii) The most serious side effect of allopurinol, which occurs in about 0.1% of patients, is the **allopurinol hypersensitivity syndrome** (**AHS**) with exfoliative dermatitis, often with vasculitis, fever, liver dysfunction, eosinophilia, and

acute interstitial nephritis. It is **more likely to occur** in patients with **renal disease** who receive "regular" doses along with **diuretic therapy** and may be fatal (~25% of patients).

    (iii) Allopurinol may induce more frequent acute gout attacks. This risk can be minimized by administration of low doses and concurrent colchicine therapy.

    (iv) Allopurinol can result in enhanced effects of azathioprine and 6-mercaptopurine when taken together.

(2) **Febuxostat** (Uloric) is a selective **xanthine oxidase inhibitor** and is the first new drug to be approved (2009) for gout in over 40 years.

    (a) Unlike allopurinol, it is a thiazolecarboxylic acid derivative and not a purine-like core structure. Thus, it does not share the same severe hypersensitivity reactions with allopurinol.

    (b) The usual dose is **40 mg/day** (**comparable efficacy to 300 mg allopurinol**). The dose can be increased to 80 mg/day after 2 weeks if the serum uric acid remains above 6 mg/dL.

    (c) No dosage adjustments are needed in patients with mild or moderate renal/hepatic impairment.

    (d) It is **much more expensive than allopurinol** and generally should be considered an alternative therapy to allopurinol (allopurinol treatment failure, hypersensitivity or other major side effects).

    (e) This agent can increase liver function tests. Baseline liver function tests (LFTs) should be taken upon initiation of therapy and repeated at 2 and 4 months.

    (f) A slightly higher incidence of thromboembolic events has been reported with febuxostat compared with allopurinol. Patients should be monitored for signs and symptoms of myocardial infarction or stroke.

(3) **Probenecid** (Benemid) is now the only available **uricosuric drug** on the U.S. market. This drug is preferred for underexcretors.

    (a) **Mechanism of action.** Probenecid **blocks uric acid reabsorption at the proximal convoluted tubule**, thereby increasing the rate of uric acid excretion (*Figure 43-2*).

    (b) **Indications.** Uricosurics generally are used to reduce hyperuricemia in patients who excrete < 600 mg of uric acid per day.

    (c) **Dosage and administration**

        (i) **Probenecid** is given initially in two daily oral doses of 250 mg for 1 week, then increased to 500 mg twice daily every 1 to 2 weeks until the serum uric acid level drops below 6 mg/dL. Most patients respond to a dose of 1.5 g/day or less (maximum of 3 g/day).

    (d) **Precautions and monitoring effects**

        (i) Patients should maintain a **high fluid intake** (at least 2 L/day) and a high urine output during uricosuric therapy to decrease renal urate precipitation. This action will minimize the formation of **uric acid crystals** in the urine and deposition of **uric acid** in the **renal tubules**, **pelvis**, or **ureter**, which may cause a reduction in renal function. Alkalinization of the urine is usually not necessary (but can be achieved with 1 g of sodium bicarbonate taken three to four times daily; plus a high fluid intake of at least 2 L/day).

        (ii) Uricosurics are **contraindicated** in patients with urinary tract stones.

        (iii) These drugs generally are ineffective in patients with creatinine clearances below 50 to 60 mL/min.

        (iv) **Aspirin** and **other salicylates** antagonize the action of uricosurics. **Daily low dose aspirin** for antiplatelet function **probably does not have this effect to any extent**.

        (v) **Probenecid** is well tolerated by most patients, but it occasionally causes **adverse effects**—for example, GI distress (8%) and hypersensitivity reactions (5%).

(4) **Pegloticase** (Krystexxa) was also approved in 2009 and is a form of **uricase** (urate oxidase), which catalyzes the oxidation of uric acid to **allantoin**, which is water soluble and easily excreted.

    (a) It is **indicated for** the relatively small number of gout patients (~50,000 Americans) who cannot be treated with other urate lowering drugs (**refractory patients**).

(b) It **needs to be given by IV infusion** every 2 to 4 weeks.

(c) Patients need to be closely monitored for anaphylaxis and infusion reactions. Pretreatment with antihistamines and corticosteroids is needed.

(d) A large percentage of patients develop pegloticase antibodies, which results in decreased effectiveness.

(e) Prophylaxis with colchicine or nonsteroidal agents is also appropriate.

(f) It is **much more expensive than other urate lowering drug therapies**.

(5) **Other drugs that increase uric acid excretion**

(a) **Losartan** (Cozaar), an angiotensin II receptor blocker (ARB), might be a useful antihypertensive agent in the patient who has **both hyperuricemia and hypertension** because this agent can lower serum uric acid levels by inhibiting the uptake of uric acid by the urate anion exchange transporter in the proximal tubule. This effect is minimal or not seen in other ARBs.

(b) **Fenofibrate** (TriCor) is a fibric acid agent used to treat elevated cholesterol and triglyceride levels. It has been shown to decrease serum uric levels by increasing renal uric acid clearance and would be a useful agent in the patient with **both hyperlipidemia and hyperuricemia**.

(c) **Vitamin C** may lower the serum uric acid level. One study noted a 0.5 mg/dL decrease when 500 mg was given daily.

V. CHRONIC TOPHACEOUS GOUT. This **rare** clinical presentation may develop if hyperuricemia and gout remain untreated for many years.

A. **Pathogenesis.** Persistent hyperuricemia leads to the development of tophi in the synovia, olecranon bursae, and various periarticular locations. Eventually, articular cartilage may be destroyed, resulting in joint deformities, bone erosions, deposition of tophi within tissues, and renal disease.

B. **Clinical evaluation**
1. Patients may develop large subcutaneous tophi in the pinna of the external ear (the classic site) as well as in other locations.
2. Typically, the urate pool is many times the normal size.

C. **Therapy.** Allopurinol and probenecid may be given in combination to treat severe cases.

Study Questions

Directions for questions 1–3: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. All of the following statements concerning an acute gouty arthritis attack are correct *except* which one?

(A) The diagnosis of gout is ensured by a good therapeutic response to colchicine because no other form of arthritis responds to this drug.

(B) To be ensured of the diagnosis, monosodium urate crystals must be identified in the synovial fluid of the affected joint.

(C) Attacks frequently occur in the middle of the night.

(D) An untreated attack may last up to 2 weeks.

(E) The first attack usually involves only one joint, most frequently the big toe (first metatarsophalangeal joint).

2. A 42-year-old obese man has been diagnosed with gout. He has had three acute attacks this year, and his uric acid level is presently 11.5 mg/dL (upper limit of normal is 7.0 mg/dL). He has no other diseases. Rational treatment of this patient during the interval period between gouty attacks might include any of the following *except*

(A) acetaminophen or aspirin 650 mg as needed for joint pain.

(B) probenecid.

(C) colchicine.

(D) allopurinol.

(E) a decrease in caloric intake.

3. A 45-year-old man is admitted to the hospital with the diagnosis of an acute attack of gout. His serum uric acid is 10.5 mg/dL (normal is 3 to 7 mg/dL). Which of the following would be the most effective initial treatment plan?

   (A) Before treating this patient, immobilize the affected joint and obtain a 24-hr urinary uric acid level to determine which drug, either allopurinol or probenecid, would be the best agent to initiate therapy.
   (B) Begin oral colchicine 1.2 mg initially, followed by 0.6 mg every 2 hrs until relief is obtained, gastrointestinal distress occurs, or a maximum of 8 mg has been taken; also, begin probenecid 250 mg twice a day concurrently.
   (C) Administer oral indomethacin 50 mg three times a day for 2 days; then gradually taper the dose over the next few days.
   (D) Administer oral naproxen 750 mg, followed by 250 mg every 8 hrs for 3 weeks.
   (E) Give colchicine 0.5 mg intramuscularly followed by 1.0 mg intravenous piggyback every 12 hrs for 2 weeks.

Directions for question 4: The question in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E.**

   (A) if **I only** is correct
   (B) if **III only** is correct
   (C) if **I and II** are correct
   (D) if **II and III** are correct
   (E) if **I, II, and III** are correct

4. Allopurinol is recommended instead of probenecid in the treatment of hyperuricemia in which of the following situations?

   (I) When the patient has several large tophi on the elbows and knees
   (II) When the patient has an estimated creatinine clearance of 15 mL/min
   (III) When the patient has leukemia and there is concern regarding renal precipitation of urate

Directions for question 5: The incomplete statement in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

5. In a patient who has had documented gouty arthritis and hyperuricemia and who also has hypertension, a preferred antihypertensive agent would be

   (A) hydrochlorothiazide
   (B) losartan
   (C) clonidine
   (D) lisinopril
   (E) irbesartan

6. Which of the following **best describes** a current important point about the use of allopurinol in the treatment of intercritical gout?

   (A) It is best dosed in a "2 months on and 2 months off" pattern
   (B) It needs to be dosed twice daily because of its short half-life.
   (C) It is the only currently available FDA-approved xanthine oxidase inhibitor on the market.
   (D) It should be used in reduced doses if the patient has significant renal impairment.
   (E) It can only be used in patients who are overproducers of uric acid.

Answers and Explanations

1. **The answer is A** *[see III.B.1–2; III.C.1; III.C.3].*
   Other forms of acute arthritis may respond to colchicine, so that the diagnosis of gout cannot be established unequivocally by a good response to this agent. A definitive diagnosis requires the presence of urate crystals in the affected joint, although the presence of other symptoms or laboratory findings may suggest a probable diagnosis of gout.

2. **The answer is A** *[see I.D.2.c.(1); IV.C].*
   Aspirin in doses < 2 g/day can inhibit uric acid secretion. Weight reduction, allopurinol or probenecid to lower the serum uric acid levels, and prophylactic colchicine are all appropriate interventions in the interval phase to reduce the incidence of acute gouty attacks.

3. **The answer is C** *[see III.E.1.c; III.E.2.a; III.E.2.b; IV.C].*
   Of the selections, the most effective initial plan in treating an acute attack of gout is to administer indomethacin orally, giving 50 mg three times a day for 2 to 3 days, then gradually tapering the dosage over the next few days. Although joint immobilization is an appropriate initial step, drugs for pain relief should be administered as soon as possible. Uric acid modification therapy (allopurinol or probenecid) should not be initiated until the acute attack is under control. Initiating therapy with probenecid at this point may prolong the resolution of an acute attack of gouty arthritis, which can usually be accomplished within 7 days of NSAID therapy. Colchicine should never be given intramuscularly because it causes tissue irritation. The IV form of this drug has been removed from the market.

4. **The answer is E (I, II, III)** *[see IV.C]*.

    In the treatment of hyperuricemia, allopurinol is indicated rather than probenecid when large tophi are present, when the creatinine clearance is $<$ 50 to 60 mL/min (probenecid would be ineffective, but the allopurinol dosage would have to be decreased), when the patient is an overproducer of uric acid, and when there is a need to prevent the formation of large amounts of uric acid (e.g., when conditions such as leukemia are present).

5. **The answer is B** *[see IV.C.3.b.(5).(a)]*.

    Losartan, an angiotensin II receptor blocker has been shown to increase urinary uric acid secretion and can, therefore, lower serum uric acid levels. Hydrochlorothiazide actually decreases urinary uric acid excretion and must be used cautiously in gout patients, if at all. The other antihypertensive agents mentioned have minimal or no effects on the serum uric acid.

6. **The answer is D** *[IV.C.3.b.(1)]*.

    Allopurinol must be given daily without interruption, its principal metabolite (oxypurinol) has a long half-life so once a day dosing is appropriate, febuxostat is another xanthine oxidase inhibitor on the market, it can be used for both overproducers and hypoexcreters of uric acid. D. is correct because doses do need to be reduced if the patient has renal impairment.

44 Peptic Ulcer Disease and Related Acid-Associated Disorders

PAUL F. SOUNEY, ANTHONY E. ZIMMERMANN

I. INTRODUCTION

A. **Definition**

1. **Peptic ulcer disease** (PUD) refers to a group of disorders characterized by circumscribed lesions of the mucosa of the upper gastrointestinal (GI) tract (particularly the stomach and duodenum). The lesions occur in regions exposed to gastric juices.

2. **Gastroesophageal reflux disease (GERD)** refers to the retrograde movement of gastric contents from the stomach into the esophagus. Reflux may occur without consequences, and thus be considered a normal physiological process, or it may lead to profound symptomatic or histological conditions (e.g., GERD). When reflux leads to inflammation (with or without erosions or ulcerations) of the esophagus, it is called **reflux (erosive) esophagitis**. Most patients (50% to 70%) report typical symptoms but lack evidence of esophageal mucosal injury (**nonerosive reflux disease**; **NERD**).

3. **Dyspepsia** is defined as persistent or recurrent abdominal pain or abdominal discomfort centered in the upper abdomen.

B. **Manifestations**

1. **Duodenal ulcers** almost always develop in the duodenal bulb (the first few centimeters of the duodenum). A few, however, arise between the bulb and the ampulla.

2. **Gastric ulcers** form most commonly in the antrum or at the antral–fundal junction.

3. **Less common forms of peptic ulcer disease**

   a. **Stress ulcers** result from serious trauma or illness, major burns, coagulopathy not related to anticoagulant therapy, need for mechanical ventilation > 48 hrs, or ongoing sepsis. The **most common site** of stress ulcer formation is the proximal portion of the stomach.

   b. **Zollinger–Ellison syndrome** is a severe form of peptic ulcer disease in which intractable ulcers are accompanied by extreme gastric hyperacidity and at least one gastrinoma (a non–β-islet cell tumor of the pancreas or another site).

   c. **Stomal ulcers** (also called marginal ulcers) may arise at the anastomosis or immediately distal to it in the small intestine in patients who have undergone ulcer surgery and have experienced subsequent ulcer recurrence after a symptom-free period.

   d. **Drug-associated ulcers** occur in patients who chronically ingest substances that damage the gastric mucosa, such as nonsteroidal anti-inflammatory drugs (NSAIDs).

4. **Reflux esophagitis** is most often recognized by the presence of recurrent symptoms (e.g., heartburn) or altered epithelial morphology visualized radiologically, endoscopically, or histologically.

   a. Heartburn is substernal burning or regurgitation that may radiate to the neck. Other symptoms include belching, water brash, chest pain, asthma, chronic cough, hoarseness, and laryngitis.

   b. Endoscopic evaluation detected **Barrett esophagus (BE)** in 6% of patients with frequent heartburn. Barrett's esophagus is a premalignant condition that may lead to adenocarcinoma of the esophagus or esophagogastric junction.

  C. Epidemiology

     1. Incidence. Peptic ulcer disease is the most common disorder of the upper GI tract.

       a. Duodenal ulcers affect 4% to 10% of the United States population; **gastric ulcers** occur in 0.03% to 0.05% of the population.

       b. Nearly 80% of peptic ulcers are duodenal; the others are gastric ulcers.

       c. Most duodenal ulcers appear in people between age 20 and 50; onset of gastric ulcers usually occurs between age 45 and 55.

       d. The 1-year point prevalence of active gastric or duodenal ulcer in the United States in men and women is about 1.8%; the lifetime prevalence of peptic ulcer ranges from 11% to 14% for men and 8% to 11% for women.

       e. Approximately 10% to 20% of gastric ulcer patients also have a concurrent duodenal ulcer.

       f. In the United States, 44% of the adult population experience **heartburn** at least once a month; 14% take some type of "indigestion" medication at least twice a week. Of patients with GERD symptoms who have undergone endoscopy, 50% to 65% have apparent esophagitis.

       g. The annual prevalence of dyspepsia in Western countries is approximately 25%; 2% to 5% of primary care consultations are for dyspepsia.

     2. Hospitalization

       a. Hospitalization rates in the United States for peptic ulcers have been declining; these rates dropped from 25.2 per 10,000 in 1965 to 16.5 per 10,000 in 1981. This reflects a decrease in hospitalization for uncomplicated cases owing to increased outpatient diagnosis and treatment. There has been little change in hospitalization rates since then.

       b. There has been little or no decrease in duodenal ulcer perforations and only a slight decrease in hemorrhages.

     3. Mortality

       a. The mortality rate for gastric ulcers declined between 1962 and 1979 from 3.5 per 100,000 to 1.1 per 100,000.

       b. For duodenal ulcer, the mortality rate declined from 3.1 per 100,000 to 0.9 per 100,000.

       c. Although death from GERD is uncommon, morbidity is not, because of the prevalence of the well-recognized complications such as esophageal ulceration (5%), stricture formation (4% to 20%), and the development of Barrett columnar-lined esophagus (8% to 20%).

  D. Description

     1. Ulcer size. The average duodenal ulcer typically has a diameter < 1 cm; most gastric ulcers are somewhat larger (1.0 to 2.5 cm in diameter).

     2. Most ulcers are sharply demarcated and have a round, oval, or elliptical shape.

     3. The mucosa surrounding the ulcer typically is inflamed and edematous.

     4. Ulcers penetrate the **muscularis propria** and, in some cases, extend into the serosa or even into the pancreas.

     5. Fibrous tissue, granulation tissue, and necrotic debris form the ulcer base. During ulcer healing, a scar forms as epithelium from the edges covers the ulcer surface.

     6. Nearly all duodenal ulcers are benign; up to 10% of gastric ulcers are malignant.

  E. Cause. The two major observations regarding PUD are the causal relationship among NSAID intake; gastroduodenal mucosal injury; the pathogenesis of gastric ulcer and, to a lesser extent, duodenal ulcer; and the association of *Helicobacter pylori* infection in the pathogenesis of duodenal ulcer (and to a lesser extent, gastric ulcer).

     1. *H. pylori* (formerly *Campylobacter pylori*) is a gram-negative microaerophilic, spiral bacterium with multiple flagella that lives and infects the gastric mucosa. This bacterium is able to survive in the acidic gastric environment by its ability to produce urease, which hydrolyzes urea into ammonia. Ammonia neutralizes gastric hydrochloric acid (HCl), creating a neutral cloud surrounding the organism.

       a. In the United States, the **prevalence** of *H. pylori* increases with age from approximately 10% at 20 years of age to approximately 50% at 60 years of age; approximately 17% of *H. pylori*–positive individuals will develop a duodenal ulcer. Prevalence is higher in developing countries.

       b. *H. pylori* is associated with several common GI disorders.

         (1) Always present in the setting of active chronic gastritis.

         (2) Present in the vast majority of duodenal ($> 90\%$) and gastric (60% to 90%) ulcers. Recent studies indicate a decline in the prevalence of *H. pylori* in duodenal ulcer patients.

(3) Sometimes present with nonulcer dyspepsia (probably in 50% of cases); eradication of *H. pylori*, when present, leads to symptom improvement in only about one-half of treated patients.

(4) In gastric cancer, 85% to 95% (Although the association is strong, no causal relationship has yet been proven in gastric cancer. The World Health Organization has classified *H. pylori* as a group 1 carcinogen.)

  c. *H. pylori* **eradication** can cure peptic ulcers and reduce ulcer recurrence; it can eliminate the need for maintenance therapy in many ulcer patients.

2. Genetic factors

  a. The lifetime prevalence of developing an ulcer in **first-degree relatives** of ulcer patients is about threefold greater than in the general population. This may be secondary to clustering of *H. pylori* within families.

  b. People with **blood type O** have an above-normal incidence of duodenal ulcers.

3. Smoking. Smokers have an increased risk of developing peptic ulcer disease. In addition, cigarette smoking delays ulcer healing and increases the risk and rapidity of relapse after the ulcer heals. Nicotine decreases biliary and pancreatic bicarbonate secretion. Smoking also accelerates the emptying of stomach acid into the duodenum.

4. NSAIDs. When ingested chronically, aspirin, indomethacin, and other NSAIDs promote gastric ulcer formation.

  a. These drugs may injure the gastric mucosa by allowing back-diffusion of hydrogen ions into the mucosa.

  b. NSAIDs also inhibit the synthesis of prostaglandins, which are substances with a cytoprotective effect on the mucosa.

  c. Selective cyclooxygenase 2 (COX-2) inhibitors, celecoxib or rofecoxib, are associated with fewer ulcers than nonselective NSAIDs, with rates comparable to placebo at 3 months. Questions regarding long-term safety of COX-2 inhibitors remain. With the recent documentation of increasing COX-2 expression with the progression of BE to cancer, trials have been initiated using COX-2 selective inhibitors in BE patients to prevent development of cancer.

5. Alcohol. A known mucosal irritant, alcohol causes marked irritation of the gastric mucosa if ingested in large quantities at concentrations of 20% or greater. The only association between ethanol intake and ulcer disease exists in patients with portal cirrhosis.

6. Coffee. Both regular and decaffeinated coffee contain peptides that stimulate release of gastrin, a hormone that triggers the flow of gastric juice. However, a direct link between coffee and peptic ulcer disease has not been proven.

7. Corticosteroids. Controversy over whether systemic corticosteroid therapy is associated with increased risk for the development of peptic ulcer disease has, for the most part, been resolved. Evidence for this direct association has always been weak in previous retrospective reviews/trials and reflected the concurrent use of an NSAID. Current data support no link between steroids and peptic ulcer disease in the absence of concurrent NSAID use.

8. Associated disorders. Peptic ulcer disease is more common in patients with hyperparathyroidism, emphysema, rheumatoid arthritis, and alcoholic cirrhosis.

9. Advanced age. Degeneration of the pylorus permits bile reflux into the stomach, creating an environment that favors ulcer formation.

10. Psychological factors. Once assigned key roles in the pathogenesis of PUD, stress and personality type now are viewed as relatively minor influences.

F. Pathophysiology. Ulcers develop when an imbalance exists between factors that protect gastric mucosa and factors that promote mucosal corrosion. Approximately 90% of patients with duodenal ulcer and 70% of patients with gastric ulcer have *H. pylori* infection.

1. Protective factors

  a. Normally, the mucosa secretes a thick mucus that serves as a barrier between luminal acid and epithelial cells. This barrier slows the inward movement of hydrogen ions, and allows their neutralization by bicarbonate ions in fluids secreted by the stomach and duodenum.

  b. Alkaline and neutral pancreatic biliary juices also help buffer acid entering the duodenum from the stomach.

  c. An **intact mucosal barrier** prevents back-diffusion of gastric acids into mucosal cells. It also has the capacity to stimulate local blood flow, which brings nutrients and other substances to

the area and removes toxic substances (e.g., hydrogen ions). Mucosal integrity also promotes cell growth and repair after local trauma.

2. **Corrosive factors.** Peptic ulcer disease reflects the inability of the gastric mucosa to resist corrosion by irritants, such as pepsin, HCl, and other gastric secretions.

   a. **Exposure to gastric acid** and **pepsin** is necessary for ulcer development.

   b. **Disrupted mucosal barrier integrity** allows gastric acids to diffuse from the lumen back into mucosal cells, where they cause injury.

3. **Physiological defects associated with peptic ulcer disease.** Researchers have identified various physiological defects in patients with duodenal and gastric ulcers.

   a. **Duodenal ulcer patients** may have the following defects:

      (1) Increased capacity for gastric acid secretion

         (a) Some duodenal ulcer patients have up to twice the normal number of parietal cells (which produce HCl).

         (b) Nearly 70% of duodenal ulcer patients have elevated serum levels of **pepsinogen I**, and a corresponding increase in pepsin-secreting capacity.

      (2) Increased parietal cell responsiveness to gastrin

      (3) Above-normal postprandial gastrin secretion

      (4) Defective inhibition of gastrin release at low pH, possibly leading to failure to suppress postprandial acid secretion

      (5) Above-normal rate of gastric emptying, resulting in delivery of a greater acid load to the duodenum

   b. **Gastric ulcer patients** typically exhibit the following characteristics:

      (a) Deficient gastric mucosal resistance, direct mucosal injury, or both

      (b) Elevated serum gastrin levels (in acid hyposecretors)

      (c) Decreased pyloric pressure at rest and in response to acid or fat in the duodenum

      (d) Delayed gastric emptying

      (e) Increased reflux of bile and other duodenal contents

      (f) Subnormal mucosal levels of prostaglandins (these levels normalize once the ulcer heals)

4. **GERD** requires both initiation and perpetuation of the reflux of gastric contents. Esophagitis develops when noxious substances in the refluxate (i.e., acid, pepsin) are in contact with the esophageal mucosa long enough to cause irritation and inflammation.

   a. In patients with GERD, 65% of reflux events occur via transient lower esophageal sphincter relaxation (TLESR). The main difference between normal individuals and those with GERD is the frequency of TLESR. GERD patients have more frequent and prolonged TLESR. TLESR represents a decrease in lower esophageal sphincter (LES) pressure that is not associated with swallowing or peristalsis.

   b. Other mechanisms of LES incompetence are increased abdominal pressure and spontaneous reflux during periods of very low LES pressure.

   c. Such motility problems are permissive—that is, they allow reflux of acid and other noxious substances.

5. Many diseases cause dyspeptic symptoms, including PUD, GERD, gastric cancer, and biliary tract disease. However, in many cases, no clear pathological reason for a patient's symptoms can be determined. Dyspepsia in the absence of an identifiable organic cause is frequently described as "functional" or "nonulcer" dyspepsia.

G. **Clinical presentation.** Signs and symptoms of PUD vary with the patient's age and the location of the lesion. Only about 50% of patients experience classic ulcer symptoms. The remainder are asymptomatic or report vague or atypical symptoms.

1. **Pain.** Patients typically describe heartburn or a gnawing, burning, aching, or cramp-like pain. Some patients report abdominal soreness or hunger sensations. It is unclear whether peptic ulcer pain results from chemical stimulation or from spasm.

   a. **Duodenal ulcer pain** usually is restricted to a small, midepigastric area near the xiphoid. Pain may radiate below the costal margins into the back or the right shoulder. Pain from a duodenal ulcer frequently awakens the patient between midnight and 2 A.M.; it is almost never present before breakfast.

      b. Gastric ulcer pain is less localized. It may be referred to the left subcostal region. Gastric ulcer rarely produces nocturnal pain.

      c. GERD patients most commonly present with heartburn, belching, regurgitation, or water brash; **atypical presentations** include chest pain, hoarseness/laryngitis, loss of dental enamel, asthma, chronic cough, or dyspepsia. Complications of GERD include esophageal ulceration, strictures, BE, and adenocarcinoma of the esophagus or esophagogastric junction.

      d. Dyspepsia applies broadly to a range of symptoms, including abdominal or retrosternal pain and discomfort, heartburn, nausea, vomiting, and other symptoms referable to the proximal GI tract.

      e. Food usually relieves duodenal ulcer pain but may cause gastric ulcer pain. This finding may explain why duodenal ulcer patients tend to gain weight, whereas gastric ulcer patients may lose weight. Pain characteristically occurs 90 mins to 3 hrs after meals in duodenal ulcer patients, whereas pain in gastric ulcer patients is usually present 45 to 60 mins after a meal. Food aggravates reflux disease.

  2. Nausea and **vomiting** may occur with either ulcer type.

  3. Disease course. Both duodenal and gastric ulcers tend to be chronic, with spontaneous remissions and exacerbations. Within a year of the initial symptoms, most patients experience a relapse.

      a. In many cases, relapse is seasonal, occurring more often in the spring and autumn.

      b. All patients with a confirmed duodenal or gastric ulcer should be tested for *H. pylori* infection. If the patient is *H. pylori*–positive, eradication therapy will reduce the recurrence rate significantly and preclude the need for maintenance medication.

      c. GERD is also a chronic disease; most patients with reflux esophagitis who are healed with antisecretory drug therapy will experience a recurrence within 6 months of discontinuation of the healing regimen. Maintenance therapy reduces the recurrence of esophagitis.

H. Clinical evaluation

  1. Physical findings. Patients with peptic ulcer disease may exhibit superficial and deep epigastric tenderness and voluntary muscle guarding. With duodenal ulcer, patients also may show unilateral spasm over the duodenal bulb. Gastric ulcer patients may have weight loss.

  2. Diagnostic test results

      a. Blood tests may show hypochromic anemia.

      b. Stool tests may detect occult blood if the ulcer is chronic.

      c. Gastric secretion tests may reveal hypersecretion of HCl in duodenal ulcer patients and normal or subnormal HCl secretion in gastric ulcer patients.

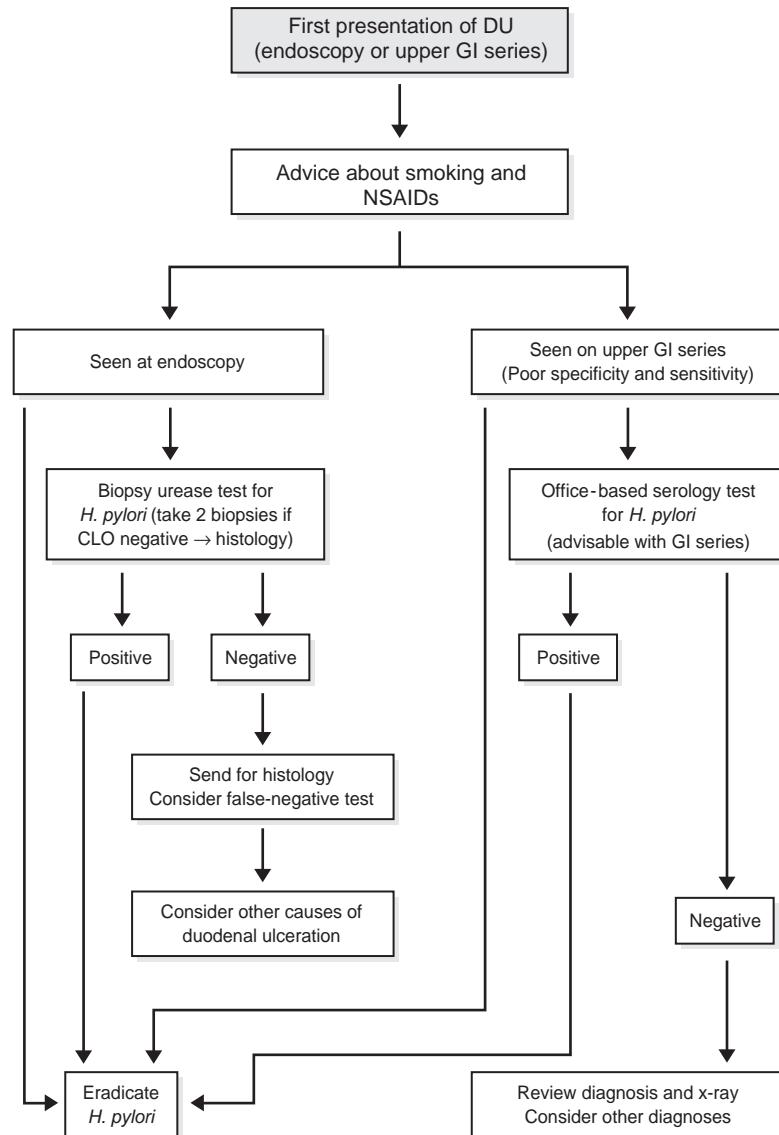
      d. Upper GI series (barium x-ray) reveals the ulcer crater in up to 80% of cases. Duodenal bulb deformity suggests a duodenal ulcer.

      e. Upper GI endoscopy, the most specific test, may be done if barium x-ray yields inconclusive results. This procedure confirms an ulcer in at least 95% of cases and may detect ulcers not demonstrable by radiography.

      f. Biopsy might be necessary to determine whether a gastric ulcer is malignant.

      g. *H. pylori* status is determined by noninvasive tests (not requiring endoscopy) or invasive methods (requiring endoscopy).

         (1) Noninvasive. Serology, the test of choice when endoscopy is not indicated, is inexpensive. Several office tests are available. Breath tests can also be used to detect the organism, and are uniquely suited as noninvasive means of confirming eradication of *H. pylori* after therapy. False-negative breath tests may occur in patients receiving proton pump inhibitors, antibiotics, or bismuth compounds.

         (2) Invasive. These methods include histological visualization of *H. pylori* or measurement of urease activity, which require biopsy.


I. Treatment objectives

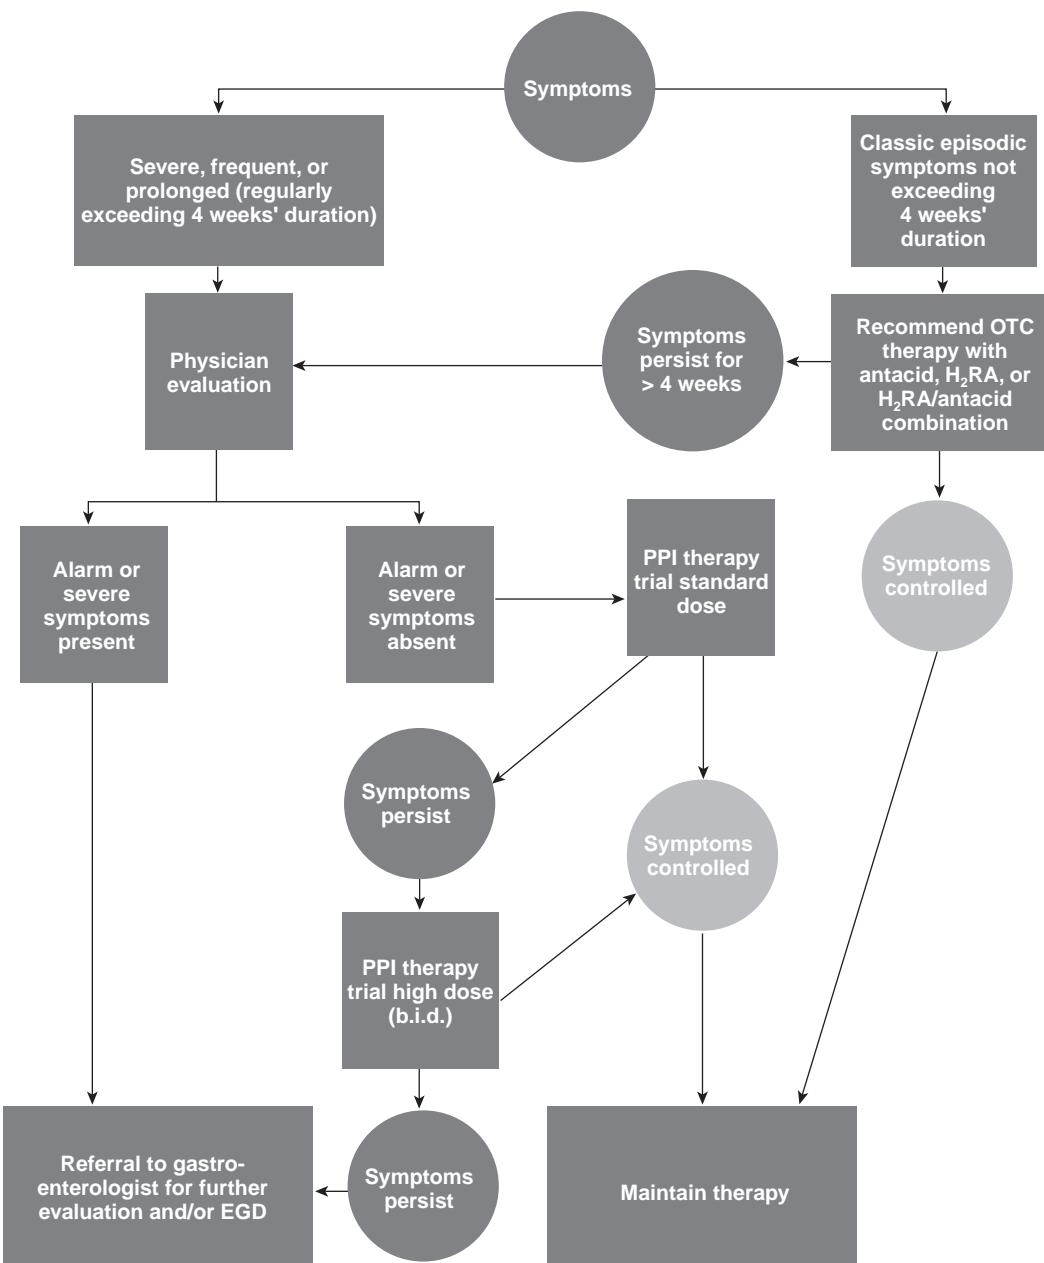
  1. Relieve pain and other symptoms and promote healing

  2. Prevent complications

  3. Minimize recurrence (eradicate *H. pylori* in PUD)

  4. Maintain adequate nutrition

  5. Teach the patient about the disease to improve therapeutic compliance

  6. Maintain the patient symptom-free


II. THERAPY

   A. Drug therapy. Peptic ulcer patients usually are treated with antacids, histamine 2(H_2)-receptor antagonists, or proton pump inhibitors; other drugs are added as necessary. Drug regimens that suppress nocturnal acid secretion are found to result in the highest duodenal ulcer healing rates. Drug therapy typically provides prompt symptomatic relief and promotes ulcer healing within 4 to 6 weeks (*Figure 44-1*). GERD management requires more aggressive acid suppression regimens; the pharmacodynamic end point is to maintain the pH in the esophagus at four or more (*Figure 44-2*).

      1. Antacids. These compounds, which neutralize gastric acid, are used to treat ulcer pain and heal the ulcer. Studies show antacids and H_2-receptor antagonists to be equally effective. Antacids are available as **magnesium**, **aluminum**, or **calcium**. The most widely used antacids are mixtures of aluminum hydroxide and magnesium hydroxide (*Table 44-1*). Duodenal ulcers rarely occur in the absence of acid or when the hourly maximum acid output is < 10 mEq. Peptic activity decreases

Figure 44-1. Treatment strategy for management of duodenal ulcer. *CLO*, *Campylobacter*-like organism; *DU*, duodenal ulcer; *GI*, gastrointestinal; *NSAIDs*, nonsteroidal anti-inflammatory drugs.

Figure 44-2. Treatment strategy for management of gastroesophageal reflux disease. *EGD*, esophagogastroduodenoscopy; *H₂RA*, histamine 2-receptor antagonist; *OTC*, over the counter; *PPI*, proton pump inhibitor. Adapted with permission from Peterson WL. GERD evidence-based therapeutic strategies (AGA Consensus Development Panel), 2002. Available at http://www.gastro.org/user-assets/documents/ GERDmonograph.pdf.

as acidity decreases; experimental ulcer formation is inhibited by antacids; and acid-reducing operations cure ulcers.

   a. **Mechanism of action and therapeutic effects.** Antacids reduce the concentration and total load of acid in the gastric contents. By increasing gastric pH, antacids also inhibit pepsin activity. In addition, they strengthen the gastric mucosal barrier.

   b. **Choice of agent**

   (1) **Nonsystemic antacids** (e.g., magnesium or aluminum substances) are preferred to systemic antacids (e.g., sodium bicarbonate) for intensive ulcer therapy because they avoid the risk of alkalosis.

Table 44-1	COMPARISON OF COMMON ANTACIDS		
Brand Name	**Acid-Neutralizing Capacity (mEq/mL or tab)**	**Therapeutic Amount (140 mEq) (mL or no. of tablets)**	**Sodium Content (mg/5 mL or tablet)**
Regular Liquids			
Aluminum hydroxide, magnesium hydroxide, simethicone			
Gelusil	2.4	58	0.09
Maalox Max	5.2	27	0.00
Mylanta	2.5	56	0.03
Mylanta Max Strength	5.0	28	0.00
Aluminum hydroxide			
Alternagel	4.0	35	0.20
Tablets			
Calcium carbonate			
Maalox Advanced Max Strength	5.0	6.0	0.00
Tums	10.0	14.0	0.00
Tums E-X	15.0	9.3	0.11
Titralac	7.5	18.7	0.00
Calcium carbonate and magnesium hydroxide			
Rolaids	8.5	16.5	0.04
Mylanta Ultra	12.8	8.4	0.00
Aluminum hydroxide and magnesium carbonate			
Gaviscon Extra Strength	8.0	16.0	29.00

    (2) Liquid antacid forms have a greater buffering capacity than tablets. However, tablets are more convenient to carry. With either dosage form, the size and frequency of doses may limit patient compliance.

    (3) Antacid mixtures (e.g., aluminum hydroxide with magnesium hydroxide) provide more even, sustained action than single-agent antacids, and permit a lower dosage of each compound. In addition, compounds in a mixture may interact so as to negate each other's untoward effects. For instance, the constipating effect of aluminum hydroxide may counter the diarrhea that magnesium hydroxide frequently produces.

    (4) Calcium carbonate usually is avoided because it causes acid rebound, may delay pain relief and ulcer healing, and induces constipation. Another potential adverse effect of this compound is hypercalcemia; the risk is increased if calcium carbonate is taken with milk or another alkaline substance. The milk-alkali syndrome (i.e., hypercalcemia, alkalosis, azotemia, nephrocalcinosis) can also occur.

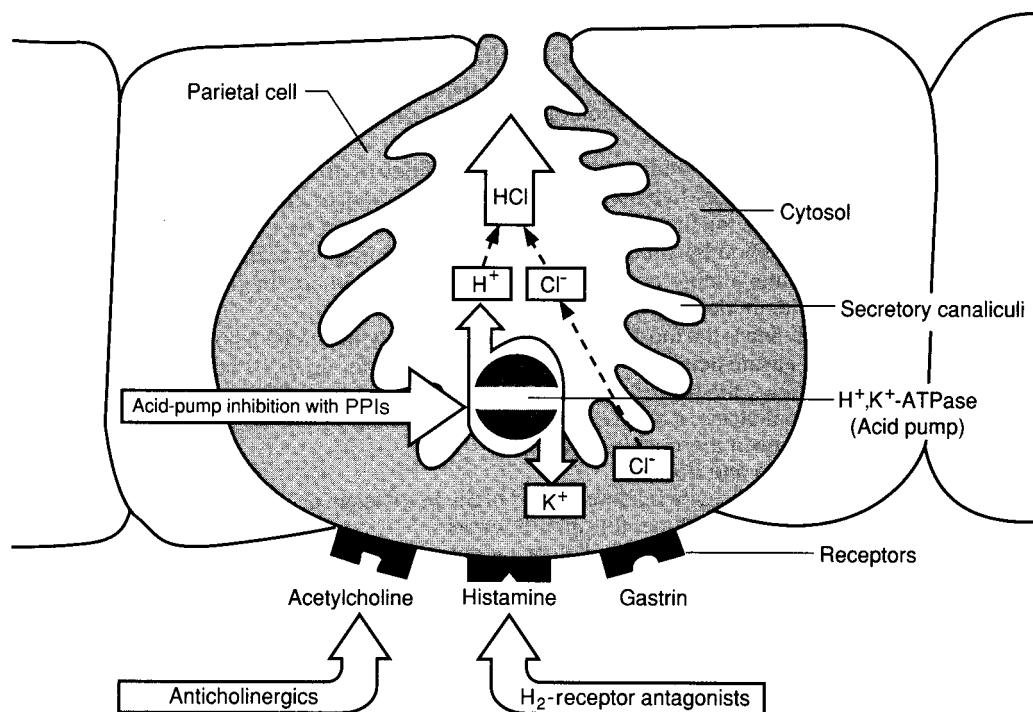
  c. Administration and dosage

    (1) Antacids differ greatly in acid-neutralizing capacity (ANC), defined as the number of milliequivalents (mEq) of a 1 N solution of HCl that can be brought to a pH of 3.5 in 15 mins. For most duodenal ulcer patients, approximately 50 mEq/hr of available antacid is needed for ongoing neutralization of gastric contents. Therefore, the required dosage depends on the ANC of the specific antacid.

    (2) In the fasting state, antacids have only a transient intragastric buffering effect (15 to 20 mins). When ingested 1 hr after a meal, they have a much more prolonged effect, about 3 to 4 hrs; therefore, they should optimally be taken 1 and 3 hrs after meals and before sleep. Consequently, the typical antacid regimen calls for doses 1 and 3 hrs after meals and at bedtime.

(3) Dosage

(a) Because the ANC of antacid products varies widely, no standard dosage can be given in terms of milliliters of suspension or number of tablets. However, patients with duodenal ulcers generally require individual dosages of 80 to 160 mEq of ANC (equivalent to 30 to 60 mL of Mylanta or Maalox). Thus the total daily dosage may be as much as 420 mL of Mylanta or Maalox if the standard seven-times–daily dosing regimen is used. Because of the large doses required, increase in adverse effects, need for frequent administration, and poor patient compliance, their role in the management of PUD is limited.

(b) Antacid therapy usually continues for 6 to 8 weeks.


d. Precautions and monitoring effects

(1) Calcium carbonate- and magnesium-containing antacids should be used cautiously in patients with severe renal disease.

(2) Sodium bicarbonate is contraindicated in patients with hypertension, congestive heart failure (CHF), severe renal disease, and edema. It should not be used for ulcer therapy.

(3) All antacids should be used cautiously in elderly patients (particularly those with decreased GI motility) and renally impaired patients.

(4) Aluminum-containing antacids should be used cautiously in patients who suffer from dehydration or intestinal obstruction.

(5) The combination of calcium carbonate with an alkaline substance (e.g., sodium bicarbonate) and milk may cause the milk-alkali syndrome.

(6) Always check brand name extension products for major ingredient changes (i.e., Maalox Total Stomach Relief contains bismuth subsalicylate).

(7) Chronic administration of calcium carbonate-containing antacids should be avoided because of hypercalcemia and calcium ion stimulation of acid secretion.

(8) Aluminum or magnesium toxicity is unlikely in patients with normal renal function. The encephalopathy of tissue deposition of aluminum occurs only in dialysis patients receiving aluminum hydroxide for control of hyperphosphatemia. Chronic use of magnesium-containing antacids is not advisable in patients with renal insufficiency.

(9) Constipation can occur in patients using calcium carbonate- and aluminum-containing antacids.

(10) Diarrhea is a common adverse effect of magnesium-containing antacids. If diarrhea occurs, the patient may alternate the antacid mixture with aluminum hydroxide.

(11) Hypophosphatemia and osteomalacia can occur with long-term use of aluminum hydroxide, but these conditions can also occur with short-term use in severely malnourished patients, such as alcoholics.

e. Significant interactions. Because antacids alter gastric pH and affect absorption of ingested substances, they have a high potential for drug interactions. To ensure consistent absorption and therapeutic efficacy, orally administered drugs should be given 30 to 60 mins before antacids.

(1) Antacids bind with **tetracycline and fluoroquinolones**, inhibiting the absorption and reducing therapeutic efficacy.

(2) Antacids may destroy the coating of **enteric-coated drugs**, leading to premature drug dissolution in the stomach.

(3) Antacids may interfere with the absorption of many drugs, including **cimetidine**, **ranitidine**, **digoxin**, **isoniazid**, **anticholinergics**, **iron products**, and **phenothiazines** (see II.A.2.e.[3]).

(4) Antacids may reduce the therapeutic effects of **sucralfate** (see II.A.3.d).

2. H$_2$-receptor antagonists. These drugs may be preferred to other antiulcer agents because of their convenience and lack of effect on GI motility. Although reasonably effective in treating mild to moderate GERD symptoms, H$_2$-receptor antagonists are less reliable for healing erosive esophagitis. All current choices require multiple, divided doses for GERD management.

a. Mechanism of action and therapeutic effects. H$_2$-receptor antagonists competitively inhibit the action of histamine at parietal cell receptor sites, reducing the volume and hydrogen ion concentration of gastric acid secretions (*Figure 44-3* and *Table 44-2*). These agonists accelerate the healing of most ulcers.

Figure 44-3. Sites of drug action in a parietal cell. *HCl*, hydrochloric acid; *PPIs*, proton pump inhibitors.

b. **Choice of agent. Cimetidine (Tagamet), ranitidine (Zantac), famotidine (Pepcid),** or **nizatidine (Axid)** may be administered to treat peptic ulcers or hypersecretory states (e.g., Zollinger–Ellison syndrome).

   (1) **Cimetidine**, the first H_2-receptor antagonist approved for clinical use, reduces gastric acid secretion by approximately 50% (at a total daily dosage of 1000 mg).

| Table 44-2 | H_2-RECEPTOR ANTAGONISTS |

Characteristic	Cimetidine (Tagamet)	Ranitidine (Zantac)	Famotidine (Pepcid)	Nizatidine (Axid)
Ring structure	Imidazole	Furan	Thiazole	Thiazole
Relative potency	1	4–10	4–10	20–50
Evening dose (mg)				
Active ulcer	800	300	40	300
Maintenance	400	150	20	150
Bioavailability (F) (%)	60–70	50–60	40–45	90–100
Peak time (t_{max}) (hr)	1–3	1–3	1.0–3.5	0.5–3.0
Volume of distribution (L/kg)	1	1.4	1.1–1.4	0.8–1.6
Protein binding (%)	20	15	15–22	32–35
Renal elimination (%)	60–75	30 oral; 70 intravenous	65–70	65–75
Half-life (hr)				
Normal	2	2–3	2.5–4.0	1.6
Anuric	4–5	4–10	20+	6.0–8.5
Clearance (L/hr)	30–48	46	19–29	40–60

      (2) Ranitidine, a more potent drug, causes a 70% reduction in gastric acid secretion (at a total daily dosage of 300 mg).

      (3) Famotidine is the most potent H_2-receptor antagonist. After a 40-mg dose, mean nocturnal gastric acid secretion is reduced by 94% for up to 10 hrs.

      (4) Nizatidine, the last H_2-receptor antagonist marketed, causes a 90% reduction in nocturnal gastric acid secretion for up to 10 hrs.

  c. Administration and dosage

      (1) Cimetidine usually is administered orally in a dosage of 300 mg four times daily (with meals and at bedtime) for up to 8 weeks.

        (a) Alternatively, duodenal ulcer patients may receive 400 mg twice daily or 800 mg at bedtime. An 800-mg bedtime dose is also effective in treating gastric ulcers.

        (b) Hospitalized patients may receive parenteral doses of 300 mg intravenously every 6 hrs.

        (c) For duodenal ulcer prophylaxis, 400 mg may be given orally at bedtime. However, the ulcer recurs in 20–40% of patients. Cimetidine is also FDA approved for the prevention of Upper GI bleeding at a dose of 50 mg/hr continuous infusion.

      (2) Ranitidine usually is given orally in a dosage of 150 mg twice daily. Duodenal ulcer patients may receive 300 mg at bedtime, alternatively. Therapy continues for up to 8 weeks.

        (a) Hospitalized patients may receive ranitidine by the intravenous or intramuscular route (50 mg every 6 to 8 hrs).

        (b) Prophylactic therapy may be administered to reduce the risk of ulcer recurrence. The approved prophylactic dosage is 150 mg at bedtime.

        (c) Ranitidine 150 mg twice daily can be administered to maintain healing of erosive esophagitis; for this purpose, it is better than placebo but less effective than the proton pump inhibitors.

        (d) Ranitidine bismuth citrate, combined with antibiotics such as clarithromycin, is indicated for eradication of *H. pylori* in patients with duodenal ulcer.

      (3) Famotidine, administered to duodenal ulcer patients, is given in an oral dosage of 40 mg at bedtime for acute therapy for a maximum of 8 weeks. For prophylactic therapy, the dosage is 20 mg at bedtime.

        (a) Hospitalized patients may receive an intravenous injection of 20 mg every 12 hrs.

        (b) As with cimetidine and ranitidine, the ulcer may recur after drug discontinuation.

      (4) Nizatidine, for the treatment of duodenal ulcers, is given orally in a dosage of 300 mg once daily at bedtime or 150 mg twice daily for up to 8 weeks. For prophylactic therapy, the dosage is 150 mg at bedtime.

  d. Precautions and monitoring effects

      (1) Ranitidine must be used cautiously in patients with hepatic impairment. Hepatotoxicity is unusual and occurs most often during intravenous administration. Cimetidine has also been associated with hepatotoxicity.

      (2) Cimetidine may cause such hematological disorders as thrombocytopenia, agranulocytosis, and aplastic anemia.

      (3) All of these agents may cause headache and dizziness. Cimetidine additionally may lead to confusion, particularly if patients are more than 60 years of age or if the dosage is not adjusted for patients with decreased kidney or liver function. All agents require dosage reductions in patients with impaired renal function.

      (4) Cimetidine has a weak androgenic effect, possibly resulting in male gynecomastia and impotence.

      (5) Cimetidine and ranitidine rarely can cause bradycardia, which is reversible on discontinuation of therapy.

      (6) Evaluate *H. pylori* status in any patient with confirmed ulcer disease; eradication of *H. pylori* reduces the need for maintenance therapy in patients with duodenal or gastric ulcers. Patients with complicated ulcer disease should continue maintenance therapy until the eradication of *H. pylori*.

      (7) Tolerance develops frequently to H_2-receptor antagonists (H2RAs) and may explain diminished responses to these agents over time.

e. **Significant interactions**
   (1) Cimetidine binds the cytochrome P450 system of the liver, and thus may interfere with the metabolism of such drugs as **phenytoin, theophylline, phenobarbital, lidocaine, warfarin, imipramine, diazepam**, and **propranolol**.
   (2) Cimetidine decreases hepatic blood flow, possibly resulting in reduced clearance of **propranolol** and **lidocaine**.
   (3) **Antacids** impair absorption of cimetidine and ranitidine, and should be given 1 hr apart from these drugs.
   (4) **Concomitant use of an H$_2$RA and an azole drug has resulted in decreased efficacy**.

3. **Sucralfate (Carafate).** This mucosal protectant is a nonabsorbable disaccharide containing sucrose and aluminum.
   a. **Mechanism of action and therapeutic effects.** Sucralfate adheres to the base of the ulcer crater, forming a protective barrier against gastric acids and bile salts.
      (1) Sucralfate's ulcer-healing efficacy compares favorably to that of the H$_2$RAs.
      (2) Duodenal ulcers respond better than gastric ulcers to sucralfate therapy.
   b. **Administration and dosage**
      (1) An oral agent, sucralfate usually is given in a dosage of 1 g four times daily (1 hr before meals) and at bedtime. Unless radiography or endoscopy documents earlier ulcer healing, therapy continues for 4 to 8 weeks.
      (2) Continued sucralfate therapy after remission postpones ulcer relapse more effectively than cimetidine therapy does.
      (3) There is no evidence that combining sucralfate with H$_2$RAs improves healing or reduces recurrence rates.
   c. **Precautions and monitoring effects.** Constipation is the most common adverse effect of sucralfate.
   d. **Significant interactions**
      (1) **Antacids** may reduce mucosal binding of sucralfate, decreasing its therapeutic efficacy, and thus should be given 30 to 60 mins apart from sucralfate if used in combination ulcer therapy.
      (2) Sucralfate may interfere with the absorption of orally administered **digoxin, tetracycline, phenytoin, iron, ciprofloxacin and other fluoroquinolones**, and **cimetidine** if doses are given simultaneously.

4. **GI anticholinergics** (e.g., belladonna leaf, atropine, propantheline) sometimes are used as adjunctive agents for relief of refractory duodenal ulcer pain. However, these agents have no proven value in ulcer healing.
   a. **Mechanism of action.** Anticholinergics decrease basal and stimulated gastric acid and pepsin secretion.
      (1) Given in combination with antacids, anticholinergics delay gastric emptying, thereby prolonging antacid retention. They are most effective when taken at night and in large doses.
      (2) Anticholinergics occasionally are used in patients who do not respond to H$_2$RAs alone.
   b. **Administration and dosage**
      (1) Taken 30 mins before food, anticholinergics inhibit meal-stimulated acid secretion by 30% to 50% for a duration of 4 to 5 hrs.
      (2) The optimal effective dose varies from patient to patient.
   c. **Precautions and monitoring effects**
      (1) All anticholinergics have side effects to varying degrees, such as dry mouth, blurred vision, tachycardia, urinary retention, and constipation.
      (2) These drugs are contraindicated in patients with gastric ulcers because they prolong gastric emptying. They also are contraindicated in patients with narrow-angle glaucoma and urinary retention.

5. **Prostaglandins.** These agents suppress gastric acid secretion and may guard the gastric mucosa against damage from NSAIDs. **Misoprostol (Cytotec)** has been approved for use in the prevention of gastric ulcers caused by NSAIDs.
   a. **Mechanism of action.** Misoprostol has both antisecretory (inhibiting gastric acid secretion) and mucosal protective properties. NSAIDs inhibit prostaglandin synthesis, and a deficiency of prostaglandin within the gastric mucosa may lead to diminishing bicarbonate

and mucus secretion, contributing to the mucosal damage caused by NSAIDs. Misoprostol increases bicarbonate and mucus production at doses of 200 mcg and above—doses that can also be antisecretory. Misoprostol also maintains mucosal blood flow.

b. Administration and dosage

   (1) Misoprostol is indicated for the prevention of NSAID-induced gastric ulcers in patients at high risk for complications from gastric ulcers (e.g., patients more than 60 years of age, patients with concomitant debilitating disease, patients with a history of ulcers).

   (2) Misoprostol has not been shown to prevent duodenal ulcers in patients taking NSAIDs.

   (3) The recommended adult dosage is 200 mcg four times daily with food; it must be taken for the duration of NSAID therapy. If this dose cannot be tolerated, 100 mcg four times daily can be used.

   (4) Adjustment of dosage in renally impaired patients is not routinely needed.

c. Precautions and monitoring effects

   (1) Misoprostol is contraindicated in pregnant women because of its abortifacient property. Patients must be advised of the abortifacient property, and warned not to give the drug to others.

   (2) Misoprostol should not be used in women with childbearing potential unless the patient requires NSAID therapy, and is at high risk of complications from gastric ulcers associated with use of the NSAIDs or is at high risk of developing gastric ulceration. In such a patient, misoprostol may be prescribed if the patient:

   (a) Is capable of complying with effective contraceptive measures

   (b) Has received both oral and written warnings of the hazards of misoprostol, the risk of possible contraception failure, and the danger to other women of childbearing potential should the drug be taken by mistake

   (c) Had a negative serum pregnancy test within 2 weeks before beginning therapy

   (d) Will begin misoprostol only on the second or third day of the next normal menstrual period

   (3) The most frequent adverse effects are diarrhea (14% to 40%) and abdominal pain (13% to 20%). Diarrhea is dose related, usually develops early in the course (> 2 weeks), and is often self-limiting. Discontinuation of misoprostol is necessary in about 2% of patients. Administration with food minimizes the diarrhea.

d. Significant interactions. None has been reported.

6. Proton pump inhibitors (PPIs). Omeprazole (Prilosec) was the first PPI available in the United States, followed by **lansoprazole (Prevacid)**, **rabeprazole (AcipHex)**, **pantoprazole (Protonix)**, **esomeprazole (Nexium)**, **and dexlansoprazole (Kapidex)** (*Table 44-3*). The intravenous forms

---

Table 44-3 PROTON PUMP INHIBITORS

Pharmacokinetics of PPIs

Characteristic	Omeprazole (Prilosec)	Lansoprazole (Prevacid)	Rabeprazole (Aciphex)	Pantoprazole (Protonix)	Esomeprazole (Nexium)	Dexlansoprazole (Kapidex)
Bioavailability (%)	30–40	80–85	52	77	64–89	n/a
Time to peak plasma concentration (hours)	0.5–3.5	1.7	2.0–5.0	1.1–3.1	1.56	First peak 1–2, Second peak 4–5
Plasma elimination half-life (hours)	0.5–1.0	1.3–1.7	1.0–2.0	1.0–1.9	0.85–1.25	1.0–2.0
Protein binding (%)	95	97	96	98	97	98
Urinary excretion of oral dose (%)	77	14–23	30–35	71–80	80	51

PPIs, proton pump inhibitors.

of esomeprazole, lansoprazole, and pantoprazole have been approved by the U.S. Food and Drug Administration (FDA).

a. **Mechanism of action and therapeutic effects.** The gastric proton pump H^+/K^+-ATPase has a sulfhydryl group near the potassium-binding site on the luminal side of the canalicular membrane. Omeprazole sulfonamide (the active form) forms a stable disulfide bond with this specific sulfhydryl, thereby inactivating the ATPase and shutting off acid secretion. All other PPIs exhibit a similar irreversible mechanism of action.

(1) Because of the potency and marked reduction in gastric acidity, the PPIs are more rapidly effective than other approved agents in treating peptic ulcer disease (i.e., PPIs tend to control symptoms and heal ulcers more rapidly than other antiulcer drugs). PPIs provide effective healing of duodenal ulcers; healing rates at 4 weeks are similar to those reported for H_2-receptor antagonist therapy at 8 weeks.

(2) All PPIs are effective in healing erosive esophagitis, provide more rapid symptom relief and more consistent healing than H_2-receptor antagonists, and are also effective in maintenance of healing of erosive esophagitis.

(3) All PPIs except dexlansoprazole and pantoprazole have been approved in various combinations of antibiotics for the eradication of *H. pylori* (*Table 44-4*).

(4) PPIs have resulted in significant improvement in patients with pathological hypersecretory conditions (e.g., Zollinger–Ellison syndrome) and GERD compared to H_2-receptor antagonists.

(5) Esomeprazole and lansoprazole have been approved by the FDA for healing and risk reduction of NSAID-induced gastric ulcers.

(6) **Esomeprazole**, omeprazole and lansoprazole have been approved by the FDA for use in infants and children for the short-term treatment of GERD and erosive esophagitis. Omeprazole is approved for use in children ages 1 to 16 years, and both esomeprazole and lansoprazole are approved for use in children 1 to 11 years old.

Table 44-4   U.S. FOOD AND DRUG ADMINISTRATION (FDA) APPROVED ORAL REGIMENS USED TO ERADICATE *HELICOBACTER PYLORI* AND REDUCE THE RISK OF DUODENAL ULCER RECURRENCE

Drug Combination	Dose and Frequency	Duration
Omeprazole	20 mg b.i.d.	Days 1–10
	20 mg q.d.	Days 11–28[a]
Clarithromycin	500 mg b.i.d.	Days 1–10
Amoxicillin	1 g b.i.d.	Days 1–10
Lansoprazole	30 mg b.i.d.	10 days
Amoxicillin	1 g b.i.d.	10 days
Clarithromycin	500 mg b.i.d.	10 days
Esomeprazole	40 mg q.d.	q.d. 10 days
Amoxicillin	1 g b.i.d.	10 days
Clarithromycin	500 mg b.i.d.	10 days
Rabeprazole	20 mg b.i.d.	7 days
Amoxicillin	1 g b.i.d.	7 days
Clarithromycin	500 m.g b.i.d.	7 days
Bismuth subsalicylate	525 mg q.i.d	Days 1–14
Metronidazole	250 mg q.i.d	Days 1–14
Tetracycline HCl	500 mg q.i.d	Days 1–14
H_2RA of choice	Ulcer healing regimen	Days 1–28

[a]In patients with an ulcer present at the time of initiation of therapy, additional omeprazole treatment is recommended for ulcer healing and relief of symptoms.
b.i.d., twice a day; *H_2RA*, histamine H_2-receptor antagonist; *q.d.*, every day; *q.i.d.*, four times a day.

b. **Administration and dosage**
  (1) PPIs are more potent than H_2-blockers. In the usual dosage (omeprazole 20 mg daily), these agents inhibit $> 90\%$ of 24-hr acid secretion in most patients, rarely producing achlorhydria. Esomeprazole 40 mg daily provided significantly higher intragastric pH values above 4 during 24-hr monitoring compared to lansoprazole 30 mg, rabeprazole 20 mg, omeprazole 20 mg, and pantoprazole 40 mg.
  (2) PPIs should optimally be taken in the morning 30 to 60 mins before eating; food activates parietal cells, maximizing the effect of the PPI. Optimal binding to proton pumps occurs when the pumps are actively secreting.
  (3) **Recommended adult dosages**
    (a) Erosive esophagitis initially is healed with 20 mg omeprazole or equivalent doses of other PPIs for 8 to 12 weeks; only omeprazole has a demonstrated dose response in GERD patients (patients failing omeprazole 20 mg daily may benefit from higher doses; this has not been demonstrated with esomeprazole, lansoprazole, rabeprazole, or pantoprazole). In addition, esomeprazole 40 mg every day has been shown to produce significantly higher healing rates than omeprazole 20 mg or lansoprazole 30 mg across all grades of erosive esophagitis.
    (b) **Dexlansoprazole 30 mg**, esomeprazole 20 to 40 mg, lansoprazole 30 mg, omeprazole 20 mg, rabeprazole 20 mg, and pantoprazole 40 mg may be used to manage GERD symptoms in patients who have failed previous therapy with H_2-receptor antagonist therapy.
    (c) The recommended dosage to maintain healing of erosive esophagitis is dexlansoprazole 30 mg, esomeprazole 20 mg, omeprazole 20 mg, lansoprazole 15 mg, pantoprazole 40 mg, or rabeprazole 20 mg daily for as long as medically necessary.
    (d) Duodenal ulcer healing requires omeprazole 20 mg, lansoprazole 15 mg, or rabeprazole 20 mg once daily. Most patients heal within 4 weeks.
  (4) Esomeprazole, lansoprazole, and omeprazole are delayed-release capsules, and should be taken before eating, can be used concomitantly with antacids, and should not be chewed or crushed. Capsule contents can be sprinkled on foods (i.e., applesauce) or mixed with acidic juices. Suspensions of omeprazole or lansoprazole in sodium bicarbonate have been used for administration to patients with nasogastric and jejunostomy tubes.
  (5) Rabeprazole and pantoprazole are available as enteric-coated tablets that should not be crushed or chewed.
  (6) Lansoprazole is available as the first orally disintegrating tablet formulation. It is placed on the tongue, with or without water, until dissolved. However, it needs to be swallowed to be absorbed.
  (7) **Dexlansoprazole is the first and only PPI available as a dual delayed-release capsule formulation**.
  (8) Omeprazole in sodium bicarbonate powder for suspension (Zegerid) is the first PPI approved by the FDA for reduction in the risk of upper GI bleeding in critically ill patients. It has a peach/mint flavor that is tolerable. It is dosed at 40 mg every 6 hrs times two doses (as a loading dose), then 40 mg daily.
  (9) **Omeprazole (20 mg daily) and lansoprazole (15 mg daily) are approved for the over-the-counter use of heartburn**.
  (10) No dosing adjustments are necessary in patients with impaired renal or hepatic function or in the elderly.
  (11) Intravenous pantoprazole is indicated for management of erosive esophagitis and treatment of Zollinger–Ellison syndrome. Esomeprazole, lansoprazole, and pantoprazole are currently being widely used for the treatment of acute bleeding gastric ulcers, though not FDA approved.
  (12) Intravenous esomeprazole (20 to 40 mg daily), lansoprazole (30 mg daily), and pantoprazole (40 mg daily) are FDA approved for the short-term use in patients with GERD with a history of erosive esophagus unable to take oral medications.
  (13) In patients with nocturnal signs and symptoms of GERD, twice daily PPIs have been effective when taken appropriately. The addition of an H_2RA to the twice-daily PPI has shown little added benefit and is not recommended.

    c. Precautions and monitoring effects
- **(1)** Headache, diarrhea, abdominal pain, nausea and vomiting, and flatulence have been reported in $> 1\%$ of patients.
- **(2)** Fever, fatigue, malaise, elevated liver enzymes, dizziness, vertigo, skin rash, and itching have been reported in $< 1\%$ of patients.

    d. Significant interactions
- **(1)** Omeprazole interferes with the hepatic microsomal enzyme metabolism (cytochrome P450) of **diazepam**, **warfarin**, and **phenytoin**, **although clinically significant interactions are infrequent**.
- **(2)** **PPIs may decrease the antiplatelet activity of clopidogrel but the exact clinical significance is still unclear**.
- **(3)** Because gastric pH plays a role in the bioavailability of **ketoconazole**, **ampicillin esters**, and **iron salts**, prolonged gastric acid inhibition with PPIs may decrease the absorption of these agents.
- **(4)** Antacids may be used concomitantly with all PPIs.
- **(5)** Food may reduce the bioavailability of esomeprazole and lansoprazole by 50%; food does not reduce the bioavailability of omeprazole or rabeprazole.

7. Bismuth compounds. In the United States, bismuth subsalicylate (Pepto-Bismol) is the only available bismuth product.

    a. Mechanism of action. Bismuth prevents adhesion of *H. pylori* to gastric mucosa, decreases resistance when used with other anti–*H. pylori* agents, inhibits release of proteolytic enzymes, and suppresses *H. pylori* growth.

    b. Administration and dosage
- **(1)** Bismuth subsalicylate is highly effective when combined with PPIs and/or antibiotics. Eradication rates with these combinations are $> 80\%$ (*Table 44-4*).
- **(2)** Preferred regimen with bismuth: bismuth subsalicylate 525 mg four times a day, metronidazole 250 mg four times a day, tetracycline 500 mg four times a day plus PPI (omeprazole 20 mg every day or lansoprazole 30 mg every day) for 2 weeks total. This regimen provides consistently high eradication rates ($> 90\%$), and may be useful for patients who have failed previous therapy. This regimen is not currently FDA approved.

    c. Precautions and monitoring effects
- **(1)** CNS toxicity with higher doses, including neurotoxicity
- **(2)** Tinnitus, hyperpyrexia, tachycardia, and confusion (salicylism) from high doses of bismuth subsalicylate

    d. Reversible proton pump inhibitors are currently under development by a number of pharmaceutical companies (AstraZeneca and Altana). When compared with the currently available irreversible proton pump inhibitors, these agents are expected to offer more rapid symptom resolution, control pH more quickly, achieve higher pH levels, and sustain these more aggressive pH levels consistently over a 24-hr period.

8. Sedatives are useful adjuncts in promoting rest for highly anxious ulcer patients.

B. Other therapeutic measures

    1. Modification of diet and social habits
- **a.** Previously emphasized in ulcer therapy, strict dietary limitations now are considered largely unnecessary.
  - **(1)** Bland or milk-based diets formerly were recommended; however, research indicates that these diets do not speed ulcer healing. In fact, most experts now advise ulcer patients to **avoid milk** because recent studies show that milk increases gastric acid secretion. Also, because milk leaves the stomach quickly, it lacks an extended buffering action.
  - **(2)** Small, frequent meals, also previously recommended, can worsen ulcer pain by causing acid rebound 2 to 4 hrs after eating.
- **b. Current dietary guidelines** emphasize avoiding foods and beverages known to exacerbate gastric discomfort or promote acid secretion. This category typically includes coffee, caffeinated beverages, and alcohol.
- **c. Smoking.** Patients who smoke should be encouraged to quit because smoking markedly slows ulcer healing, even during optimal ulcer therapy.
- **d. NSAIDs** should be avoided by ulcer patients.

2. **Surgery.** An ulcer patient who develops complications may require surgery—sometimes on an emergency basis (see III). Incapacitating recurrent ulcers also may warrant surgery.
    a. **Types of surgical procedures** for ulcer disease include antrectomy and truncal vagotomy (Billroth I procedure), partial gastrectomy and truncal vagotomy (Billroth II procedure), highly selective (proximal gastric) vagotomy, and total gastrectomy (the treatment of choice for Zollinger–Ellison syndrome that is unresponsive to medical management).
        (1) A **vagotomy** severs a branch of the vagus nerve, thereby decreasing HCl secretion.
        (2) An **antrectomy**, by removing the antrum, eliminates some acid-secreting mucosa as well as the major source of gastrin.
    b. The general indications for antireflux surgery are failure of medical therapy to heal or prevent relapse of erosive esophagitis, inability of medical therapy to prevent recurrence of stricture, or a patient whose lifestyle is adversely affected by the need for medical therapy. **Laparoscopic fundoplication** is currently the gold standard for GERD, and successfully relieves symptoms and heals lesions in approximately 85% of patients. However, recent studies have demonstrated that most patients require continued medical therapy after fundoplication.
3. **Emerging endoscopic therapies.** Three endoscopic techniques to treat GERD have recently been introduced.
    a. Augmentation of LES pressure may be achieved by delivery of radio frequency energy to the muscle of the gastroesophageal junction (Stretta procedure). The radio frequency is delivered by means of a flexible catheter made up of a bougie tip, a balloon-basket combination, and four-needle delivery sheaths.
    b. Another endoscopic procedure, the EndoCinch, augments the LES by suturing of the mucosa.
    c. The third endoscopic/endoluminal treatment is by use of Enteryx injection.
    d. Early studies have demonstrated good feasibility in performing these procedures, and an overall satisfactory safety profile. Further studies are necessary to assess long-term failure rate, early versus late complications, and success rate in the different GERD groups.

III. COMPLICATIONS of peptic ulcer disease cause approximately 7000 deaths in the United States annually.

A. **Hemorrhage.** This life-threatening condition develops from widespread gastric mucosal irritation or ulceration with acute bleeding.
    1. **Clinical features.** The patient may vomit fresh blood or a coffee grounds–like substance. Other signs include passage of bloody or tarry stools, diaphoresis, and syncope. With major blood loss, manifestations of **hypovolemic shock** may appear: The pulse rate may exceed 110, or systolic blood pressure may drop below 100.
    2. **Management**
        a. Patient stabilization, bleeding cessation, and measures to prevent further bleeding are crucial.
            (1) Airway, breathing, and circulation must be ensured.
            (2) Intravenous crystalloids and colloids (e.g., hetastarch) should be infused as needed.
            (3) The patient's electrolyte status must be monitored, and any imbalances should be corrected promptly.
        b. **Gastric lavage** may be performed via a nasogastric or orogastric tube; iced saline solution is instilled until the aspirate returns free of blood.
        c. Vasoconstrictors or continuous infusion proton pump inhibitors have been administered with good response.
            (1) Decrease rebleeding rates were found when the continuous infusion PPI maintained the gastric pH to 6 or above. The doses required were much higher than normal doses (e.g., pantoprazole 80 mg bolus plus 8 mg/hr or lansoprazole 90 mg bolus plus 9 mg/hr). However, none of the intravenous PPIs are currently FDA approved for this indication.
            (2) **Vasopressin**, an agent that causes contraction of the GI smooth muscle, may be given to constrict vessels and control bleeding but only in patients with hemorrhagic gastritis.
        d. **Emergency surgery** usually is indicated if the patient does not respond to medical management.

B. **Perforation.** Penetration of a peptic ulcer through the gastric or duodenal wall results in this acute emergency. Perforation most commonly occurs with ulcers located in the anterior duodenal wall.
   1. **Clinical features.** Sudden acute upper abdominal pain, rigidity, guarding, rebound tenderness, and absent or diminished bowel sounds are typical manifestations. Several hours after onset, symptoms may abate somewhat; this apparent remission is dangerously misleading because peritonitis and shock may ensue.
   2. **Management.** Emergency surgery is almost always necessary.
C. **Obstruction.** Inflammatory edema, spasm, and scarring may lead to obstruction of the duodenal or gastric outlet. The pylorus and proximal duodenum are the most common obstruction sites.
   1. **Clinical features.** Typical patient complaints include postprandial vomiting or bloating, appetite and weight loss, and abdominal distention. Tympany and a succussion splash may be audible on physical examination. Gastric aspiration after an overnight fast typically yields more than 200 mL of food residue or clear fluid contents. (Gastric cancer must be ruled out as the cause of obstruction.)
   2. **Management**
      a. **Conservative measures** (as in routine ulcer therapy) are indicated in most cases of obstruction.
      b. Patients with marked obstruction may require **continuous gastric suction** with careful monitoring of fluid and electrolyte status. A **saline load test** may be performed after 72 hrs of continuous suction to test the degree of residual obstruction.
      c. If < 200 mL of gastric contents are aspirated, liquid feedings can begin. **Aspiration** is performed at least daily for the next few days to monitor for retention and to guide dietary modifications as the patient progresses to a full regular diet.
      d. **Surgery** is indicated if medical management fails.
D. **Postsurgical complications**
   1. **Dumping syndrome.** Affecting about 10% of patients who have undergone partial gastrectomy, this disorder is characterized by rapid gastric emptying.
      a. **Causes.** The mechanism underlying dumping syndrome is poorly defined. However, intestinal exposure to hypertonic chyme may play a key role by triggering rapid shifts of fluid from the plasma to the intestinal lumen.
      b. **Clinical features.** The patient may experience weakness, dizziness, anxiety, tachycardia, flushing, sweating, abdominal cramps, nausea, vomiting, and diarrhea.
         (1) Manifestations may develop 15 to 30 mins after a meal (early dumping syndrome) or 90 to 120 mins after a meal (late dumping syndrome).
         (2) Reactive hypoglycemia may partly account for some cases of late dumping syndrome.
      c. **Management.** The patient usually is advised to eat six small meals of high protein and fat content and low carbohydrate content. Fluids should be ingested 1 hrs before or after a meal but never with a meal. **Anticholinergics** may be given to slow food passage into the intestine.
   2. **Other postsurgical complications** include reflux gastritis, afferent/blind loop syndrome, stomal ulceration, diarrhea, malabsorption, early satiety, and iron-deficiency anemia.
E. **Refractory ulcers.** Ulcers that fail to heal on a prolonged course of drug treatment should not be confused with ulcers that recur after therapy is stopped. It is difficult to predict which patients will have a refractory ulcer.
   1. **Differential diagnosis.** Any compliant patient who continues to have dyspeptic symptoms after 8 weeks of therapy should have gastroscopy and biopsy to exclude rare causes of ulceration in the duodenum, such as Crohn disease, tuberculosis, lymphoma, pulmonary or secondary carcinoma, and cytomegalovirus (CMV) infection in immunodeficient patients. Fasting plasma gastrin concentration should be measured to exclude Zollinger–Ellison syndrome.
   2. **Treatment**
      a. Available data indicate that only maximum acid inhibition, with a regimen such as omeprazole (20 mg twice a day) or lansoprazole (30 mg twice a day), offers advantages over continued therapy with standard antiulcer regimens.
      b. Eradication of *H. pylori* infection, when present, is likely to facilitate healing and alter the natural history of refractory ulcers.

      c. Every effort should be made to discover and reduce or eliminate NSAID use.

      d. Perform surgery.

   F. Maintenance regimens

      1. Despite healing after withdrawal of therapy, 70% of ulcers recur in 1 year, and 90% in 2 years. Similarly, erosive esophagitis will recur in more than 80% of individuals within 1 year after discontinuation of antisecretory therapy.

      2. Candidates for long-term maintenance therapy include patients with serious concomitant diseases; four relapses per year; or a combination of risk factors, producing a more severe natural history of peptic disease (e.g., old age, male sex, a long history of aspirin or NSAID use, heavy alcohol intake, cigarette smoking, a history of peptic ulcer disease in an immediate relative, high maximal acid output, and a history of ulcer complications).

      3. Patients with confirmed ulcer disease should be evaluated for presence of *H. pylori*. Eradication of *H. pylori* minimizes the recurrence of ulcer disease. Patients with a history of complicated ulcer disease should have *H. pylori* eradication confirmed.

Study Questions

Directions for questions 1–6: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. ZZ is a 43-year-old female with a chief complaint of hematemesis and abdominal pain. Serology is positive for *H. pylori*. Which of the following would be the best regimens to treat ZZ?

  (A) Omeprazole 20 mg daily plus clarithromycin 500 mg b.i.d. × 14 days

  (B) Lansoprazole 30 mg b.i.d. plus tetracycline 500 mg q.i.d. × 14 days

  (C) Rabeprazole 20 mg b.i.d. plus amoxicillin 1 g b.i.d. plus clarithromycin 500 mg b.i.d. × 7 days

  (D) Esomeprazole 40 mg b.i.d. plus amoxicillin 500 mg b.i.d. plus clarithromycin 500 mg b.i.d. × 7 days

  (E) Pantoprazole 40 mg b.i.d. plus amoxicillin 1 g b.i.d. plus clarithromycin 500 mg t.i.d. × 10 days

2. All of the following statements concerning antacid therapy used in the treatment of duodenal or gastric ulcers are correct *except* which one?

  (A) Antacids may be used to heal the ulcer but are ineffective in controlling ulcer pain.

  (B) Antacids neutralize acid and decrease the activity of pepsin.

  (C) If used alone for ulcer therapy, antacids should be administered 1 hr and 3 hrs after meals and before bedtime.

  (D) If diarrhea occurs, the patient may alternate the antacid product with aluminum hydroxide.

  (E) Calcium carbonate should be avoided because it causes acid rebound and induces constipation.

3. As part of a comprehensive management strategy to treat peptic ulcer disease, patients should be encouraged to do all of the following *except*

  (A) decrease caffeine ingestion.

  (B) eat only bland foods.

  (C) stop smoking.

  (D) avoid alcohol.

  (E) avoid the use of milk as a treatment modality.

4. A gastric ulcer patient requires close follow-up to document complete ulcer healing because

  (A) perforation into the intestine is common.

  (B) spontaneous healing of the ulcer may occur in 30% to 50% of cases.

  (C) there is the risk of the ulcer being cancerous.

  (D) symptoms tend to be chronic and recur.

  (E) weight loss may be severe in gastric ulcer patients.

5. IT is a 58-year-old male admitted to the intensive care unit with acute respiratory failure and thrombocytopenia. He is at high risk for an upper gastrointestinal bleed. Which of the following agents are approved by the U.S. Food and Drug Administration (FDA) for the prevention of this type of bleed?

  (A) Sucralfate

  (B) Famotidine

  (C) Esomeprazole

  (D) Lansoprazole

  (E) Omeprazole

6. All of the following provide acid suppression similar to omeprazole 20 mg every day *except*

   (A) dexlansoprazole 30 mg every day.
   (B) pantoprazole 40 mg every day.
   (C) rabeprazole 20 mg every day.
   (D) ranitidine 150 mg twice a day.
   (E) all provide equivalent acid suppression.

Directions for questions 7–8: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

   A if **I only** is correct
   B if **III only** is correct
   C if **I and II** are correct
   D if **II and III** are correct
   E if **I, II, and III** are correct

7. Correct statements concerning cigarette smoking and ulcer disease include which of the following?

   (I) Smoking delays healing of gastric and duodenal ulcers.
   (II) Nicotine decreases biliary and pancreatic bicarbonate secretion.
   (III) Smoking accelerates the emptying of stomach acid into the duodenum.

8. When administered at the same time, antacids can decrease the therapeutic efficacy of which of the following drugs?

   (I) sucralfate
   (II) ranitidine
   (III) cimetidine

Directions for questions 9–13: Each description in this section is most closely associated with **one** of the following agents. Each agent is used only **once**. Choose the **best** answer, **A–E**.

   A Sodium bicarbonate
   B Aluminum hydroxide
   C Calcium carbonate
   D Magnesium hydroxide
   E Propantheline

9. May cause diarrhea

10. Cannot be used by patients with heart failure

11. If used with milk and an alkaline substance can cause milk-alkali syndrome

12. May cause dry mouth

13. Can be alternated with an antacid mixture to control diarrhea.

Answers and Explanations

1. The answer is C *[see Table 44-4]*.
Though all agents are useful in the treatment of *Helicobacter pylori*, only the combination of rabeprazole with amoxicillin and clarithromycin for 7 days is correct. The other doses and duration of therapy are incorrect.

2. The answer is A *[see II.A.1]*.
Antacids have been shown to heal peptic ulcers, and their main use in modern therapy is to control ulcer pain. Antacids should be taken 1 hr and 3 hrs after meals because the meal prolongs the acid-buffering effect of the antacid. If diarrhea becomes a problem with antacid use, an aluminum hydroxide product can be alternated with the antacid mixture; this takes advantage of the constipating property of aluminum. Because calcium carbonate causes acid rebound and constipation, its use should be avoided.

3. The answer is B *[see II.B.1.a.(1)]*.
Bland food diets are no longer recommended in the treatment of ulcer disease because research indicates that bland or milk-based diets do not accelerate ulcer healing. Studies show that patients can eat almost anything; however, they should avoid foods that aggravate their ulcer symptoms.

4. The answer is C *[see I.D.6]*.
Between 5% and 10% of gastric ulcers may be the result of cancer. The ulcer may respond to therapy; however, failure of the ulcer to decrease satisfactorily in size and to heal with therapy may suggest cancer. Close follow-up is necessary to document complete ulcer healing.

5. The answer is E *[see II.6.B]*.
Though all of these agents have been used with success in the prevention of GI bleeds in critically ill patients, only omeprazole (as a powder for oral suspension) has been FDA approved for this indication.

6. The answer is D *[see II.A.6.b.(1)]*.
Doses of omeprazole 20 mg, dexlansoprazole 30 mg, pantoprazole 40 mg, and rabeprazole 20 mg administered once daily provide similar levels of acid suppression. All provide significantly better acid inhibition than ranitidine, even at doses of 150 mg twice a day or more.

7. **The answer is E** *(I, II, III) [see I.E.3; II.B.1.c]*.
Clinical studies have shown that smoking increases susceptibility to ulcer disease, impairs spontaneous and drug-induced healing, and increases the risk and rapidity of recurrence of the ulcer. These findings may result in part from nicotine's ability to decrease biliary and pancreatic bicarbonate secretion, thus decreasing the body's ability to neutralize acid in the duodenum. Also, the accelerated emptying of stomach acid into the duodenum may predispose to duodenal ulcer and may decrease healing rates.

8. **The answer is E** *(I, II, III) [see II.A.1.e.(3); II.A.3.d]*.
The mean peak blood concentration of cimetidine and the area under the 4-hr cimetidine blood concentration curve were both reduced significantly when cimetidine was administered at the same time as an antacid. The absorption of ranitidine is also reduced when it is taken concurrently with an aluminum-magnesium hydroxide antacid mixture. To avoid this interaction, the antacid should be administered 1 hr before or 2 hrs after the administration of cimetidine or ranitidine. Antacids may reduce mucosal binding of sucralfate, decreasing its therapeutic efficacy. Antacids should, therefore, be given 30 to 60 mins before or after sucralfate.

9. **The answer is D** *[see II.A.1.b.(3)]*.

10. **The answer is A** *[see II.A.1.d.(2)]*.

11. **The answer is C** *[see II.A.1.d.(5)]*.

12. **The answer is E** *[see II.A.4.c.(1)]*.

13. **The answer is B** *[see II.A.1.b.(3)]*.
Magnesium-containing products tend to cause diarrhea, possibly because of magnesium's ability to stimulate the secretion of bile acids by the gallbladder. Because of its sodium content, sodium bicarbonate is contraindicated in patients with CHF, hypertension, severe renal disease, and edema. Sodium bicarbonate is no longer used in peptic ulcer therapy. In addition to causing acid rebound, calcium carbonate, if taken with milk and an alkaline substance for long periods, may cause milk-alkali syndrome. It also may cause adverse effects such as hypercalcemia, alkalosis, azotemia, and nephrocalcinosis. Propantheline, like other anticholinergic agents, may cause dry mouth, blurred vision, urinary retention, and constipation. These agents sometimes are used as adjuncts to relieve duodenal ulcer pain. They are contraindicated in gastric ulcer because they delay gastric emptying. Aluminum hydroxide is constipating and can be alternated with the patient's current antacid when that antacid product is causing diarrhea.

Diseases of the Bowel: Inflammatory Bowel Disease and Irritable Bowel Syndrome

45

DEAN S. COLLIER

I. INTRODUCTION

A. **Definition**
1. **Inflammatory Bowel Disease** (**IBD**) is a designation commonly used to **describe** two idiopathic diseases of the gastrointestinal tract with closely related clinical presentations. These diseases are **ulcerative colitis** (**UC**) and **Crohn disease** (**CD**).
   a. UC is a chronic inflammatory condition of the gastrointestinal tract mucosa and is primarily found in the rectum and colon.
   b. CD is chronic transmural inflammation of the gastrointestinal mucosa and can be found throughout the gastrointestinal tract from the mouth to the anus. CD most commonly affects the small bowel and colon.
2. **Irritable bowel syndrome** (**IBS**) is a disorder that interferes with the normal motility functions of the gastrointestinal tract. The disorder is characterized by a principle symptom of abdominal pain. Abdominal bloating is another common symptom. These symptoms are associated with various changes in bowel habits, predominantly diarrhea or constipation, though some cases experience both or alternate between the two. Importantly, there is an absence of certain "Alarm signs or symptoms" including unintentional weight loss, anemia, bloody stools, new onset at ≥ 50 years of age and family history of colon cancer, IBD, or celiac disease. Presence of any of these red flags may indicate a disease other than IBS such as colon cancer or IBD.

B. **Manifestations**
1. **IBD**
   a. **UC** onset is frequently insidious with increasing stool urgency and frequency. In addition to urgency, bloody stool, and mucus in the stool can also gradually increase. The typical course of UC can be generalized as bouts of varied disease intensity interspersed with asymptomatic periods.
   b. **CD** onset is typically insidious but can present as severe or fulminate disease. Further, there may be patterns of symptoms, which relate to disease location as well as type (inflammatory, fibrostenotic, or fistulizing for example), which can be useful in determining therapy decisions.
2. **IBS**
   a. IBS can be characterized by pain relieved by defecation, alternating bowel habits, abdominal distention, mucus in the stool, and a sensation of incomplete defecation. IBS usually occurs as either constipation predominant IBS or diarrhea-predominant IBS.

907

    b. Constipation predominant (IBS-C) tends to present with pain and periodic constipation alternating with normal periods of bowel function. Pain has been described as colicky, periodic, and/or as a continuous dull ache. Defecation may relieve the pain and eating can commonly trigger symptoms. Other common symptoms are bloating, nausea, dyspepsia, flatulence, and heartburn.

    c. Diarrhea predominant (IBS-D) is commonly characterized by precipitous diarrhea occurring immediately on rising or during meals or immediately postprandially. Nocturnal episodes are rare. Other common presenting complaints are pain, bloating, rectal urgency, and incontinence.

    d. Mixed pattern (IBS-M) is used to describe cases where predominant symptoms include both diarrhea and constipation.

    e. Alternating pattern (IBS-A) is used to describe cases where predominant symptoms alternate from constipation to diarrhea over a period.

C. Epidemiology of IBD. It has been estimated that more than 1 million Americans have IBD and that roughly half have UC and half have CD.

  1. UC incidence and prevalence rates have remained relatively constant in North America and northern Europe and appear to be increasing in southern Europe and East Asia. UC historically has been more common than CD.

    a. UC incidence rates in North America range between 9 and 12 cases per 100,000 patients. Recent prevalence rates for UC in North America are reported to be 205 to 240 per 100,000 patients. Rates are comparable in northern European countries.

    b. UC incidence and prevalence rates are lower in southern Europe, Asia, and Central/South America.

  2. CD incidence and prevalence rates have seen a marked rise since the early 1950s. There is a great variance in published incidence rates of CD. Areas of higher CD incidence are generally similar to those of higher UC incidence. CD has become more common than UC in some areas recently.

    a. Reported CD incidence rate for North America ranges between 6 and 8 cases per 100,000 patients. CD prevalence rates in North America are estimated to be 100 to 200 cases per 100,000 patients. CD rates for northern Europe are comparable to those in North America.

    b. Rates for southern Europe, Asia and Central/South America have been reported to be lower than those seen in North America and northern Europe.

  3. Geographic related components

    a. Northern regions have historically reported higher rates of IBD than southern regions. Rates in southern Europe have recently seen increasing incidence rates compared to historical rates.

    b. CD rates have been reported to be higher in urban areas.

    c. UC rates have been reported to be higher in rural areas.

    d. IBD rates have historically been higher in developed countries compared to underdeveloped countries. This difference has been shown to decrease as underdeveloped areas are developed and a more western diet is adopted.

  4. Ethnic, racial, and socioeconomic components

    a. IBD, CD in particular, development risk is higher in Jews of European decent than non-Jews. While IBD prevalence is reported to be higher in Jews compared to non-Jews, there is considerable variation within Jewish populations from different geographic locations.

    b. Non-Jewish Whites historically have been considered to be at higher risk for IBD compared to African Americans but that difference has been questioned in recent published reports. Blacks in Africa tend to be at less risk for IBD than either North American Caucasians or African Americans.

    c. Asians appear to be at lower risk for developing IBD than Caucasians but migrant Asians to the United Kingdom interestingly have been shown to be at higher risk for UC and nearly equal risk of developing CD compared to UK-born Caucasians.

    d. Incidence rates of IBD have historically been reported to be higher in higher socioeconomic classes.

  5. Age and sex related components

    a. IBD is more common in young adult patients than older patients with peak age of onset between 15 and 30 years.

    b. Men and women are at similar risk to develop IBD, with women having a slightly higher risk to develop CD and men a slightly higher risk of developing UC.

6. **Other contributing factors**
   a. Smoking has been associated with a decrease in UC rates (roughly 60% of rates seen in non-smokers), but the risk factors to general health do not warrant forgoing counseling patients on the benefits of smoking cessation.
   b. Former smokers are at increased risk of developing UC.
   c. Smoking has been shown to be risk factor for developing CD (more than 1.75 times the rates seen in nonsmokers). CD patients who actively smoke also have increased morbidity compared to CD patients who stop smoking.
   d. Appendectomy has been shown to be protective with regard to development of UC.
   e. Use of oral contraceptives has been associated with increased risk of developing IBD.
7. **Genetic** predisposition to IBD is another area of recent research advances. Genetic predisposition to IBD is suggested by, among other factors, epidemiologic studies, studies of twins, family aggregation studies, and ethnic differences in disease patterns. The CARD15 (NOD2) genetic mutation, for example, is seen more often in CD than in the general population. The mutation has been associated with altered immune response to bacteria. There are limitations to CARD15 usefulness in clinical practice, but the identification of this mutation and others has opened the door for more work around genetic predisposition and possible disease mechanism. These may lead to new modes of therapy.

D. **Epidemiology of IBS**
   1. IBS is reported to be more common in women than men.
   2. IBS usually presents between the ages of 30 and 50 with significant decreases at ages greater than 50.
   3. Prevalence seems to be equal in Caucasians and Blacks and less in Hispanics. Overall prevalence rates are estimated at 7% to 15% of the U.S. population.
   4. IBS appears to be as common in Asian, South American, and India as in western countries.

E. **Description**
   1. UC is chronic recurring mucosal inflammation of the colon.
      a. **Proctitis**: Inflammation of the rectum.
      b. **Proctosigmoiditis**: Colitis affecting the rectum and sigmoid colon.
      c. **Left-sided colitis**: Disease starting at the rectum and extending retrograde to the splenic flexure of the colon.
      d. **Pancolitis**: Disease affecting the entire colon.
      e. **Backwash ileitis**: Inflammation of the terminal ileum due to retrograde flow of colonic contents in pancolitis patients
   2. CD is chronic recurring transmural inflammation of the gastrointestinal tract.
      a. **Ileocolitis**: The most common form of CD, affecting the ileum and colon.
      b. **Ileitis**: CD affecting the ileum.
      c. **Gastroduodenal Crohn disease**: CD affecting the stomach and duodenum.
      d. **Jejunoileitis**: CD producing inflammation of the jejunum and ileum.
      e. **Crohn (granulomatous) colitis**: CD affecting only the colon.
   3. **IBS**
      a. IBS is recognized as being part of **functional bowel disease**.
      b. IBS is characterized by symptoms of abdominal pain or discomfort that is associated with disturbed defecation patterns. IBS is typically of a constipation predominant (IBS-C) or diarrhea predominant (IBS-D) type with a minority of patients alternating between the two (IBS-A) or of a mixed presentation (IBS-M).

F. **Etiology**
   1. **IBD** is thought to be caused by a poorly understood compilation of environmental, genetic factors, and possibly infectious agents. IBD is likely a result of multiple environmental factors eliciting an abnormal immune response in genetically susceptible individuals. There is significant overlap between the clinical presentation of UC and CD, the two main idiopathic inflammatory disease states, which make up IBD, and as such clear differential diagnosis between UC and CD is not always possible.
      a. There is clear evidence of immune system activation with subsequent infiltration of the tissue by lymphocytes, macrophages, and other cells. The exact trigger of this apparent poorly regulated immune response has yet to be defined.

      b. Possible mechanisms postulated for IBD disease initiation include virus or bacterial infection, dietary antigens or inappropriate immune response to normally nonantigenic microbes, and the possibility of an inappropriate immune response to intestinal autoantigens expressed on the intestinal epithelium.

      c. Regardless of cause there appears to be failure of normal suppressor mechanisms with a resultant overly vigorous and abnormally long immune response to a disease trigger.

      d. IBD occurs 30 to 100 times more frequently in first-degree relatives of IBD patients compared to the general population.

      e. **Infectious colitis** can mimic IBD. Differential diagnosis includes bacterial, protozoal, and viral pathogens (notably *Clostridium difficile*, fungal, protozoal, viral, and helminthic pathogens).

      f. **Ischemic colitis** and **neoplastic** diseases such as cecal adenocarcinoma, lymphoma, and metastatic cancers may also present like IBD.

      g. **Microscopic colitis** and other inflammatory diseases such as **celiac sprue** and **eosinophilic colitis** can present in much the same manner as IBD.

      h. **Drug-induced enterocolitis** can induce IBD-like symptoms. The most commonly implicated classes of drugs are nonsteroidal anti-inflammatory drugs (NSAIDs), gold compounds, oral contraceptives, enteric potassium supplements, pancreatic enzymes, phospho soda bowel preps, and thermal injury secondary to colostomy irrigation.

      i. Other possibly confounding diseases include **endometriosis** and **diverticular disease**.

  2. IBS

      a. The exact cause of IBS is unknown and no anatomic cause has yet to be elucidated.

      b. Possible comorbid factors such as viral or bacterial gastroenteritis, emotional health, diet, environmental, concurrent drug therapy, and hormones have been implicated in GI dysmotility.

      c. Anxiety disorders, particularly panic disorder; major depressive disorder; and somatization disorder, have also been implicated as possible initiating factors for IBS.

      d. Learned aberrant illness behavior where patients may tend to express emotional conflict as a GI complaint, usually abdominal pain, may also be a contributing disease state. The clinician evaluating patients with IBS, particularly those with refractory symptoms, should investigate for unresolved psychological issues, including the possibility of sexual or physical abuse.

G. Pathophysiology

  1. IBD

      a. **UC.** Physiologic changes in UC begin with edema followed by loss of fine vascular pattern and increased mucosal friability. Ulceration, exudates and pseudopolyps may also be present. With longer disease history, the colon may begin to become featureless and tubular in nature. UC tends to occur in a **contiguous** manner.

      b. **CD.** Inflammation and subsequent injury of tissue known as cryptitis leads to crypt abscess and subsequently focal aphthoid ulceration. The inflammatory process can progress with influx and proliferation of macrophages and other inflammatory cells. Transmural inflammation may lead to lymphedema and bowel wall thickening. This thickening can lead to fibrosis. Affected areas are usually sharply demarcated from normal adjacent tissue and give rise to the **skip lesion** appearance of CD.

  2. IBS

      a. Abnormalities in intestinal motility in IBS appear to be related to underlying muscle dysfunction as well as hyperactive response to initiating factors such as food or parasympathomimetic drugs.

      b. Abnormal increases in frequency and amplitude of contractions can lead to functional constipation while diminished motor function of the underlying musculature can lead to diarrhea.

      c. Hypersensitivity to normal amounts of intraluminal distention exists, as does a heightened perception of pain in the presence of normal quantity and quality of intestinal gas.

      d. The pain of IBS may be caused by abnormally strong contraction of the intestinal smooth muscle or by increased sensitivity of the intestine to distention.

    e. Hypersensitivity to the hormones gastrin and cholecystokinin may also be present. However, hormonal fluctuations have not correlated with clinical symptoms.

    f. The caloric density of food intake may increase the magnitude and frequency of myoelectrical activity and gastric motility. Fat ingestion may cause a delayed peak of motor activity, which can be exaggerated in IBS.

    g. The first few days of menstruation can lead to transiently elevated prostaglandin E_2, resulting in increased pain and diarrhea.

H. Clinical presentation

  1. UC. Most patients will present with symptoms related to altered stool frequency, bowel sensation, and abdominal pain.

    a. Most UC cases begin as mild disease and worsens as the disease course progresses.

    b. UC usually follows a chronic intermittent course.

    c. Quiescent periods tend to be long with acute attacks interspersed.

    d. Attacks or flares can last weeks to months.

    e. Some patients suffer from continuous disease.

    f. Severe UC can result in **toxic megacolon**, a life-threatening condition.

    g. Elderly patients can rarely present with constipation secondary to rectal spasm.

    h. Typical presenting symptoms of UC are as follows:

      (1) Increased stool frequency

      (2) Hematochezia

      (3) Tenesmus

      (4) Lower left quadrant pain

      (5) Nausea, vomiting, and weight loss (usually only in severe disease)

    i. Extraintestinal manifestations of UC

      (1) Arthralgias

      (2) Ankylosing spondylitis

      (3) Pyoderma gangrenosum, erythema nodosum

      (4) Aphthous ulcers

      (5) Iritis and uveitis

  2. CD. Many patients present with acute symptoms mimicking appendicitis or intestinal obstruction. CD can be exacerbated by infections, smoking, and NSAID use. While not well correlated in controlled trials, stress is often implicated by patients and family members as a contributing factor.

    a. A significant number of patients have a history of perianal disease, especially fissures and fistulas, which are sometimes the most prominent or even initial complaint.

    b. Extraintestinal manifestations can be more prominent than GI symptoms in pediatric patients.

    c. Typical presenting symptoms of CD are as follows:

      (1) Abdominal pain

      (2) Diarrhea

      (3) Weight loss

      (4) Fever

    d. Extraintestinal manifestations of CD

      (1) Arthralgias

      (2) Acute peripheral arthritis

      (3) Ankylosing spondylitis, peripheral arthritis

      (4) Erythema nodosum, pyoderma gangrenosum, Sweet syndrome

      (5) Iridocyclitis, uveitis, and episcleritis

  3. IBS

    a. IBS symptoms are frequent in patients with active disease.

    b. Symptoms may be classified with either the new **Rome III criteria** or may still be classified with the **Rome II criteria**, which center around bowel movement and abdominal pain. The clinical symptoms are the same regardless of how they are classified.

      (1) Abdominal pain has been characterized as crampy, localized to the lower left abdomen with variable intensity. Patient presentation is highly variable with regard to intensity, location, and duration of pain. Some women will have exacerbations coinciding with menstrual periods.

(2) Alteration of bowel habits is the second major identifying symptom of IBS. They include diarrhea, constipation, mixed, and alternating diarrhea and constipation.

(3) IBS can also present with bloating, gas, belching, heartburn, reflux disease, achalasia, early feeling of fullness on eating and nausea, painful menstruation, sexual dysfunction, and frequent or urgent urination.

c. IBS tends to wax and wane over the long term with patients having acute bouts of disease interspersed with periods of no disease. While total prevalence numbers remain relatively constant, studies of defined patient populations at various periods show the same number of active patients, but the individual patients may be different.

I. Clinical evaluation

1. IBD differences in typical clinical presentation between UC and CD are summarized in *Table 45-1*.

a. UC

(1) Patient symptoms are usually the first signs of disease. Diarrhea, bleeding, tenesmus, mucus in the stool, and pain are the most common.

(2) The severity of symptoms correlates with disease severity.

(3) Acute disease can be associated with increased C-reactive protein, platelet count, erythrocyte sedimentation rate (ESR), and a decrease in hemoglobin.

(4) Serum albumin can fall quickly in severe disease.

(5) Sigmoidoscopy can be useful for assessing disease severity and extent before therapy. Care must be used in severe disease as risk of perforation is increased.

b. UC disease classification according to extent (distal versus extensive) and severity is of use in determining therapy.

(1) Mild UC has been defined as less than four stools per day with or without blood, normal ESR.

(2) Moderate UC has been defined as more than four stools per day but minimal signs of toxicity (fever, tachycardia, anemia, or elevated ESR).

(3) Severe UC has been defined as more than six bloody stools per day, evidence of toxicity as demonstrated by fever, tachycardia, anemia, or elevated ESR (elevated ESR is not always present, even in the most severe UC).

Table 45-1	DIFFERENCES OF UC AND CD	
	UC	**CD**
Abdominal pain	Infrequent	Frequent
Bloody diarrhea	Frequent	Occasional
Perianal involvement	Rare	Frequent
Perianal fistula	Rare	Frequent
Rectovaginal fistula	Rare	Common
Fever	Occasional	Frequent
Weight loss	Occasional	Frequent
Palpable mass	Rare	Common
Intra-abdominal abscess	Rare	Common
Bowel obstruction	Rare	Common
Antibiotic response	Rare	Frequent
Skip lesions	Rare	Frequent
Contiguous disease	Frequent	Infrequent
Effect of smoking	Often improves UC	Often worsens CD
Serologic markers		
ASCA+	15%	65%
p-ANCA+	70%	20%

ASCA, anti-*Saccharomyces cerevisiae* antibody; *p-ANCA,* perinuclear antineutrophil cytoplasmic antibody; *UC,* ulcerative colitis; *CD,* Crohn disease.

    (4) Fulminate UC has been defined as more than 10 bowel movements, continuous bleeding, toxicity, abdominal tenderness and distension, need for blood transfusion, and colonic dilation (toxic megacolon).

    (5) In addition to classifying UC as mild to fulminate, it is useful to ascertain the impact the disease is having on patient activity with a global assessment approach including extraintestinal manifestations, (ocular, oral, joint, skin, moods), general health (laboratory evaluation for anemia, liver function tests), quality of life (impairment at work or school, interpersonal relationships).

c. CD

    (1) CD patients may present with elevated ESR; C-reactive protein; and, in more severe disease with hypoalbuminemia, anemia, and leukocytosis.

    (2) CD can occur throughout the bowel and site of disease affects disease course and treatment choices.

    (3) Ileocolitis is the most common form of CD. It has been characterized by right lower quadrant pain, diarrhea, and can mimic acute appendicitis. Pain can be colicky and usually precedes defecation and is relieved by defecation.

    (4) Jejunoileitis. Extensive inflammation can lead to loss of absorptive surfaces with resultant malabsorption and steatorrhea. This malabsorptive state can lead to dietary deficiency, hypoalbuminemia, electrolyte imbalances, coagulopathy, and increased risk of bone fractures.

    (5) Colitis patients tend to present with low grade fever, diarrhea, vomiting, and epigastric pain.

    (6) Perianal CD patients may present with incontinence, stricture, anorectal fistula, and perirectal abscess.

d. CD classification based on severity and location is useful for determining therapy.

    (1) Mild-to-moderate disease has been used to define CD in patients who are ambulatory, able to take food orally, no symptoms of dehydration, no signs of toxicity (high fever, rigors, prostration), no abdominal tenderness or painful mass, no obstruction, or weight loss > 10%.

    (2) Moderate-to-severe disease describes patients who have failed to respond to therapy for mild to moderate disease or patients with more prominent symptoms of fever, significant weight loss, abdominal pain or tenderness, intermittent nausea or vomiting (without obstruction), or anemia.

    (3) Severe to fulminant disease describes patients with persisting symptoms despite therapy with steroids as outpatients, or patients with high fever, persistent vomiting, obstruction, rebound tenderness, cachexia, or evidence of abscess.

    (4) Remission refers to patients who have responded to acute medical therapy or who are postsurgical intervention without gross evidence of residual CD. Patients who require steroids to maintain control of CD are considered **steroid dependant** and are not considered to be in remission.

    (5) CD disease location is often classified as being ileocolic, small bowel, colonic, or anorectal. The **Vienna classification** of disease location and type of CD is also often used. CD type is recognized to change with regard to type and location during disease course.

        (a) Terminal ileum disease is CD in less than one-third of small bowel with or without spillover into the cecum.

        (b) Colon CD is colonic involvement anywhere from the cecum to the rectum without small bowel or upper gastrointestinal disease.

        (c) Ileocolon is CD of the terminal ileum and any location between the ascending colon and rectum.

        (d) Upper GI CD is disease in any location proximal to the terminal ileum, with or without involvement distal to the terminal ileum.

        (e) Type of disease is described as **inflammatory**, **stricturing**, **or penetrating**.

    (6) The **Crohn Disease Activity Index**, or **CDAI**, is a validated measurement tool used to assess clinical improvement. The CDAI is a complete scoring system of subjective aspects

and objective observations. It is not normally used in clinical practice but is extensively used in clinical research. Crohn disease severity, as defined by the CDAI, breaks down into the following stratifications:

    (a) A score of 150 or less is considered clinical remission.

    (b) A score of more than 150 up to 450 is considered mild to moderate disease.

    (c) A score of over 450 is considered severe disease.

2. IBS

    a. Diagnosis of IBS commonly includes identifying positive symptoms by medical history. This can be guided by older **Rome II criteria** or the recently published **Rome III criteria**. Physical exam is also done to exclude non-IBS disease (abdominal mass, palpable liver, etc.) as the majority of IBS patients do not have these physical abnormalities. Both patient history and physical exam are also needed to exclude IBD and microscopic and eosinophilic colitis, which can present in similarly to IBS.

    b. Rome II diagnostic criteria for IBS

        (1) At least 12 weeks, which need not be consecutive, in the preceding 12 months of abdominal discomfort or pain that has two of three features:

            (a) Pain relieved by defecation; and/or

            (b) pain onset associated with a change in frequency of stool; and/or

            (c) pain onset associated with a change in form (appearance) of stool.

        (2) Symptoms that cumulatively support the diagnosis of IBS:

            (a) Abnormal stool frequency (for research purposes, "abnormal" may be defined as greater than three bowel movements per day and less than three bowel movements per week);

            (b) abnormal stool form (lumpy/hard or loose/watery stool);

            (c) abnormal stool passage (straining, urgency, or feeling of incomplete evacuation);

            (d) passage of mucus; and

            (e) bloating or feeling of abdominal distension. The diagnosis of a functional bowel disorder (IBS) always presumes the absence of a structural or biochemical explanation for the symptoms.

    c. Rome III diagnostic criteria for IBS

        (1) Recurrent abdominal pain or discomfort at least 3 days per month in the last 3 months associated with two or more of the following:

            (a) Improvement with defecation

            (b) Onset associated with a change in a frequency of stool

            (c) Onset associated with a change in form (appearance) of stool

        (2) Criteria fulfilled for the last 3 months with symptoms onset at least 6 months prior to diagnosis.

        (3) Discomfort means an uncomfortable sensation not described as pain.

        (4) In pathophysiology, research, and clinical trials, a pain/discomfort frequency of at least 2 days a week during screening evaluation for subject eligibility

    d. Routine blood testing is normal in most suspected IBS patients and helps rule out other possible diagnoses.

    e. Sigmoidoscopy and colonoscopy are done to visualize the bowel when clinically appropriate to exclude other possible diagnoses.

J. Treatment objectives

  1. IBD

    a. Induce remission with control of acute inflammatory flare.

    b. Maintain remission as long as possible.

    d. Normalize bowel function when possible.

    e. Maintain nutritional status.

    b. Improve quality of life (QOL).

  2. IBS

    a. Alleviate discomfort.

    b. Normalize bowel habits.

    c. Minimize negative impact on patient QOL.

II. THERAPY

A. Overview of **agents used in IBD**

1. **Aminosalicylates** are generally considered to be effective therapy of UC, but are of little to no benefit for CD. The commercially available agents all deliver the active mesalamine or 5-aminosalicyclic acid (5-ASA) moiety. The oldest agent sulfasalazine (Azulfidine®) contains a 5-ASA molecule bound to sulfapyridine. This bond is cleaved by intestinal flora to release the active compound 5-ASA. Newer agents (enteric-coated mesalamine, olsalazine, balsalazide) have been developed to allow dosing without the sulfapyridine moiety, which has been implicated in many of the common adverse events and intolerances to sulfasalazine. Sulfasalazine is considered by many to be the first choice due to longer history of use, more convincing clinical trial data, and lower cost. Disadvantages of sulfasalazine are increased incidence of adverse events. Topical 5-ASA has been added to oral 5-ASA with improved response and time to response.

a. **Mechanism of action.** The effectiveness of 5-ASA can be attributed to its anti-inflammatory properties. Through varied mechanisms including blockade of the inflammatory mediators interleukin-1 and tumor necrosis factor-alpha (TNF-α) as well as modulation of peroxisome proliferator activated receptor-γ (PPAR-γ) colonic inflammation is reduced. Though 5-ASA differs from salicylic acid by the addition of an amino group, 5-ASA drugs retain some variable effects on prostaglandin and prostacyclin synthesis that may be beneficial in IBD as well.

b. **Administration and dosage.** There are currently several 5-ASA derivatives available (*Table 45-2*). Dosages in UC are based on disease location, severity, and overall patient condition. Enteric-coated or sustained-release products should not be crushed or chewed.

Table 45-2   AMINOSALICYLATES

Drug	Trade	Strength	Dosing (max)	Formulation	Delivery Site
Oral					
Sulfasalazine	Azulfidine®	500 mg tab	1000 mg t.i.d. (6 g/day)	Prodrug Sulfapyridine: **5-ASA**	Colon
	Azulfidine EN-tabs®	500 mg tab	1000 mg t.i.d. (6 g/day)	Prodrug Sulfapyridine: **5-ASA** enteric coated	Colon
Balsalazide	Colazal®	750 mg cap	2250 mg t.i.d. (6.75 m/day)	Prodrug 4-aminobenzoyl-β-alanine: **5-ASA**	Colon
Olsalazine	Dipentum®	250 mg cap	500 mg b.i.d. (3 gm/day)	Prodrug **5-ASA: 5-ASA**	Colon
Delayed-release					
Mesalamine	Asacol® Asacol HD®	400 mg tab 800 mg tab	800 mg t.i.d. (4.8 g/day)	Eudragit S pH-sensitive coating	Distal ileum, colon
Mesalamine	Apriso®	375 mg cap	1500 mg q.d.	Enteric coat, polymer matrix	Colon
Mesalamine	Lialda®	1200 mg tab	2400 mg q.d. (4.8 g/day)	Multimatrix system	Colon
Sustained-release					
Mesalamine	Pentasa®	250 mg cap 500 mg cap	1000 mg q.i.d.	Ethylcellulose granules	Stomach, colon
Topical					
Mesalamine	Rowasa®	4 gm/60 mL susp		Suspension for rectal administration	Rectum, splenic flexure
Mesalamine	Canasa®	500 mg sup 1000 mg sup		Suppository	Rectum

5-ASA, 5-aminosalicylic acid.

  c. **Precautions and adverse effects**

   (1) **Sulfasalazine:** The most common adverse events are fever, dizziness, headache, itching, rash, photosensitivity, GI upset, nausea, vomiting, diarrhea, reversible oligospermia and less commonly, Stevens–Johnson syndrome, Lyell syndrome, granulocytopenia, leucopenia, thrombocytopenia, aplastic anemia, hemolytic anemia, and hepatitis. Intolerance of the sulfapyridine moiety of sulfasalazine is common and is implicated in many adverse events associated with sulfasalazine. Sulfasalazine can interfere with the absorption of folic acid, thus it is advisable for such patients to take folic acid supplements.

   (2) **Mesalamine, olsalazine, balsalazide:** The most common adverse events are diarrhea, headache, abdominal pain, cramps, flatulence, and less commonly skin rash. Rarely more serious side effects such as hepatotoxicity or acute or chronic renal injury have been reported.

  d. **Significant interactions.** The aminosalicylates may increase risk of toxicity and leukopenia when given in combination with mercaptopurine by decreasing mercaptopurine clearance. 5-ASA drugs have also been associated rarely with exacerbation of IBD. Concomitant use of antacids or acid lowering agents may affect release characteristics of some of the formulations.

 2. **Steroids.** Steroids are useful for patients refractory to 5-ASA or patients with severe symptoms requiring rapid control.

  a. **Systemic corticosteroids** are effective treatment for acute UC and CD. Use as maintenance therapy for IBD is normally avoided as the risk of systemic adverse effects outweighs limited benefit. **Steroid dependency**, when a patient is unable to be tapered completely off of steroids, does occur and should not be confused with maintenance.

  b. **Topical and nonsystemic steroids** in the form of enemas, suppositories, and ileal release formulations have been effective in treating IBD. The rectally delivered topical formulations of steroids are of particular use in left-sided disease. Budesonide (Entocort®) is an oral steroid delivered in a controlled release formulation which acts in a topical manner owing to very high first-pass metabolism by the liver. Budesonide has been shown to be effective in acute IBD when the targeted release formulation is able to reach the site of disease.

  c. **Mechanism of action.** The glucocorticoid and mineralocorticoid effects of the steroids used in IBD are wide ranging. The anti-inflammatory effects are likely due to glucocorticoid suppression of proinflammatory cytokines.

  d. **Precautions and adverse effects.** Therapy with oral and intravenous (IV) corticosteroids produce systemic effects, can impact multiple organ systems, and should be closely monitored for adverse events.

   (1) Adverse effects of steroids in IBD therapy are related to dose and length of dosing and are the typical glucocorticoid and mineralocorticoid effects seen with exogenous steroid therapy.

   (2) Systemic steroids are more prone to inducing adverse effects. Topical delivery and targeted delivery of low bioavailability steroids have been developed to reduce the risk of adverse effects.

   (3) Minimizing duration of therapy as well as tapering patients off of systemic steroids are also methods of minimizing adverse effects as much as possible.

 3. **Azathioprine (Imuran®) and 6-mercaptopurine (6-MP; Purinthol®)** are effective at inducing and maintaining remission in IBD. Response is slow and may take months to be fully effective. 6-MP or azathioprine are effective for patients who do not respond to oral steroids but are not so acutely ill so as to require IV therapy.

  a. **Mechanism of action.** Azathioprine and 6-MP are purine antimetabolite drugs, which interfere with DNA synthesis, with disruption of the inflammatory response seen in IBD.

  b. **Dosing and administration.** There is known metabolic differences with regard to **thiopurine methyltransferase (TPMT)** activity, which can lead to toxicity in patients with low or absent TPMT activity. Testing for TPMT phenotype can be useful in initial dosing. Consensus on the value of monitoring of metabolite levels during therapy has not been reached. Monitoring complete blood counts 4 weeks after starting therapy and then monthly during

therapy should be done to monitor for toxicity. Azathioprine is 50% 6-MP by molecular weight and equivalent doses are twice that of 6-MP.

c. **Precautions and adverse effects.** Bone marrow suppression. Both azathioprine and 6-MP have been implicated in increased risk for Epstein Barr related non-Hodgkin lymphoma. This risk appears to be small but is serious.

4. **Methotrexate (Rheumatrex®)** given parenterally is an effective treatment for inducing remission, maintaining remission, and steroid sparing in CD. Parenteral methotrexate is also effective for maintaining remission in CD. Methotrexate appears to be of little use in UC.

   a. **Mechanism of action.** Methotrexate is a folate analog and inhibits dihydrofolate reductase with multiple modes of anti-inflammatory effects.

   b. **Dosing and administration.** A 25 mg intramuscular (IM) weekly has been shown to be effective for inducing remission of active CD, 15 mg IM weekly has been shown to be effective at maintaining remission and as steroid sparing therapy. Oral methotrexate 12.5 to 25.0 mg per week does not appear to be as effective as parenteral dosing.

   c. **Precautions and adverse effects.** Methotrexate is a known teratogen and should be avoided or used with extreme caution in patients of child-bearing age (female and male) and only when all other therapies have been ineffective and the patients understand the risks involved. The doses used in CD are lower than those used in oncology and the adverse events seen are generally less severe. The most common risks are rash, nausea, pneumonitis or *Mycoplasma* pneumonia, and elevated serum transaminases. CD patients treated with methotrexate appear to be at low risk for hepatic toxicity. It is important to avoid alcohol consumption as it can increase the risk of hepatic toxicity in CD patients on methotrexate.

5. **Cyclosporine (Neoral®) and tacrolimus (Prograf®)** are potent immunosuppressive agents that have been shown to be effective in IBD. They are typically used for severe acute IBD as there is little data to support efficacy in mild disease to offset the potential toxicities of these agents.

   a. **Mechanism of action.** Both cyclosporine and tacrolimus are calcineurin inhibitors and are potent inhibitors of T-lymphocyte activation.

   b. **Dosing and administration.** Before therapy is initiated, patients should be screened for potential drug interactions, normal renal function, cholesterol levels, blood pressure, and electrolyte status to help avoid toxicity.

      (1) Cyclosporine is started IV at 2 to 4 mg/kg/day and titrated to levels of 250 to 350 ng/mL.

      (2) Tacrolimus is initiated at 0.1 to 0.15 mg/kg/day by month and titrated to trough concentrations of 10 to 15 ng/mL.

      (3) Patients who respond are discharged on oral drug. Oral cyclosporine is dosed at twice the IV dose divided b.i.d.

      (4) Azathioprine or 6-MP is added as soon as possible and oral systemic steroids are often given concomitantly also for 3 to 4 months.

      (5) Cyclosporine and tacrolimus are normally stopped at 3 to 4 months. A steroid taper is also started at 3 to 4 months and should be done over 4 to 8 weeks.

   c. **Precautions and adverse events.** Cyclosporine and tacrolimus both have short- and long-term adverse events that can be serious. The most commonly seen in IBD patients are paresthesias, hypertension, hypertrichosis, renal insufficiency, infection, gingival hyperplasia and seizure. Patients should be closely monitored for effects on blood pressure, electrolytes, renal function, and cholesterol. Hypocholesterolemia and hypomagnesemia increase the risk of seizure.

   d. **Significant interactions.** Cyclosporine and tacrolimus are substrates of cytochrome P450-3A4 and P-glycoprotein enzymes. Significant and harmful alterations in cyclosporine and tacrolimus blood concentrations have been described as a result of concomitant administration of drugs that are also substrates or modifiers of these enzymes. Care must be used in concomitant dosing of these agents with other drugs that can adversely affect renal function such as NSAID. Cyclosporine has been noted to increase methotrexate and methotrexate metabolite concentrations.

6. **Biologics.** Infliximab (Remicade®)**,** adalimumab (Humira®), and certolizumab pegol (Cimzia®) are currently the main biologic therapies used in IBD (*Table 45-3*). These agents are **anti-tumor necrosis factor-alpha (anti-TNF-α)** antibodies. All three agents are indicated for inducing and

Table 45-3   BIOLOGIC THERAPIES OF NOTE IN IBD

Drug	Trade	Mechanism	Efficacy in IBD
Adalimumab	Humira®	Fully human IgG$_1$ monoclonal antibody to TNF	Effective in CD
Infliximab	Remicade®	Chimeric (mouse/human) IgG$_1$ monoclonal antibody to TNF	Effective therapy in CD and UC. Primary biologic therapy used in IBD.
Certolizumab pegol	Cimzia®	Humanized pegylated Fab fragment TNF antibody	Approved for CD in April 2008. Effective in CD.
Natalizumab	Tysabri®	Humanized IgG$_4$ monoclonal antibody to α4-integrin that selectively inhibits leukocyte adhesion	Removed from U.S. market in 2005 secondary to association with progressive multifocal leukoencephalopathy (PML). Natalizumab was made available again in 2006 via a restrictive company administered access program. Place in therapy is yet to be fully elucidated and the benefit must clearly outweigh the risks.
Etanercept	Enbrel®	is a p75-soluble TNF receptor FC fusion protein that binds TNF	Not of benefit.

CD, Crohn's disease; *IgG*, immunoglobulin G; *TNF*, tumor necrosis factor; *UC*, ulcerative colitis; *FC*, (please spellout); *IBD*, inflammatory bowel disease.

maintaining clinical remission of CD. Infliximab is also indicated in treating enterocutaneous and enterovaginal fistulae and maintaining remission of fistulizing CD. Infliximab is also effective in acute and quiescent UC. A fourth biologic agent, natalizumab (Tysabri®), is a humanized monoclonal antibody directed at α4-integrin on the surface of white blood cells. It is approved for use in CD as well as multiple sclerosis.

  a. **Anti-TNF-α therapy mechanism of action.** Tumor necrosis factor-alpha (TNF-α) is a cytokine involved in multiple proinflammatory and proliferative pathways in IBD. These agents bind TNF-α preventing its binding to cell surface receptors and subsequently decreases inflammatory cytokines and increasing apoptosis of activated T lymphocytes and monocytes. Infliximab is a chimeric mouse–human monoclonal anti-TNF-α antibody. It is made up of human IgG$_1$ constant regions, human κ light chains, and monoclonal murine regions that recognize TNF-α. Adalimumab is a recombinant human IgG$_1$ monoclonal antibody with human heavy and light chain variable regions and human IgG$_1$:k constant regions. Certolizumab pegol is a humanized Fab fragment of an anti-TNF-α monoclonal antibody that has been pegylated to increase half-life of the antibody.

  b. **Dosing and administration**

  (1) Infliximab initial dosing is 5 mg/kg in a three-dose induction regimen of day 0, 2, and 6 weeks. Duration of therapeutic effect appears to be 8 to 10 weeks and dosing every 8 weeks has been advocated following a response to initial dosing. Formation of antibodies to infliximab (ATI) during infliximab use has been described. The presence of ATI may increase infusion-related adverse reactions, delayed-type hypersensitivity reactions, and may decrease the effectiveness of infliximab therapy. Strategies to reduce ATI formation include a regularly scheduled maintenance regimen of infliximab (versus episodic treatment) and the use of concomitant administration of azathioprine, 6-MP, or methotrexate. These immunosuppressant drugs have not been shown to improve clinical disease control when given concomitantly with infliximab.

  (2) Adalimumab is initially dosed 160 mg on day 1 as four 40 mg injections on the first day or two 40 mg injections per day for 2 days, followed by 80 mg 2 weeks later or at day 15. Two weeks later (day 29) maintenance therapy is begun at 40 mg every other week. Formation of anti-adalimumab antibodies has been reported in 3% of patients.

  (3) Certolizumab pegol is given as a 400 mg injection on day 0 and weeks 2 and 4. If response occurs, dosing may continue with 400 mg every 4 weeks. Formation of anti-certolizumab antibodies has been reported in 8% of certolizumab treated patients.

    c. Precautions and adverse effects. Anti-TNF-α therapies share similar precautions and adverse effect profiles.

      (1) Acute infusion or injection-related reactions can occur. Risk of such a reaction is greater (22%) with infliximab use than with adalimumab (1%) or certolizumab (rare). Severe anaphylactic reactions are rare.

      (2) Delayed hypersensitivity reactions including myalgias, rash, fever, arthralgias, pruritus, edema, urticaria, sore throat, and dysphagia occur 3 to 12 days after infliximab infusion and are much less common at approximately 2% of patients receiving maintenance infliximab therapy.

      (3) All anti-TNF-α antibodies carry **black box warnings** for increased risk of opportunistic infections (e.g., tuberculosis, invasive fungal infections such as histoplasmosis, blastomycosis, or pneumocystis, viral infections such as hepatitis B). Use of concomitant immunosuppressive agents may increase risk of infection. Patients should be tested for tuberculosis prior to use of these agents and their use should be avoided or discontinued in the case of active infections.

      (4) All anti-TNF-α antibodies carry **black box warnings** for increased risk of lymphomas and other malignancies. Use of concomitant immunosuppressive agents may increase this risk.

    d. Anti-α4 integrin antibody mechanism of action. Binding of the α4-integrin protein by natalizumab effectively interrupts normal leukocyte trafficking across endothelial layers to areas of inflammation.

    e. Anti-α4 integrin antibody dosing. Natalizumab is given as an intravenous infusion of 300 mg every month. Availability of natalizumab is restricted. It is available only through entities registered with the TOUCH prescribing program.

    f. Anti-α4 integrin antibody adverse effects. Common adverse effects include headache, arthralgia, and fatigue. More serious adverse effects include increased risk of opportunistic infections and acute hypersensitivity reactions. Prescribing information for natalizumab also carries a **black box warning** for increased risk of progressive multifocal leukoencephalopathy or PML. There is no treatment for PML. Patients are to be monitored closely for symptoms so that natalizumab may be discontinued. Typical symptoms associated with PML include progressive weakness on one side of the body or clumsiness of limbs, and changes in vision, thinking, memory, and orientation. These lead to confusion and personality changes. PML symptoms progress over days to weeks. Concomitant use of other immunosuppressive agents such as azathioprine, 6-MP, methotrexate, and so forth is not advised due to increased risk of serious adverse effects.

7. Antibiotics. No specific infectious agent has been identified as the single causative factor in either UC or CD.

    a. Use of broad-spectrum antibiotics in IBD is limited to empiric treatment of fulminant disease or in patients with toxic megacolon where short-term use of these antibiotics can be justified due to the increased risk of perforation or bacteremia.

    b. Use of select antibiotics such as metronidazole (Flagyl®), ciprofloxacin (Cipro®), clofazimine (Lamprene®), or rifaximin (Xifaxan®) with the specific goal of remission of acute IBD is controversial. While few clinical trials and a recent meta-analysis indicate potential benefit, design limitations temper the strength of those findings.

    c. Metronidazole and ciprofloxacin are used widely by convention as maintenance therapy in CD but controlled trial results do not conclusively support this use.

    d. Metronidazole has been useful in patients suffering from **pouchitis** postbowel resection surgery that involves formation of a pouch.

    e. Metronidazole and ciprofloxacin both would appear to be of some benefit in treating patients with fistulous IBD.

8. Probiotic and prebiotic therapy. Probiotic involves using exogenously administered bacteria such as *Lactobacillus GG*, *Saccharomyces boulardii* and nonpathogenic *Escherichia coli* among others in an attempt to normalize the intestinal environment flora and thus decrease inflammatory triggers. Controlled trials of probiotic therapy in IBD have yet to clearly define clinical utility. There is little evidence to support their use in acute IBD. However, recent meta-analyses suggest potential benefit of probiotics, when combined with conventional therapies, for mainte-

nance of UC but not CD. Remission maintenance of pouchitis with VSL #3, a probiotic preparation of four lactobacilli strains and three *Bifidobacterium* and one strain of *Streptococcus* was shown to be of benefit. Prebiotics are orally administered substances like nondigested carbohydrates with the goal of facilitating growth of commensal gut flora to displace possible antigenic microorganisms. There is little data to support prebiotics at this time.

9. **Antispasmodics and antidiarrheals.** Cramping and abdominal IBS-like symptoms are often noted in IBD patients. Use of symptomatic therapies is not well defined in the published IBD literature as most research is aimed at the inflammatory process. Once active inflammation is controlled or ruled out, anticholinergic antispasmodics are frequently used judiciously to treat cramping or discomfort in IBD inflammation, as are antidiarrheals in mild or quiescent disease. All of these agents should be avoided in serious disease as they may further impair intestinal motility and increase risk of toxic megacolon.

10. **Antidepressants and anxiolytics** have been used when specific patient symptoms warrant their use as adjuvant therapy. Universal use of such therapies is not supported by available evidence.

11. **Analgesics.** There is rarely a need for pain control in UC as the disease is limited to the mucosa of the colon with limited involvement of tissue containing pain receptors. Narcotics are to be avoided in UC therapy outside of perioperative situations as they increase the risk of toxic megacolon and can mask signs of perforation. NSAID medications should be avoided as they have been implicated in inducing IBD flares.

12. **Surgery.** Surgical resection of the colon is considered curative in UC. Surgical resection of bowel in CD is not curative as the disease will often recur at the resection site as well as other sites.
    a. Surgery in UC is most commonly indicated for disease refractory to medical therapy, inability to wean the patient off of high corticosteroid dosages, serious drug side effects or intolerance, and occurrence of premalignant or malignant changes in the colon.
    b. Approximately one-third of UC patients eventually undergo colectomy. Patients with extensive disease (pancolitis) undergo colectomy more than patients with less extensive (distal) disease and also usually require colectomy sooner than patients with less extensive disease.
    c. **UC surgery** can be divided into two types, those that preserve continence and those which do not and subsequently require appliances to collect the fecal material.
       (1) **Proctocolectomy with permanent ileostomy** is the oldest procedure and involves formation of an abdominal stoma connected to the ileum. An external appliance is used to collect fecal material.
       (2) **Proctocolectomy with continent ileostomy** involves creation of a pouch inside the abdomen using the terminal ileum. A small leakproof opening is created in the abdomen wall, and the pouch is periodically drained.
       (3) **Colectomy with ileorectal anastomosis** involves removing diseased large bowel and reattaching the remaining small intestine to a preserved rectum. While bowel movements via the rectum are preserved patients are at risk of relapse as the rectum is often involved in UC.
       (4) **Ileal pouch anal anastomosis (IPAA)** is the most common surgical procedures done for IBD. The large bowel and rectum are removed, with preservation of the anal sphincter. A tubular pouch is formed from the small intestine and attached to the preserved sphincters, which allows bowel movements without external bags or appliances. A temporary ileostomy is often used during healing.
    d. **CD surgery** while not curative, is required in a very high percentage of patients. Surgical intervention can be limited to specific areas of diseased bowel or total ileostomy or colectomy. Surgery is most commonly indicated in CD refractory to medical therapy, medication side effects, or steroid dependency.
       (1) Small bowel resection is preferred in most patients with ileal or ileocolic CD. Primary anastomosis versus ileostomy (permanent or temporary) choice is based on patient status and CD severity.
       (2) Large bowel CD may require varying degrees of resection secondary to the typical CD disease course involving "skip lesions." Primary anastomosis of preserved bowel may be preferred for patient QOL reasons but has been linked to earlier reoccurrence of CD.
       (3) Colectomy with ileorectal anastomosis, while increasing risk of earlier CD recurrence, is useful in young patients where ileostomy may adversely affect QOL.

(4) Proctocolectomy and ileostomy is preferred in patients with extensive perianal disease or pancolitis CD.

(5) Strictureplasty can also be useful in stricturing CD.

e. Pouchitis is the most common complication of continent ileostomy and IPAA. It has been characterized as a syndrome including acute nonspecific inflammation of the reservoir pouch formed during surgery with unknown etiology.

(1) Idiopathic pouchitis must be differentiated from inflammation of the pouch due to anastomotic stricture and infection due to known pathogens.

(2) Broad-spectrum antibiotics have been the main medical therapy used for pouchitis. Metronidazole and ciprofloxacin have both been effective for acute pouchitis and have also been used as maintenance therapy.

(3) Probiotic therapy with VSL#3 has been of benefit also.

(4) Pharmacologic therapy used in IBD has been shown to be of mixed efficacy in pouchitis. Surgical revision may be required in chronic pouchitis unresponsive to medical therapy.

13. Other therapy

a. Nutritional issues are important to consider in IBD. While conclusive evidence does not exist showing particular foods cause IBD, special attention to diet in patients with IBD can be beneficial.

(1) Nutritional and hydration deficiencies can occur secondary to a poorly functioning GI tract and the chronic nature of IBD.

(2) Foods that are known to exacerbate an individual patient's IBD should be avoided and a well-balanced diet should be encouraged to maintain nutritional status. Restrictive diets are not normally required. Simply limiting offending foods while encouraging a balanced diet is usually sufficient to maintain nutritional status.

(3) Parenteral feeding is seldom used long term in IBD but can be useful to improve or maintain nutritional status in severely ill patients.

b. Emotional factors. Due to the chronic nature of IBD, many sufferers have need for emotional support during the course of their disease. While IBD does not appear to be directly affected by emotional state, the QOL experienced by these sufferers can be noticeably affected in a negative manner. Many will benefit greatly by support groups, continued open dialogue with their health care providers, and in less common cases, formal counseling or pharmacologic therapy may be needed.

B. Drug therapy of UC

1. Classifying UC based on anatomic disease extent is useful for determining medical therapy. Distal disease (below the splenic flexure) can be treated effectively with topical therapy. Extensive disease (extending proximal to the splenic flexure) normally requires systemic therapy. Severity of acute UC is also useful in determining medical therapy. Severity is generally defined as mild, moderate, severe, or fulminate.

2. Management of acute mild–moderate UC distal disease. Patients with mild to moderate distal UC respond well to oral or topical 5-ASA or topical steroids for inducing remission (control of inflammation).

a. Topical 5-ASA is superior to topical steroids or oral 5-ASA agents.

b. Topical 5-ASA plus oral 5-ASA is superior to either alone.

c. Topical 5-ASA may be effective in patients refractory to oral 5-ASA or topical steroids.

d. Oral plus topical therapy consisting of oral mesalamine 2.4 g/day in divided doses plus mesalamine 4 g/day enema may induce remission of UC more quickly.

e. Infrequently oral corticosteroids may be needed in patient's refractory to topical/oral 5-ASA agents and topical steroids in maximal doses (see oral corticosteroids under "Mild to moderate extensive or relapsing disease").

f. Therapy is largely determined by patient preference to therapy modality.

g. Oral 5-ASA doses for inducing remission in mild to moderate distal disease

(1) Sulfasalazine 3 to 6 g/day in three divided doses

(2) Mesalamine 2.4 to 4.8 g/day in divided doses where interval varies by product from one to four doses per day (see *Table 45-2*)

(3) Balsalazide 6.75 g/day in three divided doses

(4) Olsalazine 1.0 to 3 g/day in two divided doses

h. The oral 5-ASA drugs tend to work in 2 to 4 weeks and are effective in a high percentage of patients.

i. Clinical efficacy of the different oral agents is very similar. Choice is then influenced by adverse effect profile and cost.

j. Recent evidence suggests there is minimal benefit of 5-ASA oral doses greater than 2.4 g/day.

k. Oral nonsystemic corticosteroids. Budesonide is an oral corticosteroid that offers lower systemic exposure compared to prednisone secondary to high first-pass metabolism. Budesonide has been effective in UC treatment but is limited to UC when the ileal release formulation can reach the location of disease.

l. Topical therapy generally induces remission more quickly than oral therapy. Suppositories reach disease approximately 10 cm proximally. Foam products reach disease approximately 15 to 20 cm proximally. Enemas reach disease approximately to the splenic flexure (52 to 56 cm).

m. Topical 5-ASA for inducing and maintaining remission of UC
  (1) Mesalamine suppositories 1 gm/day in one or two divided doses (proctitis)
  (2) Mesalamine enemas 4 g/day (distal colitis proximally to the splenic flexure)

n. Topical corticosteroids for inducing remission of UC
  (1) Hydrocortisone enema 100 mg/day
  (2) Hydrocortisone foam, 10% one application (80 mg) q.d. to b.i.d.

3. Maintenance of distal disease
  a. 5-ASA preparation dosages for maintaining remission of distal disease.
    (1) Balsalazide 3 to 6 g/day
    (2) Mesalamine 2.4 g/day
    (3) Mesalamine suppository 500 mg q.d. or b.i.d.
    (4) Mesalamine enema 2 to 4 g daily, every other day or every third day
    (5) Olsalazine 1 g/day
    (6) Sulfasalazine 2 g/day
    (7) Mesalamine 1.6 g orally per day plus 4 g enemas twice weekly is also effective.
  b. Dose reduction from amounts used during induction of remission of acute disease may be explored. Data suggest total daily doses of 5-ASA < 2 g are less effective than total daily doses ≥ 2 g.
  c. Corticosteroids, topical or oral, are not effective in maintaining UC remission and should not be used.

4. Acute **mild to moderate extensive or relapsing disease**
  a. Oral 5-ASA
    (1) Sulfasalazine 4 to 6 g/day in four divided doses. Doses less than 2 g/day appear to offer little benefit.
    (2) Newer 5-ASA preparations are generally considered to be equal to sulfasalazine with regard to efficacy, likely superior with regard to adverse events and tolerance but are more expensive. The dosages used are a minimum of 2.4 g/day of active 5-ASA moiety titrated up to a maximum of 4.8 g/day.
  b. Oral steroids
    (1) Prednisone 40 to 60 mg/day (modest efficacy gain with 60 mg compared to 40 mg) until significant clinical effect is seen followed by a dose taper of 5 to 10 mg weekly until a daily dose of 20 mg is reached. Tapering generally continues from here at 2.5 mg per week until the patient is weaned from oral steroids.
    (2) Higher doses for longer periods increase risk of corticosteroid-associated complications.
    (3) IBD patients receiving corticosteroids for greater than 3 months should be carefully monitored for presence of corticosteroid-associated complications such as hypertension, dyslipidemia, loss of bone mineral density, etc.
    (4) For patients on long-term corticosteroid, calcium supplementation at 1 to 1.5 g/day and vitamin D supplementation at 800 mg/day should also be considered.

5. Maintenance of mild to moderate extensive or relapsing disease. Sulfasalazine is as effective as equivalent doses of newer 5-ASA agents and is less costly in long-term therapy. Systemic corticosteroids as a rule are not accepted as long-term therapy options secondary to adverse events and

questionable therapeutic effect. 6-MP or azathioprine has been useful as steroid sparing agents and as long-term options to wean patients off of corticosteroids.

   a. Oral 5-ASA therapy
   - **(1)** Balsalazide 3 to 6 g/day
   - **(2)** Mesalamine 2.4 to 4.8 g/day
   - **(3)** Olsalazine 1 g/day
   - **(4)** Sulfasalazine 2 to 4 g/day

   b. Immune modulators
   - **(1)** 6-MP 0.5 to 1.5 mg/kg once daily
   - **(2)** Azathioprine 0.5 to 2.5 mg/kg once daily

   Doses are titrated to keep white blood cell count > 4000 cells/mm^3. Patients with thiopurine methyltransferase (TPMT) deficiency are at excess risk of bone marrow suppression given usual doses of 6-MP or azathioprine. Allopurinol inhibits metabolism of 6-MP and azathioprine. 6-MP and azathioprine doses should be reduced with concomitant use of allopurinol.

6. **Acute moderate-to-severe disease.** UC patients with moderate-to-severe disease may or may not require hospitalization. Infection with enteric pathogens should be ruled out. 5-ASA should be stopped in the acute setting to avoid intolerance issues and the rare instances of 5-ASA exacerbating colitis.

   a. Corticosteroids. Intensive IV steroid therapy is indicated for patients with severe disease who are hospitalized. Doses with prednisolone 40 to 60 mg, hydrocortisone 300 mg, or methylprednisolone 32 to 48 mg/day in divided doses or as continuous infusion have been shown to be effective. Higher doses are of limited benefit and increase risk of steroid toxicity. Patients with moderate-to-severe disease but not requiring hospitalization may be treated with oral doses on an outpatient basis.

   b. Biologics
   - **(1)** Infliximab was more effective compared to placebo (reduced need for colectomy) for ambulatory patients refractory to or intolerant of systemic steroids.
   - **(2)** Infliximab 5 mg/kg at 0, 2, and 6 weeks
       - **(a)** ATI formation may be limited with concomitant dosing of azathioprine or 6-MP.
   - **(3)** Other marketed anti-TNF-α antibodies may be effective in this role, however, studies are lacking.

   c. Immune suppressants. Failure to demonstrate significant improvement within 7 to 10 days is an indication for surgical resection or alternate IV therapy such as with cyclosporine.
   - **(1)** IV cyclosporine at 2 to 4 mg/kg/day and titrated to blood levels between 200 and 400 ng/mL has been effective in a high percentage of patients who do not respond to maximal parenteral steroids.
       - **(a)** Oral cyclosporine at twice the daily IV dose is given in divided doses (b.i.d.) with oral steroids once clinical remission is reached with IV cyclosporine. However, cyclosporine is not generally recommended for long-term maintenance due to significant adverse effects.
       - **(b)** Sulfamethoxazole/trimethoprim (Bactrim®) should be added as prophylaxis against *Pneumocystis* pneumonia for patients on cyclosporine.
       - **(c)** Relapse on 5-ASA therapy alone after remission induced with cyclosporine is frequent, and azathioprine or 6-MP can be beneficial when added for maintenance.

   d. Topical steroids may provide benefit in patients with rectal urgency or tenesmus.

   e. Empiric broad-spectrum antibiotics are of little use for the treatment of moderate-to-severe UC; however, their use is justified in the case of proven bacterial infection.

   f. When possible patients should be maintained on oral feedings with modified diet to reduce abdominal discomfort, diarrhea and bowel frequency. Total parenteral nutrition is used when oral feeds are not tolerated and can be especially useful in patients with severe nutritional depletion.

   g. In patients with signs of toxicity narcotics, antidiarrheals, and anticholinergics should be avoided as they can increase the risk of worsening colonic dilation and perforation.

7. **Maintenance moderate-to-severe disease**
   a. Oral 5-ASA agents–as with mild to moderate disease, these agents have been shown effective in preventing disease relapse.

b. **Immune suppressants**
(1) Azathioprine or 6-MP–are modestly effective for patients who have failed or are intolerant of 5-ASA agents. Because of the delay in onset of effect, optimal results are seen when these agents are started during induction of remission and continued into maintenance the phase.

c. **Biologics**
(1) Infliximab–in early studies, continued injections of infliximab at 5 mg/kg/dose at 8-week intervals have been shown effective in remission maintenance compared to placebo for patients intolerant of 5-ASA, corticosteroids, or azathioprine or 6-MP. Use of infliximab and other anti-TNF-α antibodies in this capacity continues to be investigated.

8. **Fulminant disease.** Patients with fulminant colitis or toxic megacolon are treated as severe and generally kept on bowel rest. Broad-spectrum antibiotics are often used empirically due to high risk of perforation. Any worsening of disease as evidenced by radiologic, clinical, or laboratory changes while on medical therapy is an indication for immediate colectomy.

C. **Drug therapy of CD** is dependant upon disease location, disease severity and complications if present. Patient's response to initial therapy should be evident within weeks. Once control of acute disease occurs, consideration of maintenance therapy is warranted. Failure of continued symptomatic improvement or worsening of symptoms by 3 to 4 months necessitates reconsideration of chosen therapy.

1. **Mild to moderate acute CD**
a. **Budesonide orally**
(1) Targeted delivery to ileum, works well in ileal or proximal colonic disease.
(2) 9 mg/day for 8 to 16 weeks
(3) Tapered 3 mg per week over 2 to 4 weeks

b. Oral broad-spectrum antibiotics have been used with limited controlled clinical data to support such use.
(1) Possibly more beneficial in patients with primary colonic involvement.
(2) Metronidazole 750 to 1500 mg/day
(3) Ciprofloxacin 1000 mg/day

c. If these therapies fail, the presentation can be considered refractory and treated as moderate to severe.

d. Historically, 5-ASA products have been used to induce and/or maintain remission of mild to moderate CD. More recent analyses question the benefit of 5-ASA for these patients.

2. **Moderate-to-severe acute CD**
a. **Systemic steroids**
(1) Oral prednisone 40 to 60 mg/day until symptom improvement (weeks) then initiate a tapering regimen.
(2) Hospitalization for IV corticosteroids may also be considered.

b. **Methotrexate**
(1) Methotrexate 25 mg/week IM, taper to 15 mg/week IM after 16 weeks
(2) Methotrexate use trended toward improvement in remission of disease. Best results seen when given with corticosteroids
(3) Methotrexate is an antimetabolite drug and will take considerable time to reach full effect, up to 3 to 4 months may be required.
(4) Concomitant use of oral 5-ASA or antibiotics with immunosuppressant therapy has not been shown to be of benefit in controlled trials.

c. **Anti-TNF-α therapy**
(1) For patients refractory to or do not tolerate systemic steroids and immunosuppressant therapy.
(2) In perianal fistulizing CD, infliximab is effective therapy.
(3) Infliximab 5 mg/kg at 0, 2, and 6 weeks
(a) Relapse at 1 year is high if infliximab stopped.
(b) ATI formation is common in noncontinuous therapy and may decrease efficacy of future courses of therapy. ATI formation may be limited with concomitant dosing of azathioprine, 6-MP, or methotrexate.
(c) Concomitant therapy with 5-ASA, steroids, or antibiotics is of little added benefit.
(4) Adalimumab 160 mg day 1 and 80 mg day 15 followed by 40 mg every other week starting on day 29.
(5) Certolizumab pegol is given as a 400 mg injection on day 0 and weeks 2 and 4.

      d. Other biologics
        (1) Natalizumab has been shown successful in inducing remission of CD. Due to the risk of PML, its use is limited to cases failing all other therapies.

  3. Severe or fulminant acute CD includes active disease of a severe nature, toxic enteritis or colitis, megacolon, small bowel obstruction, and abdominal abscess. The patients often require hospitalization secondary to severity of disease and risk of complications.
      a. Typical therapy may include
        (1) IV fluids and bowel rest (parenteral nutrition);
        (2) IV antibiotics with metronidazole, aminoglycosides, and broad-spectrum penicillin or third-generation cephalosporins empirically for possible abscess or infections; and
        (3) IV corticosteroids.
      b. Anti-TNF-α therapy with infliximab may be useful for patients who do not respond to IV corticosteroids.
      c. Natalizumab may be useful for patients not responding to anti-TNF-α therapy.
      d. Surgical intervention may be required in patients who do not respond to IV corticosteroids and infliximab.

  4. Maintenance of CD remission strategies have been of questionable efficacy. Historically, long-term treatment with 5-ASA agents and broad-spectrum antibiotics has been advocated with a lack of convincing controlled clinical data to support these measures. Newer evidence-based approaches may change therapy strategies.
      a. Immunosuppressants
        (1) Azathioprine, 6-MP, or methotrexate have been used in maintenance but adverse events must be weighed carefully, especially in patients with mild disease.
        (2) Azathioprine, 6-MP, and methotrexate may be useful in patients unable to wean off systemic steroids.
      b. Biologics. Anti-TNF-α therapy is effective at inducing and maintaining clinical remission in Crohn disease.
        (1) Infliximab 5 mg/kg infused every 8 weeks
        (2) Adalimumab 40 mg injection every 2 weeks
        (3) Certolizumab pegol 400 mg injection monthly
        (4) Concomitant azathioprine, 6-MP, or methotrexate can also reduce ATI formation with infliximab injections and may increase efficacy.
        (5) Skillful monitoring is essential to successful use of these agents. All anti-TNF-α antibodies have black box warnings regarding infection and malignancies.
        (6) Efficacy of natalizumab for maintenance of CD remission appears to be similar to anti-TNF-α antibodies, however, due to risk of PML, its use is limited to those who have failed treatment with the former.
      c. Systemic steroids are normally avoided in long-term therapy secondary to systemic toxicity and lack of convincing data to support their use.
      d. Antibiotics have not been shown in controlled clinical trials to be effective in maintaining medically induced remission.

D. IBS
  1. The treatment of IBS is based on the nature and severity of symptoms, correlation of symptoms to food intake and/or defecation, degree of functional impairment, and the presence of psychosocial or psychiatric disorders. Treatment is highly personalized, symptom based, and can be generalized as follows.
  2. Mild IBS is the most common disease presentation and is normally associated with few psychosocial problems.
      a. Education about disease and support can be of great benefit.
      b. Diet and lifestyle changes
        (1) Specific foods are usually not as important as the size of meals with smaller meals being preferable. Care should be used and restrictive diets should be avoided.
        (2) Decrease fatty foods, gas-producing foods
        (3) Decrease alcohol
        (4) Decrease caffeine
        (5) Avoid dairy in lactose intolerant patients

(6) Excess fiber can also increase IBS symptoms

(7) Prepare strategies to handle stress

3. **Moderate IBS** symptoms, which are normally intermittent but can be disabling at times. These patients suffer from more symptom-related distress. Patient symptoms historically are also associated with more gut reactivity (worse with eating and better with defecation). Consider management strategies described earlier with drug therapy targeted predominant symptoms.

   a. Pain. Consider use of anticholinergics or antispasmodics. These agents have shown benefit in relief of IBS-related abdominal pain. Caution of anticholinergic adverse effects (dry mouth, dizziness, visual changes, etc.) is advised with their use.

    (1) Dicyclomine (Bentyl®) 10 to 20 mg PO 2 to 4 times daily

    (2) Hyoscyamine (Anaspaz®, Levsin®) 0.125 to 0.25 mg PO q.i.d. (max 1.5 mg/day)

    (3) Clidinium + chlordiazepoxide 2.5/5.0 mg (Librax®) 1 to 2 tabs PO a.c. & h.s.

    (4) Hyoscyamine + scopalamine, atropine, phenobarbital (Donnatal®) 1 to 2 tabs q6 to 8 hrs

    (5) Low dose tricyclic antidepressants (TCAs) can be effective for pain control. The dosages typically used are below effective doses used for clinical depression. TCA also may slow GI transit time and be useful in diarrhea predominate patient cases.

     (a) Amitriptyline initially 10 mg at bedtime.

     (b) Desipramine initially 10 mg at bedtime.

   b. Diarrhea. Consider use of conventional antidiarrheals prior to trial of other agents.

    (1) Diphenoxylate + atropine (Lomotil®) 0.025/2.5 mg two tabs PO q.i.d., maximum of eight tabs per day

    (2) Loperamide (Imodium®) 4 mg followed by 2 mg after each unformed bowel movement up to a maximum of 16 mg/day

    (3) Alosetron (Lotronex®) is a 5-HT$_3$-antagonist and is available in the United States through a manufacturer-sponsored access program and is only to be used for diarrhea-predominant IBS in women.

     (a) Access to prescribe is restricted in the United States to a manufacturer administered program.

     (b) Severe IBS dose in **women only** is 0.5 to 1.0 mg PO b.i.d.

    (4) Rifaximin (Xifaxan®) is a nonabsorbable antibiotic indicated for traveler's diarrhea and hepatic encephalopathy. Rifaximin has been shown in phase III trials to be more effective than placebo in relieving symptoms in non–IBS-C patients.

     (a) Rifaximin 550 mg t.i.d. for 2 weeks

   c. Constipation

    (1) Fiber and bulking agents. This class is often recommended as the first line for treating IBS-C. Various agents have shown some minimal benefit. Fiber supplementation can worsen bloating symptoms, so low-starting doses with upward titration are recommended.

     (a) Psyllium 2.5 to 30.0 gm daily in divided doses.

     (b) Methylcellulose 0.5 to 3.0 gm daily in divided doses

     (c) Calcium polycarbophil 1.25 to 5.0 gm daily in divided doses

    (2) Laxatives. Laxatives are an alternative first-line therapy for IBS-C. Their efficacy is less well-studied than bulking agents. Concerns with their use include worsening bloating or cramps and electrolyte loss. Osmotic laxatives are favored over stimulant laxatives.

     (a) Polyethylene glycol (PEG, Miralax® and others) is an osmotic laxative solution that increases the amount of water in the intestinal tract to stimulate bowel movements. Potassium, sodium, and other minerals are also included to replace electrolytes that are passed from the body in the stool. Polyethylene glycol is available by prescription or OTC and is generally considered to be very safe for constipation and may be of benefit to IBS-C patients. Caution should be used in severely constipated patients or patients who may have an obstruction.

     (b) Senna alkaloids or bisacodyl may be tried to relieve constipation where PEG was unsuccessful.

    (3) Chloride channel activators. Activation causes for movement of chloride, sodium, and water into the lumen of the intestine.

     (a) Lubiprostone (Amitiza) is a chloride channel activator indicated for idiopathic constipation. It is approved for use in women with IBS-C at a dose of 8 mcg twice daily.

4. **Severe IBS** is a very small proportion of the entire IBS population. GI complaints can be refractory and of continuous nature. Psychosocial and psychiatric comorbidities are common.

   a. Antidepressants, including the selective serotonin reuptake inhibitors, are often useful in severe IBS patients due to the increase in psychosocial components to patient presentation.

   b. Anxiolytic drugs, including diazepam, are occasionally used for IBS when patients are experiencing acute anxiety that is worsening their symptoms. In light of the risk of dependency, these drugs should only be taken for short periods.

   c. **5-HT$_4$-receptor agonist**

   Tegaserod (Zelnorm®) is a 5-HT$_4$-agonist for constipation predominant IBS in women and is only available in the United States for emergency situations via petition of the FDA. Use of this drug is so restricted due to its cardiovascular risk profile.

   (1) IBS-C dosing (**women only**) is 6 mg PO b.i.d. before meals.

III. COMPLICATIONS

A. **IBD**

1. **UC and CD** have many similar presenting features as well as commonalities in complications. The majority of UC patients will have a chronic relapsing disease course. Length of disease is related to risk of colectomy and colorectal cancer. Mortality is similar to rates in non-UC populations. CD may impose a slight increase in mortality with long-standing disease.

2. **Musculoskeletal** manifestations of IBD are the most common extraintestinal manifestations of the disease. Arthralgias in the absence of arthritis signs are the most common complaint. Five percent to 20% of IBD patients experience peripheral arthritis pain that is self-limiting and coincides with IBD disease flares and resolves with successful treatment of IBD. Occurrence is nearly equal between males and females. Ankylosing spondylitis in IBD is less common at approximately 5% and is equal in UC and CD. Males are affected more than females and course is usually not related to the course of IBD.

3. **CD fistulas and abscess.** Long-standing inflammation may progress into penetrating disease, abscess formation, and fistula formation. These penetrating communications can be from diseased organ to neighboring organ, peritoneum, and to the skin. Fistula types include perianal fistula, enteroenteric, enterocutaneous, enterovesical, and rectovaginal.

4. **Hemorrhage** in the colon is relatively rare in UC but is serious. Acute hemorrhage accounts for a significant percentage of urgent colectomies in UC. Severe bleeding tends to occur early in the course of disease. Hemorrhage in CD is extremely rare.

5. **Strictures** or narrowing of the colon or rectum occurs in a small percentage of the UC population. Importantly nearly one-third of strictures may be related to malignancy and as such strictures should be carefully evaluated.

6. **Toxic megacolon** is a serious complication mainly seen in UC but occasionally in CD as well. It occurs when the inflammatory process causes the colon to dilate with subsequent bowel wall thinning. This results in the bowel becoming more fragile. The major risk is bowel perforation. Bowel dilation that does not respond to therapy within 72 hrs is considered an indication for surgical resection.

7. **Cancer.** Overall UC patients are at higher risk of developing **colorectal cancer** compared to patients without IBD. The risk to individuals is variable and is related to duration and extent of UC as well as patient specific history risk factors. Risk is greatest in patients with pancolitis of long-standing duration. Colorectal cancer is also a risk in CD patients, especially if it is CD involving the colon. Risk of cancer of the small intestine has been noted in CD also.

8. **Primary sclerosing cholangitis** (PSC) is the most common hepatobiliary complication of IBD. PSC affects men more than woman. PSC is more common in UC than CD.

9. **Osteoporosis** as evidenced by increased fractures and diminished bone density has been shown in CD patients.

10. **Quality of life impact.** While most IBD patients are able to lead nearly normal lives, many do suffer significantly during active flares of disease. The chronic nature of disease also has a negative impact on patient QOL.

B. **IBS.** Although IBS has been shown to produce substantial physical discomfort and emotional distress, most patients with IBS do not develop serious or long-term health complications. Most patients also learn to control their individual symptoms with diet and lifestyle modification or medical therapy as needed.

Study Questions

For questions 1–2: A 35-year-old male presents to his physician with a primary complaint of abdominal pain and frequent bowel movements over the past few weeks. Upon examination and routine laboratory testing, he is found to have a low-grade fever and an elevated erythrocyte sedimentation rate. Further questioning reveals he is having four to five loose bowel movements each day. The patient is a past smoker. Stool antigen tests are negative for known GI pathogens. Physical examination and colonoscopy reveal contiguous inflammation of the rectum and most of the descending colon. The physician diagnosis is mild to moderate ulcerative colitis.

1. Which therapy would be the most effective for inducing remission?

    (A) Topical corticosteroids
    (B) Topical 5-ASA
    (C) Oral budesonide
    (D) Topical 5-ASA plus oral 5-ASA

2. Once remission is achieved, which therapy is most appropriate for maintenance?

    (A) Sulfasalazine 2 g/day
    (B) Balsalazide 2 g/day
    (C) Olsalazine 4 g/day
    (D) Topical corticosteroids

For questions 3–4: An 18-year-old female with newly diagnosed mild Crohn's disease within the ileum returns to her physician for her first follow-up since starting treatment. Three weeks ago she started oral sulfasalazine 4 g/day and azathioprine 25 mg/day. Since starting these meds, her symptoms have not improved. If anything, they are slightly worse. She is ambulatory with no signs of toxicity (blood per rectum, pain, anemia, etc.) or weight loss.

3. What would be a logical next step in therapy?

    (A) Stop azathioprine and begin IV corticosteroids
    (B) Stop sulfasalazine and begin oral budesonide 9 mg/day
    (C) Stop azathioprine and begin prednisone 40 mg orally per day
    (D) Stop sulfasalazine and begin Lialda® 4.8 gm/day

4. Remission of her first episode was successful. Unfortunately, fulldose azathioprine alone has been unable to maintain effective control of her CD. Over the past 18 months she has had numerous flare-ups. They resolve with each burst of acute therapy but return with azathioprine alone. Her symptoms are increasing (moderate disease) and her schooling is beginning to suffer. What would be a logical next step in therapy?

    (A) Change azathioprine to 6-MP at 1.5 mg/kg/day
    (B) Add metronidazole 750 mg/day
    (C) Surgical resection with ostomy
    (D) Add infliximab 5 mg/kg every 8 weeks

For question 5: A man with diarrhea-predominant IBS is experiencing interruption of his work as a truck driver secondary to frequent bouts of diarrhea. He states his symptoms are worse after eating, especially fried foods. His physician discusses the possible benefit of avoiding fat in his diet. The patient agrees to try but also asks for something to uses in emergencies.

5. What would be the most appropriate therapy to use?

    (A) Alosetron 0.5 mg b.i.d.
    (B) Hyoscyamine 0.15 mg PO p.r.n.
    (C) Loperamide 4 mg then 2 mg p.r.n. up to 16 mg/day
    (D) Fluoxetine 40 mg q.d.

6. Which of the following is the most appropriate initial therapy for a woman with severe constipation-predominant IBS?

    (A) A restrictive bland diet
    (B) Tegaserod 6 mg PO b.i.d.
    (C) Alosetron 1 mg PO b.i.d.
    (D) Psyllium 2.5 g in divided doses

7. Ulcerative colitis and Crohn's disease present in very similar ways. There are several clinical differences between the diseases that can help differentiate them. Which of the following clinical features is more common in Crohn's disease than in ulcerative colitis?

(A) abnormal bowel movements
(B) slow onset of disease
(C) joint pain
(D) fistula formation

8. Patient prescribed anti-TNF-α agents such as adalimumab should be monitored carefully for which of the following adverse events according to black box warnings included in prescribing information?

(A) Increased risk of severe loss of bone density
(B) Increased risk of critically high potassium levels
(C) Increased risk of toxic megacolon
(D) Increased risk of pneumonia

Answers and Explanations

1. The answer is D *[see II.B.2]*.
Topical 5-ASA therapy plus oral 5-ASA therapy has been shown to be superior to either alone or topical steroids at inducing remission in mild to moderate UC. Budesonide ileal release will not likely reach the site of disease in this patient as he has left-sided disease.

2. The correct answer is A *[see II.B.3]*.
The correct doses for balsalazide would be 3 to 6 g/day and for olsalazine would be 1 g/day. Topical steroids have no place in maintenance of UC.

3. The correct answer is B *[see II.C.1]*.
This patient has not responded to 5-ASA therapy for inducing remission of her mild disease. Additionally, recent evidence indicates there are more effective treatments than 5-ASA for acute CD. As such, Lialda would not be an effective treatment either. The patient is not showing signs of severe disease or toxicity and as such neither IV or oral therapy with systemic corticosteroids is warranted at this time. Azathioprine is an appropriate agent for CD maintenance but not acute CD as it may take several months to induce remission. Continuing azathioprine is a reasonable approach to transition the patient to maintenance therapy. Budesonide is an ileal release therapy and her disease is mainly confined to the ileum. Budesonide has been shown to be effective in acute mild and moderate CD. Budesonide will help control the acute disease and then it can be withdrawn as she transitions to the maintenance phase.

4. The correct answer is D *[see II.C.4]*.
Azathioprine is a first-line therapy for maintenance of CD but in this case is not working. Switching to 6-MP will not be effective as the two agents are mechanistically similar. Broad-spectrum antibiotics such as metronidazole are unlikely to be of any benefit in this patient and should not be used. In addition, long-term adverse effects associated with metronidazole may not be tolerable. While likely to be beneficial, surgery with a permanent ostomy would also be severely limiting to a young patient due to social

and QOL concerns. Infliximab has been shown to be effective for refractory CD and maintenance of CD.

5. The correct answer is C *[see II.D.3]*.
This patient is male and as such alosetron is not an appropriate option for him. Hyoscyamine is an effective antispasmodic but will likely do little for his diarrhea. The patient makes no complaint of serious impact on his life and does not show signs of severe disease. Full dose antidepressant fluoxetine dosing is not warranted. Loperamide can be of use in managing mild to moderate symptoms of IBS.

6. The correct answer is B *[see II.D.4]*.
Tegaserod has been withdrawn from the market and is available only for emergency use upon appeal to the FDA. Alosetron is effective in women with diarrhea-predominant IBS. Restrictive diets are not normally of benefit. Increasing dietary fiber is a reasonable choice prior to prescription therapy. Dietary fiber may increase bloating symptoms with IBS-C, these can be lessened by starting with smaller doses and titrating to effect. If fiber fails, laxative or lubiprostone (Amitiza) could be tested.

7. The correct answer is D *[see Table 45.1]*.
While the overlap of clinical presentation of these two diseases is substantial, fistula formation is extremely rare in ulcerative colitis.

8. The correct answer is D *[see II.A.6.c]*.
Black box warnings for all of the anti-TNF-α therapies include increased risk of serious infections such as pneumonia or reactivation of tuberculosis or hepatitis and increased risk of malignancies such as lymphoma. Changes in potassium or bone density are not adverse effects commonly associated with anti-TNF-α therapies and are not included in black box warnings. Toxic megacolon is a complication usually associated with UC and also is not included in black box warnings with anti-TNF-α use.

46 Diabetes Mellitus

JENNIFER D. SMITH

I. INTRODUCTION

A. **Definition.** The American Diabetes Association (ADA) defines diabetes mellitus as a group of metabolic diseases characterized by inappropriate hyperglycemia resulting from defects in insulin secretion, insulin action, or both. Symptoms of acute hyperglycemia include polyuria, polydipsia, polyphagia, weight loss, blurred vision, fatigue, headache, and poor wound healing. Chronic hyperglycemia can lead to damage and potentially failure of various organs, including the eyes, heart, kidneys, blood vessels, and nerves.

B. **Classification.** There are four clinical classes of diabetes: type 1, type 2, gestational, and other specific types.

1. **Type 1.** Type 1 diabetes mellitus (T1DM) is typically characterized by an absolute insulin deficiency attributed to an autoimmune destruction of the β-cells of the islets of Langerhans. Affected individuals will have autoantibodies to glutamic acid decarboxylase, pancreatic islet β cells, and/ or insulin. T1DM may be diagnosed at any age, but is most likely to be diagnosed prior to the age of 30 years.

2. **Type 2.** Type 2 diabetes mellitus (T2DM) is the most common form of DM and is typically identified in individuals over the age of 30 years; however, it has become a more prominent diagnosis in adolescents of certain ethnic origins (e.g., Hispanic, African American). Those diagnosed with T2DM are typically overweight or obese, have a positive family history of diabetes, and/or exhibit signs of insulin resistance (e.g., truncal obesity, high triglycerides, low high-density lipoprotein cholesterol [HDL-C], acanthosis nigricans); autoantibodies found in T1DM are absent in T2DM.

3. **Gestational diabetes mellitus.** Gestational diabetes mellitus (GDM) is a condition in which women first exhibit levels of elevated plasma glucose during pregnancy. Women previously diagnosed with diabetes prior to pregnancy are excluded from this classification. After pregnancy, the diagnostic classification of GDM may be changed based on postpartum testing (*see III.B.2.b*).

4. **Other specific types.** Secondary diabetes occurs when the diagnosis of diabetes is a result of other disorders (e.g., Cushing syndrome, acromegaly, cystic fibrosis, Down syndrome, pancreatic disorders) or treatments (e.g., glucocorticoids, antipsychotics). **Monogenic DM** (formerly maturity-onset diabetes of the young) should be considered in children with an atypical presentation or response to therapy. Adults may present with **Latent Autoimmune Diabetes of the Adult (LADA)**, which is a slow destruction of the pancreatic β-cells similar to T2DM, but autoantibodies are present as in T1DM.

5. **Categories of increased risk for diabetes (prediabetes):** Individuals who have elevated blood glucose levels that do not meet diagnostic criteria for diabetes, but that are too high to be considered normal, are classified as having prediabetes. Prediabetes is a high-risk category for the future development of T2DM.

C. **Diabetes demographics and statistics**

1. In the United States, an estimated 8.3% of the population has DM and 35% of adults (age 20 years and older) have prediabetes.

2. Disparities exist in the diagnosis of diabetes across ethnic groups and minority populations, with Native Americans and Alaska Natives having the highest rates of diagnosed diabetes (16.1%), followed by blacks (12.6%) and Hispanics (11.8%).

3. T2DM accounts for more than 90% of the cases of diabetes.

II. PATHOPHYSIOLOGY OF THE DIABETIC STATE

A. **Normal glucose regulation** involves many factors including insulin, counterregulatory hormones, incretin hormones, and amylin. Changes to any of these factors may result in an imbalance in glucose levels.

1. **Insulin** regulates the metabolism of carbohydrate, protein, and fat as follows:
   a. Promotes the cellular uptake of plasma glucose
   b. Stimulates conversion of glucose into energy storage molecules (e.g., glycogen, fat) in the liver, muscles, and adipose cells
   c. Facilitates cellular uptake of amino acids and their incorporation into proteins
   d. Inhibits production of glucose from liver, muscle glycogen, or amino acids
   e. Decreases the breakdown of fatty acids to ketone bodies

2. **Counterregulatory hormones** in diabetes are hormones that work against insulin. Thus, where insulin lowers blood glucose, counterregulatory hormones **increase blood glucose**. The counterregulatory hormones include:
   a. Glucagon
   b. Growth hormone
   c. Catecholamines (epinephrine and norepinephrine)
   d. Cortisol

3. **Incretin hormones:** Ingested glucose promotes a more rapid release of insulin from the pancreas than when glucose is given by intravenous injection. This occurs because the incretin hormones, gastric inhibitory peptide (**GIP**) and glucagon-like peptide-1 (**GLP-1**) are secreted by the intestines in response to glucose ingestion, before the glucose is absorbed. Postprandial secretion of GLP-1 is diminished in DM, whereas GIP secretion is normal or increased. Actions of GLP-1 include:
   a. Increases glucose-dependent insulin secretion
   b. Inhibits inappropriate glucagon secretion
   c. Increases β-cell growth/replication
   d. Slows gastric emptying
   e. Suppresses appetite

4. **Amylin** is a hormone that is **cosecreted with insulin** from the pancreatic β-cells. Thus, in individuals with T1DM, little to no amylin is produced, whereas in T2DM, amylin is produced, but in an insufficient quantity. Amylin lowers postprandial blood glucose levels by the following actions:
   a. Prolongs gastric emptying time
   b. Decreases postprandial glucagon secretion
   c. Suppresses appetite

B. **Development of diabetes**

1. **T1DM.** Genetic predisposition, environmental factors, and autoimmunity have been proposed as causes that lead to progressive β-cell dysfunction and eventually, overt diabetes mellitus. T1DM is the result of immune-mediated destruction of the β-cells and is characterized by the abrupt onset of clinical signs and symptoms.
   a. **Genetics.** Human leukocyte antigens (HLAs) DQA and DQB appear to code for either disease susceptibility (DR3, DR4, HLA-DQA1*0301, and HLA-DQA1*0302) or resistance (DRB1*04008-DQB1*0302, DRB1*0411-DQB1*0302). Greater than 90% of Caucasians diagnosed with T1DM have HLA-DR3 and/or HLA-DR4 present, but 95% of these individuals have HLA-DQA1*0301 and HLA-DQA1*0302 present. However, in studies of identical twins, there is a 50% discordance rate, suggesting that other factors such as the environment (e.g., infectious agents, chemical agents, dietary agents) may be contributing factors to disease development. The risk of developing T1DM is increased in the offspring of individuals diagnosed with diabetes.
   b. **Environment.** Environmental triggers such as viral (e.g., rubella, Coxsackie B), chemical, or dietary (e.g., cow's milk) have been suspected in the development of T1DM.
   c. **Autoimmunity.** An autoimmune component, possibly triggered by an environmental factor, is involved in the development of T1DM. Anti-insulin or anti-β-cell antibodies are present in the blood of most individuals at the time of diagnosis of T1DM. Antibodies to glutamic acid decarboxylase (GAD) are found in the blood of approximately 70% of individuals diagnosed with T1DM. Thus, the presence of these antibodies may serve as an immunologic predictor of the future development of the disease.

2. **T2DM.** Genetic factors, a β-cell defect, and peripheral site defects have been implicated.
   a. **Genetics.** There is greater than a 90% concordance rate in identical twins if one has T2DM, suggesting that the development of T2DM is predominately dependent on genetics. The risk of offspring development of T2DM is at least 15%.
   b. A primary β-**cell dysfunction** has been postulated in the development of T2DM because at diagnosis, typically only about 50% of β-cells are functioning. The number of functioning β-cells continues to decline with duration of the disease.
   c. A **peripheral site defect** may also contribute to the expression of T2DM. Defects in postreceptor binding or a decreased number of insulin receptors can lead to hyperglycemia.
3. **Secondary diabetes** may arise from other disorders (e.g., Cushing syndrome, acromegaly, cystic fibrosis, Down syndrome, pancreatic disorders) or treatments (e.g., glucocorticoids, antipsychotics).

III. CLINICAL EVALUATION

A. **Physical findings** include the "polys" (e.g., polyuria, polydipsia, and polyphagia), weight loss, blurred vision, fatigue, headache, frequent vaginal infections, and poor wound healing. Because hyperglycemia typically exists for extended periods prior to the diagnosis of T2DM, these persons may also present with signs and symptoms of chronic complications from diabetes (*see section X*).

B. **Diagnostic testing** should be performed from **venipuncture** testing. Home blood glucose monitors and point-of-care (POC) A1c monitors are not sufficiently accurate for diagnostic purposes. A1c tests reflect the average blood glucose level over the preceding 2 to 3 months and correlate with an estimated average glucose (eAG = $28.7 \times A1C - 46.7$). **A1c testing for diagnostic purposes should not be done in individuals with abnormal red cell turnover** (e.g., pregnancy, recent blood loss or transfusion, some anemias). These individuals should only be diagnosed with glucose criteria. **Repeat testing**, preferably with the same method, must be performed **to confirm diagnosis**, unless there is unequivocal hyperglycemia (e.g., random blood glucose sample > 200 in a symptomatic individual, hyperglycemia crisis). Fasting is defined as no caloric intake for at least 8 hrs.
   1. **Diabetes in nonpregnant adults and children**
      a. **Fasting** blood glucose **≥ 126 mg/dL**
      b. **Random** (casual) blood glucose and symptoms of hyperglycemia: **≥ 200 mg/dL**
      c. **Oral glucose tolerance test** (OGTT) using oral glucose load equivalent to 75 g anhydrous glycerin dissolved in water: **> 200 mg/dL**
      d. **A1c ≥ 6.5%**
   2. **Gestational diabetes mellitus (GDM)** screening should occur **between weeks 24 to 28 gestation** if not previously diagnosed with overt diabetes. A fasting 75-g oral glucose tolerance test (OGTT) should be performed in the morning. Venipuncture should be measured at fasting and 1- and 2-hr post-oral glucose solution ingestion.
      a. Diagnosis of GDM based on OGTT: Fasting ≥ 92 mg/dL; 1 hr ≥ 180 mg/dL; 2 hrs ≥ 153 mg/dL.
      b. If diagnosed with GDM, screening for persistent diabetes should occur between 6 to 12 weeks postpartum and, if negative, at least every 3 years thereafter.
   3. **Prediabetes:** relatively high risk for the future development of diabetes
      a. **Impaired fasting glucose (IFG):** fasting blood glucose **100 to 125 mg/dL**
      b. **Impaired glucose tolerance (IGT):** OGTT results of **140 to 199 mg/dL**
      c. **A1c 5.7 to 6.4%**
   4. **Testing in asymptomatic individuals:**
      a. Adults who are overweight (BMI ≥ 25 kg/m²) or who have one or more risk factors for diabetes should be tested immediately and at least every 3 years thereafter if tests are negative. Risk factors for diabetes include:
         (1) Physical inactivity
         (2) First degree relative with diabetes
         (3) High-risk ethnicity (e.g., African American, Latino, Native American, Asian American, Pacific Islander)
         (4) Women who delivered a baby weighing ≥ 9 lb or were diagnosed with GDM
         (5) Hypertension (≥ 140/90 mm Hg or on therapy for hypertension)
         (6) HDL cholesterol level < 35 mg/dL and/or a triglyceride level > 250 mg/dL
         (7) Women with polycystic ovarian syndrome (PCOS)

      (8) Previous testing indicative of prediabetes
      (9) Clinical conditions associated with insulin resistance (e.g., severe obesity, acanthosis nigricans)
      (10) History of CVD

    b. Asymptomatic adults without risk factors should have screenings beginning at the age of 45 years.

    c. Testing for T2DM in the asymptomatic **pediatric population** should occur at the **age of 10 years or the onset of puberty** (whichever comes first) in children who are **overweight** (BMI > 85th percentile for age and sex; weight for height > 85th percentile; weight > 120% for height) and have **at least two risk factors** (e.g., family history of diabetes in first or second degree relative, race/ethnicity of African, Asian, or Native American or Latino, signs of insulin resistance, or maternal history of GDM during child's gestation). If negative, repeat testing should occur every 3 years.

IV. GLYCEMIC TREATMENT GOALS.
The two available techniques for monitoring glycemic control are patient self-monitoring blood glucose (SMBG) and A1c. Important measurements for SMBG include fasting plasma glucose (FPG) and 2-hr postprandial glucose (PPG). Guideline recommendations for the use of these two techniques are provided by the American Diabetes Association (ADA) and the American Association of Clinical Endocrinologists (AACE). The guideline recommendations differ slightly, with those of AACE being more stringent (*Table 46-1*). All glucose targets should be individualized, taking into account other disease states, age of person, duration of disease, and risk for hypoglycemia.

A. Outpatient glucose targets for nonpregnant adults:
    1. ADA: A1c < 7.0%; FPG 70 to 130 mg/dL; 1- to 2-hr PPG < 180 mg/dL
    2. AACE: A1c ≤ 6.5%; FPG < 110 mg/dL; 2-hr PPG < 140 mg/dL

B. Inpatient glucose targets for nonpregnant adults is specified by ADA and AACE as a glucose range of 140 to 180 mg/dL

C. Outpatient glucose targets for pregnant adults are the same for ADA and AACE guidelines. These goals should be implemented, only if they can be achieved safely.
    1. GDM: Preprandial ≤ 95 mg/dL; 1-hr PPG ≤ 140 mg/dL; 2-hr PPG ≤ 120 mg/dL
    2. Preexisting T1DM or T2DM: A1c ≤ 6.0%; pre-meal, bedtime, and overnight values between 60 to 99 mg/dL; peak PPG of 100 to 129 mg/dL; A1c < 6%

V. PHARMACOLOGIC TREATMENT OF DIABETES MELLITUS

A. Insulin and insulin analog (*Table 46-2*)
    1. Types of insulin
      a. Rapid-acting insulin. Lispro (Humalog), aspart (NovoLog), and glulisine (Apidra) insulins
      b. Short-acting insulin. Regular insulin (Humulin regular, Novolin regular)
      c. Intermediate-acting insulin. Isophane insulin suspension (neutral protamine Hagedorn; NPH) insulin
      d. Long-acting insulins. Glargine (Lantus) and detemir (Levemir) insulins.

| **Table 46-1** | GUIDELINE RECOMMENDATIONS FOR OUTPATIENT GLYCEMIC GOALS IN NONPREGNANT ADULTS[1,2] |

	American Diabetes Association (ADA)	**American Association of Clinical Endocrinologists (AACE)**
A1c goal	< 7.0%	≤ 6.5%
Fasting plasma glucose goal	70–130 mg/dL	< 110 mg/dL
Postprandial glucose goal	< 180 mg/dL	< 140 mg/dL

[1]American Diabetes Association. Standards of medical care in diabetes—2012. *Diabetes Care* 2012;35:s11–63.
[2]AACE Diabetes Care Plan Guidelines. *Endocrine Practice* 2011;17(Suppl 2):1–53.

Table 46-2 TYPES OF INSULIN—ONSET, PEAK, AND DURATION OF ACTION[a]

Agent	Onset (hr)	Peak (hr)	Effective Duration (hr)	Variability in Absorption and Duration
Rapid acting				
Lispro (Humalog)	< 0.5	0.5–1.5	3–4	Minimal
Aspart (NovoLog)	< 0.5	0.7–1.0	3–5	Minimal
Glulisine (Apidra)	< 0.5	0.5–1.5	3–5	Minimal
Short-acting				
Regular	0.5–1.0	2–4	5–8	Moderate
Intermediate-acting				
NPH	2–4	6–10	10–16	High
Long-acting				
Glargine (Lantus)	5	n/a	20–24	Minimal-to-moderate
Detemir (Levemir)	3–4	6–12	12–24	Minimal

[a]Approximate time action in nonpregnant adult, with normal renal function.
n/a, not applicable; *NPH*, neutral protamine Hagedorn.

    e. Premixed insulin products. Each mixture gives rapid- or short-acting insulin as a premeal bolus plus an intermediate-acting insulin to control later hyperglycemia or the subsequent meal.
        (1) 50/50 insulin: 50% protamine lispro insulin with 50% lispro insulin
        (2) 70/30 insulin: 70% insulin aspart protamine with 30% aspart insulin or 70% NPH with 30% regular insulin
        (3) 75/25 insulin: 75% protamine lispro insulin with 25% lispro insulin
    f. Extemporaneous mixtures. Two insulins mixed in one syringe, before administration.
        (1) Glargine and detemir should never be mixed in the same syringe with another insulin.
        (2) When rapid-acting insulins (e.g., lispro, aspart, glulisine) are mixed with another insulin, the preparation should be used immediately.
        (3) Extemporaneous mixtures which include regular-acting and intermediate-acting insulin are stable for 14 days refrigerated or 7 days at room temperature.
2. Chemical sources of commercial insulin available in the United States
    a. Biosynthetic human, **also called human insulin.** Produced by recombinant DNA techniques
    b. Insulin analog. Produced by chemical alteration of human insulin
3. Concentration of insulin products available in the United States
    a. U-100: a concentration of 100 units/mL
    b. U-500: a concentration of 500 units/mL
        (1) Recommended for individuals with marked insulin resistance, requiring greater than 200 units of U-100 insulin daily.
        (2) U-500, a highly concentrated insulin, is available by prescription only.
        (3) Currently U-500 syringes are not available in the United States. Patients should be taught to use the mL markings on a tuberculin or U-100 syringe to prevent dosing errors in units.
4. Indications. Insulin is required for glycemic management in individuals with T1DM and may be used in combination with oral agents (e.g., metformin) or amylin agonists (e.g., pramlintide) as necessary. Insulin may be an initial or adjunctive agent for individuals with T2DM and may be used in combination with oral agents, GLP-1 agonists (e.g., exenatide), or amylin agonists to achieve glycemic control.
5. Mechanism of action. Insulin exerts its effects in several ways, including the following:
        (1) Stimulates hepatic glycogen synthesis
        (2) Increased protein synthesis
        (3) Facilitates triglyceride synthesis and storage by adipocytes; inhibits lipolysis
        (4) Stimulates peripheral uptake of glucose
6. Initial dosage of insulin
    a. T1DM, **without concomitant infection or physiologic stress condition.** Insulin should be dosed based on weight and requires a calculation of the total daily dose (TDD). The total daily

dose for an adult with T1DM is estimated as 0.6 units/kg/day, which can then be applied to determine an initial starting dose of insulin.

   (1) 50/50 rule: 50% of the TDD is given as a basal (e.g., NPH, glargine, detemir) dose and the remaining 50% is given as the bolus (e.g., regular, lispro, aspart, glulisine) dose, divided between the meals. For example, if a person who weighs 120 lb is to start insulin, the estimated TDD would be approximately 32 units. Half of the TDD (16 units) would be initiated as the basal insulin and the remaining 16 units would be divided into an approximate bolus dose as follows:

   (a) Glargine or detemir as a basal with short- or rapid-acting insulin as bolus: 16 units once daily of basal insulin; 5 units t.i.d. of bolus insulin with meals.

   (b) NPH as a basal requires twice daily dosing in persons with T1DM. Also, when using NPH, the total bolus dose should be decreased by 20% and given twice daily to prevent hypoglycemia. Thus, the regimen for this example would be 8 units of NPH and 6 units of bolus, each given b.i.d.

   (2) Premixed insulin should be initiated as two-third of the TDD in the morning and the remaining one-third of the TDD in the evening, prior to meals. This means for the same example used earlier with a TDD of 32 units, the insulin regimen would be 21 units in the morning prior to breakfast and 11 units in the evening prior to the evening meal. It should be noted that this type of dosing is not preferred for the individual with T1DM because it cannot be easily adjusted for changes in diet, exercise, or health (e.g., sick days), nor does it allow the titration of one insulin type to target the specific phase of insulin release that is primarily contributing to the impaired glycemic control.

b. Type 2 DM

   (1) Basal insulin alone may be initiated as 10 units once daily in the average-sized individual or 0.1 to 0.2 units/kg/day in the overweight or obese individual. If administered in the evenings, the dose of insulin should be titrated as necessary to achieve fasting blood glucose levels in the target range. Bolus insulin can be added as needed based on pre- and post-meal blood glucose monitoring.

   (2) Premixed insulin should be initiated based on TDD of 0.2 units/kg/day, with two-thirds of the TDD given in the morning prior to breakfast and one-third of the TDD given in the evening prior to the last meal.

7. **Insulin adjustment algorithms** allow for the correction of an elevated blood glucose level or dosing for carbohydrate intake. Though useful for optimizing glycemic control, adjustment algorithms are not for everyone.

   a. Adjustment based on blood glucose level: Several variations exist in the dosing of correction insulin for elevated blood glucose. The rule of 1500 is typically used for dosing short-acting (e.g., Regular) insulin, while the rule of 1800 is used for dosing rapid-acting insulin. However, there are a myriad of algorithms used between 1500 and 2200. The higher the "rule" used, the lower the risk of inducing hypoglycemia.

   (1) The **rule of 1800** is used to determine the correction factor (i.e., how many mg/dL the blood glucose will decrease with the injection of 1 unit of insulin). The calculation is: 1800/TDD = **correction factor (CF)**. For example, for the individual with a TDD of 32, one unit of insulin should change the blood glucose level by approximately 56 mg/dL (1800/32 = 56).

   (2) The correction factor can then be used as a point-of-care calculation to determine how much insulin to inject. The calculation is: [Current blood glucose—target blood glucose]/CF. For the individual previously mentioned, if the blood glucose level is 230 mg/dL, to achieve a target of 120 mg/dL with the above calculated CF of 56 mg/dL, the individual would need to inject 2 units of rapid-acting insulin to bring the blood glucose back into the target range. The target blood glucose is typically set by practice site protocol. The CF should be rechecked at least once per year or when there is a significant change in weight, as this is a weight-based calculation.

   b. Adjustment based on carbohydrate intake uses the "**rule of 500.**" The "rule of 500" is as follows: 500/TDD = (x) grams of carbohydrate. This equation estimates how many grams of carbohydrates will be covered by 1 unit of insulin. Use of this rule requires the ability of the individual with diabetes or the caretaker to count carbohydrates.

8. **Insulin adjustments for repeated, time-sequenced events of hypoglycemia or hyperglycemia:** When individuals experience repeated hypoglycemia or hyperglycemia at particular periods, several factors should be taken into consideration (e.g., appropriateness of insulin dose(s), eating habits, changes in exercise routine). Adjustments to insulin dosing should be made based on clinical evaluation of the blood glucose levels and on the knowledge of insulin onset, peak, and duration of action (*Table 46-2*). For example, if an individual who is taking 16 units of NPH insulin and 6 units of regular insulin twice daily (6 a.m. and 6 p.m.) has in-target pre-lunch blood glucose levels, but is having hypoglycemia pre-supper, a downward adjustment to the morning NPH dose would be most appropriate based on its longer duration of action. Adjusting the morning dose of Regular insulin would be inappropriate because the main effect of Regular insulin in this instance would be on the pre-lunch blood glucose value. Changes in insulin doses may also be necessary for the following causes of hyperglycemia:

a. **Dawn phenomenon** produces **fasting hyperglycemia** due to the release of counterregulatory hormones, which typically occurs during the early morning hours (2:00 a.m. to 4:00 a.m.). Evening basal insulin doses should be increased or moved to bedtime dosing to correct for hyperglycemia attributed to dawn phenomenon.

b. **Somogyi effect** is considered **rebound hyperglycemia**. This can occur at any time (day or night) and is when the blood glucose goes too low and counterregulatory hormones are released to increase the blood glucose. When the somogyi effect produces fasting hyperglycemia, the evening basal doses of insulin should be decreased to prevent hypoglycemia.

9. **Routes of insulin administration**

a. **Subcutaneous (SQ) injection** is the method used most often for self-administration of insulin. Vials of insulin with syringes have been the traditional method to deliver a SQ injection; however, the insulin pens are rapidly becoming popular due to the convenience and portability the devices offer (*see section XII*).

(1) **Site selection:** Insulin may be injected into the subcutaneous tissue of the **abdomen**, **buttocks**, **upper arm**, **and thigh** (upper and outer only). The rate of absorption may differ depending on the anatomical site used. The abdomen is typically the fastest site for insulin absorption, followed by the arm, buttocks, and thigh.

(2) **Injection site rotation:** Within an anatomical region, the **injection site should be rotated** to avoid lipohypertrophy and fibrosis.

b. **Continuous intravenous (insulin drip):** The IV route is used to administer regular U-100 insulin, typically in a hospital setting, for the treatment of acute hyperglycemia, hyperglycemic emergency (e.g., DKA or HHS), or during surgical procedures. The following applies to transitioning from IV to SQ insulin:

(1) Short or rapid-acting insulin should be administered 1 to 2 hrs prior to IV insulin discontinuation.

(2) Intermediate or long-acting insulin should be administered 2 to 3 hrs prior IV insulin discontinuation.

c. **Continuous subcutaneous infusion (insulin pump therapy)** is a method to provide tighter glycemic control by continuously infusing rapid-acting insulin into the body. Users must be able to understand the complexity of the pump, check blood glucose levels, and determine bolus insulin doses for dietary intake.

B. **Insulin secretagogues** (oral hypoglycemic agents)

1. **Agents**

a. **Sulfonylureas** generally target fasting blood glucose levels and are classified as first- or second-generation agents.

(1) First-generation agents are typically not prescribed with the evolution of the second-generation agents, which are associated with fewer adverse events. First-generation sulfonylureas have been associated with thrombocytopenia, agranulocytosis, hemolytic anemia, hyponatremia, SIADH, and disulfiram-like reactions. The three agents in this class include tolbutamide (Orinase), tolazamide (Tolinase), and chlorpropamide (Diabinese).

(2) **Second generation:**

(a) Glyburide (DiaBeta, Glynase)

(b) Glipizide (Glucotrol)

(c) Glimepiride (Amaryl)

      b. **Meglitinides:** Repaglinide (Prandin)

      c. **Phenylalanine derivatives:** Nateglinide (Starlix)

  2. **Indication:** The secretagogues are indicated for the management of T2DM only. The focus of sulfonylureas is overall glycemic control, whereas the meglitinide and phenylalanine derivative target postprandial control. Sulfonylureas have traditionally been seen as a first-line agent for the management of T2DM; however, this class has lost some favor with the evolution of agents that are multifactorial in the management of blood glucose.

  3. **Contraindications:** Individuals with severe renal or hepatic dysfunction should avoid the use of secretagogues. Caution should be used in the elderly due to the increased risk of falls with hypoglycemic events. It should be noted that neither repaglinide nor nateglinide are effective in patients who have failed sulfonylurea therapy.

  4. **Mechanisms of action: stimulates enhanced secretion of insulin** from pancreatic β-cells, reduces hepatic glucose output

  5. **Administration and dosage** (*Table 46-3*)

  6. **Patient education and other concerns:**

      a. **Hypoglycemia** is an adverse effect of insulin secretagogues that warrants significant counseling. Sulfonylureas are more likely to cause hypoglycemia, but repaglinide and nateglinide are likely to induce hypoglycemia as well, if taken without food. Education should include signs and symptoms of hypoglycemia and appropriate treatment (*see IX.B and IX.D*).

      b. **Weight gain**, secondary to increased insulin secretion, can occur.

C. **Biguanides**

  1. **Agents:** The only available biguanide is **metformin** (Glucophage, Glucophage XR, Fortamet, Glumetza, Riomet).

  2. **Indication:** Metformin may be used for the glycemic management of **T1DM or T2DM** and is **recommended to be initiated at diagnosis of T2DM** unless there is an existing contraindication. Metformin primarily targets fasting blood glucose levels.

  3. **Contraindications**

      a. **Renal disease:** Metformin is contraindicated in renal disease due to the potential for lactic acidosis. Metformin should be discontinued when the **Scr is ≥ 1.4 mg/dL for females or ≥ 1.5 mg/dL for males**. It should be understood that metformin does not cause renal dysfunction, but rather accumulation of the drug can contribute to toxicity (lactic acidosis) in the individual with renal dysfunction.

      b. **Hepatic impairment** or those with alcoholism or binge drinking

      c. Heart failure: Metformin may be initiated or continued in those with stable heart failure; however, in **unstable or acute heart failure**, the risk of lactic acidosis can be increased secondary to hypoperfusion.

      d. Intravascular **iodinated contrast media:** Metformin should be withheld, if possible, at least 24 hrs prior to the procedure and may be reinitiated 48 hrs after, or when normal renal function returns. However, metformin can be withdrawn as few as 6 hrs prior to the procedure with adequate hydration.

  4. **Mechanisms of action:** The primary role of metformin is to **inhibit hepatic glucose output**, thus exerting beneficial effects on fasting blood glucose levels. The secondary role of metformin is to promote glucose uptake by fat and muscles, thereby improving insulin sensitivity. Thirdly, metformin has a minor role in decreasing intestinal absorption of glucose.

  5. **Administration and dosage** (*Table 46-3*)

  6. **Patient education and other concerns**

      a. **Up to 30% of individuals using metformin are affected by GI effects** (e.g., abdominal bloating, nausea, cramping, feeling of fullness, loss of appetite, or diarrhea). GI effects are self-limiting over 7 to 14 days. Effects can be minimized by taking the medication with food, starting with a low dose, and slow upward titration of dosage.

      b. Minimal weight loss can be seen initially with this agent, but is not a continued effect.

      c. Metformin use has been associated with a reduction in vitamin B_{12} levels. Monitoring of vitamin B_{12} levels should be considered.

      d. Miscellaneous effects include sweating and a metallic taste.

Table 46-3   ORAL AND NONINSULIN INJECTABLE AGENTS[a]

Agent	Initial Dose (Maximum Dose)	Comments
α-Glucosidase Inhibitors		
Acarbose (Precose)	25 mg t.i.d. with the first bite of each main meal (< 60 kg: 50 mg t.i.d.; > 60 kg: 100 mg t.i.d.)	Adverse effects include diarrhea and abdominal stress, which is dose dependent and subsides with continued use; adverse effects typically limit the favorability of these agents
Miglitol (Glyset)	25 mg t.i.d. with first bite of each main meal (100 mg t.i.d.)	Glucose or lactose should be used to treat hypoglycemia that occurs within 2 hrs of taking medication
		Dose should be increased slowly as tolerated
Biguanide		
Metformin (Glucophage, Glucophage XR, Glumetza, Fortamet, Riomet)	500 mg once or twice daily with meals (Short-acting: 2550 mg/day; long-acting: 2000 mg/day)	Adverse effects: transient nausea and abdominal cramping (typically lasts up to 2 weeks); lactic acidosis (rare, but fatal)
		Contraindicated in persons with renal or hepatic disease, unstable heart failure, or alcoholism
Thiazolidinediones (TZDs)		
Pioglitazone (Actos)	15–30 mg once daily without regard to meals (45 mg/day)	Adverse effects include weight gain and peripheral edema
Rosiglitazone (Avandia)	4 mg once daily without regard to meals (8 mg/day)	Contraindicated in hepatic disease and heart failure (class III or IV)
		Rosiglitazone has restricted access
		Therapy may take 6–12 weeks for maximum effectiveness
Sulfonylureas		
Glipizide (Glucotrol, Glucotrol XL)	5 mg once daily (Immediate release: 40 mg/day; extended release: 20 mg/day)	Adverse effects: hypoglycemia, weight gain
	IR given 30 mins before a meal and > 15 mg/day is given in divided doses	Micronized tablet (Glynase) formulation is **NOT** bioequivalent to regular glyburide
Glyburide (DiaBeta, Glynase PresTab)	DiaBeta: 2.5–5.0 mg/day with a meal (20 mg/day)	Contraindications: Glyburide is not recommended if CrCl < 50 mL/min; however, glimepiride and glipizide may be used to a lower CrCl
	Glynase 1.5–3.0 mg/day with a meal (12 mg/day)	
Glimepiride (Amaryl)	1–2 mg once daily with a meal (8 mg/day)	
Meglitinides		
Repaglinide (Prandin)	Not previously treated for DM or A1c < 8%: 0.5 mg before each meal	Primary adverse effect: hypoglycemia
	Previously treated for DM or A1c > 8%: 1–2 mg before each meal (16 mg/day)	Targets postprandial blood glucose values
Phenylalanine Derivatives		
Nateglinide (Starlix)	120 mg t.i.d., up to 30 mins prior to each meal (180 mg/day)	Adverse effects: hypoglycemia; increased uric acid levels
	If near goal A1c may initiate 60 mg t.i.d.	Targets postprandial blood glucose values

Table 46-3	Continued.	
Agent	**Initial Dose (Maximum Dose)**	**Comments**
DPP-IV Inhibitors		
Sitagliptin (Januvia)	100 mg once daily regardless of a meal (100 mg/day)	Adverse effects: upper respiratory tract infection, nasopharyngitis, angioedema, urticaria
Saxagliptin (Onglyza)	2.5–5.0 mg once daily regardless of a meal (5 mg/day)	Sitagliptin and saxagliptin require dosage adjustments for CrCl < 50 mL/min
Linagliptin (Tradjenta)	5 mg once daily regardless of a meal (5 mg/day)	All three may be used in mild-to-moderate hepatic impairment
		Avoid use in persons with pancreatitis
		Drug–drug interactions: Saxagliptin levels may be increased by strong CYP3A4 inhibitors and the risk of edema is more than doubled when combined with a TZD; saxagliptin dose should be 2.5 mg when initiated with a TZD or strong CYP3A4 inhibitor
Bile Acid Sequestrants		
Colesevelam (Welchol)	1.875 g (3 tablets) b.i.d. or 3.75 g (6 tablets) once daily	Adjunctive treatment only
		Take other oral medications 1 hr before or 4 hrs after colesevelam
		Avoid in persons with obstructive bowel disease or triglyceride levels > 500 mg/dL
Dopamine Agonists		
Bromocriptine (Cycloset)	0.8 mg once daily (4.8 mg/day) with a meal within 2 hrs of wakening	Adjunctive treatment only
		Adverse effects: gastrointestinal symptoms
		Contraindications: use with caution in persons with cardiovascular disease, peptic ulcer disease, psychosis, or dementia
GLP-1 Agonists		
Exenatide (Byetta)	5 mcg b.i.d. within 60 mins of a meal (10 mcg b.i.d.)	Available in pen devices for subcutaneous injection
Liraglutide (Victoza)	0.6 mg once daily regardless of a meal (1.8 mg/day)	Adverse effects: Dose-related nausea and/or vomiting that may decrease with continued use, weight loss unrelated to GI symptoms, possible pancreatitis, injection site reaction
		Contraindications: Liraglutide is contraindicated in persons with or a family history of medullary thyroid cancer or in persons with multiple endocrine neoplasia syndrome type 2 (MEN2). Both liraglutide and exenatide are contraindicated in persons with pancreatitis or a history of pancreatitis, T1DM, and gastroparesis
		Slow titrations will minimize GI effects: Liraglutide dose of 0.6 mg should be used for 1 week prior to increasing to 1.2 mg/day; exenatide 5 mcg b.i.d. should be used for 30 days prior to increasing to 10 mcg b.i.d.
		Targets postprandial blood glucose

Table 46-3   Continued.

Agent	Initial Dose (Maximum Dose)	Comments
	Amylin Agonists	
Pramlintide (Symlin)	T1DM: 15 mcg immediately prior to meals (60 mcg t.i.d.) T2DM: 60 mcg immediately prior to meals (120 mcg t.i.d.)	Adverse effects: nausea/vomiting, increased risk of severe hypoglycemia in persons with T1DM within 3 hrs of dosing Indicated for adjunctive therapy to basal and bolus insulin: reduce prandial (bolus) insulin by 50% when initiating pramlintide to avoid hypoglycemia Do not mix together with insulin or inject into the same site as insulin Drug–drug interactions: oral medications needing rapid onset (e.g., analgesics) should be administered 1 hr before or 2 hrs after pramlintide Targets postprandial blood glucose

^aConsult package insert for detailed prescribing information. Dosage should be reduced if frequent hypoglycemia occurs without apparent cause (e.g., medication error, changes in diet, exercise, timing of regimen).
BID, twice a day; *CrCl*, çcreatinine clearance; *DM*, diabetes mellitus; *DPP*, dipeptidyl peptidase; *GI*, gastrointestinal; *GLP*, glucagon-like peptide; *IR*, immediate release; *TID*, three times a day; *T1DM*, type 1 diabetes mellitus; *T2DM*, type 2 diabetes mellitus.

D. **Thiazolidinediones** (TZDs)
1. **Agents**
   a. Pioglitazone (Actos)
   b. Rosiglitazone (Avandia)
2. **Indication:** TZDs are indicated for glycemic control in T2DM and primarily affect the fasting blood glucose levels.
3. **Contraindications**
   a. TZDs should be used with caution in patients with **hepatic dysfunction**. Several linked cases of liver toxicity are owed to troglitazone (Rezulin) which was removed from the market in 1999. Manufacturers of Avandia and Actos have taken caution, but have made great strides in overcoming the stigma associated with the class. For instance, when the agents first became available, LFTs had to be monitored every 2 months during the first year. In 2004, manufacturers of the two available TZDs achieved FDA approval for LFTs to be monitored at baseline, at 6 months, and periodically thereafter.
   b. **Class III/IV heart failure:** TZDs may cause **fluid retention**, which can exacerbate or lead to heart failure. Patients should be observed for signs and/or symptoms of heart failure. In 2007, FDA mandated manufacturers of TZDs to add CHF as a black box warning.
   c. Anemia: TZDs may cause plasma volume expansion. This may result in a small **decrease in hemoglobin and hematocrit**. Use cautiously in persons with anemia.
   d. **Fracture risk:** TZDs have been associated with **fractures**, typically in the distal upper or lower limbs of females.
   e. **Rosiglitazone** has been associated with increased risk of **cardiovascular events** (e.g., myocardial infarction, angina) and thus its **use has been restricted** by the Food and Drug Administration (FDA). Rosiglitazone is available only from certain mail order pharmacies for certain individuals under the Avandia-Rosiglitazone Medicines Access Program.
   f. **Pioglitazone** is under an ongoing safety review for the potential increased risk of **bladder cancer**. At this time, the FDA has not concluded an overall associated risk.
4. **Mechanism of action:** promote glucose uptake by fat and muscles and inhibit hepatic glucose output by the stimulation of peroxisome-proliferator-activated receptor-gamma (PPAR-γ).
5. **Administration and dosage** (*Table 46-3*)

6. **Patient education and other concerns**
   a. TZDs as a class cause significant **weight gain** that is likely associated with fluid retention and fat accumulation. **Report unusual weight gain**, **shortness of breath**, **or swelling of the lower extremities.**
   b. Benefits may not be seen prior to 2 to 4 weeks of use, with **maximum effectiveness not seen until 6 to 12 weeks of use.**

E. **α-Glucosidase inhibitors**
   1. **Agents**
      a. Acarbose (Precose)
      b. Miglitol (Glyset)
   2. **Indication:** α-glucosidase inhibitors are for management of **postprandial blood glucose**
   3. **Contraindications**
      a. Inflammatory bowel disease, colonic ulceration, or obstructive bowel disorders
      b. Acarbose is not recommended in patients with serum creatinine > 2.0 mg/dL and neither agent is recommended in patients with creatinine clearance of < 25 mL/min.
      c. Acarbose is contraindicated in patients with hepatic impairment; dose-dependent elevation in serum transaminases can be seen.
   4. **Mechanism of action:** Competitive **inhibition of alpha-glucosidases** in the intestinal brush border, which leads to a **slower absorption of complex carbohydrates**.
   5. **Administration and dosage** (*Table 46-3*)
   6. **Patient education and other concerns**
      a. α-glucosidase inhibitors **cause increased gas formation in the colon**, which can result in **flatulence**.
      b. The dose should be **taken with the first bite of the meal** for effectiveness.
      c. If **hypoglycemia** occurs within 2 hrs of dosing, patient should be treated with oral **glucose** if the patient is conscious or intravenous glucose or glucagon if the patient is unconscious. **Lactose** is also an acceptable alternative in the conscious patient.
      d. GI side effects will lessen over time, but timing is variable for each patient.

F. **Dipeptidyl peptidase-IV (DPP-IV) inhibitors**
   1. Agents
      a. Sitagliptin (Januvia)
      b. Saxagliptin (Onglyza)
      c. Linagliptin (Tradjenta)
   2. Indication: DPP-IV inhibitors are appropriate for use in individuals with T2DM with normal or impaired hepatic and renal function.
   3. Contraindications
      a. **Pancreatitis:** use cautiously in an individual with a past medical history of pancreatitis and discontinue use if an individual develops pancreatitis while on a DPP-IV inhibitor.
      b. T1DM: DPP-IV inhibitors provide a glucose-dependent insulin secretion and thus are not appropriate for individuals with T1DM.
   4. Mechanisms of action: Prevents the inactivation of incretin hormones (e.g., GLP-1) by the enzyme DPP-IV. GLP-1 works to stimulate insulin secretion and decrease glucagon secretion from the pancreas during hyperglycemia; thus inhibiting the breakdown of GLP-1 would allow for increased insulin secretion and decreased hepatic glucose production.
   5. **Administration and dosage** (*Table 46-3*)
   6. Patient education and other concerns
      a. Notify prescriber if develop signs/symptoms of pancreatitis (e.g., persistent abdominal pain, nausea, or vomiting).
      b. Hypersensitivity reactions may include angioedema, severe skin rash, or difficulty breathing.

G. **Bile acid sequestrant**
   1. Agent: Colesevelam (Welchol)
   2. Indication: adjunctive therapy for the management of T2DM
   3. Contraindications
      a. Persons with a history of bowel obstruction, hypertriglyceridemia-induced pancreatitis, or serum triglyceride concentration > 500 mg/dL.
      b. Persons with gastroparesis or other severe GI motility disorders due to constipating effects

    4. Mechanism of action for improved glycemic control is unknown.

    5. Administration and dosage (*Table 46-3*)

    6. Patient education and other concerns

       a. Oral medications should be taken 1 hr before or 4 hrs after colesevelam.

       b. Constipation is the most common adverse effect.

H. Dopamine agonist

    1. Agent: Bromocriptine (Cycloset)

    2. Indication: adjunctive therapy for the management of T2DM

    3. Contraindications: Use with caution in persons with cardiovascular disease (e.g., myocardial infarction, arrhythmias), dementia, psychosis, or peptic ulcer disease.

    4. Mechanism of action for improvement in glycemic control is unknown; however, it is postulated that bromocriptine may affect circadian rhythms, which may play a role in obesity and insulin resistance.

    5. Administration and dosage (*Table 46-3*)

    6. Patient education and other concerns

       a. May cause dizziness and fatigue. Use caution when performing tasks that require mental alertness.

       b. May cause **gastrointestinal discomfort**, nausea, or vomiting. **Take with food** to lessen gastrointestinal discomfort.

       c. Take within 2 hrs after waking in the morning. Dose will be increased weekly until the maximum tolerated dose is achieved.

I. Available oral combination products

    1. Metformin/glyburide (Glucovance)

    2. Metformin/glipizide (Metaglip)

    3. Metformin/rosiglitazone (Avandamet): restricted access medication

    4. Metformin/pioglitazone (Actoplus Met, Actoplus Met XR)

    5. Metformin/repaglinide (PrandiMet)

    6. Metformin/saxagliptin (Kombiglyze)

    7. Metformin/sitagliptin (Janumet, Janumet XR)

    8. Rosiglitazone/glimepiride (Avandaryl): restricted access medication

    9. Pioglitazone/glimepiride (Duetact)

J. Incretin mimetics (GLP-1 agonists)

    1. Agents

       a. Exenatide (Byetta)

       b. Liraglutide (Victoza)

    2. Indication: management of T2DM

    3. Contraindications

       a. Individuals with severe GI motility disease (e.g., gastroparesis)

       b. Pancreatitis or a history of pancreatitis

       c. Severe renal impairment or hepatic impairment

       d. Liraglutide is contraindicated in individuals with a history or family history of medullary thyroid carcinoma (MTC) and individuals with multiple endocrine neoplasia syndrome type 2 (MEN2). It may be used in individuals with other thyroid disorders, including hypothyroidism or hyperthyroidism.

    4. Mechanisms of action. Increases glucose dependent insulin secretion, decreases hepatic glucose output, increases β-cell growth and replication, slows gastric emptying, and enhances satiety.

    5. Administration and dosage (*Table 46-3*)

    6. Patient education and other concerns

       a. Exenatide should be administered within 60 mins of a meal twice daily. Liraglutide may be dosed independent of meals once daily.

       b. Administration sites include the upper arm, thigh, or abdomen.

       c. Nausea and vomiting may occur with initiation and dose changes, but is typically a transient effect. Weight loss is a sustained effect unrelated to gastrointestinal effects.

       d. Report unusual lump or swelling of the neck, difficulty swallowing, or unusual hoarseness with the use of liraglutide.

K. Amylin receptor agonist

    1. Agent: Pramlintide (Symlin)

    2. Indication: enhanced postprandial control in individuals with **T1DM or T2DM**

3. **Contraindication:** Use should be avoided in individuals with gastric motility disorders, such as **gastroparesis**

4. **Mechanisms of action.** Slows gastric emptying; decreases postprandial glucagon secretion; suppresses appetite

5. **Administration and dosage** (*Table 46-3*)

6. **Patient education and other concerns**
   a. When concomitantly given with insulin, may produce severe hypoglycemia within 3 hrs of administration.
   b. Pre- and post-blood glucose monitoring should be used to determine efficacy of agent.
   c. Administration is into abdomen or thigh; injection into upper arm should be avoided due to variable absorption.
   d. Oral medications needing rapid onset of action (e.g., antibiotics, analgesics) should be administered 1 hr before, or 2 hrs after pramlintide.
   e. Do not mix in same syringe as insulin. Inject at least 2 inches away from insulin injection.

L. **Emerging treatment options**
   1. **Once weekly exenatide** (Bydureon)*: Dosed once weekly as a 2 mg subcutaneous injection, this agent targets over-all blood glucose control rather than postprandial as seen with other GLP-1 agonists; because it takes 6 weeks for this agent to hit steady state, there is no dose titration necessary and less pronounced gastrointestinal effects. Onset of action is approximately 2 weeks.
   2. **Sodium glucose transporter 2 (SGLT2) inhibitors:** SGLT2 is a transporter in the kidneys that is responsible for approximately 90% of renal glucose reabsorption. The SGLT2 inhibitors are proposed to inhibit this transporter, thus increasing the urinary excretion of glucose and lowering blood glucose levels. These agents are unique in that they provide an insulin-independent mechanism of action with near absence of hypoglycemia. Agents currently in clinical trials include dapagliflozin, sergliflozin, and remogliflozin.

VI. GLYCEMIC MANAGEMENT OF T2DM

A. **Initiation of therapy.** Unless contraindications exist, metformin is the preferred initial agent for the management of T2DM. However, therapy should be individualized, taking into account the significance of the hyperglycemia and the desired target of therapy.

1. **Treatment based on current A1c level:**
   a. **6.5% to 7.5%:** Metformin is the preferred initial agent, but a DPP-IV inhibitor, GLP-1 agonist, or α-glucosidase inhibitor may be considered when the postprandial blood glucose is of most concern. A TZD may also be initial therapy when metabolic syndrome and/or nonalcoholic fatty liver disease (NAFLD) is present. Monotherapy should be tried for 2 to 3 months with the initiating agent prior to adding other agents to the regimen.
   b. **7.6% to 9.0%:** Dual therapy should be initiated with metformin providing the backbone of therapy, unless contraindicated. A GLP-1, DPP-IV inhibitor, TZD, sulfonylurea, or meglitinide may be used in combination with the metformin. The chosen therapy should be continued for 2 to 3 months before consideration of an additional agent for glycemic control.
   c. **> 9.0%**
      (1) Symptomatic: Insulin with or without additional oral agents
      (2) Asymptomatic: Dual or triple oral therapy with metformin as the backbone.

2. **Targeted blood glucose control**
   a. **Fasting blood glucose target:** consider metformin, sulfonylurea, TZD, or long-acting basal insulin
   b. **Postprandial blood glucose target:** consider GLP-1 agonist, meglitinide, rapid-acting insulin, or α-glucosidase inhibitor

B. **Management.** Maintaining glycemic control should also be individualized. Consideration should be given to initiating insulin if more than three oral agents are needed to maintain glycemic control or if the A1c remains > 8.5% with dual oral therapy.

---

*In January 2012, Bydureon (long-acting exenatide) was FDA-approved for once weekly injection as adjunct therapy in the management of type 2 diabetes. Mixing of the agent is required immediately prior to injection.

VII. PHARMACOLOGIC THERAPY OF PREDIABETES. Therapy with data to delay or prevent the disease progression include metformin, pioglitazone, orlistat, and alpha-glucosidase inhibitors (e.g., miglitol, acarbose).

VIII. HYPERGLYCEMIC EMERGENCIES. The two most common hyperglycemic emergencies are **diabetic ketoacidosis (DKA)** and **hyperosmolar hyperglycemic state (HHS)**. DKA and HHS **differ in the presence of ketoacidosis and the degree of hyperglycemia** (*Table 46-4*).

    A. DKA, which is caused by profound insulin deficiency, typically occurs in persons with T1DM, but can also occur in those with T2DM. It is characterized by hyperglycemia, ketosis, dehydration, and electrolyte imbalance.

        1. Pathophysiology

            a. Insulin deficiency leads to the following actions:

                (1) impairs glucose uptake in the peripheral tissues, resulting in hyperglycemia

                (2) impairs protein synthesis and promotes breakdown of protein, thus leading to a loss of lean body mass

                (3) increases hydrolysis of triglycerides, which leads to increased hepatic glucose production (further hyperglycemia) and formation of ketone bodies

            b. Hyperglycemia causes **osmotic diuresis**, which leads to hypotonic fluid losses, dehydration, and electrolyte depletion.

        2. Precipitating factors: illness or infection, inadequate dosing of insulin or discontinuation of insulin

        3. Signs and symptoms often include those typical of hyperglycemia (e.g., polyuria, polydipsia, weight loss, blurred vision), **Kussmaul respirations** (deep, rapid breathing), dehydration, and mental status changes. Persons may appear **lethargic**, have a fruity odor to the breath, or have **gastrointestinal symptoms** (e.g., nausea, vomiting, abdominal pain).

        4. Laboratory findings typically include plasma glucose level > 250 mg/dL, but < 600 mg/dL; positive urine and serum ketones; arterial pH < 7.3; sodium bicarbonate < 15 mEq/L

        5. Treatment is focused on correction of dehydration, hyperglycemia, and electrolyte imbalance. Treatment may include any of the following as necessary: IV fluids, insulin, potassium, and/or sodium bicarbonate.

    B. HHS predominantly **affects elderly** individuals and is an extreme manifestation of impaired glucose regulation. HHS is associated with a **higher mortality** than DKA, likely due to severe metabolic changes, delay in diagnosis, or other medical complications that can affect the elderly individual.

        1. Pathophysiology: The pathogenesis of HHS is not as clear as DKA. However, HHS does differ from DKA in that insulin deficiency is not as profound, thus increased lipolysis does not occur.

Table 46-4   RECOGNITION OF DKA AND HHS[3]

	DKA	HHS
Onset	Sudden	Gradual
Affected individuals	T1DM (occasionally T2DM)	Elderly
Plasma glucose	Between 250 mg/dL and 600 mg/dL	> 600 mg/dL
Gastrointestinal symptoms (e.g., nausea, vomiting, abdominal pain)	Present	Negative
Serum or urine ketones (nitroprusside reaction)	Positive	Minimal to none
Kussmaul respirations	Positive	Negative
Arterial pH	< 7.3	> 7.3
Serum osmolality 2[(*sodium* + *glucose*)/18]	Variable	> 320 mOsm/kg
Sodium bicarbonate	< 15 mEq	> 15 mEq

DKA, diabetic ketoacidosis; *HHS*, hyperosmolar hyperglycemic state; *T1DM*, type 1 diabetes mellitus; *T2DM*, type 2 diabetes mellitus.
[3]American Diabetes Association. Position statement: Hyperglycemic crises in patients with diabetes. Diabetes Care 2003;26:s109–117.

Individuals with HHS do have osmotic diuresis that produces dehydration, electrolyte depletion, and hypotonic fluid loss to a greater extent than seen in DKA.

2. **Precipitating factors:** illness or infections, hypertonic feedings, excessive fluid loss secondary to hyperglycemia, severe burns, severe diarrhea, dialysis, or the use of diuretics

3. **Signs and symptoms** may include hyperglycemic symptoms (e.g., polyuria, polydipsia, polyphagia, blurred vision, decreased wound healing), **decreased mentation** (e.g., lethargy and mild confusion), or **focal neurological signs** that mimic a cerebrovascular accident.

4. **Laboratory findings** typically include **plasma glucose levels $>$ 600 mg/dL**, normal sodium bicarbonate level, **minimal to no ketones**, **normal arterial pH**, and **high serum osmolality** (measure of dehydration).

5. **Treatment goals** are **similar to DKA**; however, in HHS, caution should be used with aggressive fluid replacement to avoid fluid overload in elderly individuals.

IX. HYPOGLYCEMIA. Hypoglycemia is the limiting factor for providing aggressive insulin therapy in individuals with T1DM or T2DM.

A. **Definition.** Hypoglycemia is difficult to define, but typically is represented by plasma glucose levels $<$ 70 mg/dL. However, symptoms are the driving determinant rather than an absolute glycemic value since the threshold for the onset of symptoms varies among individuals.

B. **Symptoms** of mild hypoglycemia include sweating, shaking, vision changes, immediate hunger, confusion, and lack of coordination. Severe hypoglycemia occurs when an individual is unable to self-treat due to mental confusion, lethargy, or unconsciousness. Some individuals may have neuroglycopenia and present with symptoms of crying, argumentativeness, inappropriate giddiness, or euphoria.

C. **Causes** can include advanced age, poor nutrition, renal disease, excess of glucose-lowering agents (insulin or insulin secretagogues), or strenuous activity.

D. **Treatment**
1. Mild hypoglycemia: Individuals should check their blood glucose level prior to treating, if possible. If the blood glucose level is low, the person should **eat or drink 10 to 15 g of a fast-acting glucose source** (e.g., 4 oz of fruit juice or regular soda, 3 pieces of peppermint candy) to raise the plasma glucose level 30 to 45 mg/dL. If plasma glucose levels are $<$ 50 mg/dL, treatment with 20 to 30 g of carbohydrate may be necessary. The blood glucose level **should be rechecked 15 to 20 mins after treatment**. If blood glucose levels are low, then hypoglycemia treatment can be repeated.

2. Severe hypoglycemia: Individuals able to swallow may be treated with glucose gel, syrup, or jelly placed inside the individual's check. If this is not possible, **glucagon**, which stimulates hepatic glucose production, may be given by SQ or IM injection. **Nausea and vomiting** are primary adverse effects of a glucagon injection, so the treated person may not immediately feel like consuming further carbohydrates. However, the glycemic response to glucagon is transient (approximately 1.5 hrs), so a small snack should be eaten when the individual is able.

E. **Other types of hypoglycemia**
1. **Pseudohypoglycemia occurs when the individual** perceives hypoglycemic symptoms, but the blood glucose level may be normal, or slightly above normal. Some literature states that there is no need to treat pseudohypoglycemia; however, providing 5 to 10 g of a rapid-acting glucose source can diminish the symptoms without causing significant elevations in blood glucose.

2. **Hypoglycemia unawareness** occurs when hormonal counterregulation and autonomic symptoms disappear. However, individuals do typically have select symptoms, such as those associated with neuroglycopenia, but they may be recognized too late to allow for timely treatment.

X. CHRONIC COMPLICATIONS

A. **Macrovascular complications** include three major types: **coronary artery**, **cerebral vascular**, **and peripheral vascular disease**. These events occur earlier and at a higher rate in those with diabetes than those who do not have diabetes. Attention to multiple risk factors (e.g., lipids, blood pressure, smoking cessation, and antiplatelet therapy) for prevention of these complications is paramount in the diabetes care plan.

1. **Dyslipidemia:** The **primary focus of lipid management is to lower LDL to $<$ 100 mg/dL** in those without overt CVD and $<$ 70 mg/dL in those individuals with overt CVD (optional

goal). However, the triglyceride value may be the primary target when it exceeds 400 mg/dL. When controlled, the focus should return to lowering the LDL levels. Statins are the drug of choice in lowering LDL levels and should be initiated in any patient with overt CVD and any patient over the age of 40 without overt CVD but with other CVD risk factors, regardless of baseline LDL. **Goals for HDL and triglycerides levels are > 40 mg/dL and < 150 mg/dL, respectively**. Of note, **correcting poor glycemic control will have positive impact on the triglyceride levels**.

2. **Hypertension:** Development of hypertension in persons with T1DM is often the result of nephropathy, whereas in T2DM, it is part of the conglomeration of cardiovascular risk factors. The goal blood pressure should be < 130/80 mm Hg, but this may require more than 2 agents at maximum doses in the individual with diabetes. Initial therapy should be with either an ACE-I or ARB; a thiazide diuretic can be added, if necessary, to meet the blood pressure goal. Lifestyle modifications should include reduction in sodium intake (< 1500 mg/day), weight loss (if appropriate), increased physical activity, and increased consumption of fresh fruits and vegetables.

3. **Smoking cessation** should be recommended at every visit for individuals who smoke because nicotine contributes significantly to the development of both macrovascular and microvascular complications of diabetes.

4. **Antiplatelet therapy:** Aspirin therapy has cardiovascular morbidity and mortality data when used as secondary prevention, but the benefits of aspirin for primary prevention is more controversial.
   a. **Aspirin (75 to 162 mg/day)** should be considered for primary prevention in those with T1DM or T2DM who are at increased cardiovascular risk (e.g., men > age 50 or women > age 60 with another CVD risk factor).
   b. Aspirin is currently not recommended for primary prevention in individuals with diabetes who are at low CVD risk because risks outweigh benefits.
   c. Aspirin should be used as secondary prevention in any individual with diabetes and a history of CVD. If aspirin cannot be tolerated, clopidogrel 75 mg/day should be used.

B. **Eye disease**, considered a microvascular complication, is 25 times more common in the individual with diabetes. In fact, diabetes is the leading cause of new blindness in the United States. Several significant diabetic eye complications can occur (e.g., vitreal hemorrhage, retinal detachment), but **diabetic retinopathy** is the most common.

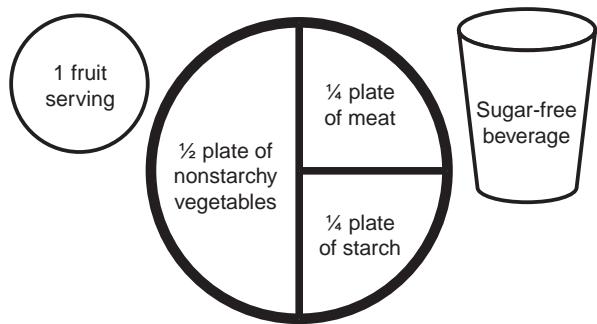
1. **Cause:** Diabetic retinopathy occurs when damage occurs to the retinal blood vessels, resulting in leakage of blood components through the vessel walls.

2. **Classification:** Retinopathy may be classified as **proliferative diabetic retinopathy (PDR)** or **nonproliferative diabetic retinopathy (NPDR)**.
   a. PDR occurs in response to the lack of oxygen following capillary closure. New vessels are formed along the surface of the retina, but these new vessels are weak and prone to rupture, leading to vitreous hemorrhage and/or macular edema. Visual alteration can range from mild blurring of vision to severe visual obstruction.
   b. NPDR occurs prior to growth of new blood vessels along the retina and may remain asymptomatic for years. NPDR can range from mild to severe and is typically progressive.

3. **Prevention** measures include optimizing control of blood glucose and blood pressure, achieving lipid goals, and avoidance of nicotine-containing products. Routine dilated eye exams should occur within 5 years of diagnosis of T1DM and at diagnosis of T2DM and annually thereafter. Some individuals may be cleared to have eye exams performed at 2-year intervals, but the standard recommendation is an annual exam.

4. **Treatment:** NPDR management is by observation and modifying risk factors. PDR can be treated with panretinal photocoagulation to reduce severe vision loss.

C. **Diabetic nephropathy.** Approximately 20% to 40% of individuals with diabetes will develop diabetic nephropathy, which is the **leading cause of end-stage renal disease (ESRD)**. Markers of kidney damage (e.g., serum creatinine, urine microalbumin levels) are used to detect early stages of kidney disease.

1. **Assessment:** Persistent microalbuminuria is the earliest stage of kidney disease in individuals with T1DM and a marker for the future development in those with T2DM. Serum creatinine is


used to estimate the glomerular filtration rate (GFR) and stage the level of chronic kidney disease (CKD).

   a. Albumin-to-creatinine ratio in random spot collection can be used to screen for microalbuminuria or macroalbuminuria.

   (1) Classification

   (a) Normal: < 30 μg/mg creatinine

   (b) Microalbuminuria: 30 to 299 μg/mg creatinine

   (c) Macroalbuminuria : > 300 μg/mg creatinine

   (2) Interpreting results: At least **two positive screenings** should occur within a **3- to 6-month** period to classify an individual as having microalbuminuria or macroalbuminuria, due to the variability in urinary albumin excretion. Levels may be affected by exercise within 24 hrs, infection, fever, heart failure, or significant hyperglycemia or hypertension.

   b. Serum creatinine should be measured at least annually, regardless of the albumin-to-creatinine ratio. Scr levels can then be used to determine an estimated GFR for staging chronic kidney disease, which ranges from Stage 1 (kidney damage with GFR ≥ 90 mL/min) to Stage 5 (kidney failure with GFR < 15 mL/min or dialysis).

   2. Prevention: attaining and maintaining glycemic and blood pressure control, dietary protein restriction, and the use of ACEI or ARB

   3. Treatment for microalbuminuria or macroalbuminuria should be with an **ACE-I or ARB** to slow the progression of renal disease. ARBs have data to support their use in individuals with T2DM and macroalbuminuria.

D. Diabetic neuropathies include distal symmetric polyneuropathy (DPN) and autonomic neuropathy.

   1. Peripheral neuropathy, also known as DPN, is a major pathophysiologic risk factor for foot ulceration and amputation.

   a. Presentation: DPN occurs at the most distal portions of the lower extremities in a **"stocking and glove" pattern**. Protective sensation is first diminished in the toes and feet, then in the fingers and hands. Affected individuals may complain of **burning**, **numbness**, **or tingling in the lower extremities**.

   b. Screening should occur at least **annually** with several simple clinical tests, including the vibration perception (using a 128-Hz tuning fork) and **10-g monofilament** pressure sensation.

   c. Treatment is for **symptomatic relief** and may include antidepressants, anticonvulsants, or opioids.

   2. Autonomic neuropathy involves multiple systems throughout the body, including the cardiovascular, gastrointestinal, and genitourinary systems.

   a. Presentation: Clinical manifestations include resting tachycardia, exercise intolerance, orthostatic hypotension, constipation, gastroparesis, erectile dysfunction, and hypoglycemia unawareness.

   b. Treatment: Improve glycemic control; symptoms associated with the gastrointestinal and genitourinary tracts may be improved with pharmacologic agents, but progression of the disease will not be affected.

XI. PATIENT EDUCATION AND SELF-CARE.
Education and development of self-management goals should be provided for individuals diagnosed with diabetes and prediabetes. Self-care for diabetes typically involves significant lifestyle changes, including dietary changes and activity implementation. Lifestyle changes can often be difficult and therefore require positive reinforcement and involvement of the person with diabetes in the decision-making process.

A. Medical Nutrition Therapy (MNT) is nutrition care that provides assessment, education, goal setting, and evaluation of outcomes in an attempt to attain and maintain optimal metabolic control (e.g., glucose, lipid, and blood pressure goals). Exchanges, based on the amount of carbohydrates in different food groups, were previously recommended for regulating blood glucose levels. However, this strategy has been replaced by carbohydrate counting and the plate method.

   1. Carbohydrate counting: Consistency in carbohydrate intake at meals and snacks is essential for achieving glycemic control, particularly for the postprandial blood glucose levels. Foods that contain a significant amount of carbohydrates (e.g., breads, milk, fruit, rice, beans, corn, and potatoes)

Figure 46-1. The plate method.

should not be eliminated from the meal plan, but incorporated at regularly scheduled intervals. Total carbohydrate intake should be the focus, but protein and fat intake should also be considered due to comorbid conditions (e.g., nephropathy, cardiovascular disease) associated with diabetes.

2. **The plate method** is a tool to provide portion control with healthier food group choices. The concept is to divide and fill a standard-sized dinner plate as follows: half of plate with nonstarchy vegetables (e.g., broccoli, salad, cabbage, collards); one-fourth of the plate with meat (3 oz, cooked); one-fourth of plate with starch (e.g., potatoes, beans, bread, noodles). A serving of fruit may also be combined with the meal in addition to the plate described (*Figure 46-1*).

B. **Physical activity** may be gradually incorporated into daily routines with the goal of at least 150 mins per week of moderate-intensity aerobic exercise. Muscle strengthening activities should be performed at least 2 or more days per week.

C. **Prevention**, **recognition**, **and treatment of acute hypoglycemic and hyperglycemic episodes** should be reviewed at every opportunity.

D. **Reduction of modifiable risk factors** to minimize or prevent the development of chronic complications
   1. Achievement of glycemic, lipid, and blood pressure goals
   2. Smoking cessation
   3. Reduction in weight, if appropriate

E. **Pattern control** to determine effect of sickness, dietary choices, stress, and physical activity on ability to attain and maintain glycemic goals.

F. Implementation of **specific self-care measures**
   1. **Foot care.** Peripheral neuropathy and peripheral vascular disease in individuals with T1DM or T2DM increase the likelihood of developing lower extremity complications and amputations. Proper foot care is essential to minimize these risks.
      a. The feet should be inspected daily, looking for abnormalities (e.g., cuts, sores, blisters, or irritated areas). Medical attention should be sought if abnormalities are present.
      b. Shoes should be properly fitted and free of foreign objects. Shoes should be worn at all times to avoid trauma to a bare foot.
      c. Toenails should be trimmed straight across with the edges filed.
      d. Lotions, creams, or ointments applied between the toes may lock in moisture, leading to maceration. Avoid applying these agents between the toes.
   2. **Dental care.** A yearly dental exam is recommended. In the absence of teeth in the adult with diabetes, examination of the gums is essential due to the high prevalence of periodontal disease in this population.
   3. **Eye care.** An annual dilated eye exam should be recommended, beginning 5 years after diagnosis of T1DM and at diagnosis of T2DM. Increased frequency of eye exams may be necessary, depending on the development and severity of eye disease.

XII. DEVICES FOR DIABETES

A. **Syringes**
   1. **Barrel size:** Syringes for insulin administration are marked in units. Markings may differ based on size of insulin syringe barrel chosen. Barrel sizes include 0.25-, 0.3-, 0.5-, and 1.0-mL capacity.

The recommendation of a particular size of insulin syringe should be the smallest capacity size available for the prescribed dose of insulin:
   a. up to 25 units of insulin: 0.25 cc (0.25-mL)
   b. up to 30 units of insulin: 0.3 cc (0.30-mL)
   c. up to 50 units of insulin:0.5 cc (0.50-mL)
   d. up to 100 units of insulin: 1 cc (1.0 mL)
   2. Needle length: available as original ½ inch (12.7 mm) and short 5/16 inch (8 mm)
   3. Needle gauge simply refers to the **"thickness" of the needle** and is an **inverse relationship (i.e., the higher the gauge, the thinner the needle).** Typical gauges for insulin administration range from 28 to 31 gauge. Because higher gauge needles are thinner, they are also more fragile. Thus, higher gauge needles are typically shorter needles.

B. Insulin pens allow for enhanced portability and eliminate the need for coordination in drawing up a dose of insulin. Most devices are prefilled with insulin and are disposable. It is important to note that insulin pens are for **single-person use** to prevent the spread of blood-borne illnesses.
   1. Devices
      a. Solostar (Sanofi Aventis products): glargine (Lantus); glulisine (Apidra)
      b. Flexpen (Novo Nordisk products): detemir (Levemir); aspart (Novolog); aspart mix (Novolog Mix 70/30)
      c. Kwikpen (Eli Lilly products): lispro (Humalog); lispro mix (Humalog Mix 50/50, 75/25)
   2. Pen needles are available in several lengths:
      a. ½ inch (12.7 mm)
      b. 5/16 inch (8 mm)
      c. 3/16 inch (5 mm)
      d. 5/32 inch (4 mm)

C. Home blood glucose monitors. A plethora of meters are available to patients today.
   1. Meter selection: Some patients choose meter on size, others on cost, and still others on appearance of the meter. When recommending a meter for an elderly patient, the cost of the meter and the manual dexterity and vision of the individual should be kept in mind. Children usually do better with a meter that requires only a minimal amount of blood sample applied to the strip. Meter choices for the visually impaired have tactile markings on the strip or speech output on the meter.
   2. Alternate site testing has become more prominent in all populations. However, it is not appropriate in all situations.
      a. Conditions when alternate site testing may be appropriate include:
         (1) In pre-meal or fasting state (> 2 hrs since last meal)
         (2) 2 or more hours after taking insulin
         (3) 2 or more hours after exercise
      b. Alternate site testing should *not* be used if:
         (1) The results from the alternate site do not match how the person feels
         (2) Symptoms of hypoglycemia are present.

XIII. SIGNIFICANT DRUG INTERACTIONS AFFECTING GLYCEMIC CONTROL. This is only a partial list of potential drug interactions that may affect glycemic control. Consult standard references or drug package inserts for more detailed information.

A. Potential hyperglycemia, as a dose-dependent, direct glucogenic effect. Corticosteroids, nicotinic acid, phenytoin, pentamidine (long-term effect), protease inhibitors, sympathomimetics, isoniazid, furosemide, thiazide diuretics

B. Potential hypoglycemia, as a direct hypoglycemic effect; monoamine oxidase (MAO) inhibitors, fluoxetine, salicylates (large doses), fenfluramine, alcohol, pentamidine (initial effect)

C. Prolonged hypoglycemia and masking of hypoglycemic symptoms. β-Blockers

D. Altered protein binding of, or other drug interaction with, sulfonylurea agents. Alcohol, salicylates, nonsteroidal anti-inflammatory drugs (NSAIDs), methyldopa, chloramphenicol, MAO inhibitors, clofibrate, probenecid

Study Questions

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which patient meets the diagnostic criteria for diabetes, assuming tests were taken on separate visits?
   - (A) An elderly female with fasting blood glucose values of 102 mg/dL and 132 mg/dL.
   - (B) A teenage boy with a fasting blood glucose of 128 mg/dL and an A1c of 6.6%.
   - (C) A 10-year-old girl with a random blood glucose value of 180 mg/dL and 190 mg/dL.
   - (D) A morbidly obese male with a random blood glucose value of 102 mg/dL and an oral glucose tolerance test result of 160 mg/dL.

2. A 45-year-old obese female has just been diagnosed with diabetes. Otherwise, she is healthy with no other medical conditions. Her blood pressure today is 110/75 mm Hg; spot urine microalbumin < 30; TC 180; HDL 32; LDL 122; TG 150. Based on ADA guidelines, which should be started today?
   - (A) Aspirin 81 mg daily
   - (B) Pravastatin 10 mg daily
   - (C) Lisinopril 10 mg daily
   - (D) Irbesartan 150 mg daily

3. A patient is currently on a regimen of Humalog Mix 70/30, 24 units in the morning and 12 units in the evening. Based on the following averages obtained from his blood glucose meter, which would be the most appropriate recommendation for his glycemic control today?

   Pre-Breakfast: 220 mg/dL
   Pre-Lunch: 110 mg/dL
   Pre-Supper: 90 mg/dL
   Bedtime: 108 mg/dL
   3 AM: 62 mg/dL

   - (A) Increase evening dose of Humalog Mix to 15 units
   - (B) Decrease evening dose of Humalog Mix to 10 units
   - (C) Continue current regimen without changes
   - (D) Increase morning dose of Humalog Mix to 28 units
   - (E) Decrease morning dose of Humalog Mix to 20 units

4. A 222-lb male presents to the diabetes care team for routine diabetes management. His fingerstick blood glucose value is 452 mg/dL (445 mg/dL on repeat) and his urine is negative for ketones. Per clinic protocol, he may be treated in the office for hyperglycemia. Which is the most appropriate treatment to bring his blood glucose to a target of 120 mg/dL?
   - (A) Glargine 20 units
   - (B) Lispro 60 units
   - (C) Aspart 30 units
   - (D) Glulisine 11 units
   - (E) Detemir 24 units

5. A 400-lb male has just been diagnosed with type 2 diabetes. His A1c is greater than 15% and his kidney and liver function are normal. Which would be the most appropriate initial agent for monotherapy?
   - (A) Metformin 850 mg q.d.
   - (B) Pioglitazone 30 mg q.d.
   - (C) Glargine 36 units q.d.
   - (D) Liraglutide 0.6 mg q.d.
   - (E) Glimepiride 4 mg q.d.

6. An individual with T2DM currently takes metformin XR 500 mg 2 b.i.d., pioglitazone 45 mg, and glimepiride 4 mg b.i.d. He takes his morning medications at 8 A.M. with breakfast and his evening medications at 6 P.M. with supper. He does not eat lunch. He brings in his log book and meter today, which reveal multiple hypoglycemic events (45 to 62 mg/dL) around 1 P.M. to 2 P.M. His A1c today is 6.0%. Which would be the most appropriate recommendation for glycemic control at this time?
   - (A) Discontinue morning dose of metformin
   - (B) Discontinue evening dose of metformin
   - (C) Discontinue daily dose of pioglitazone
   - (D) Discontinue morning dose of glimepiride
   - (E) Discontinue evening dose of glimepiride

7. A 64-year-old female is taking metformin, pioglitazone, and sitagliptin for T2DM. Her liver function tests were elevated (AST 132 u/L and ALT 140 u/L) and she tested positive for Hepatitis C. Which is the best recommendation at this time?
   - (A) Discontinue metformin only
   - (B) Discontinue pioglitazone only
   - (C) Discontinue sitagliptin only
   - (D) Discontinue metformin and pioglitazone
   - (E) Discontinue all agents for glycemic control

8. Which best describes the mechanism of action of repaglinide?

(A) Insulin secretagogue
(B) Insulin sensitizer
(C) DPP-IV inhibitor
(D) GLP-1 agonist
(E) α-glucosidase inhibitor

9. A patient has been hospitalized for the past 3 days following a severe asthma exacerbation, but is being discharged today. He weighs 228 lb, but he has no previous history of diabetes. Blood work today shows a random blood glucose of 320 mg/dL and an A1c of 5.2%. His current medication list includes albuterol nebules, prednisone, pulmicort, and oxygen. Which statement is most appropriate?

(A) The patient has diabetes and should be discharged on an insulin regimen.
(B) The patient has hyperglycemia induced by his inhaled corticosteroid.
(C) The patient has hyperglycemia induced by his β agonist.
(D) The patient has hyperglycemia induced by his oral glucocorticoid.

10. A patient currently takes Amaryl, Actos, Januvia, and Lantus. He presents to the clinic today concerned about the swelling in his lower extremities, significant weight gain, and shortness of breath. Which is the most likely cause of presenting symptoms?

(A) Amaryl
(B) Actos
(C) Januvia
(D) Lantus

11. A person newly diagnosed with T1DM will need to start an insulin regimen. Based on her weight of 100 lb, which would be the most appropriate *basal* regimen?

(A) Levemir 13 units daily
(B) Lantus 27 units daily
(C) Novolog 4 units three times daily
(D) NPH 15 units once daily
(E) U-500 1.5 mL twice daily

12. Which formulation is the best recommendation for a patient needing an intravenous insulin infusion?

(A) Regular insulin, U-500
(B) Regular insulin, U-100
(C) NPH insulin, U-100
(D) Aspart insulin, U-100
(E) Aspart insulin, U-400

13. A patient presents for treatment of his type 2 diabetes mellitus (T2DM). His A_{1C} is 7.2% and he has hepatitis C (AST = 150 units/L; ALT = 132 units/L), hypertension, dyslipidemia, rheumatoid arthritis, and mild renal impairment (SCr = 1.6). Which would be the best initial agent at this time?

(A) saxagliptin
(B) metformin
(C) pioglitazone
(D) glulisine

14. An obese woman (350 lb) has used metformin 1000 mg bid to control her T2DM for the past 2 years. Her A_{1C} today is 8%. Which would be the most appropriate recommendation to improve glycemic control without providing further weight gain?

(A) sulfonylurea
(B) thiazolidinedione
(C) GLP-1 agonist
(D) amylin agonist

15. All of the following are correct statements about metformin *except*

(A) metformin may cause renal impairment.
(B) metformin should not be used in patients who are alcoholic.
(C) metformin should be discontinued in women with a SCr > 1.4.
(D) metformin may cause vitamin B_{12} depletion.

16. A patient takes neutral protamine Hagedorn (NPH) 16 units bid and regular insulin 6 units bid. Based on her average blood glucose values below, what is the best recommendation for adjusting her insulin regimen?

(A) fasting: 82 mg/dL
(B) pre-lunch: 180 mg/dL
(C) pre-supper: 110 mg/dL
(D) bedtime: 98 mg/dL

17. A patient has been using continuous intravenous insulin infusion at 0.8 units/hr with steady control after being diagnosed with type 1 diabetes mellitus (T1DM). He is to be discharged from the hospital with prescriptions for detemir and glulisine. When is the most appropriate time to initiate the detemir?

(A) 30 minutes prior to discontinuing the continuous insulin infusion
(B) 1 hour prior to discontinuing the continuous insulin infusion
(C) 2 hours prior to discontinuing the continuous insulin infusion
(D) 1.5 hours after discontinuing the continuous insulin infusion
(E) 3 hours after discontinuing the continuous insulin infusion

Answers and Explanations

1. **The answer is B** *[see III.B]*.
   Regardless of age or gender, diagnostic criteria for diabetes in the nonpregnant individual is a positive of at least two of the following values: random blood glucose > 200 mg/dL; fasting blood glucose ≥ 126 mg/dL; OGTT ≥ 200; A1c ≥ 6.5%.

2. **The answer is B** *[see X.A.1]*.
   Based on ADA guidelines, aspirin should be initiated for primary prevention in women greater than age 60; statin therapy should be initiated in patients with overt CVD or any patient over the age of 40 without overt CVD, but with other CVD risk factors; ACEI and ARBs are recommended for blood pressure control if necessary (not needed here) and when urine microalbumin is > 30.

3. **The answer is B** *[see Table 46-2; V.A.8.b]*.
   Increasing the morning dose will only lower the lunch and supper readings further. Increasing the evening dose will lower the 3 A.M. even more. This patient is most likely experiencing rebound hyperglycemia (Symogyi) as evidenced by the hypoglycemia at the 3 A.M. readings and elevated fasting readings pre-breakfast.

4. **The answer is D** *[see V.A.7.a]*.
   The blood glucose needs to come down rapidly in-office, thus he would not choose glargine or detemir as agents due to their longer onset of action. Lispro, aspart, and glulisine would all be appropriate choices, but the dose should be based on the point-of-care correction equation ([Current blood glucose-Target blood glucose]/CF). Steps to solve:

   1. Weight in kg: Weight is 222lb = 101 kg
   2. Determine TDD: (101)(0.6) = 60
   3. Determine CF: 1800/60 = 30
   4. Plug into equation: (452–120)/30 = 11 units

5. **The answer is C** *[see VI.A.1.c]*.
   Metformin would typically be the initial agent of choice in a patient diagnosed with type 2 diabetes. However, with this patient's A1c greater than 15%, insulin is the most appropriate choice. Metformin can be started in addition to the insulin, but not as monotherapy. Oral agents and non-insulin injections will bring the A1c down no greater than 1%.

6. **The answer is D** *[see V.B.1.a; Table 46-3]*.
   The pharmacologic agent most responsible for causing hypoglycemia is the sulfonylurea (glimepiride), which is compounded by the fact that the patient does not eat lunch. The morning dose of glimepiride would peak around lunch time when food intake should be occurring. In the absence of lunch, hypoglycemia results.

7. **The answer is D** *[see V.C.3.b; V.D.3.a; V.F]*.
   Metformin and pioglitazone should not be used in a patient with liver disease and elevated LFTs. Sitagliptin may be used in hepatic impairment. When the LFTs go back to a normal range, it can be considered to reinitiate metformin and pioglitazone.

8. **The answer is A** *[see V.B.1.b]*.
   Repaglinide is a meglitinide, which works to produce a rapid burst of insulin secretion from the pancreas.

9. **The answer is D** *[see III.B; XIII.A]*.
   Inhaled corticosteroids have no effect on the blood glucose of an individual without diabetes and β agonists have no effect. However, oral steroids, such as prednisone can induce significant hyperglycemia, particularly in the midafternoon when dosed in the morning.

10. **The answer is B** *[see V.D.6.a; Table 46-3]*.
    Patients taking a TZD such as Actos should be monitored for peripheral edema, weight gain, and shortness of breath due to its propensity to cause or worsen heart failure.

11. **The answer is A** *[see V.A.6.a]*.
    NovoLog is not a basal insulin and U-500 is reserved for patients with severe insulin resistance. NPH is dosed twice daily. Basal insulin should be initiated at 50% of TDD. TDD is 27 units, which gives 13.5 units as basal.

12. **The answer is B** *[see V.A.9.b]*.
    Regular insulin, U-100 is the most logical choice for an IV infusion. Aspart may be given in an emergency preparedness situation, but should not be given routinely due to the additional cost above that of regular U-100 insulin.

13. **The answer is A** *[see V.F.2; VI.A.1.a]*.
    Metformin and pioglitazone should not be used in liver impairment and metformin must be used cautiously in renal impairment. Rapid acting insulin would help with postprandial blood glucose values, but is not considered a standard recommendation for initial insulin therapy in T2DM. Saxagliptin may be used in patients with hepatic and renal impairment.

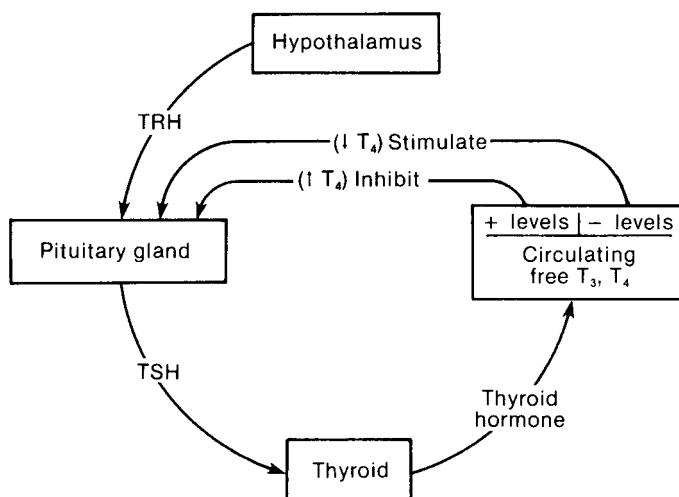
14. **The answer is C** *[seeV.B.6.b; V.D.6.a; Table 46-3]*.
Both sulfonylureas and TZDs have the potential to increase weight, whereas GLP-1 agonists and amylin agonists can provide weight loss. Amylin agonist is not appropriate because it should only be added after a basal and bolus insulin have been added.

15. **The answer is A** *[see V.C.3.a]*.
Metformin should not be used in patients with renal disease, but the metformin itself does not cause renal impairment.

16. **The answer is B** *[see V.A.8; Table 46-2]*.
Increasing morning NPH will cause further decrease of pre-supper reading. Increasing evening doses of insulin will cause fasting blood glucose to be too low.

17. **The answer is C** *[see V.A.9.b.(2)]*.
Long-acting insulin should be injected 2 hours prior to discontinuation of a continuous insulin infusion to allow adequate onset time.

47 Thyroid Disease

ERIC C. NEMEC


I. DEFINITION

A. Thyroid disease consists of a multitude of disorders affecting the production or secretion of thyroid hormones resulting in an altered metabolic state. The clinical and biochemical syndromes resulting from too little or too much thyroid hormone production are called **hypothyroidism** and **hyperthyroidism**, respectively.

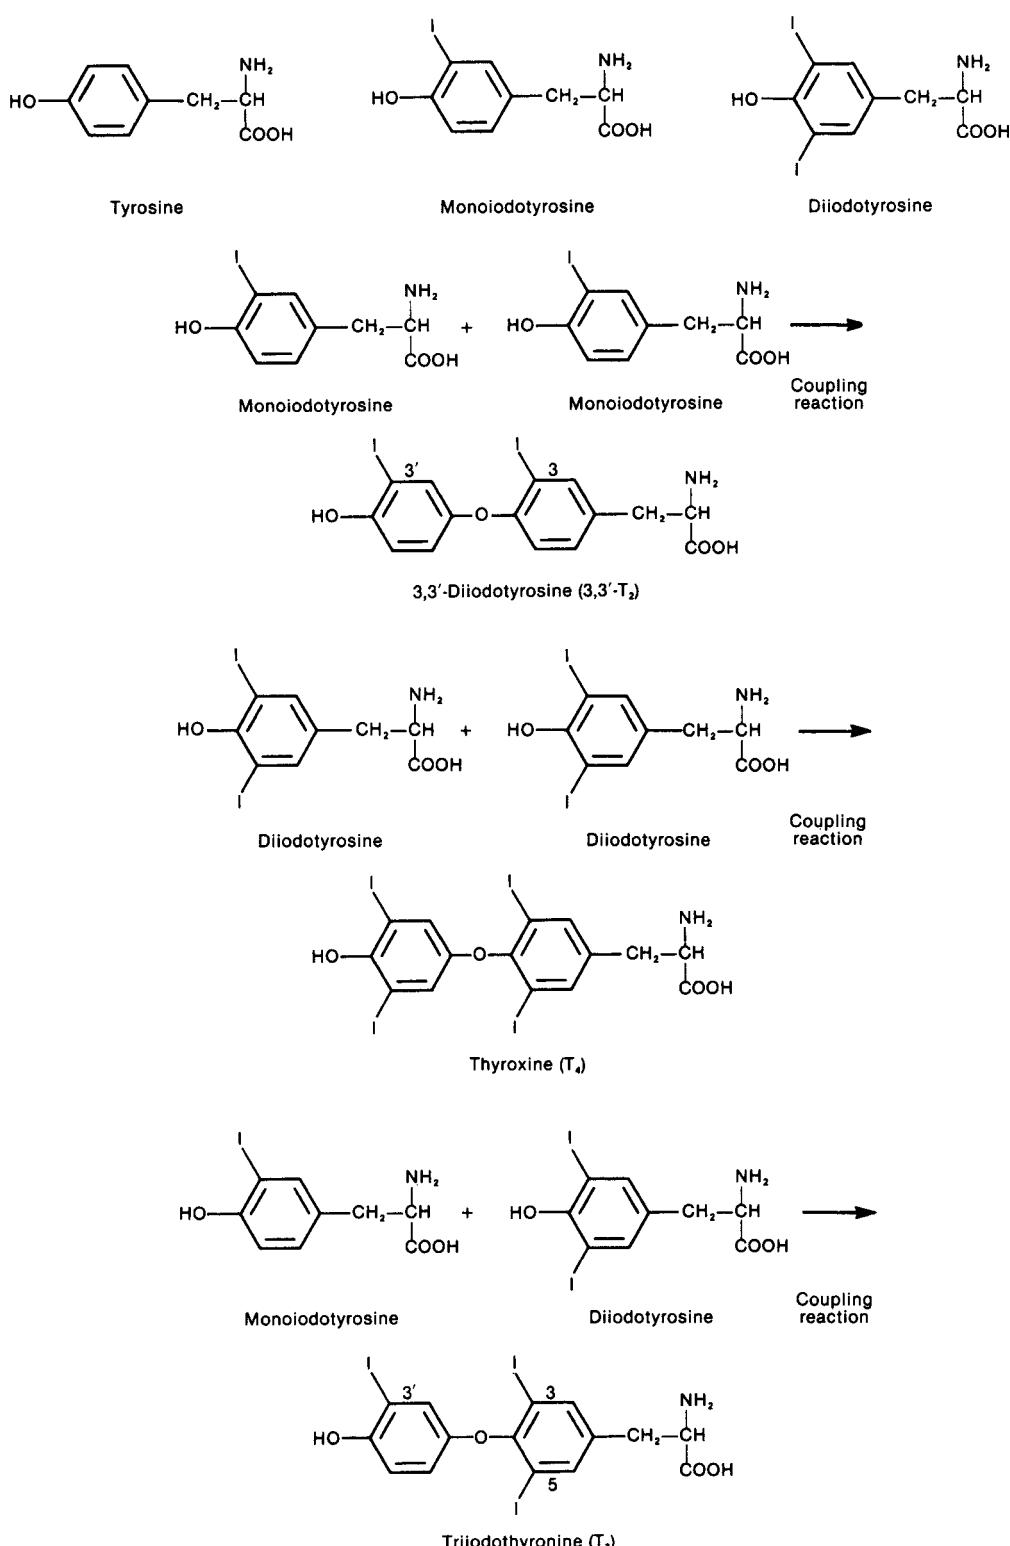
II. PHYSIOLOGY

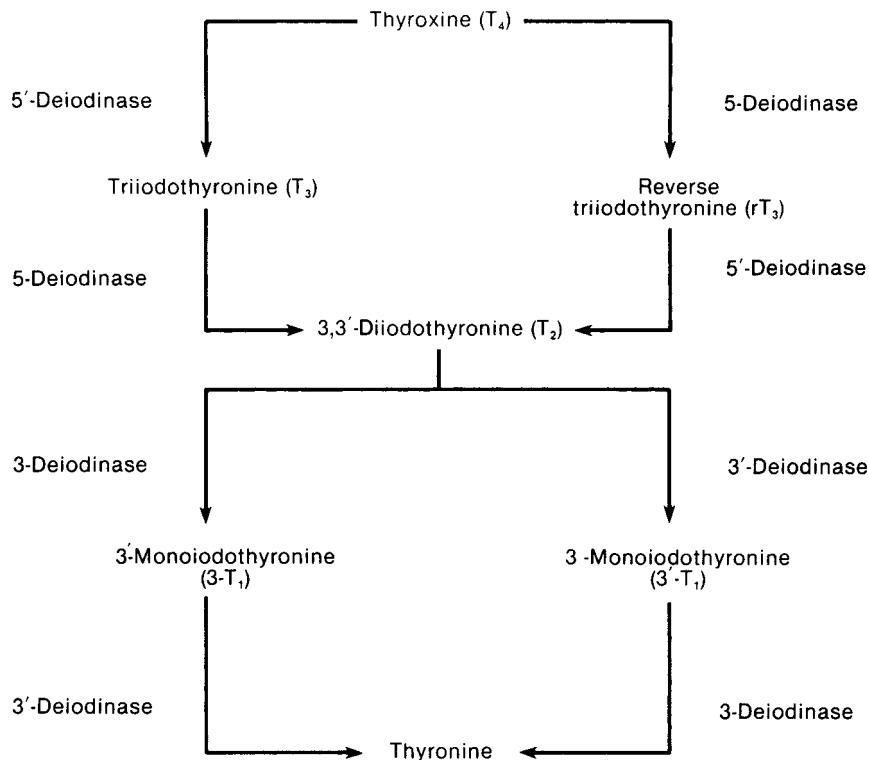
A. **Thyroid hormone regulation**
   1. The thyroid gland synthesizes, stores, and secretes **thyroxine (T_4)** and **triiodothyronine (T_3)** hormones that are important to growth, development, metabolic rate, as well as the maintenance of healthy, mature, central nervous and skeletal systems.
   2. Thyroid hormone secretion and transport are controlled by **thyroid-stimulating hormone (thyrotropin; TSH)**. TSH is released by the anterior pituitary gland that is triggered by **thyrotropin-releasing hormone (TRH)**, secreted from the hypothalamus.
      a. Stimulation of the thyroid by TSH produces increased levels of thyroid hormone (circulating free T_4 and free T_3), which, in turn, signals the pituitary to stop releasing TSH (**negative feedback**).
      b. Conversely, low blood levels of free hormone trigger pituitary release of TSH, which stimulates the thyroid to secrete T_4 and T_3 until free hormone levels return to normal. At this point, the pituitary gland ceases to release TSH, which completes the feedback loop (*Figure 47-1*).
      c. This negative feedback mechanism attempts to maintain the level of circulating thyroid hormone within a narrow range.
   3. The thyroid gland also secretes **calcitonin**, which plays a role in calcium homeostasis by reducing blood calcium ion concentration.

Figure 47-1. Thyroid hormone regulation loop. This carefully balanced hormone regulation system uses both positive (stimulating) and negative (inhibiting) feedback to maintain homeostasis. Disruption of any of these elements can produce serious consequences, such as myxedema crisis (under availability of thyroid hormone) or thyroid storm (overabundance of thyroid hormone). T_3, triiodothyronine; T_4, thyroxine; TRH, thyroid-releasing hormone; TSH, thyroid-stimulating hormone.

B. **Biosynthesis** (*Figure 47-2*)
1. Essential to synthesis of thyroid hormones is dietary iodine, reduced to **inorganic iodide**, which the thyroid actively extracts from the plasma through iodide trapping (**iodide pump**). Some of this iodide is stored within the colloid; some diffuses into the lumen of thyroid follicles.
2. Iodide is oxidized by thyroid peroxidase, and bound to tyrosine residues within the thyroglobulin molecule in the colloid via a process called **organification**.
    a. The oxidation of inorganic iodide to iodine and incorporation into tyrosine residues occurs within thyroglobulin molecules in the colloid, forming **monoiodotyrosine (MIT)**.
    b. **Diiodotyrosine (DIT)** results from the iodization of MIT.
    c. The combination of two DIT molecules forms **tetraiodothyronine (thyroxine, T_4)**, and the combination of MIT with DIT forms **triiodothyronine (T_3)**. These reactions are also catalyzed by thyroid peroxidase.

C. **Hormone transport**
1. After TSH stimulation of the thyroid gland, T_4 and T_3 are cleaved from thyroglobulin and released into the circulation.
2. When in the circulation, thyroid hormone is transported bound to several plasma proteins, a process that:
    a. Helps protect the hormone from premature metabolism and excretion
    b. Prolongs its half-life in the circulation
    c. Allows the thyroid hormone to reach its site of action
3. Most thyroid hormone is transported by **thyroxine-binding globulin (TBG)**. Transthyretin (TBPA, thyroxine-binding prealbumin) and **albumin** also serve as carriers.
4. T_4 and T_3 are lipophilic molecules and cross the cell membrane easily, however there are iodothyronine transporters that facilitate transportation.

D. **Hormone metabolism**
1. T_4 is solely a product of the thyroid gland, whereas T_3 is a product of both the thyroid as well as many other tissues; it is produced by deiodination of T_4.
2. Peripheral conversion of T_4 to T_3 occurs in the pituitary gland, liver, and kidneys and accounts for about 80% of T_3 generation.
3. **Deiodination** accounts for most thyroid hormone degradation. The major steps in this process are shown in *Figure 47-3*.
4. Deiodinated hormones are excreted in feces and urine.
5. Minor nondeiodination pathways of metabolism include conjugation with sulfate and glucuronide, deamination, and decarboxylation.




E. **Hormone function**
1. Although the effects of thyroid hormones are known, the basic mechanisms producing these effects elude precise definition; however, they seem to activate the messenger RNA (mRNA) transcription process, and can promote protein synthesis or (in excessive amounts) protein catabolism.
2. **Thyroid hormones** affect the following:
    a. Growth and development by regulating long bone growth and affecting protein synthesis
    b. Calorigenesis by increasing the rate of basal metabolism
    c. Cardiovascular system by increasing the metabolic rate, which increases blood flow, cardiac output, and heart rate (may be related in part to an increased tissue sensitivity to catecholamines)
    d. The central nervous system (CNS) by increasing or diminishing cerebration
    e. Musculature by causing a fine tremor
    f. Sleep by inducing wakefulness with hyperthyroidism or somnolence with hypothyroidism
    g. Lipid metabolism by stimulating lipid mobilization and degradation

F. **Thyroid function studies** (*Table 47-1*)
1. **Serum thyrotropin (TSH) assays**
    a. This test is the **most sensitive** test for detecting the hypothyroid state because the hypothalamic–pituitary axis compensates very quickly for even slight decreases in circulating free hormone by releasing more TSH. The TSH levels may be elevated even before low circulating levels of serum total T_4 are detectable by diagnostic testing.

Figure 47-2. Biosynthesis of thyroid hormones. The major products are thyroxine (T_4) and triiodothyronine (T_3). These are formed in the follicle cells of the thyroid gland by iodination of tyrosine residues. Monoiodotyrosine and diiodotyrosine residues are formed first. These then react to form T_3 and T_4.

Figure 47-3. Thyroxine metabolism—major steps in the primary and alternative deiodination pathways.

b. The early TSH assay used radioimmunoassay (RIA) methodology. The sensitivity of the assay has improved since, moving to the use of monoclonal antibodies in the late 1980s. Nomenclature established by the American Thyroid Association (ATA) has classified the improvement in sensitivity based on the lower limit of detection. The new classification follows a generational format, as shown in *Table 47-3.*

c. The current (third-generation) serum TSH assay (level of detection 0.01 to 0.02 mIU/L) uses monoclonal antibodies referred to as immunoradiometric (IRMA) or immunometric (IMA) methodology (instead of the older RIA techniques), and demonstrates greater sensitivity in the detection of thyroid disease than older tests.

d. This assay is usually used to diagnose thyroid disease and monitor patients receiving replacement therapy to control overtreatment. Overtreatment—TSH < 0.4 mIU/L—may contribute to excessive bone demineralization (reduced bone density), electrocardiogram (ECG) changes, atrial fibrillation, or elevation of liver function tests.

Table 47-1   TEST RESULTS IN THYROID DISORDERS

Thyroid Function Test	Hypothyroidism	Hyperthyroidism
Serum resin triiodothyronine uptake (RT₃U)	↓ (< 35%)	↑ (> 45%)
Serum total thyroxine (TT₄)	↓ (< 5 μg/dL)	↑ (> 12 μg/dLl)
Serum total triiodothyronine (TT₃)	↓ (< 80 ng/dL)	↑ (> 180 ng/dLl)
Free thyroxine index (FTI)	↓ (< 5.5)	↑ (< 10.5)
Serum thyrotropin (TSH) assay[a]	↑ (> 4.5 μU/mL)	↓ (< 0.4 μU/mL)[b]

[a]In clinical practice the third-generation test is commonly used with sensitivity to detect 0.01–0.02 mIU/L.
[b]Fourth-generation assays detect 0.001–0.002 mIU/L.
↑, increased levels; ↓, decreased levels.

    e. The IMA technique is very sensitive. The fourth-generation IMA can detect TSH levels in the range of 0.001 to 0.002 mIU/L.

    f. The third-generation IMA assays may also detect subclinical thyroid disease (TSH = 0.1 to 0.45 mIU/L). Treatment of subclinical hypothyroidism is controversial because there is insufficient evidence to indicate a benefit.

    g. TSH levels may also be influenced by psychiatric illness. Some studies of hospitalized patients have reported abnormally high or low TSH levels in otherwise euthyroid patients. Current findings in HIV-positive patients are uncertain; however, autoimmune thyroid disease appears to be more prevalent in these patients.

    h. Effects of drugs on the serum TSH are shown in *Tables 47-2* and *47-4*.

    i. There is some controversy as to the appropriate upper limit of normal for serum TSH. Most laboratories use values of about 4.5 to 5.0 mIU/L.

2. Serum total thyroxine (TT_4)

    a. This test provides the most direct reflection of thyroid function by indicating hormone availability to tissues. It determines total (free and bound) T_4 by RIA, which is sensitive and rapid.

    b. Virtually all (99.97%) of serum T_4 is bound to TBG, TBPA, or albumin.

    c. Changes in thyroid globulin concentration, particularly TBG, which increases during pregnancy, alter the total concentration of T_4, and may produce a misleading high or low test result.

    d. However, these changes in TBG do not affect the concentration of free T_4. Therefore, to clarify thyroid function, either protein-binding (T_3 uptake test) or free T_4 must be measured.

    e. An elevated TT_4 level indicates hyperthyroidism; a decreased TT_4 level, hypothyroidism. However, the TT_4 level in a euthyroid patient can be altered by other factors, such as pregnancy or febrile illnesses (which elevate the TT_4), nephrotic syndrome or cirrhosis (which lower the TT_4), and various drugs (*Table 47-2*).

    f. Normal ranges vary among laboratories; a typical range is 4.6 to 11.2 mcg/dL

3. Serum total triiodothyronine (TT_3)

    a. This sensitive and highly specific test measures total (free and bound) T_3 via RIA.

    b. T_3 is less tightly bound to TBG and TBPA, but more tightly bound to albumin than T_4.

    c. Serum T_4 and T_3 usually rise and fall together; however, hyperthyroidism commonly causes a disproportionate rise in T_3, and the TT_3 can rise before the TT_4 level. Therefore, TT_3 is useful for early detection or to rule out hyperthyroidism. Many of the symptoms associated with hyperthyroidism are the result of the elevated TT_3.

    d. This test may not be diagnostically significant for hypothyroidism in which TT_3 levels may fall but stay within the normal range. The TT_3 may be low in only 50% of patients with hypothyroidism.

    e. If there is an abnormality in binding proteins, this test can yield the same misleading results as the TT_4 readings. Other factors affecting test results include pregnancy (which increases TT_3 levels), malnutrition or hepatic or renal disease (which lower TT_3 levels), or various drugs (*Table 47-2*).

    f. Normal ranges vary among laboratories; a typical range is 75 to 195 ng/dL.

4. Resin triiodothyronine uptake (RT_3U)

    a. This test clarifies whether abnormal T_4 levels are the result of a thyroid disorder or to abnormalities in the binding proteins because it evaluates the binding capacity of TBG.

    b. If an abnormal amount (high or low) of thyroid hormone is present in the blood, the RT_3U results **change in the same direction** as the altered level—elevated in hyperthyroidism, decreased in hypothyroidism.

    c. However, if there is an underlying abnormality in binding proteins the abnormal levels of TT_4, TT_3, or both, the RT_3U results **change in the opposite direction**—decreasing as TBG increases, increasing as TBG decreases.

    d. Several drugs can cause spurious changes in the RT_3U (*Table 47-2*).

5. Free thyroxine index (FTI)

    a. Free hormone represents only 0.03% of serum total T_4.

    b. The FTI has the advantage that the clinician is given both a total T_4 and a thyroid hormone binding ratio or index (THBI), making it clear when the patient has a potential binding protein abnormality.

$$THBI = RT_3U/mean\ serum\ RT_3U$$

Table 47-2   EFFECTS OF DRUGS ON THYROID FUNCTION TESTS

Drug	Serum T_4	Resin T_3 Uptake	Free Thyroxine Index	Serum T_3	Serum TSH	Comment
p-Aminosalicylic acid	↓	n/d	↓	n/d	↑[a]	Antithyroid effect, rarely, with long-term use
Aminoglutethimide (Cytadren)[b]	↑	n/d	n/d	n/d	↑	Inhibits peripheral conversion of T_4 to T_3
Amiodarone[b]	↑	n/d	n/d	↓	↑[q]	Decreased serum TBG
Anabolic steroids and androgens	→	↑	0	↓[a]	n/d	
Antithyroid drugs (propylthiouracil or methimazole)	→	→	→	↑	0 or ↑	TSH may increase if patient becomes hypothyroid
Asparaginase (Elspar)	↓	↑	n/d	↑[a]	↑[a]	Decreased serum TBG
Barbiturates	↓[c]	n/d	↓	n/d	n/d	Stimulates T_4 metabolism
Calcium carbonate[d]	↓	n/d	n/d	0	↑	Subclinical signs of hypothyroidism; separate time of ingestion of calcium and levothyroxine
Ciprofloxacin[e]	↓	n/d	n/d	→	↑	Clinical signs of hypothyroidism; separate administration by 6 hrs.
Contraceptives, oral	↑	→	0	↑	0	TBG usually increased
Corticosteroids	0 or ↓	0 or ↑	0 or ↓	→	→	Usual doses decrease TBG; high doses may increase TBG
Danazol (Danocrine)	→	↑	0[p]	→	0 or ↓	Decreased serum TBG
Estrogens and SERMs[g]	↑	→	0	↑	0	Increased serum TBG
Ethionamide (Trecator-SC)	→	n/d	↓[a]	n/d	↑[a]	Antithyroid effect
Fluorouracil (Adrucil)	↑	→	n/d	↑	0	Patients clinically euthyroid; TBG increased
Heparin, IV	↑[h]	0 or ↑	↑[a]	0	n/d	FTI is increased with some measures
Hypoglycemics (sulfonylureas)	0[i]	0[i]	0[i]	n/d	n/d	
Iodides, inorganic	0	0	0	n/d	n/d	
Iodides, organic	0	0	0	n/d	n/d	
Levodopa and levodopa-carbidopa (Sinemet, Parcopa)	0	0	0	0	↓	
Levothyroxine (Levothroid, Levoxyl, Synthroid, Unithroid)	↑s[k,l]	↑ or 0 or ↓[k,l]	0 or ↑[k,l]	↑ or 0[k,l]	↑ or 0[k]	
Liothyronine (Cytomel)	↓[k]	0 or ↓[k]	↓[k]	↑ or ↓[k,l]	0[k]	
Liotrix (Thyrolar)	0[k] or ↓s	0[k]	0[k]	0[k,l]	0[k]	

Table 47-2 Continued.

Drug	Serum T_4	Resin T_3 Uptake	Free Thyroxine Index	Serum T_3	Serum TSH	Comment
Lithium carbonate (Eskalith, Lithobid)	0 or ↓	0 or ↓	0 or ↓	0 or ↓	0 or ↑	
Methadone (Dolophine)	↑s	↓	0	↑	0	Increased serum TBG
Mitotane (Lysodren)	↓	0	0^a	n/d	n/d	Clinical hypothyroidism
Nitroprusside (Nitropress)	↓	n/d	n/d	n/d	n/d	
Oxyphenbutazone and phenylbutazone (Butazolidin)	0 or ↓	↑	↓	n/d	$↑^a$	May compete with T_4 for TBG binding, rarely, overt hypothyroidism and goiter may occur
Perphenazine (Trilafon)	↑	↓	↓	↑	0^a	
Phenytoin (Dilantin)	↓	0 or ↑s	0 or ↓s	↓	0	Stimulates T_4 metabolism and may compete with T_4 for TBG binding
Propranolol (Inderal)	0 or $↑^m$	0^n	n/d	$↓^o$	0	
Raloxifene^g (Evista)	↑	↓	0	↑	0	Increased serum TBG
Resorcinol (excessive topical use)	↓	↑s	↓	↓	↑	
Salicylates (large doses)	↓	↑s	$↓^a$	↓	0^a	Compete with T_4 for TBG binding
Tamoxifen^g	↑	↓	0	↑	0	Increased serum TBG

[a] Effect deduced, not based on reported clinical evidence.
[b] Data from Rae P, Farrar J, Beckett G, et al. Assessment of thyroid status in elderly people. *Br Med J.* 1993;307(6897):177–180.
[c] Patients requiring thyroid replacement therapy have decreased serum thyroxine when barbiturates are given.
[d] Data from Singh N, Singh PN, Hershman JM. Effect of calcium carbonate on the absorption of levothyroxine. *JAMA.* 2000;283(21):2822–2825.
[e] Data from Cooper JG, Harboe K, Frost SK, et al. Ciprofloxacin interacts with thyroid replacement therapy. *Br Med J.* 2005;330(7498):1002.
[f] May increase slightly but usually remains in the normal range.
[g] Data from Siraj ES, Gupta MK, Reddy SS. Raloxifene causing malabsorption of levothyroxine. *Arch Intern Med.* 2003;163(11):1367–1370.
[h] T_4 assay by competitive protein binding is spuriously increased, but T_4 radioimmunoassay is probably not affected. Free thyroxine measured by dialysis may be increased.
[i] May occasionally decrease serum T_4 and increase resin T_3 uptake.
[j] Slight decrease in euthyroid patients; but in long-standing hypothyroid patients, levodopa considerably decreases the elevated TSH.
[k] In a patient on adequate doses for thyroid replacement.
[l] Increased T_4, FTI, and T_3 tend to return to normal after several months of therapy with levothyroxine. After liothyronine, T_3 may be elevated 2 hrs after a dose and depressed 24 hrs after a dose.
[m] Increased T_4 levels are reported in one study, but not in others.
[n] With short-term propranolol in hyperthyroid patients.
[o] In euthyroid patients, the decreased serum T_3 returns to normal with continued propranolol therapy.
[p] Free thyroxine index may increase slightly but usually remains in the normal range.
[q] Data from Batcher EL, Tang XC, Singh BN, et al. Thyroid function abnormalities during amiodarone therapy for persistent atrial fibrillation. *Am J Med.* 2007;120(10):880–885.

FTI, free thyroxine index; *IV*, intravenous; *n/d*, no data; *s*, slight effect; *SC*, subcutaneous; *SERMs*, selective estrogen receptor modulators; T_3, triiodothyronine; T_4, thyroxine; *TBG*, thyroxine-binding globulin; *TSH*, thyroid-stimulating hormone; *0*, no effect; ↑, increased; ↓, decreased.

Table 47-3	SERUM THYROID-STIMULATING HORMONE ASSAY NOMENCLATURE

Generation	Lower Level of Detection
First (RIA method)	1–2 mIU/L
Second	0.1–0.2 mIU/L
Third	0.01–0.02 mIU/L
Fourth	0.001–0.002 mIU/L

RIA, radioimmunoassay

    c. FTI is not a separate test but rather an estimation of the free T_4 level through a mathematical interpretation of the relationship between RT_3U and serum T_4 levels.

$$FTI = TT_4 \times RT_3U/\text{mean serum } RT_3U$$

    d. FTI values are elevated in hyperthyroidism, when TBG is low, and decreased in hypothyroidism, when TBG is elevated.

    e. Effects of drugs on FTI are shown in *Table 47-2*.

G. Strategies and cost considerations for testing

  1. The ATA recommends a free thyroxine (FT_4) and a sensitive TSH assay as the primary laboratory tests for diagnosing thyroid disease (*Figure 47-4*).

  2. Thyroid disease screening for the otherwise generally healthy population has been shown to **not be cost-effective** based on the rate of detection and cost associated with massive screening. However, with increased use and improvements in technology, costs have been falling (*Figure 47-5*).

  3. Screening of asymptomatic individuals is controversial, and recommendations from major medical groups have been conflicting. The most appropriate **target population** for screening includes:

    a. Women older than 60 years and others at high risk for thyroid dysfunction (history of autoimmune disease or type 1 diabetes)

    b. Family history of thyroid disease

    c. Patients with clinical symptoms of hypothyroidism/hyperthyroidism

    d. Pregnant women or those hoping to become pregnant

  4. The sensitive TSH assay is useful in detecting patients at risk of receiving an excess amount of thyroxine as replacement therapy.

III. HYPOTHYROIDISM is the inability of the thyroid gland to supply sufficient thyroid hormone.

There are varying degrees of hypothyroidism from mild, clinically insignificant forms to the life-threatening extreme, myxedema coma.

A. Classification

  1. Primary hypothyroidism ($> 90\%$ of hypothyroidism cases)

    a. Gland destruction or dysfunction caused by disease or medical therapies (e.g., radiation, surgical procedures)

    b. Failure of the gland to develop or congenital incompetence (i.e., **cretinism**)

  2. Secondary hypothyroidism

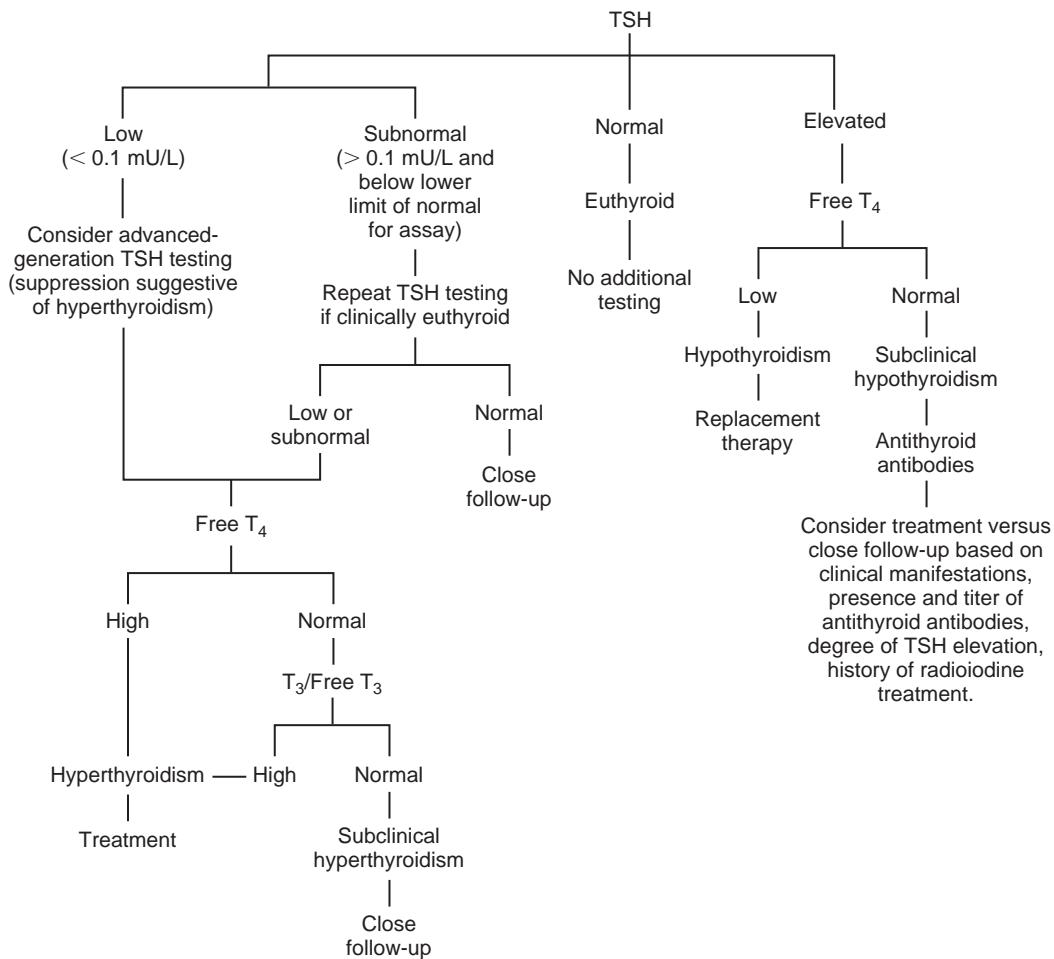
    a. Result of a **pituitary** disorder that inhibits TSH secretion. The thyroid gland is normal but lacks appropriate stimulation by TSH.

  3. Tertiary hypothyroidism

    a. Refers to a condition in which the pituitary–thyroid axis is intact, but the **hypothalamus** lacks the ability to secrete TRH to stimulate the pituitary.

  4. Subclinical hypothyroidism

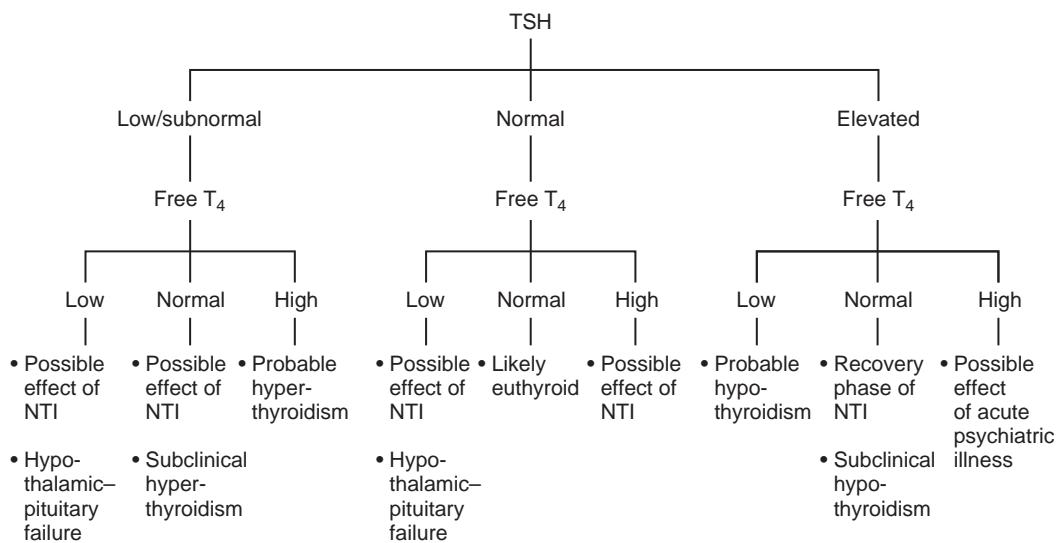
    a. Refers to patients without clinical symptoms, a normal FT_4, and elevated TSH levels. Currently, there is insufficient evidence to support treatment because consequences of nontreatment are minimal. However, pregnant women with subclinical hypothyroidism may benefit from T_4 replacement.

Table 47-4　MEDICATIONS INFLUENCING THYROID-STIMULATING HORMONE (TSH) LEVELS


Agent	Mechanisms	Potential Clinical Thyroid Effect(s)	Effect on TSH	Effect on Other Thyroid Function Tests	Comments
Amiodarone	Iodine effects (see Iodine below)	Clinical or subclinical detected hypothyroidism; subclinical hyperthyroidism infrequently	Hypothyroidism is usually during the first 3 months after starting therapy; continue to detect patients at 6 months. Overt hypothyroidism (TSH > 10 μU/mL) has been observed at 6 months. Mild elevations (TSH 4.5–10.0 μU/mL) have been observed at 12 months. Subclinical hyperthyroidism (TSH < 0.35 μU/mL) has been observed occasionally	Increased total T_4 levels	The large iodine load with the administration of amiodarone is the primary contributor to the drug interaction. Regions where patients have adequate intake of iodine in their diet have been associated with higher rates of hypothyroidism. Biochemical changes in thyroid function noted in a majority of patients on therapy, requiring frequent monitoring
	Direct inhibition of T_4 to T_3 conversion			Increased free T_4 levels	
	Direct toxic effects on thyroid			Increased reverse T_3 levels	
	Induction of thyroid autoimmunity	Hyperthyroidism		Decreased total and free T_3	
Calcium carbonate	Adsorption of levothyroxine to calcium in acid environment	Subclinical hypothyroidism	Elevation	Decrease free T_4 and total T_4	
Ciprofloxacin	Decreases absorption of levothyroxine	Hypothyroidism	Elevation	Decreased thyroid hormone levels	Clinical hypothyroidism detected
Corticosteroids	Central suppression of TSH release	Minimal or none	Suppression	Usually within normal range, although total T_4, free T_4, T_3 reduced, and reverse T_3 increased from baseline	Compensatory mechanisms lead to normalization of TSH levels with chronic exposure

Agent	Mechanism	Thyroid condition	TSH	Thyroid hormone levels	Comments
Dopamine and dopamine agonists	Reduction of thyroid iodine uptake Inhibition of T_4 to T_3 conversion Reduction of thyroid-binding globulin levels Central suppression of TSH release	Minimal or none	Suppression	Normal or decreased hormone levels	Prolonged use of dopamine in high doses may potentiate the low thyroxine state of critical illness
Dopamine antagonists	Release of central TSH inhibition	Minimal or none	Elevation	Usually normal	Effects not well characterized
Iodine	Inhibition of iodine uptake and organification	Clinical or subclinical hypothyroidism	Elevation	Decreased thyroid hormone levels	Clinical hypothyroidism most common in those with underlying organification defects, such as autoimmune thyroiditis or previous radioiodine therapy; iodine-induced hyperthyroidism is generally confined to those with iodine deficiency or autoimmune thyroid disease
	Impairment of thyroid hormone Inhibition of T_4 to T_3 conversion Induction of thyroid autoimmunity	Hyperthyroidism	Suppression	Elevated thyroid hormone levels	
Interferon	Unclear; likely owing to immunomodulating properties and stimulation of autoimmunity	Hypothyroidism (silent thyroiditis, Graves disease)	Elevation	Decreased thyroid hormone levels	No apparent direct influence on TSH secretion: pretreatment detectable antimicrosomal antibodies may represent a risk factor for interferon-induced thyroid disease
		Hyperthyroidism (with or without autoantibodies)	Suppression	Increased thyroid hormone levels	

Table 47-4   Continued.

Agent	Mechanisms	Potential Clinical Thyroid Effect(s)	Effect on TSH	Effect on Other Thyroid Function Tests	Comments
Lithium salts	Inhibition of iodothyronine biosynthesis Reduction of thyroid iodine concentration Suppression of thyroid hormone release Induction of thyroid autoimmunity	Clinical or subclinical hypothyroidism	Elevation	Normal or decreased thyroid hormone levels	Some sources recommend thyroid function testing at 6-month intervals while on therapy
Radiographic contrast media	Iodine effects (See Iodine above) Direct inhibition of T_4 to T_3 conversion	Minimal or none	Elevation	Normal or decreased thyroid hormone levels Elevation of reverse T_3 levels	Alterations are maximal 3–4 days after administration and may persist for up to 2 weeks
Raloxifene	Malabsorption; mechanism unknown	Hypothyroidism	Elevation	Decreased thyroid hormone levels	Clinical hypothyroidism detected
Somatostatin and analogs	Central suppression of TSH release	Minimal or none	Suppression	Usually normal	Effects not well characterized


T_3, triiodothyronine; T_4, thyroxine.

Figure 47-4. Algorithm for using a sensitive thyroid-stimulating hormone (TSH) assay as a single test of thyroid function. The algorithm assumes a clinically intact hypothalamic–pituitary axis, absence of medications known to influence TSH or other thyroid indices, and generally good physical and psychiatric health. The TSH assay should meet the American Thyroid Association criteria for a sensitive assay and/or have a known functional sensitivity limit at the second-generation (0.1 mIU/L) level or greater. *Close follow-up*, clinical observation for signs and symptoms of hyperthyroidism or hypothyroidism and repeated TSH determinations at intervals of 6 to 12 months. T_3, triiodothyronine; T_4, thyroxine.

B. **Causes**
   1. **Hashimoto thyroiditis**, a chronic lymphocytic thyroiditis that is considered to be an autoimmune disorder
   2. **Treatment of hyperthyroidism**, such as radioactive iodine therapy, subtotal thyroidectomy, or administration of antithyroid agents
   3. **Surgical excision** of thyroid gland
   4. **Goiter** (enlargement of the thyroid gland)
      a. **Endemic goiter** results from inadequate intake of dietary iodine. This is common in regions with iodine-depleted soil and in areas of endemic malnutrition.
      b. **Sporadic goiter** can follow ingestion of certain drugs or foods containing **progoitrin** (L-5-vinyl-2-thiooxazolidone), which is inactive and converted by hydrolysis to goitrin.
         (1) Goitrins inhibit oxidation of iodine to iodide and prevent iodide from binding to thyroglobulin, thereby decreasing thyroid hormone production.
         (2) Progoitrin has been isolated in cabbage, kale, peanuts, Brussels sprouts, mustard, rutabaga, kohlrabi, spinach, cauliflower, and horseradish.
         (3) **Goitrogenic drugs** include propylthiouracil (PTU), iodides, amiodarone, and lithium.

Figure 47-5. Algorithm for the use of sensitive thyroid-stimulating hormone (TSH) testing in patients with nonthyroidal illness (NTI). The TSH assay should meet the American Thyroid Association criteria for a sensitive assay and/or have a known functional sensitivity limit at the second-generation (0.1 mIU/L) level or greater. Medications known to alter TSH levels (i.e., corticosteroids, dopamine) must be considered when interpreting results.

      c. **Less common causes** include acute (usually traumatic) and subacute thyroiditis, nodules, nodular goiter, and thyroid cancer.

    5. **Amiodarone's** intrinsic drug effects as well as its high iodine content can cause thyroid dysfunction (both hypothyroidism and hyperthyroidism)

      a. It causes decreased T_3 production, T_3 receptor binding, and direct toxic effect on thyroid follicular cells.

      b. Amiodarone's iodine content has a direct toxic effect on the thyroid, and can cause both hypothyroidism and hyperthyroidism based on other underlying disease states.

C. **Signs and symptoms**

    1. Early clinical features tend to be somewhat vague: lethargy, fatigue, depression, forgetfulness, sensitivity to cold, unexplained weight gain, and constipation.

    2. Progressively, the characteristic features of myxedema emerge: dry, flaky, inelastic skin; coarse hair; slowed speech and thought; hoarseness; puffy face, hands, and feet; eyelid droop; hearing loss; menorrhagia; decreased libido; and slow return of deep tendon reflexes (especially in the Achilles tendon). If untreated, myxedema coma will develop.

D. **Laboratory findings** (*Table 47-1*)

E. **Treatment goal** is replacement therapy to mimic normal, physiologic levels and alleviate signs, symptoms, and biochemical abnormalities (*Table 47-5*).

F. **Therapeutic agents**

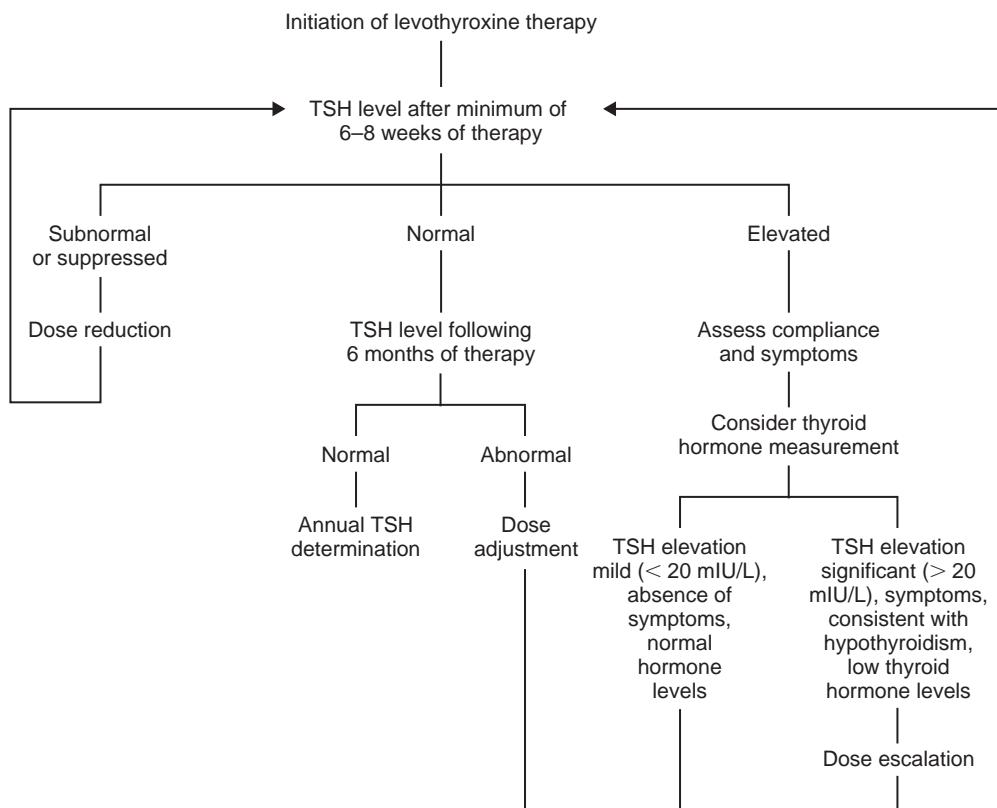
    1. **Desiccated thyroid preparations**

      a. At one time the agent of choice, desiccated thyroid (Armour Thyroid, Westhroid) has fallen out of favor since standardized synthetic levothyroxine preparations have become available.

      b. Desiccated thyroid preparations are not considered bioequivalent; they have evidenced varying amounts of active substances. Although they met established *United States Pharmacopeia* (*USP*) criteria for iodine content, variation in hormonal content and activity was noted. The content assay, while specific for iodine, was unable to specify the ratio of T_3 to T_4, and this ratio varies with the animal source. Porcine gland preparations are most commonly used, and have a higher T_3 to T_4 ratio than those from ovine and bovine sources.

    2. **Fixed-ratio liotrix (Thyrolar) preparations**. In an effort to standardize the T_3 to T_4 ratio, substances that mimic glandular content were developed. However, the T_3 component proved unnecessary (because T_4 is metabolized to T_3) and even disadvantageous because of T_3-induced **adverse effects** (e.g., tremor, headache, palpitations, diarrhea).

Table 47-5	THYROID REPLACEMENT PREPARATIONS			
Preparation (Trade Names)	**Advantage**	**Disadvantage**	**Comments**	**Source**
Desiccated thyroid (Thyroid USP, Thyroid Strong, Armour Thyroid, Thyrar, S-P-T)	Low cost	Some preparations have unpredictable results; inconsistent T_3:T_4 ratio T_3 increases adverse effects	Contains T_3; some brands are standardized by iodine content[a]	Porcine, bovine, or ovine thyroid glands
Liothyronine (Cytomel)	Predictable results; useful for myxedema crisis	Lacks T_4	Usually reserved for myxedema crisis	Synthetic
Liotrix (Thyrolar)	Standardized formulation	T_3 increases adverse effects; expensive	Fixed T_3:T_4 ratio of 1:4; metabolism of T_4 to T_3 renders T_3 component unnecessary	Synthetic
Levothyroxine[b] (Levothroid, Synthroid, Levoxyl, Unithroid)	Predictable results, intravenous preparation available	Expensive	Agent of choice; does not contain T_3; all preparations may be interchangeable	Synthetic

[a]Iodine content and T_3:T_4 ratio vary with species.
[b]Generic formulations manufactured by Pharmaceuticals Basics for Geneva Generics and Rugby have been shown to be bioequivalent to Synthroid and Levoxyl.
T_3, triiodothyronine; T_4, thyroxine; *USP, United States Pharmacopeia.*
From Dong BJ, Hauck WW, Gambertoglio JG, et al. Bioequivalence of generic and brand-name levothyroxine products in the treatment of hypothyroidism. *JAMA.* 1997;277(15):1205–1213.


3. **Levothyroxine**
   a. Predictable results of the synthetic T_4 preparation and lack of T_3-induced side effects have made levothyroxine (Levothroid, Synthroid, and Levoxyl) the agent of choice.
   b. Levothyroxine preparations are generally considered bioequivalent despite significant controversy. However, when switching formulations, it is recommended to monitor the patient closely because there may be some individual patient variability among formulations (*Figure 47-6*).
   c. The **average adult maintenance** dose is 75 to 150 mcg/day. The dose range has been shown to be 1.5 to 1.7 mcg/kg/day or an average of 1.6 mcg/kg/day for otherwise healthy adults. Levothyroxine should be administered preferably on an empty stomach in the morning, before breakfast.
   d. **Elderly** or **chronically ill patients** require an average dose of 50 to 100 mcg/day, which is 25 to 50 mcg/day less than otherwise healthy adults of the same height and weight.
   e. Athyreotic **pregnant patients** may require a 25% to 50% increase in levothyroxine dosage when pregnancy is confirmed (FDA pregnancy category A). Prepregnancy dosage can be reinstated immediately following delivery.
   f. Thyroxine levels usually return to normal within a few weeks. Clinical improvement begins in 2 weeks with full resolution of signs and symptoms of hypothyroidism by 3 to 6 months of therapy.
   g. TSH levels begin to decrease after starting thyroid replacement. TSH remains elevated for some time after T_4 levels return to normal. Generally, TSH levels return to normal after a minimum of 6 to 8 weeks, but may continue to fall over 6 to 12 months (*Figure 47-6*).
4. **Liothyronine**
   a. Liothyronine (Cytomel) is the L-isomer of T_3
   b. **Average adult maintenance** is 25 to 75 mcg/day
   c. Liothyronine is generally not recommended for treating hypothyroidism. However, it may be useful treating patients with persistent clinical symptoms on levothyroxine. Assessment of this therapy requires measurement of serum T_3 and TSH, since liothyronine will not affect serum T_4.

Figure 47-6. Algorithm for management of patients on levothyroxine therapy. *TSH*, thyroid-stimulating hormone.

G. **Precautions and monitoring effects**

1. Adult patients with a history of cardiac disease and elderly patients should begin therapy with lower doses (e.g., 25 mcg/day of levothyroxine). After 2 to 4 weeks, the dose should be increased gradually (12.5 to 25.0 mcg) to an individually adjusted maintenance dose (usually < 100 mcg daily).

2. Patients should be observed on initiation of therapy for possible **cardiac complications**, such as angina, palpitations, or arrhythmias.

3. Serum thyroid levels should be monitored, particularly T_4, sensitive TSH and RT_3U levels, and the FTI. Serum thyroxine tests may remain elevated during the first few months of treatment even with the presence of clinical symptoms. Serum thyroxine tests do not predict the clinical state. Testing is unnecessary unless noncompliance is suspected.

4. It is recommended to monitor the sensitive TSH test 2 to 6 months after the last dose change. However, this test continues to change for up to 1 year. Testing early may result in overtreatment. Refer to *Figure 47-6* for the management of patients on levothyroxine therapy.

5. Levothyroxine administration, particularly long-term therapy, can induce thyrotoxicosis; T_4 levels can rise even though the dosage remains unchanged. Monitor for clinical signs of thyroid disease.

6. **Accelerated bone loss** has been associated with overtreatment. Patients receiving replacement therapy with low TSH values may have lower bone mineral density because excess hormone accelerates the rate of remodeling (rate of resorption > rate of formation), and may contribute to an increased incidence of nontraumatic fracture.

7. **Drug interactions**

   a. **Cholestyramine (Questran) and colestipol (Colestid)**, bile acid sequestrants, can contribute to a decrease in **thyroxine** bioavailability when administered concomitantly. Bile acid sequestrants should be administered at least 6 hrs after oral thyroxine to reduce the potential for this clinically significant drug interaction.

    b. Calcium carbonate (Os-Cal, Tums) can reduce thyroxine bioavailability by adsorption in an acid environment. These should be administered separately to avoid interaction.

    c. Estrogens (Estrace, Premarin) and selective estrogen receptor modulators (SERMs) tamoxifen (Nolvadex) or raloxifene (Evista) may contribute to lower levels of FT_4 and elevated TSH levels, requiring an increase in levothyroxine dose.

    d. Raloxifene has been shown to cause malabsorption of levothyroxine when coadministered resulting in hypothyroidism. Absorption studies demonstrated that separating administration times by ~12 hrs for the two medications prevents the interaction.

    e. Ciprofloxacin (Cipro) has been reported to interact with levothyroxine when given together, resulting in elevated TSH and reduced FT_4 and FT_3 levels. Administration of the drugs separately, with a 6-hr interval, resulted in rapid normalization of the thyroid function tests.

  8. FDA black box warning: Do not use thyroid hormones, including levothyroxine, either alone or with other therapeutic agents, for the treatment of obesity or for weight loss. They are ineffective for weight reduction in euthyroid patients, and may produce serious or even life-threatening manifestations of toxicity, particularly when given in association with sympathomimetic amines such as those used for their anorectic effects.

  9. Approximate oral dose equivalency: Levothyroxine 100 mcg = Liothyronine 25 mcg = Thyrolar 1 grain = Desiccated Thyroid 1 grain

H. Myxedema coma is defined as severe hypothyroidism leading to decreased mental status, hypothermia, and other symptoms related to slowing of function in multiple organs. It is a life-threatening complication with a high mortality rate.

  1. It is **most common** in elderly patients with preexisting, although usually undiagnosed, hypothyroidism.

  2. Precipitating factors include alcohol, sedative hypnotic, or narcotic use; overuse of antithyroid agents; abrupt discontinuation of thyroid hormone therapy; infection; exposure to cold temperatures; and iatrogenic insult owing to radiation therapy or thyroid surgery.

  3. The patient usually declines from profound lethargy to coma, hypothermia, and a significant decrease in respiratory rate, potentially leading to respiratory failure as the crisis progresses. Hypometabolism produces a fluid and electrolyte imbalance that leads to fluid retention and hyponatremia. **Cardiac effects** include decreased heart rate and contractility, decreasing cardiac output.

  4. Treatment consists of rapid restoration of T_3 and T_4 levels to normal.

    a. A loading dose of levothyroxine 300 to 500 mcg is given as an intravenous (IV) bolus followed by a daily dose of 1.6 mcg/kg thereafter. Liothyronine, may be given simultaneously as a dose of 5 to 20 mcg, followed by 2.5 to 10.0 mcg given orally every 8 hrs.

    b. Treatment is continued until improvement is noted. Then liothyronine is discontinued, and levothyroxine is changed to the oral preparation. A maintenance dose is then determined (see III.F.3).

IV. HYPERTHYROIDISM is the overabundance of thyroid hormone. **Thyrotoxicosis** is the general term applied to overactivity of the thyroid gland.

A. Graves disease (diffuse toxic goiter)

  1. The **most common form** of hyperthyroidism, Graves disease occurs primarily, but not exclusively, in **young women**.

  2. The basis of this disease is an **autoimmune disorder** in which antibodies (TSHR-Ab) bind to and activate TSH receptors, resulting in the overproduction of thyroid hormone.

    a. TSHR-Ab are termed **long-acting thyroid stimulators (LATSs)** because their duration of action extends beyond that of TSH. As TSH is only mimicked, not overabundant, neither testing for TSH nor attempts to influence it are productive.

    b. Antibody titers often are elevated in patients with Graves disease.

  3. Signs and symptoms characteristic of Graves disease include:

    a. Diffusely enlarged nontender goiter

    b. Nervousness, irritability, anxiety, and insomnia

    c. Heat intolerance and profuse sweating

    d. Weight loss despite increased appetite

    e. Tremor and muscle weakness

    f. Palpitations and tachycardia

g. Exophthalmos, stare, and lid lag (slow upper lid closing)

h. Diarrhea

i. Thrill or bruit over the thyroid

j. Periorbital edema

B. Plummer disease (toxic nodular goiter)

1. This **form of thyrotoxicosis** is less common than Graves disease. Its underlying cause remains unknown, but its incidence is highest in patients > 50 years of age, and it arises usually from a long-standing nontoxic goiter.

2. The thyrotoxicosis is a result of one or more adenomatous nodules autonomously secreting excessive thyroid hormone, which suppresses the rest of the gland. Scanning confirms the diagnosis if it indicates that activity and iodine uptake are confined to the nodular mass, unless TSH is introduced.

3. **Signs and symptoms** are essentially the same as for Graves disease except that one or more nodular masses are found, rather than diffuse glandular enlargement, and ophthalmopathy is usually absent. **Cardiac abnormalities** (e.g., congestive heart failure [CHF], tachyarrhythmias) are commonly seen with Plummer disease.

C. Less common forms of hyperthyroidism

1. **Jod-Basedow phenomenon** is an overproduction of thyroid hormone following a sudden, large increase in iodine ingestion—through either a sudden reversal of an iodine-deficient diet or the introduction of iodide or iodine in contrast agents or drugs (e.g., the antiarrhythmic agent amiodarone).

2. **Factitious hyperthyroidism** occurs with abusive ingestion of thyroid-replacement agents, usually in a misguided effort to lose weight. Diagnosis is aided by the absence of glandular swelling and of exophthalmos and the lack of autoimmune activity found in Graves disease.

3. **Subclinical hyperthyroidism** refers to patients without clinical symptoms, a normal FT_4 and FT_3 and TSH levels below the lower limits of normal (< 0.4 mIU/L). Currently, there is insufficient evidence to support treatment because consequences of nontreatment are minimal.

D. Laboratory findings (*Table 47-1*)

E. Treatment goal. Symptomatic relief is provided until definitive treatment can be effected.

F. Therapeutic agents

1. **Antithyroid agents (thioamides)—PTU and methimazole (Tapazole)**

   a. These agents may help attain remission through direct interference with thyroid hormone synthesis. Both agents inhibit iodide oxidation and iodothiouracil coupling. In addition, PTU (but not methimazole) diminishes peripheral deiodination of T_4 to T_3.

   b. **Therapeutic uses** of these drugs include

   (1) **Definitive treatment** in which remission is achieved

   (2) **Adjunctive therapy** with radioactive iodine until the radiation takes effect

   (3) **Preoperative preparation** to establish and maintain a euthyroid state until definitive surgery can be performed

   c. **Dosages**

   (1) **Propylthiouracil**

   (a) For **adults**, the initial dose is 300 to 450 mg/day in three divided doses (i.e., 100 to 150 mg every 8 hrs). Adult patients with severe disease may require as much as 600 to 900 mg/day initially.

   (b) The initial dose is continued for about 2 months; then a maintenance dose of 100 to 150 mg/day is given, as a single dose or divided into two doses.

   (c) Maintenance therapy is continued for approximately 1 year, then gradually discontinued over 1 to 2 months while the patient is monitored for signs of recurrent hyperthyroidism. The patient may remain in remission for several years. A recurrent episode of hyperthyroidism is most likely to occur within 3 to 6 months of drug discontinuation.

   (d) If hyperthyroidism recurs after drug therapy is stopped, the agent should be restarted, and alternative therapy should be considered (e.g., thyroid gland ablation or removal).

   (e) **FDA black box warning**: Severe liver injury and acute liver failure, in some cases are fatal, have been reported in patients treated with PTU.

   (f) A medication guide must be dispensed with this product.

(2) Methimazole (Tapazole, MMI)

    (a) The initial dose range is 15 to 60 mg/day in three divided doses, depending on disease severity. After 2 months of therapy, a maintenance dose of 5 to 30 mg/day is initiated.

    (b) Maintenance therapy is continued for approximately 1 year at which time the drug is gradually discontinued, usually over 1 to 2 months.

    (c) **MMI** is generally preferred because of its longer duration of action, more rapid efficacy, and lower incidence of side effects. However, PTU may be the treatment of choice when therapy is indicated during or just prior to the first trimester of pregnancy due to risk of fetal abnormalities with MMI. MMI may be resumed during the second trimester.

d. Precautions and monitoring effects

    (1) Serum thyroid levels and the FTI should be monitored for a return to normal. An elevated T_3 may indicate inadequate treatment, whereas an elevated TSH may indicate excessive antithyroid treatment.

    (2) Goiter size should decrease with reduced hormone output.

    (3) The **adverse effects** are similar for the two agents.

        (a) The most bothersome are **dermatologic reactions** (e.g., rash, urticaria, pruritus, hair loss, skin pigmentation). Others include headache, drowsiness, paresthesia, nausea, vomiting, vertigo, neuritis, loss of taste, arthralgia, and myalgia.

        (b) **Severe adverse effects**—agranulocytosis, granulocytopenia, thrombocytopenia, drug fever, hepatitis, and hypoprothrombinemia—occur less frequently. Patients receiving methimazole who are $>$ 40 years old and are receiving doses above 40 mg/day are at increased risk of developing agranulocytosis. Patients receiving PTU who are $>$ 40 years old are at increased risk of developing agranulocytosis, but no dose association has been established.

2. Radioactive iodine (RAI)

  a. Action. The thyroid gland picks up the radioactive element iodine-131 (^{131}I) as it would regular iodine. The radioactivity subsequently destroys some of the cells that would otherwise concentrate iodine and produce T_4, thus decreasing thyroid hormone production.

  b. Advantages

    (1) **High cure rate**—almost 100% for patients with Graves disease and only slightly less for patients with Plummer disease

    (2) **Avoids surgical risks**—such as adverse reaction to anesthetics, hypoparathyroidism, nerve palsy, bleeding, and hoarseness

    (3) **Less expensive**—avoids cost of hospitalization

  c. Disadvantages

    (1) Risk of delayed hypothyroidism

    (2) Slight, though undocumented, risk of genetic damage

    (3) Multiple doses, which may be required, may delay therapeutic efficacy for a long period (many months or a year).

  d. Usual dosage is 4 to 10 mCi administered orally. Toxic nodular goiter and other special situations will require the use of larger doses.

  e. Precautions and monitoring effects

    (1) Radioiodine is not typically used in patients younger than 30 years old especially women because effects on future offspring are not known.

    (2) Response to ^{131}I is difficult to gauge, and patients must be monitored early for recurrence of hyperthyroidism, and later for hypothyroidism, which may develop even 20 years or more after therapy.

3. β-Adrenergic blocking agents

  a. Propranolol (Inderal) usually dosed 20 to 40 mg four times daily reduces some of the thyrotoxic manifestations (e.g., tachycardia, sweating, severe tremor, nervousness) of hyperthyroidism.

  b. In addition to providing symptomatic relief, propranolol at high doses ($>$ 160 mg/day) inhibit the peripheral conversion of T_4 to T_3.

  c. β-Blockers are primary adjunctive therapy to RAI

4. **Subtotal thyroidectomy**. Partial removal of the thyroid gland may be indicated if drug therapy fails or radioactive iodine is undesirable or contraindicated. This is a difficult procedure, but the success rate is high, and the cure is rapid. Risks include those mentioned in IV.F.2.b.(2), precipitating thyroid storm (see IV.G.2), and permanent postoperative hypothyroidism. The risk of inducing thyroid storm can be minimized by obtaining a euthyroid state through use of antithyroid agents (see IV.F.1) or propranolol (see IV.F.3).

G. **Complications**

1. **Hypothyroidism** may occur iatrogenically or, it has been proposed, as a natural sequel to Graves disease.

2. **Thyroid storm (thyrotoxic crisis)** is a sudden exacerbation of hyperthyroidism caused by rapid release (leakage) of thyroid hormone. It is invariably fatal if not treated rapidly. In this crisis, unchecked hypermetabolism leads ultimately to dehydration, shock, and death.

   a. **Precipitating factors** include thyroid trauma or surgery, RAI therapy, infection, severe emotional stress, and sudden discontinuation of antithyroid therapy.

   b. **Characterized** by a severe hyperpyrexia, tachycardia, agitation, delirium, psychosis, stupor, or coma

   c. **Treatment** is similar to that of uncomplicated hyperthyroidism; however, the doses are higher and given more frequently

      (1) Thioamide selection recommendations vary. **PTU**, in doses of 800 to 1200 mg/day given as 200 to 300 mg every 4 to 6 hrs, may provide additional benefits over MMI as it prevents peripheral deiodination of T_4 to T_3. However, **MMI** 20 to 25 mg every 6 hrs has a longer duration of action.

      (2) **Propranolol**, in doses of 60 to 80 mg every 4 hrs or 1 to 3 mg intravenously every 4 to 6 hrs, should be administered unless β-blockade is contraindicated (e.g., if the patient has CHF).

      (3) **Potassium iodide** (Lugol's solution, SSKI) Lugol's solution, 10 drops three times daily, or SSKI, five drops every 6 hrs, can be given after PTU to block thyroid hormone release.

      (4) Other supportive therapy includes rehydration, cooling, antibiotics, rest, and sedation.

Study Questions

Directions for questions 1–16: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. What is the correct formula to use for calculating the FTI?

   (A) $T_4 \times RT_3U$/mean serum RT_3U
   (B) $T_3 \times T_3$/mean serum RT_3U
   (C) $T_3 \times RT_3U$/mean serum RT_3U
   (D) $T_4 \times RT_3U \times$ mean serum RT_3U
   (E) $T_3 \times RT_3U \times$ mean serum RT_3U

2. What is the necessary precursor besides dietary iodine required for thyroxine biosynthesis?

   (A) T_3
   (B) threonine
   (C) tyrosine
   (D) TSH
   (E) TBG

3. All of the following conditions are causes of hyperthyroidism *except*

   (A) Graves disease
   (B) Hashimoto thyroiditis
   (C) toxic multinodular goiter
   (D) triiodothyronine toxicosis
   (E) Plummer disease

4. Which of the following preparations is used to attain remission of thyrotoxicosis?

   (A) propranolol
   (B) liotrix
   (C) levothyroxine
   (D) PTU
   (E) desiccated thyroid

5. The thyroid gland normally secretes which of the following substances into the serum?

   (A) TRH
   (B) TSH
   (C) DIT
   (D) thyroglobulin
   (E) T_4

6. All of the following conditions are causes of hypothyroidism *except*

   (A) endemic goiter
   (B) surgical excision
   (C) Hashimoto thyroiditis
   (D) goitrin-induced iodine deficiency
   (E) Graves disease

7. Common tests to monitor patients receiving replacement therapy for hypothyroidism include all of the following *except*

   (A) TSH stimulation test
   (B) serum TSH assay
   (C) FTI
   (D) RT_3U
   (E) TT_4

8. The FTI allows the clinician to evaluate all of the following *except*?

   (A) TT_4
   (B) THBI
   (C) Estimated Free T_4
   (D) Exact Free T_4
   (E) RT_3U

9. The inhibition of pituitary thyrotropin secretion is controlled by which of the following?

   (A) free T_4
   (B) TRH
   (C) FTI
   (D) reverse triiodothyronine (rT_3)
   (E) TT_4

10. Which of the following agents has been shown to interact with oral T_4 replacement therapy?

   (A) PTU
   (B) Cholestyramine
   (C) Thyrotropin
   (D) Levothyroxine
   (E) Lovastatin

11. What laboratory tests are currently recommended by the ATA to diagnose thyroid disease?

   (A) RT_3U and TT_4
   (B) TSH and FTI
   (C) TT_4 and sensitive TSH assay
   (D) free T_4 and sensitive TSH assay
   (E) free T_4 and RT_3U

12. Which of the following patient populations should not routinely be screened for thyroid disease?

   (A) Pregnant women
   (B) Patients with type I diabetes
   (C) Patients with a family history of thyroid disease
   (D) College students
   (E) Women > 60 years old

13. What is the average replacement dose of levothyroxine for an otherwise healthy adult?

   (A) 25 to 50 mcg/day
   (B) 50 to 100 mcg/day
   (C) 75 to 150 mcg/day
   (D) 100 to 200 mcg/day
   (E) 200 to 400 mcg/day

14. What factors affect the optimal replacement dose of levothyroxine?

   (A) Age, height, and weight
   (B) Duration of hypothyroidism
   (C) Pretreatment TSH level
   (D) Presence of chronic illness
   (E) All of the above

15. Which of the values represents the lower level of detection for the fourth-generation sensitive TSH assay as established by the ATA?

   (A) 0.5 to 5.0 mIU/L
   (B) 1 to 2 mIU/L
   (C) 0.01 to 0.02 mIU/L
   (D) 0.001 to 0.002 mIU/L
   (E) 0.0001 to 0.0002 mIU/L

16. In which of the following clinical presentations should the TSH assay be used?

   (A) Population screening for thyroid disease
   (B) Screening hospitalized patients
   (C) Patients receiving thyroid replacement after 6 to 8 weeks of therapy
   (D) Patients who are HIV positive
   (E) Screening patients with psychiatric illness

Directions for question 17: The question in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

   A   If **I only** is correct
   B   If **III only** is correct
   C   If **I and II** are correct
   D   If **II and III** are correct
   E   If **I, II**, **and III** are correct

17. A 62-year-old woman with a 5-year history of well-managed hypothyroidism was recently started on raloxifene 60 mg daily in the morning for the prevention of postmenopausal osteoporosis. Her thyroid disease had been well-controlled on 150 mcg levothyroxine (Synthroid) daily in the morning. Her TSH has remained within the normal range while on treatment. Her most recent TSH of 2.5 mIU/L and normal FT_4 values where noted last year. She presents today with an elevated TSH 15.5 mIU/L after 4 months of raloxifene therapy and symptoms of hypothyroidism. What change in therapy would be best for this patient?

   (I) Repeat the TSH test and FT_4 Tests
   (II) Increase the dose of levothyroxine to 200 mcg daily
   (III) Switch the dosing of the raloxifene to the evening

Directions for question 18: The question in this section can be correctly answered by **one** of the suggested answers. Choose the **best** answer.

18. A 69-year-old woman with hypertension and hypothyroidism is being treated for a wound infection. In the past, she was maintained on 125 mcg levothyroxine (Levoxyl) daily with a normal TSH of 2.0 mIU/L. After 6 weeks of treatment with oral ciprofloxacin (500 mg twice a day) she complains of fatigue and sensitivity to cold. Her serum TSH level was 14 mIU/L and FT_4 was below normal. What is the best management for this patient.

   (A) Increase the dose of levothyroxine
   (B) Switch the patient from Levoxyl to Synthroid
   (C) Discontinue levothyroxine until the wound is healed
   (D) Continue therapy without any changes
   (E) Separate the administration of ciprofloxacin and levothyroxine by at least 6 hrs

Directions for question 19: The questions in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

   (A) If **I only** is correct
   (B) If **IV only** is correct
   (C) If **I and IV** are correct
   (D) If **I, II, III, and IV** are correct
   (E) If **II, III, and V** are correct

19. Which of the following agents have been shown to interact with oral T_4 replacement therapy?

   I Atenolol
   II Calcium carbonate
   III Ciprofloxacin
   IV Levothyroxine
   V Raloxifene

20. What is the effect of amiodarone therapy on thyroid function?

   (A) Patients with underlying thyroid dysfunction are at an increase risk of developing hypothyroidism within 6 months of therapy.
   (B) Patients without underlying thyroid dysfunction routinely develop subclinical hyperthyroidism with amiodarone therapy.
   (C) Amiodarone interacts directly with circulating serum thyrotropin.
   (D) Amiodarone has no effect on thyroid function.
   (E) None of the above.

21. A 33-year-old underweight woman presents to you. She is currently taking levothyroxine (Synthroid) 200 mcg daily. Her TSH level is reported to be 0.15 mIU/L. What would be the most appropriate change to make to her therapy?

   (A) Continue current therapy
   (B) Repeat TSH, continue levothyroxine 200 mcg daily
   (C) Decrease levothyroxine to 175 mcg daily and recheck TSH in 6 weeks
   (D) Decrease levothyroxine to 150 mcg daily, recheck TSH in 6 weeks
   (E) Repeat TSH, TT_4, continue levothyroxine 200 mcg daily

22. What is the correct formula to use for calculating THBI?

   (A) RT_3U/mean serum RT_3U
   (B) $RT_3U \times$ mean serum RT_3U
   (C) $TT_4 \times RT_3U$/mean serum RT_3U
   (D) $T_4 \times RT_3U \times$ mean serum RT_3U
   (E) $T_3 \times RT_3U \times$ mean serum RT_3U

Directions for question 23: The question in this section can be correctly answered or completed by **one or more** of the above suggested answers. Choose the answer, **A–E**.

   (A) If **I only** is correct
   (B) If **III only** is correct
   (C) If **I and II** are correct
   (D) If **II and III** are correct
   (E) If **I, II, and III** are correct

23. Which of the following drugs are possible treatment options for primary hypothyroidism?

   I Desiccated Thyroid (Armour Thyroid)
   II Levothyroxine (Levoxyl)
   III PTU

Questions 24 and 25 are based on the following case:

AB is a 58-year-old female with a history of Graves disease who has been suffering from severe emotion distress from a recent divorce. She began to develop heart palpitations, a fever, and delirium. She is transported to the emergency department where she admits to stopping her methimazole 2 weeks prior.

24. Which of the following disease states is most likely related to AB's clinical presentation?

    (A) Hashimoto thyroiditis

    (B) Thyrotoxic crisis

    (C) Jod-Basedow phenomenon

    (D) Factitious hyperthyroidism

    (E) Plummer disease

25. Which of the following is part of the normal therapy for thyroid storm?

    (A) Quetiapine to treat delirium

    (B) A β-blocker like lisinopril

    (C) PTU to inhibit the synthesis of thyroid hormones

    (D) Levothyroxine to help augment the negative feedback mechanism and decrease production of thyroid hormone

    (E) Methimazole because it is a thioamide and also prevents peripheral deiodination of T_4 to T_3

26. The FDA black box warning for thyroid hormone replacement therapy is:

    (A) May cause life-threatening toxicity if used for weight loss

    (B) Risk of hepatotoxicity

    (C) Risk of nephrotoxicity

    (D) May cause tendon ruptures

    (E) May cause lactic acidosis

Answers and Explanations

1. The answer is A *[see II.F.5.c]*.

The FTI is a mathematical interpretation of the relationship between the rRT$_3$U and T$_4$ levels, compared to the mean population value for RT$_3$U. The FTI is calculated using reported values for TT$_4$ and RT$_3$U. The normal FTI value in euthyroid patients is 5.5 to 12.0.

2. The answer is C *[see II.B]*.

Biosynthesis of thyroid hormones begins with iodide binding to tyrosine, which forms MIT. MIT binds another iodide atom to form DIT. When MIT and DIT are formed, a coupling reaction occurs, which produces T$_3$, T$_4$, rT$_3$, and other by-products.

3. The answer is B *[see III.B.1; IV.A–B]*.

Hashimoto thyroiditis (chronic lymphocytic thyroiditis) is a cause of hypothyroidism. The incidence of Hashimoto thyroiditis is 1% to 2%, and it increases with age. It is more common in women than in men and more common in whites than in blacks. There may be a familial tendency. Patients with Hashimoto thyroiditis have elevated titers of antibodies to thyroglobulin: A titer < 1:32 is seen in > 85% of patients. Two variants of Hashimoto thyroiditis have been described: gland fibrosis and idiopathic thyroid atrophy, which is most likely an extension of Hashimoto thyroiditis.

4. The answer is D *[see IV.F.1–2]*.

In hyperthyroid patients, remission of thyrotoxicosis is achieved with PTU by two mechanisms: (1) interference of iodination of the tyrosyl residues, ultimately reducing production of T$_4$ and (2) inhibition of peripheral conversion of T$_4$ to T$_3$. Propranolol is commonly used as an adjunct to PTU for symptomatic management of hyperthyroidism.

5. The answer is E *[see II.A.1]*.

The major compounds secreted by the thyroid gland, after its stimulation by thyrotropin, are T$_3$ and T$_4$. When released from the thyroid, T$_3$ and T$_4$ are transported by plasma proteins—namely TBG and albumin.

6. The answer is E *[see III.B; IV.A.1]*.

Graves disease (diffuse toxic goiter) is the most common form of hyperthyroidism. It occurs most often in women in the third and fourth decades of life. There is a genetic and familial predisposition. The cause is linked to an autoimmune reaction between immunoglobulin G (IgG) and the thyroid.

7. The answer is A *[see III.G.3]*.

The TSH stimulation test measures thyroid tissue response to exogenous TSH. It is not commonly used to monitor thyroid replacement therapy. It may be useful in the initial diagnosis of hypothyroidism.

8. **The answer is D** *[see II.F.5.d]*.
The FTI is not an exact measure of free T_4 rather it is a mathematical interpretation between RT_3U and serum T_4 levels that estimates free T_4. The correct formula use would mean that a clinician has knowledge of TT_4, THBI, and estimated free T_4, RT_3U.

9. **The answer is A** *[see II.A.2.a]*.
An increase in the blood level of thyroid hormone (see circulating free T_4 and free T_3) signals the pituitary to stop releasing TSH. The free fraction of T_4 is available to bind at the pituitary receptors.

10. **The answer is B** *[see III.G.7.a]*.
Euthyroid patients receiving oral replacement therapy have become hypothyroid after concomitant administration of bile acid sequestrant therapy. It appears that bioavailability is reduced as a result of administering these agents at close dosing intervals. It is recommended that at least 6 hrs pass before administration of a bile acid sequestrant. It would be preferable to select another nonbile acid sequestrant when clinically possible.

11. **The answer is D** *[see II.G.1]*.
The free T_4 and the (third-generation) TSH assay should be used only for the diagnosis of patients most likely to have thyroid disease based on clinical presentation and relative risk (e.g., age, sex, family history), not for population screening. The third-generation TSH assay is also more commonly used to monitor replacement therapy, and to minimize overtreatment and the corresponding risk of accelerated bone loss.

12. **The answer is D** *[see II.G.3]*.
Cost versus benefit is critical to the decision of choosing to screen entire populations, and screening for thyroid disease has been shown to not be cost effective in the general healthy population. Screening recommendations from major medical groups has been conflicting; however, none of them recommend the routine screening of young, healthy adults.

13. **The answer is C** *[see III.F.3.c]*.
The average adult maintenance dose is 75 to 150 mcg/day, which has been shown to be 1.5 to 1.7 mcg/kg/day. The dose is usually adjusted in increments of 25 to 50 mcg/day every 4 weeks. The total daily dose used to be 100 to 200 mcg/day, which resulted in overtreatment after the introduction of the sensitive TSH assay. Elderly or chronically ill patients require an average dose of 50 to 100 mcg/day, which is 25 to 50 mcg/day less than otherwise healthy adults of the same height and weight.

14. **The answer is E** *[see III.F.3]*.
Elderly or chronically ill patients require an average dose of 50 to 100 mcg/day, which is 25 to 50 mcg/day less than otherwise healthy adults of the same height and weight. Because the average dose for replacement therapy is between 1.5 and 1.7 mcg/kg/day, weight affects the total daily dose.

15. **The answer is D** *[see II.F.1.b–f; Table 47-3]*.
The ATA has established standard nomenclature that indicates each technological improvement and the ability to detect lower levels of TSH using monoclonal antibodies. As the sensitivity of the assay improves, the lower level of detection is reported as a range in milli-International Units per liter. The most sensitive test is currently the fourth-generation IMA, with a reported lower level of detection of 0.001 to 0.002 mIU/L. In usual clinical practice the third-generation IMA is most commonly used, with sensitivity in the range of 0.01 to 0.02 mIU/L.

16. **The answer is C** *[see III.F.3.g; III.6; Figure 47-6]*.
The current third-generation TSH assay is not indicated for use in hospitalized patients who are not suspected to have thyroid disease. Studies have indicated that abnormally high or low TSH levels are detected in euthyroid hospitalized patients. Psychiatric illness may also influence TSH levels.

17. **The answer is B (IV)** *[see III.G.7; Tables 47-2 and 47-4]*.
The patient is most likely experiencing a drug interaction between raloxifene and levothyroxine. The best choice is to separate the medications by at least 12 hrs. A repeat of the TSH assay will only confirm the results, which are significantly elevated. Increasing the dose of levothyroxine may result in overtreatment.

18. **The answer is E** *[see III.G.7; Tables 47-2 and 47-4]*.
This patient is most likely experiencing a drug interaction between levothyroxine and ciprofloxacin when taken concomitantly. There is no benefit to switching to another brand of levothyroxine or increasing the dose. The best solution is to separate the doses of ciprofloxacin by 6 hrs.

19. **The answer is E (I, III, V)** *[see III.G.7; Tables 47-2 and 47-4]*.
Patients receiving oral replacement therapy who take calcium carbonate concomitantly have been shown to experience decreased free T_4 and total T_4 levels that resulted in an elevated TSH. The mechanism appears to be adsorption of levothyroxine to calcium carbonate at acid pH levels, which may reduce bioavailability. It is recommended to separate the time of ingestion of each product to reduce the chance of this interaction. Ciprofloxacin and raloxifene have also been shown to interact with levothyroxine when administered together. Separate administration times by 6 hrs for ciprofloxacin and by 12 hrs for raloxifene.

20. **The answer is A** *[see Tables 47-2 and 47-4].*

    Patients receiving amiodarone therapy are at risk of developing hypothyroidism especially if there is underlying thyroid disease. Amiodarone delivers high levels of iodine to the system contributing to subclinical or clinical hypothyroidism more often. Subclinical hyperthyroidism has been observed rarely. Some patients without underlying thyroid disease may experience changes in thyroid function, while patients with underlying disease are more likely to present with hypothyroidism. Patients should be monitored closely for thyroid function when beginning amiodarone therapy.

21. **The answer is C** *[see II.G; III.F.3.c].*

    The goal of levothyroxine therapy is to normalize TSH. Over replacement can result in symptoms of hyperthyroidism and lead to bone mineral density loss, osteoporosis, and palpitations. A suppressed TSH can identify excessive replacement. Serum T4 concentrations can be useful when nonadherence is suspected, but these concentrations are not routinely needed to monitor levothyroxine therapy. Dose adjustments to levothyroxine therapy should only be made in 12.5–25.0 mcg increments and the average adult dose is typically 75–150 mcg/day.

22. **The answer is A** *[see II.F.5.b].*

    The thyroid hormone binding index (THBI) is a mathematical interpretation of the normalized T_3-resin uptake value (RT_3U). The THBI is calculated using the reported values from RT_3U: the patient's T_3 resin and the normal pool T_3 resin. The mean THBI is therefore by definition 1.00, with a normal range of approximately 0.83 to 1.16.

23. **The answer is C** *[see II.F; IV.F].*

    Levothyroxine and desiccated thyroid are both oral thyroid hormone preparations that are indicated for primary hypothyroidism. PTU inhibits the synthesis of thyroid hormones by blocking the oxidation of iodine in the thyroid gland and is indicated in hyperthyroid disorders.

24. **The answer is B** *[see IV.G.2; IV.B].*

    The most likely disease state is thyrotoxic crisis (thyroid storm). AB has many risk factors for developing a thyrotoxic crisis: Underlying Graves disease, severe emotional stress, and a sudden discontinuation of her antithyroid medication. Hashimoto thyroiditis is an autoimmune hypothyroid disorder and is unlikely as the patient already has a history of Graves hyperthyroidism. Jod-Basedow phenomenon is hyperthyroidism following ingestion of iodine or iodide, there is not anything in the patient's history to suggest iodine ingestion. Factitious hyperthyroidism is the result of an overdose of thyroid hormone, while the clinical symptoms may suggest this; her medical history rules it out. Plummer disease would be evident on physical exam.

25. **The answer is C** *[see IV.F.1; IV.G.2].*

    PTU is a thioamide which inhibits the synthesis thyroid hormones which would be essential for the treatment of a hyperthyroid state like thyroid storm. β-Blockers are effective at controlling the symptoms induced by increased adrenergic tone, however, lisinopril is not a β-blocker. The addition of a synthetic thyroid hormone like levothyroxine has no place in thyroid storm; it will not induce negative feedback; on the contrary, it would contribute to the hyperthyroid state. Methimazole is a thioamide, however, only PTU prevents peripheral deiodination of T_4 to T_3. Delirium will resolve with the treatment of the underlying disease, quetiapine may actually increase TSH, and is not warranted in thyroid storm.

26. **The answer is A** *[see III.G.8].*

    FDA black box warning: Do not use thyroid hormones, including levothyroxine, either alone or with other therapeutic agents, for the treatment of obesity or for weight loss. They are ineffective for weight reduction in euthyroid patients and may produce serious or even life-threatening manifestations of toxicity, particularly when given in association with sympathomimetic amines such as those used for their anorectic effects.

48 Renal Disorders

HEATHER A. SWEENEY

I. ACUTE RENAL FAILURE

- **A. Definition.** Acute renal failure (ARF) is the sudden, potentially reversible interruption of kidney function, resulting in retention of nitrogenous waste products in body fluids.
- **B. Classification and etiology.** ARF is classified according to its cause.
    1. **Prerenal ARF** stems from impaired renal perfusion, which may result from
        - **a.** reduced arterial blood volume (e.g., dehydration, hemorrhage, vomiting, diarrhea, other gastrointestinal [GI] fluid loss).
        - **b.** urinary losses from excessive diuresis.
        - **c.** decreased cardiac output (e.g., from congestive heart failure [CHF] or pericardial tamponade).
        - **d.** renal vascular obstruction (e.g., stenosis).
        - **e.** severe hypotension.
    2. **Intrinsic ARF (intrarenal or parenchymal ARF)** reflects structural kidney damage resulting from any of the following conditions.
        - **a. Acute tubular necrosis (ATN)**, the leading cause of ARF, may be associated with
            - **(1)** exposure to nephrotoxic aminoglycosides, anesthetics, pesticides, organic metals, and radiopaque contrast materials.
            - **(2)** ischemic injury (e.g., surgery, circulatory collapse, severe hypotension).
            - **(3)** pigment (e.g., hemolysis, myoglobinuria).
        - **b.** Acute glomerulonephritis
        - **c.** Tubular obstruction, as from hemolytic reactions or uric acid crystals
        - **d.** Acute inflammation (e.g., acute tubulointerstitial nephritis, papillary necrosis)
        - **e.** Renal vasculitis
        - **f.** Malignant hypertension
        - **g.** Radiation nephritis
    3. **Postrenal ARF** results from obstruction of urine flow anywhere along the urinary tract including:
        - **a.** Ureteral obstruction, as from calculi, uric acid crystals, or thrombi
        - **b.** Bladder obstruction, as from calculi, thrombi, tumors, or infection
        - **c.** Urethral obstruction, as from strictures, tumors, or prostatic hypertrophy
        - **d.** Extrinsic obstruction, as from hematoma, inflammatory bowel disease, or accidental surgical ligation
- **C. Pathophysiology.** ARF progresses in three phases.
    1. **Initiating phase**
        - **a.** The initiating phase is defined as the time between the renal insult and the point at which extrarenal factors no longer reverse the damage caused by the obstruction or other cause of ARF. This phase may not be well defined clinically and may escape notice or diagnosis.
        - **b. Urine output** may drop markedly to 400 mL/day or less **(oliguria)**. In some patients, urine output falls below 100 mL/day **(anuria)**. Oliguria may last only hours or as long as 4 to 6 weeks. However, it has been shown that 40% to 50% of ARF patients are not oliguric or anuric.
        - **c. Nitrogenous waste products** accumulate in the blood.
            - **(1) Azotemia** reflects urea accumulation due to impaired glomerular filtration and concentrating capacity.
            - **(2)** Serum creatinine concentration, sulfate, phosphate, and organic acid levels climb rapidly.

d. The **serum sodium concentration** falls below normal from intracellular fluid shifting and dilution.

e. **Hyperkalemia** occurs due to the accumulation of organic acids (metabolic acidosis). If potassium intake is not restricted or body potassium is not removed, hyperkalemia results. Without treatment, hyperkalemia may lead to neuromuscular depression and paralysis, impaired cardiac conduction, arrhythmias, respiratory muscle paralysis, cardiac arrest, and ultimately death.

2. Maintenance phase

a. This phase begins when urine output rises above 500 mL/day—typically after several days of oliguria. A rise in urine output or a "diuretic response" may not be seen in non-oliguric patients. Increased urinary output does not signal recovery of renal function.

b. Urine output rises in increments of several milliliters to 300 to 500 mL/day. Urine output may double from day-to-day in the initial recovery period.

c. Azotemia and associated laboratory findings may persist until urine output reaches 1000 to 2000 mL/day.

d. The maintenance phase carries a risk of fluid and electrolyte abnormalities, GI bleeding, infection, and respiratory failure.

3. Recovery phase. During the recovery phase, renal function gradually returns to normal. Most recovered renal function appears in the first 2 weeks; however, recovery of renal function may continue for a year. Residual impairment may persist indefinitely.

D. Clinical evaluation

1. Physical findings. Initially, ARF causes azotemia and, in 50% to 60% of cases, oliguria. Later, electrolyte abnormalities and other severe systemic effects occur.

a. **Urine output** typically is **low**, from 20 to 500 mL/day. Complete anuria is rare.

b. **Signs** and **symptoms of hyperkalemia**, resulting from metabolic acidosis and reduced potassium excretion by impaired kidneys, include:

(1) neuromuscular depression (e.g., paresthesias, muscle weakness, paralysis)

(2) diarrhea and abdominal distention

(3) slow or irregular pulse

(4) electrocardiographic changes with potential cardiac arrest

c. **Uremia**, caused by excessive nitrogenous waste retention, leads to nausea, vomiting, diarrhea, edema, confusion, fatigue, neuromuscular irritability, and coma.

d. **Metabolic acidosis**, a common complication of ARF, is evidenced by:

(1) deterioration of mental status, obtundation, coma, and lethargy.

(2) depressed cardiac contractility and decreased vascular resistance, leading to hypotension, pulmonary edema, and ventricular fibrillation.

(3) nausea and vomiting

(4) respiratory abnormalities (e.g., hyperventilation, Kussmaul's respiration)

e. **Hyperphosphatemia** arises from decreased phosphate excretion. It is generally not seen in ARF.

(1) As serum phosphate rises, hypocalcemia results from the formation of insoluble calcium phosphate complexes.

(2) The signs and symptoms relate to resultant hypocalcemia and metastatic soft tissue calcification.

(3) Manifestations of hypocalcemia include:

(a) neuromuscular irritability, cramps, spasms, and tetany.

(b) hypotension.

(c) soft tissue calcification.

(d) mental status changes (e.g., confusion, mood changes, loss of intellect and memory).

(e) hyperactive deep-tendon reflexes, and Trousseau's and Chvostek's signs.

(f) abdominal cramps.

(g) stridor and dyspnea.

f. **Hyponatremia** results from dilution and intravascular fluid shifts during the diuretic phase of ARF. Physical findings include lethargy, weakness, seizures, cognitive impairment, and possible reduction in level of consciousness.

g. **Intravascular volume depletion**, suggesting **prerenal failure**, may cause:
   (1) flat jugular venous pulses when the patient lies supine.
   (2) orthostatic changes in blood pressure and pulse.
   (3) poor skin turgor and dry mucous membranes.

h. **Other findings** suggesting **prerenal failure** include:
   (1) an abdominal bruit, possibly indicating renal artery stenosis.
   (2) increased paradoxus, suggesting pericardial tamponade.
   (3) increased jugular venous pressure, pulmonary rales, and a third heart sound, signaling CHF.

i. **Postrenal failure** caused by obstructed urinary flow may manifest itself in:
   (1) a suprapubic or flank mass.
   (2) bladder distention.
   (3) costovertebral angle tenderness.
   (4) prostate enlargement.

2. **Diagnostic test results**

   a. **Urinalysis** includes an examination of sediment; identification of proteins, glucose, ketones, blood, and nitrites; and measurement of urinary pH and urine specific gravity (concentration) or osmolality (dilution). Prior administration of fluids, diuretics, and changes in urinary pH may confound accurate diagnosis, using urinalysis.
      (1) **Urinary sediment examination**
         (a) Few casts and formed elements are found in prerenal ARF.
         (b) Pigmented cellular casts and renal tubular epithelial cells appear with ATN.
         (c) Red blood cell and white blood cell casts generally reflect inflammatory disease.
         (d) Large numbers of broad white cell casts suggest chronic renal failure.
      (2) The presence of blood in the urine (**hematuria**) or proteins (**proteinuria**) indicates renal dysfunction.
      (3) **Urine-specific gravity** ranges from 1.010 to 1.016 in ARF.
      (4) **Urine osmolality** typically rises in prerenal ARF due to increased secretion of antidiuretic hormone.

   b. **Measurement of urine sodium** and **creatinine levels** can help classify ARF.
      (1) In **prerenal** ARF, the urine creatinine concentration **increases** and urine sodium level **decreases**.
      (2) In **intrinsic** ARF resulting from ATN, the urine creatinine concentration **decreases** and the urine sodium level **increases**.

   c. **Creatinine clearance**, an index of the **glomerular filtration rate (GFR)**, allows estimation of the number of functioning nephrons; decreased creatinine clearance indicates renal dysfunction. A timed urine collection should be used to calculate GFR in acute renal failure.

   d. **Blood chemistry** provides an index of renal excretory function and body chemistry status. Findings typical of ARF include:
      (1) increased blood urea nitrogen (BUN).
      (2) increased serum creatinine concentration.
      (3) possible increase in hemoglobin and hematocrit values due to dehydration.
      (4) abnormal serum electrolyte values.
         (a) Serum potassium level above 5 mEq/L
         (b) Serum phosphate level above 2.6 mEq/L (4.8 mg/dL)
         (c) Serum calcium level below 4 mEq/L (8.5 mg/dL), reflecting hypocalcemia. (The serum calcium level must be correlated with the serum albumin level. Each rise or fall of 1 g/dL of serum albumin beyond its normal range is responsible for a corresponding increase or decrease in serum calcium of approximately 0.8 mg/dL. A below-normal serum albumin level may result in a deceptively low serum calcium level.)
         (d) Serum sodium level below 135 mEq/L, reflecting hyponatremia
      (5) Abnormal arterial blood gas values (pH below 7.35, bicarbonate concentration [HCO^-3] below 22), reflecting metabolic acidosis

   e. **Renal failure index (RFI)** is the ratio of urine sodium concentration to the urine-to-serum creatinine ratio. The RFI helps determine the etiology of ARF. Typically, the RFI is less than 1 in prerenal ARF or acute glomerulonephritis (a cause of intrinsic ARF). The RFI is greater than 2 in postrenal ARF and in other intrarenal causes of ARF.

    f. Electrocardiography (ECG) may show evidence of hyperkalemia—that is, tall, peaked T waves; widening QRS complexes; prolonged PR interval, progressing to decreased amplitude and disappearing P waves; and, ultimately, ventricular fibrillation and cardiac arrest.

    g. Radiographic findings

      (1) Ultrasound may detect upper urinary tract obstruction.

      (2) Kidney, **ureter**, or **bladder radiography** may reveal:

        (a) urinary tract calculi.

        (b) enlarged kidneys, suggesting ATN.

        (c) asymmetrical kidneys, suggesting unilateral renal artery disease, ureteral obstruction, or chronic pyelonephritis.

      (3) Radionuclide scan may reveal:

        (a) bilateral differences in renal perfusion, suggesting serious renal disease.

        (b) bilateral differences in dye excretion, suggesting parenchymal disease or obstruction as the cause of ARF.

        (c) diffuse, slow, dense radionuclide uptake, suggesting ATN.

        (d) patchy or absent radionuclide uptake, possibly indicating severe, acute glomerulonephritis.

      (4) Computed tomography (CT) scan may provide better visualization of an obstruction.

    h. Renal biopsy may be performed in selected patients when other test results are inconclusive.

E. Treatment objectives

  1. Correct reversible causes of ARF, preventing or minimizing further renal damage or complications.

    a. Discontinue nephrotoxic drugs; remove other nephrotoxins through dialysis or gastric lavage for poisonings.

    b. Treat underlying infection.

    c. Remove any urinary tract obstructions.

  2. Correct and maintain proper fluid and electrolyte balance. Match fluid, electrolyte, and nitrogen intakes to urine output.

  3. Treat body chemistry alterations, especially hyperkalemia and metabolic acidosis, when present. Treatment may include renal dialysis.

  4. Improve urine output.

  5. Treat systemic manifestations of ARF.

F. Therapy

  1. Conservative management alone may suffice in uncomplicated ARF.

    a. Fluid management

      (1) Fluid intake should match fluid losses. **Sensible losses** (i.e., urine, stool, tube drainage) and **insensible losses** (i.e., skin, respiratory tract) of 500 to 1000 mL/day should be included in fluid balance calculations.

      (2) Volume overload should be avoided to minimize the risk of hypertension and CHF.

      (3) The patient should be weighed daily to determine fluid volume status.

    b. Dietary measures

      (1) Because catabolism accompanies renal failure, the patient should receive a **high-calorie**, **low-protein diet**. Such a diet helps to

        (a) reduce renal workload by decreasing production of end products of protein catabolism that the kidneys cannot excrete.

        (b) prevent ketoacidosis.

        (c) alleviate manifestations of uremia (e.g., nausea, vomiting, confusion, fatigue).

      (2) If edema or hypertension is present, sodium intake should be restricted.

      (3) Potassium intake must be limited in most patients. Fruits, vegetables, and salt substitutes containing potassium should be limited or avoided.

  2. Management of body chemistry alterations

    a. Treatment of hyperkalemia

      (1) Dialysis may be used to treat acute, life-threatening hyperkalemia (see *II.F.7*).

      (2) Calcium chloride or calcium gluconate

        (a) Mechanism of action and therapeutic effects. Calcium chloride or calcium gluconate replaces and maintains body calcium, counteracting the cardiac effects of acute hyperkalemia.

(b) Administration and dosage. When used to reverse hyperkalemia-induced cardiotoxicity, calcium chloride is given intravenously, as 5 to 10 mL of a 10% solution (1.4 mEq Ca^{2+}/mL) administered over 2 mins. Doses of up to 20 mL of a 10% solution are safe when given slowly. Another 10 to 20 mL of a 10% solution placed in a larger fluid volume and administered slowly may follow the initial dose. Calcium gluconate is administered as 10 mL of a 10% solution (1 g) for 2 to 5 mins. This may be repeated a second time.

(c) Precautions and monitoring effects

(i) Intravenous (IV) calcium is contraindicated in patients with ventricular fibrillation or renal calculi.

(ii) The infusion rate should not exceed 0.5 mL/min. Patients should remain recumbent for about 15 mins after infusion.

(iii) The ECG should be monitored during calcium gluconate therapy.

(iv) Calcium gluconate should not be mixed with solutions containing sodium bicarbonate because this can lead to precipitation.

(v) Adverse effects include hypotension, tingling sensations, and renal calculus formation.

(d) Significant interactions. Calcium may cause increased digitalis toxicity when administered concurrently with digitalis preparations.

(3) Sodium bicarbonate may be given as an emergency measure for severe hyperkalemia or metabolic acidosis.

(a) Mechanism of action and therapeutic effect. IV sodium bicarbonate restores bicarbonate that the renal tubules cannot reabsorb from the glomerular filtrate and increases arterial pH. This results in a shift of potassium into cells and reduces serum potassium concentration.

(b) Onset of action is 15 to 30 mins.

(c) Administration and dosage

(i) Sodium bicarbonate is administered intravenously.

(ii) The dosage is calculated as follows:

[50% of body weight (kg)] $\times$ [desired arterial bicarbonate (HCO^-3) $-$ actual HCO^-3]

One ampule (50 mEq) may be given intravenously for 5 mins.

(d) Precautions and monitoring effects

(i) To avoid sodium and fluid overload, sodium bicarbonate must be given cautiously. Half of the patient's bicarbonate deficit is replaced over the first 12 hrs of therapy.

(ii) Sodium bicarbonate may precipitate calcium salts in IV solutions and should not be mixed in the same infusion fluid.

(iii) Arterial blood gas values and serum electrolyte levels should be monitored closely during sodium bicarbonate therapy.

(4) Regular insulin with dextrose

(a) Mechanism of action and therapeutic effect. The insulin causes an intracellular shift of potassium. The combination of insulin with dextrose deposits potassium with glycogen in the liver, reducing the serum potassium.

(b) Onset of action is 15 to 30 mins.

(c) Administration and dosage. Regular insulin (10 units in 500 mL of 10% dextrose) is administered intravenously for 60 mins.

(d) Precautions and monitoring effects

(i) The serum glucose level should be monitored during therapy.

(ii) The patient should be assessed for signs and symptoms of fluid overload.

(5) Sodium polystyrene sulfonate (SPS) (Kayexalate®)

(a) Mechanism of action. SPS is a potassium-removing resin that exchanges sodium ions for potassium ions in the intestine (1 g of SPS exchanges 0.5 to 1 mEq/L of potassium). The SPS is distributed throughout the intestines and excreted in the feces.

(b) Therapeutic effect. Administered as an adjunctive treatment for hyperkalemia, SPS reduces potassium levels in the serum and other body fluids.

(c) Onset of action of orally administered SPS is 2 hrs; effects are seen in 1 hr when SPS is administered as a retention enema.

(d) Administration and dosage

  (i) SPS is usually administered orally, although it may be given through a nasogastric tube. The oral dose is 15 to 30 g in a suspension of 70% sorbitol, administered every 4 to 6 hrs until the desired therapeutic effect is achieved.

  (ii) When oral or nasogastric administration is not possible due to nausea, vomiting, or paralytic ileus, SPS may be given by retention enema. The rectal dose is 30 to 50 g in 100 mL of sorbitol as a warm emulsion, administered deep into the sigmoid colon every 6 hrs. Administration may be done with a rubber tube that is taped in place or via a Foley catheter with a balloon inflated distal to the anal sphincter.

(e) Precautions and monitoring effects

  (i) The patient's serum electrolyte levels should be monitored closely during SPS therapy. Sodium, chloride, bicarbonate, and pH should be monitored in addition to potassium.

  (ii) SPS therapy usually continues until the serum potassium level drops to between 4 and 5 mEq/L.

  (iii) The patient should be assessed regularly for signs of potassium depletion, including irritability, confusion, cardiac arrhythmias, ECG changes, and muscle weakness.

  (iv) SPS exchanges sodium for potassium, so sodium overload may occur during therapy. Patients with hypertension or CHF should be closely monitored.

  (v) For oral administration, SPS should be mixed only with water or sorbitol. Orange juice, which has a high potassium content, should not be used because it decreases the effectiveness of the SPS. For rectal administration, SPS should be mixed only with water and sorbitol, never with mineral oil.

  (vi) Adverse effects of SPS include constipation, fecal impaction with rectal administration, nausea, vomiting, and diarrhea.

  (vii) SPS should not be used as the sole agent in the treatment of severe hyperkalemia; other agents or therapies should be used in conjunction with this agent.

(f) Significant interactions. Magnesium hydroxide and other nonabsorbable cation-donating laxatives and antacids may decrease the effectiveness of potassium exchange by SPS and may cause systemic alkalosis.

b. Treatment of metabolic acidosis. Sodium bicarbonate may be given if the arterial pH is below 7.35.

c. Treatment of hyperphosphatemia

(1) IV calcium is first-line therapy for severe life-threatening hyperphosphatemia. Calcium reduces the serum phosphorus concentration by chelation.

(2) Oral calcium salts bind dietary phosphorus in the GI tract.

(3) Sevelamer (Renagel®) is a non ionic polymer that binds dietary phosphorus in the GI tract.

(4) Dialysis may be used to treat acute, life-threatening hyperphosphatemia accompanied by acute hypocalcemia. It is also performed when volume overload is present.

(5) Aluminum hydroxide (AlternaGel®) (an aluminum-containing antacid)

(a) Mechanism of action and therapeutic effect. Aluminum binds excess phosphate in the intestine, thereby reducing phosphate concentration.

(b) Onset of action is 6 to 12 hrs.

(c) Administration and dosage. Aluminum hydroxide is administered orally as a tablet or suspension. For the treatment of hyperphosphatemia, 0.5 to 2.0 or 15 to 30 mL of suspension is administered three or four times daily with meals.

(d) Precautions and monitoring effects

  (i) Aluminum hydroxide may cause constipation and anorexia.

  (ii) Serum phosphate levels should be monitored because aluminum hydroxide can cause phosphate depletion.

  (iii) Aluminum hydroxide can cause calcium resorption and bone demineralization.

    d. Treatment of hypocalcemia. Immediate treatment is necessary if the patient has severe hypocalcemia, as evidenced by tetany.

        (1) Calcium gluconate

            (a) Mechanism of action and therapeutic effect. This drug replaces and maintains body calcium, raising the serum calcium level immediately.

            (b) Administration and dosage. When used to reverse hypocalcemia, calcium gluconate is administered intravenously in a dosage of 1 to 2 g for a period of 10 mins, followed by a slow infusion (for 6 to 8 hrs) of an additional 1 g.

            (c) Precautions, monitoring effects, and significant interactions

                (i) Frequent determinations of serum (or ionized in the critically ill patient) calcium concentrations should be performed.

                (ii) Serum calcium concentrations usually should not be allowed to exceed 12 mg/dL.

                (iii) Avoid administration of IV calcium in patients taking digoxin as inotropic and toxic effects are synergistic and arrhythmias can occur.

        (2) Oral calcium salts. Calcium carbonate, chloride, gluconate, or lactate may be given by mouth when oral intake is permitted or if the patient has relatively mild hypocalcemia. The usual adult dosage is 4 to 6 g/day given in three or four divided doses.

    e. Treatment of hyponatremia

        (1) Moderate or asymptomatic hyponatremia may require only **fluid restriction**.

        (2) Sodium chloride may be given for severe symptomatic hyponatremia (i.e., a serum sodium level below 120 mEq/L).

            (a) Mechanism of action and therapeutic effect. Sodium chloride replaces and maintains sodium and chloride concentration, thereby increasing extracellular tonicity.

            (b) Administration and dosage

                (i) A 3% or 5% sodium chloride solution may be administered by slow IV infusion. The amount of solution needed is calculated from the following equation:

$$\text{(Normal serum sodium level} - \text{actual serum sodium level) total body water}$$

                (ii) Typically, 400 mL or less is administered.

            (c) Precautions and monitoring effects

                (i) Hypertonic sodium chloride must be administered very slowly to avoid circulatory overload, pulmonary edema, or central pontine demyelination.

                (ii) Serum electrolyte levels must be monitored frequently during therapy.

                (iii) Excessive infusion may cause hypernatremia and other serious electrolyte abnormalities and may worsen existing acidosis. Infusion rates should not exceed 0.5 mEq/kg/hr.

3. Management of systemic manifestations

    a. Treatment of fluid overload and edema. As water and sodium accumulate in extracellular fluid during ARF, fluid overload and edema may occur. **Diuretics** and dopamine may be given to reduce fluid volume excess and edema. Treatment should be initiated as soon as possible after oliguria begins. **Mannitol** or a **loop diuretic** may be used; thiazide diuretics are avoided in renal failure because they are ineffective when creatinine clearance is less than 25 mL/min, and they may worsen the patient's clinical status.

        (1) Step 1. **Loop (high-ceiling) diuretics**. These agents include **furosemide (Lasix®)**, **bumetanide (Bumex®)**, **torsemide (Demadex®)**, and **ethacrynic acid (Edecrin®)**. Loop diuretics are more potent and faster acting than thiazide diuretics.

            (a) Mechanism of action and therapeutic effects. Loop diuretics inhibit sodium and chloride reabsorption at the loop of Henle, promoting water excretion.

            (b) Onset of action for an oral dose is 1 hr; several minutes for an IV dose. Duration of action for an oral dose is 6 to 8 hrs; 2 to 3 hrs for an IV dose.

            (c) Administration and dosage

                (i) Furosemide, the **most commonly used** loop diuretic, usually is administered intravenously in patients with ARF to hasten the therapeutic effect. The dose is titrated to the patient's needs; the usual initial dose is 1.0 to 1.5 mg/kg. If the first dose does not produce a urine output of 10 to 15 mL within 20 to

30 mins, a dose of 2 to 3 mg/kg is administered; if the desired response still does not occur, a dose of 3 to 6 mg/kg is administered 20 to 30 mins after the second dose.

  (ii) **Bumetanide** may be given to patients who are unresponsive or allergic to furosemide. The usual dosage, administered intravenously or intramuscularly in the treatment of ARF, is 0.5 to 1.0 mg/day; however, some patients may require up to 20 mg/day. A second or third dose may be given at intervals of 2 to 3 hrs. When bumetanide is given orally, the dosage is 0.5 to 2.0 mg/day, repeated up to two times, if necessary, at intervals of 2 to 3 hrs.

  (iii) **Ethacrynic acid** is **less commonly used** to treat ARF because ototoxicity (sometimes irreversible) is associated with its use. It may be given intravenously (slowly for several minutes) in a dose of 50 to 100 mg. The usual oral dosage is 50 to 200 mg/day; some patients may require up to 200 mg twice daily. Ethacrynic acid can be safely given to patients who may have a sulfonamide allergy, which would preclude them from therapy with furosemide or torsemide.

  (iv) **Torsemide** may also be given to patients unresponsive to or allergic to furosemide. The usual dose is 20 mg, administered intravenously. Doses may be increased by doubling up to 200 mg; 10 to 20 mg of torsemide is equipotent to 40 mg of furosemide or 1 mg bumetanide. Torsemide offers better bioavailability compared to other loop diuretics; however, it is considerably more expensive.

(d) **Precautions and monitoring effects**

  (i) Loop diuretics must be used cautiously because they may cause overdiuresis leading to orthostatic hypotension and fluid and electrolyte abnormalities, including volume depletion and dehydration, hypocalcemia, hypokalemia, hypochloremia, hyponatremia, hypomagnesemia, and transient ototoxicity, especially with rapid IV injection.

  (ii) Serum electrolyte levels should be monitored frequently and the patient assessed regularly for signs and symptoms of electrolyte abnormalities.

  (iii) Blood pressure and pulse rate should be assessed during diuretic therapy.

  (iv) GI reactions include abdominal pain and discomfort, diarrhea (with furosemide and ethacrynic acid), and nausea (with bumetanide).

  (v) Blood glucose levels should be monitored in diabetic patients receiving loop diuretics because these agents may cause hyperglycemia and impaired glucose tolerance.

  (vi) Patients who are allergic to sulfonamides may be hypersensitive to bumetanide and furosemide.

  (vii) Furosemide and ethacrynic acid may cause agranulocytosis.

(e) **Significant interactions**

  (i) **Aminoglycoside antibiotics** may potentiate ototoxicity when administered with any loop diuretic.

  (ii) **Nonsteroidal anti-inflammatory drugs (NSAIDs)** may hamper the diuretic response to furosemide and bumetanide; **probenecid** may hamper the diuretic response to bumetanide.

  (iii) Ethacrynic acid may potentiate the anticoagulant effects of **warfarin (Coumadin®)**.

(2) **Step 2. Mannitol**, an osmotic diuretic, is a non-reabsorbable polysaccharide.

(a) **Mechanism of action and therapeutic effect**. Mannitol increases the osmotic pressure of the glomerular filtrate; fluid from interstitial spaces is drawn into blood vessels, expanding plasma volume and maintaining or increasing the urine flow. This drug may be given to prevent ARF in high-risk patients, such as those undergoing surgery or suffering from severe trauma or hemolytic transfusion reactions.

(b) **Onset of action** is 15 to 30 mins. Duration of action is 3 to 4 hrs.

(c) **Administration and dosage**. Mannitol is available in solutions ranging from 5% to 25%. For the treatment of oliguric ARF or the prevention of ARF, the usual initial dose is 12.5 to 25.0 g, administered intravenously; the maximum daily dosage is 100 g, administered intravenously. The exact concentration of the solution is determined by the patient's fluid requirements.

(d) **Precautions and monitoring effects**
  (i) Mannitol is contraindicated in patients with anuria, pulmonary edema or congestion, severe dehydration, and intracranial hemorrhage (except during craniotomy).
  (ii) Mannitol may cause or worsen pulmonary edema and circulatory overload. If signs and symptoms of these problems develop, the infusion should be stopped.
  (iii) Other adverse effects of mannitol include fluid and electrolyte abnormalities, water intoxication, headache, confusion, blurred vision, thirst, nausea, and vomiting.
  (iv) Vital signs, urine output, daily weight, cardiopulmonary status, and serum and urine sodium and potassium levels should be monitored during mannitol therapy.
  (v) Mannitol solutions with undissolved crystals should not be administered.
4. **Dialysis**. If the previously mentioned strategies fail, hemodialysis or peritoneal dialysis may be necessary in ARF patients who develop anuria, acute fluid overload, severe hyperkalemia, metabolic acidosis, or a BUN level above 100 mg/dL.

II. CHRONIC KIDNEY DISEASE

A. **Definition.** Chronic kidney disease (CKD) is the progressive, irreversible deterioration of renal function. Usually resulting from long-standing disease, CKD sometimes derives from ARF that does not respond to treatment.
B. **Classification and pathophysiology**
  1. CKD is defined as kidney damage or GFR < 60 mL/min/1.73 m^2 for ≥ 3 months. Kidney damage is defined as pathological abnormalities or markers of damage, including abnormalities in blood or urine tests or imaging studies. CKD has recently been reclassified as stages I to V to denote the severity of renal impairment. Generally, CKD, if left untreated, progresses at a predictable, steady rate from stage I through stage V.
    a. **Stage I** is defined as kidney damage with a normal or increased GFR. The corresponding GFR in stage I CKD is usually > 90 mL/min/1.73 m^2.
    b. **Stage II** is defined as kidney damage or a mildly decreased GFR (60 to 89 mL/min/1.73 m^2).
    c. **Stage III** signifies moderate reductions in GFR (30 to 59 mL/min/1.73 m^2).
    d. **Stage IV** connotes a GFR of 15 to 29 mL/min/1.73 m^2.
    e. **Stage V** is kidney failure or a GFR of < 15 mL/min/1.73 m^2.
  2. As CKD progresses, nephron destruction worsens, leading to deterioration in the kidneys' filtration, reabsorption, and endocrine functions.
  3. Renal function typically does not diminish until about 75% of kidney tissue is damaged. Ultimately, the kidneys become shrunken, fibrotic masses.
C. **Etiology**. **Causes of CKD in adults**
  1. Diabetic nephropathy
  2. Hypertension
  3. Glomerulonephritis
  4. Polycystic kidney disease
  5. Long-standing vascular disease (e.g., renal artery stenosis)
  6. Long-standing obstructive uropathy (e.g., renal calculi)
  7. Exposure to nephrotoxic agents
D. **Clinical evaluation**
  1. **Physical findings.** Signs and symptoms, which vary widely, do not appear until renal insufficiency progresses to renal failure.
    a. **Metabolic abnormalities** include loss of the ability to maintain sodium, potassium, and water homeostasis, leading to hyponatremia or hypernatremia, based on relative sodium or water intake. Hyperkalemia is uncommon until end-stage disease. Fluid overload, edema, and CHF may become a problem unless fluid intake is closely managed. As renal failure progresses, the inability to excrete acid and maintain buffer capacity leads to metabolic acidosis (see *I.D.1.b, d, g, h*). Calcium and phosphate metabolism is altered due to hyperparathyroidism.
    b. **Neurological manifestations** include short attention span, loss of memory, and listlessness. As CKD progresses, these advance to confusion, stupor, seizures, and coma. Neuromuscular findings include peripheral neuropathy and pain, itching, and a burning sensation,

particularly in the feet and legs. Patients may appear intoxicated. If dialysis is not started after these abnormalities occur, motor involvement begins, including loss of deep-tendon reflexes, weakness, and finally, quadriplegia.

    c. **Cardiovascular problems** include arterial hypertension, peripheral edema, CHF, and pulmonary edema. Uremic pericarditis is now increasingly infrequent as a result of early dialysis.

    d. **GI manifestations** include hiccups, anorexia, nausea, vomiting, constipation, stomatitis, and an unpleasant taste in the mouth. CKD patients have an increased incidence of ulcers, pancreatitis, and diverticulosis.

    e. **Respiratory problems** include dyspnea when CHF is present, pulmonary edema, pleuritic pain, and uremic pleuritis.

    f. **Integumentary findings** typically include pale yellowish, dry, scaly skin; severe itching; uremic frost; ecchymoses; purpura; and brittle nails and hair.

    g. **Musculoskeletal changes** range from muscle and bone pain to pathological fractures and calcifications in the brain, heart, eyes, joints, and vessels. Soft tissue calcification and renal osteodystrophy may occur.

    h. **Hematological disturbances** include anemia. The signs and symptoms of anemia arise from lack of epoetin alfa and reduced life span of red blood cells, including

        (1) pallor of the skin, nail beds, palms, conjunctivae, and mucosa.

        (2) abnormal bruising or ecchymoses, and uremic bleeding due to platelet inactivation.

        (3) dyspnea and angina pectoris.

        (4) extreme fatigue.

  2. **Diagnostic test results**

    a. **Creatinine clearance** may range from 0 to 90 mL/min, reflecting renal impairment.

    b. **Blood tests** typically show

        (1) elevated BUN and serum creatinine concentration.

        (2) reduced arterial pH and bicarbonate concentration.

        (3) reduced serum calcium level.

        (4) increased serum potassium and phosphate levels.

        (5) possible reduction in the serum sodium level.

        (6) normochromic, normocytic anemia (hematocrit 20% to 30%).

    c. **Urinalysis** may reveal glycosuria, proteinuria, erythrocytes, leukocytes, and casts. Specific gravity is fixed at 1.010.

    d. **Radiographic findings**. Kidney, ureter, and bladder radiography, IV pyelography, renal scan, renal arteriography, and nephrotomography may be performed. Typically, these tests reveal small kidneys (less than 8 cm in length).

E. **Treatment objectives**

  1. Improve patient comfort and prolong life.

  2. Treat systemic manifestations of CKD.

  3. Correct body chemistry abnormalities.

F. **Therapy.** Management of the CKD patient is generally conservative. Dietary measures and fluid restriction relieve some symptoms of CKD and may increase patient comfort and prolong life until dialysis or renal transplantation is required or available.

  1. **Treatment of edema. Angiotensin-converting enzyme (ACE) inhibitors** and **diuretics** may be given to manage edema and CHF and to increase urine output.

    a. **ACE inhibitors—captopril (Capoten®)**, **enalapril (Vasotec®)**, **lisinopril (Prinivil®, Zestril®)**, **fosinopril (Monopril®)**—are widely used to delay progression of CKD because they help preserve renal function and typically cause fewer adverse effects than other antihypertensive agents. They also decrease proteinuria and nephrotic syndrome.

    b. **Diuretics**. An osmotic diuretic, a loop diuretic, or a thiazide-like diuretic may be given.

        (1) **Osmotic and loop diuretics**. See I.F.3.a.(1), (2) for information on the use of these drugs in renal failure.

        (2) **Thiazide-like diuretics**. **Metolazone (Zaroxolyn®)** is the most commonly used thiazide diuretic in CKD.

            (a) **Mechanism of action and therapeutic effect**. Metolazone reduces the body's fluid and sodium volume by decreasing sodium reabsorption in the distal convoluted tubule, thereby increasing urinary excretion of fluid and sodium.

        (b) Administration and dosage. Metolazone is given orally at 5 to 20 mg/day; the dose is titrated to the patient's needs. Due to its long half-life, metolazone may be given every other day. Furosemide and metolazone act synergistically. Combination use is common, and metolazone should be administered 30 mins before furosemide to achieve the optimal diuretic effect.

        (c) Precautions and monitoring effects
- **(i)** Metolazone should not be given to patients with hypersensitivity to sulfonamide derivatives, including thiazides.
- **(ii)** To avoid nocturia, the daily dose should be given in the morning.
- **(iii)** Metolazone may cause hematological reactions, such as agranulocytosis, aplastic anemia, and thrombocytopenia.
- **(iv)** Fluid volume depletion, hypokalemia, hyperuricemia, hyperglycemia, and impaired glucose tolerance may occur during metolazone therapy.
- **(v)** Metolazone may cause hypersensitivity reactions, including vasculitis and pneumonitis.

        (d) Significant interactions
- **(i) Diazoxide** may potentiate the antihypertensive, hyperglycemic, and hyperuricemic effects of metolazone.
- **(ii) Colestipol** and **cholestyramine** decrease the absorption of metolazone.

2. Treatment of hypertension. Antihypertensive agents may be needed if blood pressure becomes dangerously high as a result of edema and the high renin levels that occur in CKD. Antihypertensive therapy should be initiated in the lowest effective dose and titrated according to the patient's needs.

    a. ACE inhibitors—captopril, enalapril, lisinopril, fosinopril—as mentioned in II.F.1.a.

    b. Dihydropyridine calcium-channel blockers, including **amlodipine (Norvasc®)** and **felodipine (Plendil®)**, have similar effects and may be used instead of ACE inhibitors.

    c. β-Adrenergic blockers, including **propranolol (Inderal®)** and **atenolol (Tenormin®)**, reduce blood pressure through various mechanisms.

    d. Other antihypertensive agents are sometimes used in the treatment of CKD, including α-adrenergic drugs, **clonidine (Catapres®)**, and vasodilators, such as **hydralazine (Apresoline®)**.

3. Treatment of hyperphosphatemia involves administration of a phosphate binder, such as aluminum hydroxide or calcium carbonate (see *I.F.2.c*).

4. Treatment of hypocalcemia

    a. Oral calcium salts [see *I.F.2.d.(2)*]

    b. Vitamin D

        (1) Mechanism of action and therapeutic effect. Vitamin D promotes intestinal calcium and phosphate absorption and utilization and, thus, increases the serum calcium concentration.

        (2) Choice of agent. For the treatment of hypocalcemia in CKD and other renal disorders, **calcitriol (Rocaltrol®)** (vitamin D_3, the active form of vitamin D) is the preferred vitamin D supplement because of its greater efficacy and relatively short duration of action. Other single-entity preparations include dihydrotachysterol, ergocalciferol (Calciferol®), doxercalciferol (Hectorol®) and paricalcitol (Zemplar®).

        (3) Administration and dosage. Calcitriol is given orally or via IV; the dose is titrated to the patient's needs (0.5 to 1.0 mg/day may be effective).

        (4) Precautions and monitoring effects
- **(a)** Vitamin D administration may be dangerous in patients with renal failure and must be used with extreme caution.
- **(b)** Vitamin D toxicity may cause a wide range of signs and symptoms, including headache, dizziness, ataxia, convulsions, psychosis, soft tissue calcification, conjunctivitis, photophobia, tinnitus, nausea, diarrhea, pruritus, and muscle and bone pain.
- **(c)** Vitamin D has a narrow therapeutic index, necessitating frequent measurement of BUN and serum urine calcium and potassium levels.

5. **Treatment of other systemic manifestations of CKD**
   a. **Treatment of anemia** includes administration of iron (e.g., ferrous sulfate), folate supplements, and epoetin alfa.
      (1) Severe anemia may warrant transfusion with packed red blood cells.
      (2) Epoetin alfa (Procrit®, Epogen®) stimulates the production of red cell progenitors and the production of hemoglobin. It also accelerates the release of reticulocytes from the bone marrow.
         (a) An initial dose of epoetin alfa is 50 to 100 U/kg intravenously or subcutaneously three times a week. The dose may be adjusted upward to elicit the desired response.
         (b) Epoetin alfa works best in patients with a hematocrit below 30%. During the initial treatment, the hematocrit increases 1.0% to 3.5% in a 2-week period. The target hematocrit is 33% to 35%. Maintenance doses are titrated based on hematocrit after this level is reached.
         (c) Epoetin alfa therapy should be temporarily stopped if hematocrit exceeds 36%. Additional side effects include hypertension in up to 25% of patients. Headache and malaise have been reported.
         (d) The effects of epoetin alfa are dependent on a ready supply of iron for hemoglobin synthesis. Patients who do not respond should have iron stores checked. This includes serum iron, total iron-binding capacity, transferrin saturation, and serum ferritin. Iron supplementation should be increased as indicated.
      (3) Darbepoetin (Aranesp®) is an epoetin alfa analogue. Its advantage is a prolonged plasma half-life, thus allowing it to be administered once weekly or biweekly.
      (4) Intravenous iron products may be given to replete iron stores. This route is preferred to oral supplementation due to low oral bioavailability and GI intolerance. Iron dextran is commonly used; however, it is associated with hypotension and anaphylaxis. Newer iron products include sodium ferric gluconate and iron sucrose, which are better tolerated and can be infused more rapidly compared to iron dextran. Patients with severe iron deficiency may receive up to a total of 1 g of an iron preparation over several days. The rate of infusion depends on the preparation used.
   b. **Treatment of GI disturbances**
      (1) Antiemetics help control nausea and vomiting.
      (2) Docusate sodium or methylcellulose may be used to prevent constipation.
      (3) Enemas may be given to remove blood from the GI tract.
   c. **Treatment of skin problems**. An antipruritic agent, such as diphenhydramine (Benadryl®), may be used to alleviate itching.
6. **Management of body chemistry abnormalities** (see *I.F.2*)
7. **Dialysis**. When CKD progresses to end-stage renal disease and no longer responds to conservative measures, long-term dialysis or renal transplantation is necessary to prolong life.
   a. **Hemodialysis** is the preferred dialysis method for patients with a reduced peritoneal membrane, hypercatabolism, or acute hyperkalemia.
      (1) This technique involves shunting of the patient's blood through a dialysis membrane-containing unit for diffusion, osmosis, and ultrafiltration. The blood is then returned to the patient's circulation.
      (2) Vascular access may be obtained via an arteriovenous fistula or an external shunt.
      (3) The procedure takes only 3 to 8 hrs; most patients need three treatments a week. With proper training, patients can perform hemodialysis at home.
      (4) The patient receives heparin during hemodialysis to prevent clotting.
      (5) Various complications may arise, including clotting of the hemofilter, hemorrhage, hepatitis, anemia, septicemia, cardiovascular problems, air embolism, rapid shifts in fluid and electrolyte balance, itching, nausea, vomiting, headache, seizures, and aluminum osteodystrophy.
   b. **Peritoneal dialysis** is the preferred dialysis method for patients with bleeding disorders and cardiovascular disease.
      (1) The peritoneum is used as a semipermeable membrane. A plastic catheter inserted into the peritoneum provides access for the dialysate, which draws fluids, wastes, and electrolytes across the peritoneal membrane by osmosis and diffusion.

(2) Peritoneal dialysis can be carried out in three different modes.
  (a) **Intermittent peritoneal dialysis** is an automatic cycling mode lasting 8 to 10 hrs, performed three times a week. This mode allows nighttime treatment and is appropriate for working patients.
  (b) **Continuous ambulatory peritoneal dialysis** is performed daily for 24 hrs with four exchanges daily. The patient can remain active during the treatment.
  (c) **Continuous cyclic peritoneal dialysis** may be used if the other two modes fail to improve creatinine clearance. Dialysis takes place at night; the last exchange is retained in the peritoneal cavity during the day, then drained that evening.
(3) **Advantages** of peritoneal dialysis include a lack of serious complications, retention of normal fluid and electrolyte balance, simplicity, reduced cost, patient independence, and a reduced need (or no need) for heparin administration.
(4) **Complications** of peritoneal dialysis include hyperglycemia, constipation, and inflammation or infection at the catheter site. Also, this method carries a high risk of peritonitis.

8. **Renal transplantation**. This surgical procedure allows some patients with end-stage renal disease to live normal and, in many cases, longer lives.
   a. **Histocompatibility** must be tested to minimize the risk of transplant rejection and failure. Human leukocyte antigen (HLA) type, mixed lymphocyte reactivity, and blood group types are determined to assess histocompatibility.
   b. Renal transplant material may be obtained from a living donor or a cadaver.
   c. **Three types of graft rejection** can occur.
      (1) **Hyperacute (immediate) rejection** results in graft loss within minutes to hours after transplantation.
         (a) Acute urine flow cessation and bluish or mottled kidney discoloration are intraoperative signs of hyperacute rejection.
         (b) Postoperative manifestations include kidney enlargement, fever, anuria, local pain, sodium retention, and hypertension.
         (c) Treatment for hyperacute rejection is immediate nephrectomy.
      (2) **Acute rejection** may occur 4 to 60 days after transplantation.
      (3) **Chronic rejection** occurs more than 60 days after transplantation.
         (a) Signs and symptoms include low-grade fever, increased proteinuria, azotemia, hypertension, oliguria, weight gain, and edema.
         (b) Treatment may include alkylating agents, cyclosporine, antilymphocyte globulin, and corticosteroids. In some cases, nephrectomy is necessary.
   d. **Complications** include
      (1) infection, diabetes, hepatitis, and leukopenia, resulting from immunosuppressive therapy.
      (2) hypertension, resulting from various causes.
      (3) cancer (e.g., lymphoma, cutaneous malignancies, head and neck cancer, leukemia, colon cancer).
      (4) pancreatitis and mental and emotional disorders (e.g., suicidal tendencies, severe depression, brought on by steroid therapy).

Study Questions

1. Severe hypotension may result in what type of acute renal failure?
   (A) Prerenal
   (B) Intrarenal
   (C) Postrenal
   (D) Intrinsic
   (E) Parenchymal

2. Why might sodium polystyrene sulfonate (SPS) be utilized in ARF?
   (A) It reduces calcium levels in the serum.
   (B) It increases calcium levels in the serum.
   (C) It increases potassium levels.
   (D) It reduces potassium levels in the serum.
   (E) It elevates glucose levels.

3. Why are thiazide diuretics avoided in patients with renal failure?

   (A) Overdiuresis may occur.
   (B) Patients are often allergic to furosemide.
   (C) They are ineffective when creatinine clearance is less than 25 mL/min.
   (D) They are too costly.
   (E) Sodium and potassium are already depleted.

4. The following are causes of chronic kidney disease *except*

   (A) diabetic nephropathy.
   (B) hypertension.
   (C) glomerulonephritis.
   (D) long-term exposure to acetaminophen.
   (E) polycystic kidney disease.

5. What is the major difference between epoetin alfa and darbepoetin?

   (A) Epoetin alfa has a longer plasma half-life.
   (B) Darbepoetin has a longer plasma half-life.
   (C) Epoetin alfa does not require adequate iron stores.
   (D) Darbepoetin does not require adequate iron stores.
   (E) Epoetin alfa is a newer agent.

Answers and Explanations

1. **The answer is A** *[see I.B.1.e]*.
   Prerenal ARF stems from impaired renal perfusion, which may result from reduced arterial volume, urinary losses from excessive dieresis, decreased cardiac output, renal vascular obstruction, and severe hypotension.

2. **The answer is D** *[see I.F.2.a.(5).(b)]*.
   SPS is a potassium-removing resin that exchanges sodium ions for potassium ions in the intestine (1 g of SPS exchanges 0.5 to 1.0 mEq/L of potassium). The SPS is distributed throughout the intestines and excreted in the feces. It is administered as an adjunctive treatment for hyperkalemia since SPS reduces potassium levels in the serum and other body fluids.

3. **The answer is C** *[see I.F.3.a]*.
   Thiazide diuretics are avoided in renal failure because they are ineffective when creatinine clearance is less than 25 mL/min and they may worsen the patient's clinical status.

4. **The answer is D** *[see II.C]*.
   Long-term exposure to acetaminophen (APAP) has not been shown to be a cause of chronic kidney disease. APAP can lead to chronic hepatic disorders such as chronic liver failure. The other listed conditions have been shown to lead to chronic kidney disease.

5. **The answer is B** *[see II.F.5.a.(3)]*.
   Darbepoetin is an epoetin analogue that has a prolonged plasma half-life that allows for once weekly or biweekly dosing compared to a three times a week regimen with epoetin alfa.

49 Hepatic Disorders

HEATHER A. SWEENEY

I. ACUTE LIVER FAILURE (ALF)

    A. General information
1. ALF is a rare condition. The United States approximates 2000 cases a year.
2. It is classified by a rapid deterioration (less than 26 weeks) of liver function, which results in jaundice, coagulopathy (international normalized ratio [INR] greater than 1.5), and hepatic encephalopathy in previously normal individuals.
3. The most common causes of ALF are drug-induced liver injury, viral hepatitis, autoimmune liver disease, and hypoperfusion.

    B. Signs and symptoms
1. Right upper quadrant tenderness
2. Nausea, vomiting
3. Jaundice

    C. Diagnosis
1. All patients with clinical or laboratory evidence of moderate-to-severe acute hepatitis should have a measurement of prothrombin time.
2. If the prothrombin time is prolonged by ~4 to 6 secs or more (INR ≥ 1.5) and there is evidence of altered sensorium, the diagnosis of ALF is established and hospital admission is mandatory.
3. Since ALF may progress rapidly, early transfer to the ICU is recommended once the diagnosis of ALF is made.
4. Seek specific cause of ALF.

    D. Treatment
1. Admit patient to ICU.
2. Specific treatment is dependent on etiology of ALF.
3. Consider need for liver transplantation.

II. ACETAMINOPHEN HEPATOTOXICITY

    A. General information
1. In the United States, acetaminophen (APAP) is the leading cause of acute liver failure.
2. APAP is a dose-related toxin. To cause toxicity, an acute overdose usually totals ≥ 150 mg/kg (about 7.5 g in adults) within 24 hrs.
3. The main toxic metabolite of APAP is *N*-acetyl-*p*-benzoquinone imine (NAPQI), which is produced by the hepatic P450 system. Glutathione in the liver normally detoxifies NAPQI. An acute overdose of APAP depletes glutathione stores which results in an accumulation of NAPQI that causes hepatocellular necrosis.
4. Likelihood and severity of hepatotoxicity from an acute APAP ingestion is predicted by the serum APAP level.

    B. Signs, symptoms, and labs (Postingestion times)
1. Stage I (0 to 24 hrs): anorexia, nausea, vomiting
2. Stage II (24 to 72 hrs): right upper quadrant pain, elevated aspartate aminotransferase (AST) and alanine aminotransferase (ALT), possible elevation of bilirubin and prothrombin time (PT)
3. Stage III (72 to 96 hrs): vomiting, peaking of AST, ALT, bilirubin, and INR
4. Stage IV (greater than 5 days): resolution of hepatotoxicity or progression to multiple organ failure

C. Treatment
1. Administer activated charcoal
   a. Ideally give within 1 hr of ingestion. It may be of benefit as long as 3 to 4 hrs after ingestion.
   b. Adult oral dose: 25 to 100 g as a single dose; if multiple doses are needed, additional doses may be given as 12.5 g/hr.
2. Administer *N*-acetylcysteine (Acetadote®)
   a. *N*-acetylcysteine is a precursor for glutathione and decreases APAP toxicity by increasing glutathione hepatic stores. It does not reverse damage to liver cells that have already been injured.
   b. Ideally begin treatment within 8 hrs of ingestion. It may be of value 48 hrs or more after ingestion.
   c. Adult oral dose: 140 mg/kg, followed by 70 mg/kg every 4 hrs times 17 doses.
   d. Adult IV dose: 150 mg/kg infused over 60 mins, followed by 50 mg/kg infused over 4 hrs, followed by 100 mg/kg infused over 16 hrs.

D. Chronic APAP toxicity
1. Chronic excessive use or repeated overdoses of APAP can lead to chronic APAP poisoning. Often patients are treating pain with high doses of APAP from multiple or single source products.
2. Symptoms may be similar to those symptoms listed with acute ingestion or may be absent.
3. Labs
   a. If AST and ALT are normal and APAP level is less than 10 mcg/mL, significant hepatotoxicity is unlikely.
   b. If AST and ALT are normal and APAP level is greater than 10 mcg/mL, significant hepatotoxicity is possible.
   c. If initial AST and ALT are initially high regardless of APAP levels, significant hepatotoxicity is assumed.
4. Sometimes *N*-acetylcysteine is used, but its role is unclear in the treatment of chronic APAP toxicity.

III. HEPATITIS: INFLAMMATION OF THE LIVER

A. Hepatitis A
1. General information
   a. The primary means of hepatitis A virus (HAV) transmission in the United States is via the fecal–oral route.
   b. Hepatitis A does not become chronic.
   c. Most persons with acute disease recover with no lasting liver damage.
   d. Incubation period is 15 to 50 days (average: 28 days).
2. Persons at risk
   a. Travelers to regions with high or intermediate hepatitis A
   b. Sex contacts of infected persons
   c. Household members or caregivers of infected persons
   d. Men who have sex with men
   e. Users of certain illegal drugs
   f. Persons with clotting-factor disorders
3. Prevention
   a. Vaccination with the full, two-dose series of hepatitis A vaccine (Havrix®, Vaqta®) given 6 months apart
   b. Immune globulin administered intramuscularly is available for short-term protection (~3 months) against hepatitis A both preexposure and postexposure
   c. Good hygiene (e.g., hand washing)
4. Signs and symptoms
   a. Some patients are asymptomatic, particularly young children.
   b. Symptoms occur abruptly and can include fever, fatigue, jaundice, nausea, vomiting, abdominal pain, loss of appetite, and dark urine.
   c. Symptoms usually last less than 2 months.
5. Serologic tests
   a. Acute—IgM anti-HAV
   b. Chronic—not applicable

6. Treatment
    a. Postexposure prophylaxis
        (1) Healthy persons 12 months to 40 years: hepatitis A vaccine
        (2) People older than 40 years: IM immune globulin
        (3) Children younger than 12 months, immunocompromised, people with chronic liver disease: IM immune globulin
    b. Confirmed infection
        (1) No specific antivirals are available.
        (2) Supportive treatment is recommended.

B. **Hepatitis B**
    1. **General information**
        a. Hepatitis B virus (HBV) is transmitted by contact with infectious blood, semen, and other body fluids.
        b. Among unimmunized persons, chronic infection occurs in 6% to 10% of adults. In chronically infected persons, 15% to 25% of people will develop chronic liver disease including cirrhosis, liver failure, or liver cancer.
        c. Most persons with acute disease recover with no lasting liver damage.
        d. The incubation period is 45 to 160 days (average: 120 days).
    2. Persons at risk
        a. Infants born to infected mothers
        b. Sex partners of infected persons
        c. Persons with multiple sex partners
        d. Injectable drug users
        e. Health care workers exposed to blood
        f. Hemodialysis patients
    3. Prevention
        a. Vaccination with hepatitis B vaccine (Recombivax HB®, Engerix-B®)
            (1) Infants and children: 3 to 4 doses given over a 6- to 18-month period depending on vaccine type and schedule
            (2) Adults: 3 doses given over a 6-month period
        b. Passive immunization is obtained with hepatitis B immune globulin (HBIG), which provides temporary protection for about 3 to 6 months.
    4. Signs and symptoms
        a. Fever, fatigue
        b. Nausea, vomiting
        c. Abdominal pain
        d. Jaundice
        e. Joint pain
    5. Serologic tests
        a. HBsAg in acute and chronic infection
        b. IgM anti-HBc is positive in acute infection only
    6. Treatment
        a. Acute
            (1) No medication is available
            (2) Provide supportive care
        b. Chronic
            (1) Goal of treatment is amelioration of hepatic dysfunction and seroconversion of HBsAg-positive (surface antigen) to HBsAg-negative and production of HBs antibodies.
            (2) Treatment is indicated for chronic HBV infection with high pretreatment ALT level, detectable serum HBV DNA, and moderately active necroinflammation with or without fibrosis on liver biopsy.
            (3) First-line drugs
                (a) Pegylated interferon-alfa 2a (Pegasys®)
                    (i) Class: Interferon
                    (ii) Dose: 180 mcg SQ weekly
                    (iii) Duration: 48 weeks

(b) Entecavir (Baraclude®)
- **(i)** Class: reverse transcriptase inhibitor (nucleoside)
- **(ii)** Dose: 0.5 mg daily
- **(iii)** Duration for HBeAg+(antigen is a marker for active replication): treat for more than 1 year until HBeAg seroconversion and undetectable serum HBV DNA; continue treatment for more than 6 months after HBeAg seroconversion
- **(iv)** Duration for HBeAg negative: treat for more than 1 year until HBsAg (surface antigen) clearance

(c) Tenofovir (Viread®)
- **(i)** Class: Reverse transcriptase inhibitor (nucleotide)
- **(ii)** Dose: 300 mg daily
- **(iii)** Duration for HBeAg+: treat for more than 1 year until HBeAg seroconversion and undetectable serum HBV DNA; continue treatment for more than 6 months after HBeAg seroconversion
- **(iv)** Duration for HBeAg negative: treat for more than 1 year until HBsAg clearance.

C. Hepatitis C

1. General information
- **a.** Hepatitis C virus (HCV) is transmitted by contact with blood of an infected person.
- **b.** Of people newly infected, 75% to 85% develop a chronic infection. Of these chronically infected persons, 60% to 70% will develop chronic liver disease such as cirrhosis or liver cancer.
- **c.** The incubation period is 14 to 180 days (average: 45 days).

2. Persons at risk
- **a.** Current or former injectable drug users
- **b.** Recipients of clotting factor concentrates before 1987
- **c.** Recipients of blood transfusions before 1992
- **d.** Long-term hemodialysis patients
- **e.** Health care workers after needle sticks
- **f.** HIV-infected persons
- **g.** Babies born to infected mothers

3. Prevention
- **a.** No vaccines are available.
- **b.** Don't reuse needles.

4. Signs and symptoms
- **a.** Fever, fatigue
- **b.** Nausea, vomiting
- **c.** Abdominal pain
- **d.** Jaundice
- **e.** Joint pain

5. Serologic tests
- **a.** Acute—no serologic markers
- **b.** Chronic
  - **(1)** Screening assay for anti-HCV
  - **(2)** Verification by a specific assay for HCV RNA

6. Treatment
- **a.** Acute
  - **(1)** There is no specific treatment for acute exposure until viremia is established.
  - **(2)** Typically, a period of at least 12 weeks is observed to see if the HCV will spontaneously clear. If it does not clear, then the patient should be treated.
  - **(3)** Pegylated interferon monotherapy can cure recent HCV infection in approximately 90% of the patients.
- **b.** Chronic
  - **(1)** All patients with chronic hepatitis C are potential candidates for antiviral therapy with combination pegylated interferon and ribavirin. For patients with chronic HCV genotype 1 who are candidates for therapy, it is recommended that they receive triple therapy with pegylated interferon, ribavirin, and one protease inhibitor (telaprevir or boceprevir).

      (2) The actual duration of treatment is determined in part by viral response. Viral load should be monitored throughout therapy.

      (3) Medications for HCV genotype 1

         (a) Pegylated interferon-alfa 2a (Pegasys®)

           (i) Class: Interferon

           (ii) Dose: 180 mcg SQ weekly

           (iii) Duration: 48 weeks

         (b) Ribavirin (Copegus®) - weight based dosing

           (i) Class: Antiviral

           (ii) Dose: if weight is less than or equal to 75 kg, then 1000 mg per day divided into two doses or if weight is greater than 75 kg, then 1200 mg per day divided into two doses

           (iii) Duration: 48 weeks

         (c) Boceprevir (Victrelis®)

           (i) Class: Antiviral; protease inhibitor

           (ii) Dose: 800 mg TID

           (iii) Duration: After 4 weeks of lead-in treatment with pegylated interferon-alfa and ribavirin only, boceprevir is combined with pegylated interferon-alfa and ribavirin for 24 to 44 weeks

         (d) Telaprevir (Incivek®)

           (i) Class: Antiviral; protease inhibitor

           (ii) Dose: 750 mg TID

           (iii) Duration: Together with pegylated interferon-alfa and ribavirin for 12 weeks followed by an additional 12 to 36 weeks of pegylated interferon-alfa and ribavirin only

      (4) Medications for HCV genotypes 2, 3, and 4

         (a) Pegylated interferon-alfa 2a (Pegasys®)

           (i) Class: Interferon

           (ii) Dose: 180 mcg SQ weekly

           (iii) Duration genotype 2 or 3: 24 weeks

           (iv) Duration genotype 4: 48 weeks

         (b) Ribavirin (Copegus®)

           (i) Class: Antiviral

           (ii) Dose genotype 2 or 3: 800 mg per day divided into two doses

           (iii) Duration genotype 2 or 3: 24 weeks

           (iv) Dose genotype 4: if weight is less than or equal to 75 kg, then 1000 mg per day divided into two doses or if weight is greater than 75 kg, then 1200 mg per day divided into two doses

           (v) Duration genotype 4: 48 weeks

D. Hepatitis D

  1. General information

    a. Hepatitis D virus (HDV) is transmitted through percutaneous or mucosal contact with infectious blood.

    b. HDV is an incomplete virus that requires the helper function of HBV to replicate and only occurs in people infected with HBV.

    c. HDV is uncommon in the United States.

  2. Persons at risk

    a. Persons infected with HBV

    b. Injectable drug users

  3. Prevention

    a. There is no vaccine for HDV.

    b. Give hepatitis B vaccine to prevent infection with HBV.

  4. Signs and symptoms

    a. Fever, fatigue

    b. Nausea, vomiting

    c. Abdominal pain

       d. Jaundice
       e. Joint pain
   5. Serologic tests
       a. Acute
          (1) IgM anti-HDV
          (2) HDAg
       b. Chronic—HDAg
   6. Treatment—pegylated interferon-alfa
E. Hepatitis E
   1. General information
       a. Hepatitis E virus (HEV) is spread by the fecal–oral route.
       b. HEV usually results in a self-limited, acute illness.
       c. HEV is uncommon in the United States.
   2. Persons at risk are those who travel to developing countries.
   3. Prevention
       a. Good sanitation
       b. Clean drinking water
   4. Signs and symptoms
       a. Fever, fatigue
       b. Nausea, vomiting
       c. Abdominal pain
       d. Jaundice
       e. Joint pain
   5. Treatment
       a. Hepatitis E usually resolves on its own.
       b. Treatment is supportive (e.g., rest, fluids)

IV. ALCOHOL-INDUCED LIVER DISEASE

A. General information
   1. The cause of alcoholic liver disease (ALD) is chronic, heavy alcohol ingestion.
       a. About 40 to 80 g per day in men for 10 to 12 years
       b. About 20 to 40 g per day in women for 10 to 12 years
   2. Prevalence in the United States is estimated at greater than 2 million people.
B. Stages of liver damage
   1. Fatty liver
       a. It is represented by a fatty infiltration in the liver.
       b. Clinical findings include hepatomegaly and mild liver enzyme abnormalities.
       c. The condition is potentially reversible if alcohol is stopped and nutrition maintained.
   2. Alcoholic hepatitis
       a. It is characterized by hepatic inflammation with necrosis.
       b. Clinical features include fever, abdominal pain, anorexia, nausea, and weight loss.
   3. Cirrhosis
       a. It is marked by severe hepatic fibrosis.
       b. ALD is the most common cause of cirrhosis.
C. Signs and symptoms
   1. Fatigue
   2. Anorexia, weight loss
   3. Nausea, vomiting
   4. Jaundice
   5. Right upper abdominal pain
D. Liver-related labs
   1. In ALD patients, the AST is almost always elevated.
   2. The classic ratio AST/ALT greater than 2 is seen in 70% of the cases.
   3. ALT and AST may be in the normal range in patients with advanced cirrhosis due to the lack of viable hepatocytes left to produce transaminases.

E. **Treatment**
1. No approved pharmacotherapy
2. Alcohol abstinence
3. Optimal nutrition
4. Consideration for liver transplantation in patients with end-stage ALD

V. CIRRHOSIS

A. **General information**
1. Cirrhosis describes a diseased liver characterized by fibrosis usually due to many years of continuous injury.
2. The most common causes of cirrhosis are:
   a. Long-standing alcohol abuse
   b. Chronic hepatitis B or C
   c. Nonalcoholic steatohepatitis
3. Cirrhosis has no cure.

B. **Classification**
1. Compensated cirrhosis
   a. Cirrhosis present
   b. Preservation of hepatic synthetic function
   c. No evidence of complications related to portal hypertension, hepatic encephalopathy, and/or jaundice
2. Decompensated cirrhosis
   a. Cirrhosis present
   b. Reduced hepatic synthetic function
   c. Portal hypertension including ascites, gastroesophageal varices, and variceal bleeding
   d. Hepatic encephalopathy
   e. Jaundice

C. **Signs and symptoms**
1. Fatigue
2. Jaundice
3. Varices
4. Ascites
5. Edema
6. Hepatic encephalopathy

D. **Treatment**
1. Treat underlying causative condition (e.g., hepatitis B, hepatitis C)
2. Avoid substances that injure the liver (e.g., alcohol, high-dose APAP)
3. Treat complications
   a. Ascites—the most common complication
      (1) Dietary sodium restriction: less than 2 g per day
      (2) Diuretics
         (a) Combination of spironolactone (Aldactone®) and furosemide (Lasix®) is the usual diuretic regimen.
         (b) Starting doses are usually 100 mg spironolactone and 40 mg furosemide.
         (c) Doses can be increased every 3 to 5 days with typical maximal doses of 400 mg per day of spironolactone and 160 mg per day of furosemide.
      (3) Avoid non-steroidal anti-inflammatory drugs (NSAIDs)
   b. Refractory ascites
      (1) This condition is defined as fluid overload that is unresponsive to a sodium-restricted diet and high-dose diuretic treatment or recurs rapidly after therapeutic paracentesis.
      (2) Options
         (a) Large-volume paracentesis (LVP) and albumin replacement
         (b) Transjugular intrahepatic portosystemic shunt (TIPS)
         (c) Consideration for liver transplantation

    c. Esophageal varices

        (1) Acute bleeding in a cirrhotic patient

            (a) Admit patient to intensive care unit (ICU) for resuscitation and management.

            (b) Maintain hemoglobin at ~8 g/dL.

            (c) Administer short-term prophylactic antibiotics

                (i) Shown to increase survival rate

                (ii) Norfloxacin (Noroxin®) 400 mg bid orally or ceftriaxone (Rocephin®) 1 g daily IV

            (d) Initiate octreotide (Sandostatin®) at 50 mcg IV bolus followed by 50 mcg/hr continuous infusion for 3 to 5 days for vasoconstriction.

            (e) Use sclerotherapy or endoscopic variceal ligation (EVL) to control hemorrhage.

            (f) Balloon tamponade can be used to temporarily control bleeding by applying pressure to the bleeding sites.

            (g) If the above measures fail, then a shunt (e.g., TIPS) is indicated.

        (2) Ongoing prevention

            (a) Initiate a nonselective β-blocker (e.g., nadolol [Corgard®], propranolol [Inderal®]).

            (b) Conduct an EVL.

            (c) If the aforementioned therapy fails, a shunt (e.g., TIPS) should be considered.

    d. Hepatic encephalopathy

        (1) Encompasses a spectrum of neuropsychiatric abnormalities as a result of liver dysfunction

            (a) Cognitive deficits

            (b) Extrapyramidal alterations

            (c) Sleep disturbances

        (2) Ammonia has been implicated as a neurotoxin in the pathogenesis of this condition.

            (a) Ammonia is a by-product of protein metabolism and is normally metabolized by the liver to urea (blood urea nitrogen [BUN]), which is renally eliminated.

            (b) Cirrhosis impairs hepatic blood flow and metabolism, which can result in increased levels of ammonia in the central nervous system (CNS).

        (3) Treatment options

            (a) Correct precipitating factors (e.g., excessive protein intake, infection)

            (b) Reduce nitrogenous load

                (i) Reduce protein intake.

                (ii) Administer lactulose (Enulose®) 20 to 30 g (30 to 45 mL) three to four times a day. Lactulose results in acidification of the colon, which converts ammonia into a less readily absorbed ammonium ion.

Study Questions

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. What is the toxic metabolite that builds up with an acute acetaminophen overdose?

  (A) Glutathione

  (B) NAPQI

  (C) HBV

  (D) ALD

  (E) *N*-acetylcysteine

2. What are the three first-line drugs for the treatment of chronic Hepatitis B?

  (A) Lamivudine, telbivudine, entecavir

  (B) Pegylated interferon-alfa, lamivudine, acyclovir

  (C) Adefovir, telbivudine, tenofovir

  (D) Pegylated interferon-alfa, entecavir, tenofovir

  (E) Entecavir, acyclovir, telbivudine

3. What medication is administered to patients with hepatic encephalopathy to decrease nitrogenous load?

   (A) Lactulose
   (B) Furosemide
   (C) Spironolactone
   (D) Propranolol
   (E) Norfloxacin

4. What medication is administered to patients to decrease APAP toxicity?

   (A) Naloxone
   (B) Interferon-alfa
   (C) Tenofovir
   (D) Neomycin
   (E) *N*-acetylcysteine

5. Which types of viral hepatitis have vaccines available?

   (A) Hepatitis A, B, and C
   (B) Hepatitis A and B
   (C) Hepatitis B and C
   (D) Hepatitis A and C
   (E) Hepatitis A, B, and D

6. What is the most common cause of cirrhosis?

   (A) APAP toxicity
   (B) Hepatitis A
   (C) Hepatitis E
   (D) Alcoholic liver disease
   (E) Renal dysfunction

7. What medication maybe used to treat bleeding of esophageal varices by causing vasoconstriction?

   (A) Propranolol
   (B) Spironolactone
   (C) Ribavirin
   (D) Diphenhydramine
   (E) Octreotide

Answers and Explanations

1. **The answer is B** *[see II.A.3]*.
   The main toxic metabolite of APAP metabolism is NAPQI. Normally, glutathione in the liver detoxifies NAPQI, but an acute overdose of APAP depletes glutathione stores, which results in accumulation of NAPQI, which causes hepatic necrosis.

2. **The answer is D** *[see III.B.6.b.(3)]*.
   The American Association for the Study of Liver Diseases (AASLD) has stated that the first-line drugs for the treatment of chronic Hepatitis B are pegylated interferon-alfa, entecavir, and tenofovir. In choosing which antiviral agent to use as the first-line therapy, consideration should be given to the safety and efficacy of the treatment, risks of drug resistance, and costs.

3. **The answer is A** *[see V.D.3.d.(3).(b).(ii)]*.
   Lactulose (Enulose®) 20 to 30 g (30 to 45 mL) administered three to four times a day is given to patients with hepatic encephalopathy. Lactulose results in acidification of the colon, which converts ammonia into a less readily absorbed ammonium ion, therefore decreasing the nitrogenous load.

4. **The answer is E** *[see II.C.2]*.
   N-acetylcysteine is a precursor for glutathione and decreases APAP toxicity by increasing glutathione hepatic stores. It does not reverse damage to liver cells that have already been injured. Ideally begin treatment within 8 hrs of ingestion. It may be of value 48 hrs or more after ingestion.

5. **The answer is B** *[see III.A.3.a; III.B.3.a]*.
   Hepatitis A can be prevented with the full, two-dose series of hepatitis A vaccine given 6 months apart in adults. Hepatitis B can be prevented with a three-dose series of hepatitis B vaccine given over a period of 6 months in adults.

6. **The answer is D** *[see IV.B.3.b]*.
   Alcoholic liver disease is the most common cause of cirrhosis in the United States. Alcohol is metabolized in the liver and oxidative stress promotes hepatocyte necrosis and severe hepatic fibrosis develops.

7. **The answer is E** *[see V.D.3.c.(1).(d)]*.
   Pharmacologic therapy such as octreotide should be initiated as soon as variceal hemorrhage is suspected, and continued for 3 to 5 days. The vasoconstrictive action of octreotide helps to control bleeding.

Cancer Chemotherapy

<div style="text-align:right;">**50**</div>

BROOKE BERNHARDT

I. PRINCIPLES OF ONCOLOGY. The term *cancer* refers to a heterogeneous group of diseases caused by an impairment of the normal functioning of genes, which leads to genetic damage.

A. **Characteristics of cancer cells.** Cancer cells are also referred to as tumors or neoplasms. Tumors are thought to arise from a single abnormal cell, which continues to divide indefinitely. Uncontrolled growth, the ability to invade local tissues, and the ability to spread, or **metastasize**, are unique characteristics of cancer cells.

1. **Carcinogenesis.** The mechanism of how many cancers occur is thought to be a multistage, multifactorial process that involves both genetic and environmental factors.

   a. **Initiation.** The first step involves the exposure of normal cells to a carcinogen, producing genetic damage to a cell.

   b. **Promotion.** The environment becomes altered to allow preferential growth of mutated cells over normal cells. The mutated cells become cancerous.

   c. **Progression.** Increased proliferation of cancer cells allows for invasion into local tissue and metastasis.

2. **Types of cancer.** Tumors can be benign or malignant. **Benign** tumors are generally slow growing, resemble normal cells, are localized, and are not harmful. **Malignant** tumors often proliferate more rapidly, have an atypical appearance, invade and destroy surrounding tissues, and are harmful if left untreated. Malignant cancers are further categorized by the location from where the tumor cells arise.

   a. **Solid tumors. Carcinomas** are tumors of epithelial cells. These include specific tissue cancers (e.g., lung, colon, breast). **Sarcomas** include tumors of connective tissue such as bone (e.g., osteosarcoma) or muscle (e.g., leiomyosarcoma).

   b. **Hematological malignancies. Lymphomas** are tumors of the lymphatic system and include Hodgkin and non-Hodgkin lymphomas. **Leukemias** are tumors of blood-forming elements and are classified as acute or chronic and myeloid or lymphoid.

B. **Incidence.** Cancer is the **second leading cause of death** in the United States. The most common cancers are breast, prostate, and colorectal. The leading cause of cancer death is lung cancer.

C. **Cause.** Many factors have been implicated in the origin of cancer. Some of these factors are as follows:

1. **Viruses**, including Epstein-Barr virus (EBV), hepatitis B virus (HBV), and human papillomavirus (HPV)

2. **Environmental and occupational exposures**, such as ionizing and ultraviolet radiation and exposure to chemicals, including vinyl chloride, benzene, and asbestos

3. **Lifestyle factors**, such as high-fat, low-fiber diets and tobacco and ethanol use

4. **Medications**, including alkylating agents and immunosuppressants

5. **Genetic factors**, including inherited mutations, cancer-causing genes (oncogenes), and defective tumor-suppressor genes

D. **Detection** and **diagnosis** are critical for the appropriate treatment of cancer. Earlier detection may improve response to treatment.

1. **Warning signs** of cancer have been outlined by the American Cancer Society. General signs and symptoms of cancer may include unexplained weight loss, fever, fatigue, pain, and skin changes. Signs and symptoms of specific types of cancer can include changes in bowel habits or bladder

function, a sore that does not heal, white patches or spots in the mouth or on the tongue, unusual bleeding or discharge, thickening or lump in the breast or other body part, indigestion or difficulty swallowing, a recent change in a wart or mole, other skin changes, or a nagging cough or hoarseness.

2. **Guidelines for screening** asymptomatic people for the presence of cancer have been established by the American Cancer Society, the National Cancer Institute, and the U.S. Preventive Health Services Task Force, among others. Because many cancers do not produce signs or symptoms until they have become large, the goal of screening is to detect cancers early, when the disease may be more likely to be curable, thus potentially reducing cancer-related mortality. The different sets of guidelines vary slightly in their recommendations for age and frequency of screening procedures.

3. **Tumor markers** are biochemical indicators of the presence of neoplastic proliferation detected in serum, plasma, or other body fluids. These tumor markers may be used initially as screening tests, to reveal further information after abnormal test results, or to monitor the efficacy of therapy. Elevated levels of these markers are not definitive for the presence of cancer because levels can be elevated in other benign and malignant conditions, and false-positive results do occur. Examples of some commonly used markers include the following:
   a. Carcinoembryonic antigen (CEA) for colorectal cancer
   b. α-Fetoprotein (AFP) for hepatocellular carcinoma or hepatoblastoma
   c. Prostate-specific antigen (PSA) for prostate cancer

4. **Tumor biopsy.** The definitive test for the presence of cancerous cells is a biopsy and pathological examination of the biopsy specimen. Several types of procedures are used in the pathological analysis of tumors, including evaluating the morphological features of the tissue and cells (via pathologic evaluation), looking for cell-surface markers (via flow cytometry), and cytogenetic evaluation for specific chromosomal abnormalities (via fluorescence in situ hybridization).

5. **Imaging studies**, such as radiograph, CT scans, MRI, and positron emission tomography (PET), may be used to aid in the diagnosis or location of a tumor and to monitor response to treatment.

6. **Other laboratory tests** commonly used for cancer diagnosis include complete blood counts (CBCs) and blood chemistries. A CBC measures the levels of the three basic blood cells—white cells, red cells, and platelets.
   a. The CBC will often include an absolute neutrophil count (ANC), which measures the absolute number of neutrophils in a person's white blood count. The ANC is calculated by multiplying the white blood count (WBC) $\times$ total neutrophils (segmented neutrophils percent + segmented bands percent) = ANC. Segmented neutrophils are often listed as "polys" and segmented bands are immature "polys."

E. **Staging** is the categorizing of patients according to the extent of their disease. The stage of the disease is used to determine prognosis and treatment. In adult patients with cancer, two different staging systems are widely employed for the staging of neoplasms.
   1. **TNM classification**
      a. *T* indicates tumor size and is classified from 0 to 4, with 0 indicating the absence of tumor.
      b. *N* indicates the presence and extent of regional lymph node spread and is classified from 0 to 3, with 0 indicating no regional lymph node involvement and 3 indicating extensive involvement.
      c. *M* indicates the presence of distant metastases and is classified as 0 (for absence) or 1 (for presence of distant metastases).
      d. For example, T2N1M0 indicates a moderate-size tumor with limited nodal disease and no distant metastases.
   2. **AJCC** staging, developed by the American Joint Committee on Cancer, classifies cancers as stages 0 to IV. An assigned TNM translates into a stage. A high number indicates larger tumors with extensive nodal involvement and/or metastasis. Generally, high numbers also indicate a worse prognosis. There are specific staging criteria for each tumor type.

F. **Survival** depends on the tumor type, the extent of disease, and the therapy received. Although some patients are free of all detectable disease, not all patients are cured. The terms **complete response** and **remission** are used to indicate that the patient has no evidence of disease after treatment. This is not a synonym for *cure*, as several patients who have achieved complete remission may **relapse**. Other markers used to describe disease response or survival include partial response (PR), very good partial response (VGPR), stable disease (SD), progressive disease (PD), time to progression (TTP), and progression-free survival (PFS).

II. CELL LIFE CYCLE. Knowledge of the cell life cycle and cell cycle kinetics is essential to the understanding of the activity of chemotherapy agents in the treatment of cancer (*Figure 50-1*).

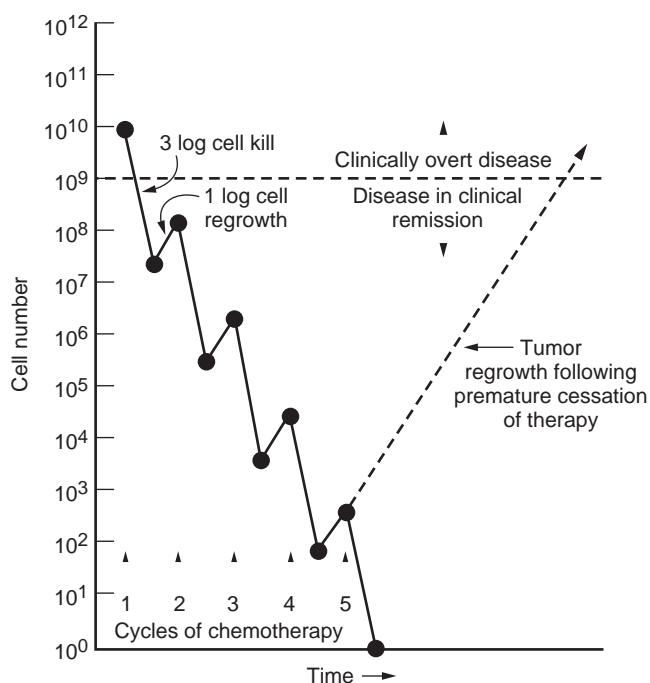
  A. **Phases of the cell cycle**
  1. **M phase**, or **mitosis**, is the phase in which the cell divides into two daughter cells.
  2. **G_1 phase**, or **postmitotic gap**, is when RNA and the proteins required for the specialized functions of the cell are synthesized in preparation for DNA synthesis.
  3. **S phase** is the phase in which DNA synthesis and replication occurs.
  4. **G_2 phase**, or the **premitotic** or **postsynthetic gap**, is the phase in which RNA and the enzymes topoisomerase I and II are produced to prepare for duplication of the cell.
  5. **G_0 phase**, or **resting phase**, is the phase in which the cell is not committed to division. Cells in this phase are generally not sensitive to chemotherapy. Some of these cells may reenter the actively dividing cell cycle. In a process called **recruitment**, some chemotherapy regimens are designed to enhance this reentry by killing a large number of actively dividing cells.
  B. **Cell growth kinetics.** Several terms describe cell growth kinetics.
  1. **Cell growth fraction** is the proportion of cells in the tumor dividing or preparing to divide. As the tumor enlarges, the cell growth fraction decreases because a larger proportion of cells may not be able to obtain adequate nutrients and blood supply for replication.
  2. **Cell cycle time** is the average time for a cell that has just completed mitosis to grow and again divide and again pass through mitosis. Cell cycle time is specific for each individual tumor.
  3. **Tumor doubling time** is the time for the tumor to double in size. As the tumor gets larger, its doubling time gets longer because it contains a smaller proportion of actively dividing cells owing to restrictions of space, nutrient availability, and blood supply.
  4. The **gompertzian growth curve** illustrates these cell growth concepts (*Figure 50-2*).
  C. **Tumor cell burden** is the number of tumor cells in the body.
  1. Because a large number of cells is required to produce symptoms and be clinically detectable (approximately 10^9 cells), the tumor may be in the plateau phase of the growth curve by the time it is discovered.
  2. The **cell kill hypothesis** states that a certain percentage of tumor cells will be killed with each course of cancer chemotherapy.
    a. As tumor cells are killed, cells in **G_0** may be recruited into **G_1**, resulting in tumor regrowth.
    b. Thus, repeated cycles of chemotherapy are required to achieve a complete response or remission (*Figure 50-3*).
    c. The percentage of cells killed depends on the chemotherapy dose.
  3. In theory, the tumor burden would never reach absolute zero because only a percentage of cells are killed with each cycle. Less than 10^4 cells may depend on elimination by the host's immune system.


Figure 50-1. The cell cycle. The cell growth cycle, emphasizing the relationship between proliferating cell populations. (Reprinted with permission from Lenhard RE Jr, Osteen RT, Gansler T, eds. *The American Cancer Society's Clinical Oncology*. Atlanta, GA: American Cancer Society; 2001.)

Figure 50-2. The gompertzian growth curve. During the early stages of its development, a tumor grows exponentially. But as a tumor enlarges, its growth slows. By the time a tumor becomes large enough to cause symptoms and be clinically detectable, the majority of its growth has already occurred and is no longer exponential. (Reprinted with permission from Lenhard RE Jr, Osteen RT, Gansler T, eds. *The American Cancer Society's Clinical Oncology*. Atlanta, GA: American Cancer Society; 2001.)

D. Chemotherapeutic agents may be classified according to their **reliance on cell cycle kinetics** for their cytotoxic effect. Combinations of chemotherapy agents that are active in different phases of the cell cycle may result in a greater cell kill. A cell cycle classification of some commonly used chemotherapeutic agents is given in II.D.1.a–d.
   1. **Phase-specific agents** are most active against cells that are in a specific phase of the cell cycle. These agents are most effective against tumors with a high growth fraction. Theoretically, administering these agents as continuous intravenous infusions or by multiple repeated doses may increase the likelihood of hitting the majority of cells in the specific phase at any one time. Therefore, these agents are also considered schedule-dependent agents. Examples are as follows:
      a. M phase: mitotic inhibitors (e.g., vinca alkaloids, taxanes)
      b. G_1 phase: asparaginase, prednisone
      c. S phase: antimetabolites
      d. G_2 phase: bleomycin, etoposide

Figure 50-3. Chemotherapy and tumor cell survival. Relationship between tumor cell survival and chemotherapy administration. The exponential relationship between chemotherapy drug dose and tumor cell survival dictates that a constant proportion, not number, of tumor cells is killed with each cycle of treatment. In this example, each cycle of drug administration results in 99.9% (3 log) cell kill, and 1 log of cell regrowth occurs between cycles. The broken line indicates what would occur if the last cycle of therapy were omitted. Despite complete clinical remission of disease, the tumor would ultimately recur. (Reprinted with permission from Lenhard RE Jr, Osteen RT, Gansler T, eds. *The American Cancer Society's Clinical Oncology*. Atlanta, GA: American Cancer Society; 2001.)

2. **Phase-nonspecific agents** are effective while cells are in the active cycle but do not require that the cell be in a particular phase. These agents generally show more activity against slow-growing tumors. They may be administered as single bolus doses because their activity is independent of the cell cycle. These drugs are also considered dose-dependent agents. Examples are alkylating agents and antitumor antibiotics.

3. **Cell cycle–nonspecific agents** are effective in all phases, including G_0. Examples are carmustine and lomustine. Radiation therapy is also considered cell cycle nonspecific.

III. CHEMOTHERAPY

A. **Objectives of chemotherapy**

1. **For cancers like leukemias and lymphomas, several phases of chemotherapy are necessary**. A **cure** may be sought with aggressive therapy for a prolonged period to eradicate all disease. For leukemias, this curative approach may consist of the following components:

   a. **Remission induction**: therapy given with the intent of maximizing cell kill.

   b. **Consolidation** (also known as intensification or post-remission therapy): therapy to eradicate any clinically undetectable disease and to lower the tumor cell burden below 10^3, at which level host immunological defenses may keep the cells in control.

   c. **Maintenance**: therapy given in lower doses with the aim of maintaining or prolonging a remission.

2. For solid tumors, one or more approaches to chemotherapy may be used when seeking a cure based on the known utility of chemotherapy in line with other modalities, such as surgery or radiation.

   a. **Adjuvant** chemotherapy is given after more definitive therapy, such as surgery, to eliminate any remaining disease or undetected micrometastasis.

   b. **Neoadjuvant** chemotherapy is given to decrease the tumor burden before definitive therapy, such as surgery or radiation.

4. **Palliative** therapy is usually given when complete eradication of the tumor is considered unlikely or the patient refuses aggressive therapy. Palliative chemotherapy may be given to decrease the tumor size, control growth, and reduce symptoms.

5. **Salvage** chemotherapy is given as an attempt to get a patient into remission, after previous therapies have failed.

B. **Chemotherapy dosing** may be based on body **weight**, body surface area (**BSA**), or area under the concentration versus time curve (**AUC**). BSA is most frequently used because it provides an accurate comparison of activity and toxicity across species, making it easier to translate preclinical dosing into clinical trials and practice in humans. In addition, BSA correlates with cardiac output, which determines renal and hepatic blood flow and thus affects drug elimination. In very young or very small patients (e.g., infants less than a year of age or less than 10 to 12 kg of body weight), the BSA is not a good measure for calculating the dose as it can overestimate the patient's size and lead to overdosing of chemotherapeutic agents, resulting in excessive toxicities. In this patient population, dosing chemotherapy based on body weight (in kilograms) is often a more frequently employed technique.

C. **Dosing adjustments** may be required for kidney or liver dysfunction to prevent toxicity. For some agents, dose adjustments are also made based on hematologic or non-hematologic toxicities. Very little is known about dosing chemotherapy in the obese population.

D. **Combination chemotherapy** is usually more effective than single-agent therapy.

1. When combining chemotherapy agents, factors to consider include

   a. Antitumor activity

   b. Different mechanisms of action

   c. Minimally overlapping toxicities

2. The reasons for administering combination chemotherapy include

   a. Overcoming or preventing resistance

   b. Cytotoxicity to resting and dividing cells

   c. Biochemical enhancement of effect

   d. Rescue of normal cells

3. **Dosing** and **scheduling** of combination regimens are important because they are designed to allow recovery of normal cells. These regimens generally are given as short courses of therapy in cycles.

4. **Acronyms** often are used to designate chemotherapy regimens. For example, CMF refers to a combination of cyclophosphamide, methotrexate, and fluorouracil used in the treatment of breast cancer.

E. **Administration**

1. **Routes** of administration vary depending on the agent and the disease state. Although intravenous (IV) administration is most commonly employed, oral administration of chemotherapy is becoming increasingly more common.

2. Other administration techniques include oral, subcutaneous, intrathecal, intra-arterial, intraperitoneal, intravesical, continuous IV infusion, bolus IV infusion, and hepatic artery infusion.

3. Drugs that may be given **intrathecally** include methotrexate, cytarabine, and hydrocortisone. Drugs should not be administered by the intrathecal route without specific information supporting intrathecal administration. **Inadvertent administration of vinca alkaloids (e.g., vincristine) by the intrathecal route results in ascending paralysis and death**. The U.S. Food and Drug Administration (FDA) requires that specific wording alerting the provider to this error must be included on the packaging of each dose of vincristine. They also recommend that safety measures are employed in the preparation and delivery of vinca alkaloids.

4. Products with different formulations, including liposomal or pegylated agents (e.g., liposomal doxorubicin, pegfilgrastim), are being used to decrease frequency of administration and/or reduce toxicities.

F. **Response to chemotherapy** is defined in several ways and does not always correlate with patient survival.

1. **Complete response (CR)** indicates disappearance of all clinical, gross, and microscopic disease.

2. **PR** indicates a greater than 50% reduction in tumor size, lasting a reasonable period. Some evidence of disease remains after therapy.

3. **Response rate (RR)** is defined as CR + PR.

4. **SD** indicates tumor that neither grows nor shrinks significantly (less than 25% change in size).

5. **PD** or **no response** after therapy is defined by a greater than 25% increase in tumor size or the appearance of new lesions.

G. **Factors affecting response to chemotherapy**

1. **Tumor cell heterogeneity**. Large tumors have completed multiple cell divisions, resulting in several mutations and genetically diverse cells.

2. **Drug resistance**. The **Goldie-Coldman hypothesis** states that genetic changes are associated with drug resistance, and the probability of resistance increases as tumor size increases. The hypothesis assumes that at the time of diagnosis, most tumors possess resistant clones. A well-studied mechanism of resistance involves the multidrug resistance (*mdr*) gene, which codes for membrane-bound P-glycoprotein. P-glycoprotein serves as a channel through which cellular toxins (i.e., chemotherapeutic agents) may be excreted from the cell.

3. **Dose intensity** is defined as a specific dose delivered over a specific period. Occasionally, the full dose cannot be given or a cycle is delayed owing to complications or toxicities. Suboptimal doses have resulted in reduced response rates and survival. **Dose density** involves shortening the usual interval between doses to maximize the drug effects on the tumor growth kinetics.

4. **Patient-specific factors** such as poor functional status, impaired organ function, or concomitant diseases may compromise how a chemotherapy regimen is given and affect how the patient responds to treatment.

IV. CLASSIFICATION OF CHEMOTHERAPEUTIC AGENTS

A. Examples of the following agents and their toxicities are listed in *Table 50-1*.

B. **Alkylating agents** were the first group of antineoplastic agents. The prototype of this class is mechlorethamine, or **nitrogen mustard**, which was researched as a chemical warfare agent. Alkylating agents cause cross-linking and abnormal base pairing of DNA strands, which inhibit replication of the DNA. This mechanism is known as **alkylation**. These are phase-nonspecific agents.

C. Most of the **antitumor antibiotics** are obtained from organisms of the *Streptomyces* genus. These agents may act by either alkylation (mitomycin) or **intercalation**. Intercalation is the process by which the drug slides between DNA base pairs and inhibits DNA synthesis. These are phase-nonspecific agents.

D. **Antimetabolites** are structural analogs of naturally occurring substrates for biochemical reactions. They inhibit DNA synthesis by acting as false substitutions in the production of nucleic

| Table 50-1 | CANCER CHEMOTHERAPEUTIC AGENTS BY MECHANISM OF ACTION AND TOXICITIES |

Drug	Toxicities
Alkylating agents	
Altretamine (hexamethylmelamine)	Nausea and vomiting, myelosuppression, paresthesias, CNS toxicity
Busulfan	Myelosuppression, pulmonary fibrosis, aplastic anemia, skin hyperpigmentation
Carmustine	Delayed myelosuppression, nausea and vomiting, hepatotoxicity
Chlorambucil	Myelosuppression, pulmonary fibrosis, hyperuricemia
Carboplatin	Myelosuppression, nausea and vomiting, peripheral neuropathy, ototoxicity
Cisplatin	Nephrotoxicity, nausea and vomiting, peripheral neuropathy, myelosuppression, ototoxicity
Cyclophosphamide	Myelosuppression, hemorrhagic cystitis, immunosuppression, alopecia, stomatitis, SIADH
Dacarbazine	Myelosuppression, nausea and vomiting, flulike syndrome, hepatotoxicity, alopecia, flushing
Estramustine	Myelosuppression, ischemic heart disease, thrombophlebitis, hepatotoxicity, nausea and vomiting
Ifosfamide	Myelosuppression, hemorrhagic cystitis, somnolence, confusion
Lomustine	Delayed myelosuppression, nausea and vomiting, hepatotoxicity, neurotoxicity
Mechlorethamine	Myelosuppression, nausea and vomiting, phlebitis, gonadal dysfunction
Melphalan	Myelosuppression, anorexia, nausea and vomiting, gonadal dysfunction
Oxaliplatin	Sensory peripheral neuropathy, nausea and vomiting, diarrhea, mucositis, transaminase elevations, alopecia
Procarbazine	Myelosuppression, nausea and vomiting, lethargy, depression, paresthesias, headache, flulike syndrome
Streptozocin	Renal toxicity, nausea and vomiting, diarrhea, altered glucose metabolism, liver dysfunction
Temozolomide	Myelosuppression, nausea and vomiting, fatigue, headache, peripheral edema
Thiotepa	Myelosuppression, nausea and vomiting, mucositis, skin rashes
Antitumor antibiotics	
Bleomycin	Pneumonitis, pulmonary fibrosis, fever, anaphylaxis, hyperpigmentation, alopecia
Dactinomycin	Stomatitis, myelosuppression, anorexia, nausea and vomiting, diarrhea, alopecia
Daunorubicin	Myelosuppression, cardiotoxicity, stomatitis, alopecia, nausea and vomiting
Doxorubicin	Myelosuppression, cardiotoxicity, stomatitis, alopecia, nausea and vomiting
Epirubicin	Myelosuppression, nausea and vomiting, cardiotoxicity, alopecia
Idarubicin	Myelosuppression, nausea and vomiting, stomatitis, alopecia, cardiotoxicity
Mitomycin C	Myelosuppression, nausea and vomiting, anorexia, alopecia, stomatitis
Mitoxantrone	Myelosuppression, cardiotoxicity, alopecia, stomatitis, nausea and vomiting
Valrubicin	Urinary frequency, dysuria, hematuria, bladder spasm, incontinence, cystitis (For intravesical bladder administration)
Antimetabolites	
Azacytidine	Myelosuppression, nausea and vomiting, diarrhea, constipation, injection site pain, muscle aches, fatigue, edema, dizziness
Capecitabine	Diarrhea, stomatitis, nausea and vomiting, hand–foot syndrome, myelosuppression
Cladribine	Myelosuppression, fever, rash
Clofarabine	Tachycardia, hypotension, headache, fever, chills, fatigue, pruritis, rash, nausea, vomiting, transaminitis, hyperbilirubinemia
Cytarabine	Myelosuppression, nausea and vomiting, diarrhea, stomatitis, hepatotoxicity, fever, conjunctivitis, CNS toxicity

(Continued on next page)

Table 50-1   Continued.

Drug	Toxicities
Decitabine	Myelosuppression, petechiae, fatigue, diarrhea, constipation, hyperglycemia, myalgias/arthralgias, rash, edema
Fludarabine	Myelosuppression, nausea and vomiting, fever, malaise, pulmonary infiltrates
Floxuridine	Hepatotoxicity, gastritis, mucositis
Fluorouracil	Stomatitis, myelosuppression, diarrhea, nausea and vomiting, cerebellar ataxia
Gemcitabine	Myelosuppression, fever, flu-like syndrome, rash, mild nausea and vomiting
Hydroxyurea	Myelosuppression, mild nausea and vomiting, rash
Mercaptopurine	Myelosuppression, nausea and vomiting, anorexia, diarrhea, cholestasis
Methotrexate	Mucositis, myelosuppression, pulmonary fibrosis, hepatotoxicity, nephrotoxicity, diarrhea, skin erythema
Nelarabine	Neurologic toxicities, somnolence, hypoesthesia, seizures, thrombocytopenia, anemia, and neutropenia, fatigue, and nausea
Pemetrexed	Myelosuppression, edema, fatigue, nausea and vomiting, diarrhea, mucositis, skin rash
Pentostatin	Nephrotoxicity, CNS depression, myelosuppression, nausea and vomiting, conjunctivitis
Thioguanine	Myelosuppression, hepatotoxicity, stomatitis
Mitotic inhibitors	
Docetaxel	Myelosuppression, fluid retention, hypersensitivity, paresthesias, rash alopecia
Ixabepilone	Peripheral sensory neuropathy, neutropenia, fatigue, myalgia, arthralgia, stomatitis, hypersensitivity reactions, anorexia
Paclitaxel	Myelosuppression, peripheral neuropathy, alopecia, mucositis, anaphylaxis, dyspnea
Vinblastine	Myelosuppression, paralytic ileus, alopecia, nausea, stomatitis
Vincristine	Peripheral neuropathy, paralytic ileus, SIADH
Vinorelbine	Peripheral neuropathy, myelosuppression, nausea and vomiting, hepatic dysfunction
Topoisomerase inhibitors	
Etoposide	Myelosuppression, nausea and vomiting, diarrhea, fever, hypotension with infusion, alopecia
Irinotecan	Myelosuppression, diarrhea, nausea and vomiting, anorexia
Teniposide	Myelosuppression, nausea and vomiting, alopecia, hepatotoxicity, hypotension with infusion
Topotecan	Myelosuppression, fever, flulike syndrome, nausea and vomiting
Enzymes	
Asparaginase	Allergic reactions, nausea and vomiting, liver dysfunction, CNS depression, hyperglycemia
Pegaspargase	Hypersensitivity reactions, hepatotoxicity, fever, nausea and vomiting
Protein tyrosine kinase inhibitors	
Dasatinib (Sprycel)	Pleural and pericardial effusions, diarrhea, myelosuppression, gastrointestinal hemorrhage, rash
Erlotinib (Tarceva)	Acneiform rash, diarrhea, nausea, pruritus, fatigue, eye irritation
Imatinib mesylate (Gleevec)	Myelosuppression, hepatotoxicity, fluid retention, nausea, diarrhea
Lapatinib (Tykerb)	Diarrhea, rash, nausea, fatigue, anemia, left ventricular and liver dysfunction
Nilotinib (Tasigna)	Rash, headache, nausea, fatigue, thrombocytopenia, neutropenia
Sorafenib (Nexavar)	Hand-and-foot syndrome, fatigue, hypertension, rash/desquamation, diarrhea
Sunitinib (Sutent)	Hand-and-foot syndrome, skin and hair discoloration, fatigue, diarrhea, hypothyroidism, hypertension, left ventricular dysfunction, mucositis/stomatitis, nausea
mTOR kinase inhibitors	
Temsirolimus (Torisel)	Hyperglycemia, hypophosphatemia, anemia, hypertriglyceridemia, rash, diarrhea, mucositis/stomatitis

| Table 50-1 | Continued. |

Drug	Toxicities
Histone deacetylase inhibitors	
Vorinostat (Zolinza)	Thrombocytopenia, anemia, diarrhea, nausea/vomiting, hyperglycemia
Miscellaneous	
Arsenic trioxide	Arrhythmias, hyperleukocytosis, nausea and vomiting, diarrhea, abdominal pain, APL differentiation syndrome (fever, dyspnea, weight gain, pulmonary infiltrates)
Bexarotene (Targretin)	Hyperlipidemia, pancreatitis, hypothyroidism, hypercalcemia, leukopenia, peripheral edema, rash
Bortezomib (Velcade)	Fatigue, peripheral neuropathy, myelosuppression, hypotension, arthralgias, diarrhea, nausea and vomiting, headache, fever
Isotretinoin (13-cis-retinoic acid, Accutane)	Dry skin and mucous membranes epistaxis, chelitis, photosensitivity, back pain, arthralgias, hypertriglyceridemia, hypercalcemia, major fetal toxicity
Tretinoin (all-trans-retinoic acid, ATRA; Vesanoid)	Leukocytosis, arrhythmias, headache, nausea and vomiting, scaling of skin, ATRA syndrome (fever, dyspnea, weight gain, pulmonary infiltrates)
Lenalidomide	Myelosuppression, thromboembolic events, bacterial infection, fatigue, diarrhea
Thalidomide	Fatigue; headache; numbness in hands, feet, arms, and legs; constipation; increased risk for thrombotic events major fetal toxicities
Hormonal agents	
Adrenocorticoids Dexamethasone Methylprednisolone Prednisone	Fluid retention, hyperglycemia, hypertension, infection
Estrogens Estradiol	Fluid retention, feminization, uterine bleeding, nausea and vomiting, thrombophlebitis
Progestins Medroxyprogesterone Megestrol acetate	Weight gain, fluid retention, feminization, cardiovascular effects
Antiestrogens Fulvestrant Tamoxifen Toremifene	Hot flashes, nausea and vomiting, altered menses
Estrogen agonist/antagonist Raloxifene	Hot flashes, arthralgias, flu-like syndrome
Aromatase inhibitors Aminoglutethimide Anastrozole Exemestane Letrozole	Rash, electrolytes disturbance, drowsiness, nausea, anorexia
Androgens Testosterone Methyltestosterone Fluoxymesterone	Masculinization, amenorrhea, gynecomastia, nausea, water retention, changes in libido, skin hypersensitivity, hepatotoxicity
Antiandrogens Bicalutamide Flutamide Nilutamide	Hot flashes, decreased libido, impotence, diarrhea, nausea and vomiting, gynecomastia, hepatotoxicity
LHRH analogs Leuprolide Goserelin	Hot flashes, menstrual irregularity, sexual dysfunction, edema
LHRH antagonist Abarelix	Hypersensitivity reactions, hypotension, syncope, hot flashes, breast enlargement, prolongation of QT interval

APL, acute promyelocytic leukemia; *ATRA,* all-*trans*-retinoic acid; *CNS,* central nervous system; *LHRH,* luteinizing hormone-releasing hormone; *SIADH,* syndrome of inappropriate antidiuretic hormone.

acids. These are S phase–specific agents. Unique features involving the use of antimetabolites are as follows:

1. **Leucovorin rescue** must be given following with high-dose methotrexate administration to rescue normal, healthy cells from the cytotoxicity of methotrexate. Leucovorin serves as a reduced folate (i.e., folinic acid) that enters the folic acid synthesis pathway downstream of the site of effect of methotrexate. Timing and dosing of leucovorin is critical to ensure the maximal benefit with the least risk of reversing the cytotoxic effects of methotrexate.

2. **Polymorphisms of thiopurine methyltransferase** (**TPMT**) may produce excessive toxicity in patients receiving mercaptopurine. Dose reductions may be necessary in some patients.

E. **Mitotic inhibitors.** The vinca alkaloids arrest cell division by preventing microtubule formation. The taxanes promote microtubule assembly and stabilization, thus prohibiting cell division. These are M phase–specific agents.

F. **Topoisomerase inhibitors** inhibit the enzymes topoisomerase I or II. The topoisomerases are necessary for DNA replication and RNA transcription. These are G_2 phase–specific agents.

G. **Enzymes.** Asparaginase is an enzyme that causes the degradation of the amino acid asparagine to aspartic acid and ammonia. Unlike normal cells, tumor cells lack the ability to synthesize asparagine. This is a G_1 phase–specific agent.

H. **Protein tyrosine kinase inhibitors.** These agents are also known as targeted agents because they affect specific receptors to induce cancer cell death.

1. Imatinib, dasatinib, and nilotinib are selective tyrosine kinase inhibitor that causes apoptosis or arrest of growth in cells expressing the Bcr-Abl oncoprotein. Bcr-Abl is the product of a specific chromosomal abnormality (Philadelphia chromosome), which is present in virtually all patients with chronic myelogenous leukemia (CML).

2. Erlotinib is a selective inhibitor of epidermal growth factor receptor (EGFR) tyrosine kinase. EGFR is a cell surface receptor that is overexpressed in certain solid tumors. The binding of the EGFR receptor to its ligand activates tyrosine kinase, which then stimulates cell proliferation and growth of the tumor. Erlotinib blocks the tyrosine kinase signaling cascade and inhibits cancer cell growth.

I. Various **miscellaneous** agents have a critical role in the treatment of specific cancers.

1. **Retinoid derivatives**
   a. **Tretinoin** (all-*trans*-retinoic acid; ATRA) is a retinoic acid derivative that is used in the treatment of a specific type of acute myelogenous leukemia, known as acute promyelocytic leukemia (APL), to help cells differentiate into functionally mature cells.
   b. **Isotretinoin** (13-*cis*-retinoic acid; 13-CRA) is a retinoic acid derivative that is used in the treatment of neuroblastoma, a type of solid tumor seen in young children.
   c. **Bexarotene** is a selective retinoid X receptor (RXR) ligand used for cutaneous T-cell lymphoma. Activation of the retinoid receptors leads to regulation of gene expression and apoptosis.

2. **Arsenic trioxide** is an antineoplastic compound used in the treatment of APL that may induce selective apoptosis of APL cells.

3. **Bortezomib** is a proteosome inhibitor currently used in patients with multiple myeloma and under investigation for the treatment of several other types of cancer.
   a. Proteosomes are enzyme complexes that are responsible for degrading proteins that control the cell cycle.
   b. Bortezomib is specific in that it interferes with the degradation of nuclear factor κβ (NF-κβ). NF-κβ is released from its inhibitory partner protein and moves to the nucleus. When the inhibitory partner does not degrade because of the action of bortezomib, NF-κβ is prevented from transcribing the genes that promote cancer growth.

4. **Thalidomide and lenalidomide** are immunomodulatory agents with various mechanisms of action. They work as angiogenesis inhibitors by interfering with the growth of new blood vessels needed for tumor growth and survival. They inhibit the production of tumor necrosis factor α (TNF-α) production, induce oxidative damage to DNA, and help stimulate human T cells. They can be used as treatment for multiple myeloma in combination with dexamethasone.

J. **Hormones** are a class of heterogeneous compounds that have various effects on cells.

K. **Biological response modifiers** alter or enhance the patient's immune system to fight cancer or to lessen the side effects of the cancer treatment. Examples are given in *Table 50-2*.

1. **Cytokines** are soluble factors secreted or released by cells that affect the activity of other cells and/or the secreting cell itself. These agents generally act as regulatory or hematopoietic growth factors.

Table 50-2	BIOLOGICAL AGENTS USED IN ONCOLOGY

Agent	Indications	Toxicity
Cytokine		
Interferon-α -2a, -2b (Intron A)	Malignant melanoma, chronic myelogenous leukemia, hairy cell leukemia, Kaposi sarcoma, chronic hepatitis B and C, follicular lymphoma	Flulike syndrome, anorexia, depression, fatigue
Interleukin 2 (aldesleukin, Proleukin)	Renal cell carcinoma, malignant melanoma	Chills, fever, dyspnea, pulmonary congestion, edema, nephrotoxicity, hypotension, mental status changes, anemia, thrombocytopenia, diarrhea, nausea and vomiting
Interleukin 11 (oprelvekin, Neumega)	Thrombocytopenia	Fluid retention, peripheral edema, dyspnea, tachycardia, atrial arrhythmias, dizziness, blurred vision
Filgrastim (G-CSF, Neupogen)	Decrease incidence/duration of neutropenia, hematopoietic stem cell mobilization	Bone pain, fever, malaise
Pegfilgrastim (Neulasta)	Decrease incidence/duration of neutropenia	Bone pain, fever, malaise
Sargramostim (GM-CSF, Leukine)	Acceleration of myeloid recovery, BMT failure or engraftment delay, induction for acute myelogenous leukemia, hematopoietic stem cell mobilization, myeloid reconstitution after BMT	Bone pain, arthralgia/myalgia, chills, fever, rash, first-dose reaction (hypotension, tachycardia, dyspnea)
Epoetin α (erythropoietin, Epogen, Procrit)	Anemia associated with chronic renal failure, cancer chemotherapy or HIV treatments, reduction of blood transfusions in surgery patients	Hypertension, headache, arthralgias
Darbepoetin α (Aranesp)	Anemia associated with chronic renal failure, chronic renal insufficiency, cancer- and chemotherapy-associated anemia	Hypertension, myalgia, headache, fever, tachycardia, nausea
Monoclonal antibody		
Alemtuzumab (Campath)	B-cell chronic lymphocytic leukemia	Infusion-related fevers, chills, rash, hypotension, shortness of breath, nausea and vomiting, opportunistic infections, neutropenia, thrombocytopenia
Bevacizumab (Avastin)	Metastatic colorectal cancer, non-small cell lung cancer (nonsquamous)	Hypertension, proteinuria, GI perforation, thrombotic events, impaired wound healing
Cetuximab (Erbitux)	Metastatic colorectal cancer	Acneiform rash, infusion-related reactions, fatigue, nausea and vomiting, diarrhea
Ibritumomab tiuxetan (Zevalin)	Non-Hodgkin lymphoma	Infusion-related fevers, chills, rigors, hypersensitivity, hypotension, myelosuppression
Panitumumab	EGFR-expressing, metastatic colorectal carcinoma with disease progression on or following fluoropyrimidine-, oxaliplatin-, and irinotecan-containing chemotherapy regimens.	Transient acneiform skin rash, erythema, dry skin, skin fissures/exfoliation, diarrhea
Rituximab (Rituxan)	Non-Hodgkin lymphoma	Hypersensitivity, infusion-related fevers, chills, rigors, hypotension
Tositumomab (Bexxar)	Non-Hodgkin lymphoma	Hypersensitivity reactions, fever, chills, myelosuppression, especially thrombocytopenia, rash, nausea and vomiting, diarrhea

Table 50-2   Continued.

Agent	Indications	Toxicity
Trastuzumab (Herceptin)	Breast cancer	Infusion-related fevers, chills, cardiac dysfunction including dyspnea, cough, peripheral edema, nausea and vomiting, hypersensitivity, hypotension, diarrhea
Immunotoxin		
Denileukin diftitox (Ontak)	Cutaneous T-cell lymphoma	Acute hypersensitivity, including hypotension, dyspnea, rash, chest pain, tachycardia, vascular leak syndrome, dizziness, nausea and vomiting, diarrhea

BMT, bone marrow transplant; *EGFR,* epidermal growth factor receptor; *G-CSF,* granulocyte colony-stimulating factor; *GI,* gastrointestinal; *GM-CSF,* granulocyte-macrophage colony-stimulating factor.

2. **Monoclonal antibodies** are recombinant antibodies designed to identify cancer-specific antigens, bind to the antigens on the patient's cancer cells, and allow the patient's immune system to eliminate those cells.
   a. Some monoclonal antibodies have been conjugated to radioisotopes (e.g., ibritumomab tiuxetan) to help target cytotoxic therapy to the tumor cells.
   b. Bevacizumab (Avastin) is a chimeric monoclonal antibody that targets and inhibits vascular endothelial growth factor (VEGF). VEGF is an important regulator of the growth and survival of blood vessels, known as angiogenesis. Bevacizumab works by inhibiting angiogenesis and, therefore, inhibiting the blood supply to the tumor.
   c. Trastuzumab (Herceptin) is a humanized monoclonal antibody that binds to the HER2/neu (ErbB2) receptor. This receptor is overexpressed in many patients with breast cancer. Trastuzumab has several proposed mechanisms, including antibody-dependent cell-mediated cytotoxicity, downregulation of the HER2/neu receptors resulting in disruption of downstream signaling, cell cycle arrest in the G1 phase, and suppression of angiogenesis.
   d. Other monoclonal antibodies are listed in *Table 50-2.*
3. **Immunotoxins.** Denileukin diftitox is a fusion protein composed of diphtheria toxin and interleukin 2 (IL-2). It is designed to direct the cytocidal action of diphtheria toxin to cells with the IL-2 receptor on their surface. This form of therapy is able to bypass the need for a functioning immune system, which may be defective in many cancer patients.
4. **Tumor vaccines.** Sipuleucel-T (Provenge) is a therapeutic, patient-specific cancer vaccine. It was the first therapeutic cancer vaccine to demonstrate a survival advantage in phase III clinical trials.

V. TOXICITIES OF CHEMOTHERAPY AGENTS. Chemotherapeutic agents are most toxic to rapidly proliferating cells, including mucous membranes, skin, hair, gastrointestinal (GI) tract, and bone marrow.

A. **Bone marrow suppression** is the **most common** dose-limiting **side effect** of cancer therapy and may be one of the most life threatening.
   1. **Complications**
      a. **Infections.** White blood cells are most affected due to their short life span (6 to 12 hrs).
         (1) A significant decrease in the white blood cell count, particularly a neutrophil count less than 500/mm³ (**neutropenia**), predisposes the patient to development of serious infections.
         (2) The usual signs and symptoms of infection may be absent, and fever may be the only indicator (**febrile neutropenia**).
         (3) **Colony-stimulating factors**—for example, granulocyte colony-stimulating factor (**G-CSF**) and granulocyte-macrophage colony-stimulating factor (**GM-CSF**)—may be used to stimulate neutrophil production and lessen the degree and duration of neutropenia.

      b. Bleeding. Platelets have an intermediate life span of 5 to 10 days. Decreased platelets (**thrombocytopenia**) can also occur from chemotherapy, which can lead to bleeding and may require platelet transfusions. Oprelvekin (interleukin-11, IL-11) has been used with the goal of stimulating platelet production; however, its use is not routine in clinical practice.

      c. Anemia and **fatigue** secondary to cancer chemotherapy may also occur. It generally does not occur as quickly as other bone marrow toxicities because of the long life span of red blood cells (about 120 days). **Human recombinant erythropoietin** (e.g., epoetin α, darbepoetin α) may be used to increase hemoglobin, decrease transfusion requirements, and decrease fatigue. Recent data suggests that the risks (i.e., tumor progression and thrombosis) associated with the use of these agents (erythropoietin-stimulating agents, or ESAs) in patients with cancer can outweigh their benefits. A FDA-required REMS program has been implemented for the use of these agents in patients with cancer.

  2. The **time course** of myelosuppression varies with the chemotherapy regimen. In general, the onset of myelosuppression is 7 to 10 days after the chemotherapy has been administered. The lowest point of the counts, called the **nadir**, is usually reached in 10 to 14 days, though for some agents this can be much longer. Recovery of counts usually occurs in 2 to 3 weeks.

  3. The **depth and duration** of myelosuppression is related to the chemotherapy agents used and doses given.

      a. Drugs that can cause severe myelosuppression include carmustine, cytarabine, daunorubicin, doxorubicin, and paclitaxel.

      b. Some chemotherapy agents cause little or no myelosuppression. These include asparaginase, bleomycin, and vincristine.

      c. Sufficient **count recovery** is typically required before receiving subsequent chemotherapy cycles. Requirements vary based on the treatment protocol and the agents to be administered. Some protocols include requirements such as an ANC more than $1000/mm^3$ and platelets more than $100,000/mm^3$ prior to the administration of additional chemotherapy.

B. Dermatological toxicity

  1. Alopecia is the loss of hair associated with chemotherapy. Not all agents cause alopecia, and hair loss may be partial or complete. Chemotherapy agents that commonly cause alopecia include cyclophosphamide, doxorubicin, mechlorethamine, and paclitaxel.

  2. Drugs associated with necrosis of tissue are called **vesicants**. Local tissue necrosis may result from **extravasation** of vesicant chemotherapeutic agents outside the vein and into the subcutaneous tissue during administration.

      a. Most vesicant extravasations produce immediate pain or burning. However, a delayed reaction may occur hours to weeks later. Significant tissue injury, including ulceration or necrosis, may require plastic surgery intervention.

      b. The treatment of extravasations varies, depending on the vesicant. Heat or cold packs and chemicals such as hyaluronidase or dexrazoxane (Totect) may be used.

      c. Examples of vesicant agents include dactinomycin, daunorubicin, doxorubicin, idarubicin, mechlorethamine, mitomycin, vinblastine, vincristine, and vinorelbine.

      d. Some agents are classified as **irritants** (e.g., etoposide) and can cause irritation but not necessarily necrosis when extravasated.

  3. The EGFR inhibitors have been associated with a **papulopustular, acneiform-like skin rash**. The development of this rash may be associated with a greater success in treating specific types of cancers.

  4. Cancer chemotherapy can cause other **skin changes** such as **dryness and photosensitivity**. Examples are fluorouracil and methotrexate.

C. GI toxicities are frequently experienced by patients receiving chemotherapy.

  1. Nausea and **vomiting** are often among the most distressing toxicities from the patient's perspective. However, this side effect can generally be prevented or controlled with the use of currently available antiemetics.

      a. Nausea and vomiting may be classified as **acute**, **delayed**, **anticipatory**, **or breakthrough** in nature. Antiemetics should be used prophylactically to prevent the occurrence of nausea and vomiting, particularly with chemotherapeutic agents that have a high emetogenic risk. Various clinical guidelines have been created to guide the use of antiemetics in patients receiving chemotherapy.

b. Severe vomiting can result in dehydration, electrolyte imbalances, and esophageal tears and may result in interruptions in therapy or therapy discontinuation.

c. *Table 50-3* lists **commonly used chemotherapeutic agents** and their emetogenic potential on a scale of 1 to 5.

(1) The emetogenic potential of combinations of chemotherapy agents can be estimated by identifying the most emetogenic agent in the combination.

(2) The contribution of the other agents can then be evaluated by using the following guidelines:

(a) Level 1 agents do not contribute to the emetogenicity of the regimen.

(b) Adding one or more level 2 agents increases the emetogenicity to one level higher than the most emetogenic agent in the combination.

(b) Adding level 3 or 4 agents increases the level of emetogenicity by one level per agent.

d. The occurrence of nausea and vomiting is influenced by the emetogenicity of the chemotherapeutic agent or combination of agents, the chemotherapeutic dose, the method of administration, and individual patient characteristics.

2. Stomatitis is a generalized inflammation of the oral mucosa or other areas of the GI tract. Because of the rapid turnover of epithelial cells in the GI tract, this is a common site of toxicity.

a. Signs and **symptoms** include erythema, pain, dryness of the mouth, burning or tingling of the lips, ulcerations, and bleeding.

b. Chemotherapy agents commonly associated with stomatitis include capecitabine, fluorouracil, and methotrexate.

c. Time course. Stomatitis usually appears within a week after the offending agent is administered and resolves in 10 to 14 days.

d. Consequences of stomatitis include infection of the ulcerated areas, inability to eat, pain requiring opioid analgesics, and subsequent decreases in chemotherapy doses.

Table 50-3   EMETOGENIC POTENTIAL OF CANCER CHEMOTHERAPEUTIC AGENTS

Level 5: Very Highly Emetogenic	Level 4: Highly Emetogenic	Level 3: Moderately Emetogenic	Level 2: Low Emetic Risk	Level 1: Very Low Emetic Risk
Carmustine > 250 mg/m^2	Carmustine ≤ 250 mg/m^2	Carboplatin	Docetaxel	Asparaginase
Cisplatin ≥ 50 mg/m^2	Cisplatin < 50 mg/m^2	Cyclophosphamide ≤ 750 mg/m^2	Etoposide	Bleomycin
Cyclophosphamide ≥ 1500 mg/m^2	Cyclophosphamide 750–1500 mg/m^2	Cytarabine < 1000 mg/m^2	Fluorouracil	Capecitabine
Dacarbazine	Cytarabine > 1000 mg/m^2	Daunorubicin	Gemcitabine	Chlorambucil
Mechlorethamine	Dactinomycin	Doxorubicin ≤ 60 mg/m^2	Irinotecan	Dasatinib
Streptozocin	Doxorubicin > 60 mg/m^2	Idarubicin	Methotrexate 50–250 mg/m^2	Decitabine
	Lomustine	Ifosfamide	Mitomycin	Erlotinib
	Melphalan (intravenous > 50 mg/m^2)	Methotrexate 250–1000 mg/m^2	Paclitaxel	Gemtuzumab
	Methotrexate > 1000 mg/m^2	Mitoxantrone	Thiotepa < 15 mg/m^2	Hydroxyurea
	Procarbazine	Temozolamide	Topotecan	Lenalidomide
	Temozolomide	Melphalan > 50 mg/m^2	Pemetrexed	Methotrexate ≤ 50 mg/m^2
	Thiotepa ≥ 15 mg/m^2			Melphalan (oral)
				Nelarabine
				Rituximab
				Sorafenib
				Sunitinib
				Thalidomide
				Thioguanine
				Trastuzumab
				Vinblastine
				Vincristine
				Vinorelbine

     e. **Topical and local analgesics** in the form of mouth rinses are commonly used and can help with mouth and throat pain.

    3. Other GI toxicities include **diarrhea** (e.g., irinotecan, fluorouracil), **constipation** (e.g., vincristine), **anorexia**, and **taste changes**.

D. **Tumor lysis syndrome** (**TLS**) may occur in hematological malignancies such as leukemia and lymphoma in which there is a high tumor cell burden or rapidly growing tumors. Owing to the spontaneous lysis of cells from treatment with chemotherapy, cell lysis causes release of intracellular products, including uric acid, potassium, and phosphate, which can lead to renal failure and cardiac arrhythmias. This may be prevented by giving intravenous hydration, by alkalinizing the urine, and by giving agents such as **allopurinol** or **rasburicase** (Elitek) to decrease uric acid.

E. **Hypercalcemia** may occur in patients with solid or hematologic malignancies and can often be the presenting sign of malignancy. The major cause of hypercalcemia is increased osteoclastic bone resorption, which is generally caused by the release of parathyroid hormone-related protein (PTHrP) by the tumor cells. Common presenting symptoms include mental status changes, fatigue and muscle weakness, polyuria, polydipsia, nausea, and vomiting. Treatment includes aggressive hydration with normal saline; calciuric therapy, which consists of calcitonin; and bisphosphonates such as pamidronate (Aredia) or zoledronic acid (Zometa).

F. **Chills** and **fever** may occur after the administration of some chemotherapy and biological agents. This fever generally can be differentiated from fever owing to infection because of its temporal relationship to chemotherapy administration. This reaction is commonly associated with bleomycin, cytarabine, monoclonal antibodies, and IL-2.

G. **Pulmonary toxicity** is generally irreversible and may be fatal.

    1. **Signs** and **symptoms** are shortness of breath, nonproductive cough, and low-grade fever. In some cases, the risk of pulmonary toxicity increases as the cumulative dose of the drug increases (e.g., bleomycin).

    2. Chemotherapeutic agents associated with pulmonary toxicity include bleomycin, busulfan, carmustine, and mitomycin.

H. **Cardiac toxicity** may manifest as an acute or chronic problem.

    1. **Acute changes** are generally transient electrocardiograph abnormalities that may not be clinically significant.

    2. **Chronic cardiac toxicity** presents as irreversible, left-sided heart failure. **Risk factors** include chest irradiation and high cumulative doses of cardiotoxic chemotherapy.

    3. Chemotherapy agents that are associated with chronic cardiotoxicity include daunorubicin, doxorubicin, epirubicin, idarubicin, and mitoxantrone. **Dexrazoxane** is a cardioprotective agent that may be used with doxorubicin to help prevent or lessen its toxic effects to the heart.

I. **Hypersensitivity reactions** may occur with any chemotherapy agent. Life-threatening reactions, including anaphylaxis, appear to be more common with asparaginase, carboplatin, cisplatin, etoposide, paclitaxel, and teniposide.

J. **Neurotoxicity** may occur with systemic or intrathecal chemotherapy.

    1. Vincristine is associated with **autonomic** and **peripheral** neuropathies. Patients may experience gait disturbances, numbness and tingling of hands and feet, and loss of deep-tendon reflexes. Inadvertent intrathecal administration of vincristine results in fatal neurotoxicity.

    2. **Peripheral neuropathy** and **ototoxicity** are common dose-limiting toxicities of cisplatin. **Sensory** neuropathies, including tingling or numbing of the hands and feet, may be associated with capecitabine, oxaliplatin, and paclitaxel.

    3. **Cerebellar toxicity** has been reported with high doses of cytarabine and it manifests initially as loss of eye–hand coordination and may progress to coma.

    4. **Arachnoiditis** has been associated with intrathecal administration of cytarabine and methotrexate.

    5. **Encephalopathy** has been reported in patients receiving ifosfamide. Patient-related risk factors have been identified with this adverse event and include high serum creatinine, low serum albumin, and the presence of pelvic disease.

K. **Hemorrhagic cystitis** is a bladder toxicity that is seen most commonly after administration of cyclophosphamide and ifosfamide. **Acrolein**, a metabolite of these agents, is thought to cause a chemical irritation of the bladder mucosa, resulting in bleeding. Preventive measures include aggressive hydration with subsequent frequent urination, and the administration of the uroprotectant mesna. **Mesna** acts by binding to acrolein and preventing it from contacting the bladder mucosa.

L. **Renal toxicity** may manifest by elevations in serum creatinine and blood urea nitrogen (BUN) as well as electrolyte abnormalities. Nephrotoxicity is associated with cisplatin, ifosfamide, methotrexate, and streptozocin. Intravenous hydration is used to protect the kidneys from the nephrotoxic effects of cisplatin. Osmotic diuresis with mannitol may help reduce the incidence of cisplatin nephrotoxicity.

M. **Hepatotoxicity** may manifest as elevated liver function tests, jaundice, or hepatitis. Asparaginase, cytarabine, mercaptopurine, and methotrexate are known to cause hepatic toxicity.

N. **Secondary malignancies**, such as solid tumors, lymphomas, and leukemias, may occur many years after chemotherapy or radiation. Antineoplastic agents known to possess a high carcinogenic risk include cyclophosphamide, etoposide, melphalan, and mechlorethamine.

O. Chemotherapy may cause **infertility**, which may be temporary or permanent. Cyclophosphamide, chlorambucil, mechlorethamine, melphalan, and procarbazine are associated with a significant incidence of infertility in males and females.

VI. OTHER THERAPEUTIC MODALITIES

A. **Surgery** may be diagnostic (biopsy, exploratory laparotomy, second look) or therapeutic (tumor debulking or removal). Surgery is often combined with chemotherapy and/or radiation.

B. **Radiation therapy** involves high doses of ionizing radiation directed at the cancerous tissue. Radiation may be combined with surgery and/or chemotherapy. **Adverse reactions** vary based on the area of the body being irradiated and may include stomatitis, nausea and vomiting, diarrhea, and myelosuppression. In patients who have received anthracyclines, **radiation recall dermatitis** may occur resulting in skin inflammation in the area of previously received radiation.

C. **Hematopoietic stem cell transplantation** involves intravenous infusion of stem cells from a compatible donor to a recipient following high-dose chemotherapy. It is used for treatment of diseases involving the bone marrow or immune system and to allow for administration of high-dose chemotherapy or radiation for tumors resistant to standard doses. Stem cells can be obtained from bone marrow or peripheral blood.

1. In **autologous** transplants, stem cells are obtained from the patient, preserved, and later reinfused into the same patient. **Allogeneic** transplants involve two separate individuals. Cells are obtained from a matched donor and then infused into a separate patient. A **syngeneic** transplant occurs when both the donor and recipient are identical twins.

2. Transplant-related complications include hepatic veno-occlusive disease (VOD), acute and chronic graft versus host disease (GVHD), infection, and pulmonary complications.

Study Questions

Directions for questions 1–14: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Body surface area (BSA) is used in calculating chemotherapy doses because

   (A) BSA is an indicator of tumor cell mass.
   (B) BSA correlates with cardiac output.
   (C) BSA correlates with gastrointestinal transit time.
   (D) the National Cancer Institute requires that BSA be used.
   (E) the U.S. Food and Drug Administration (FDA) requires that BSA be used.

2. The rationale for combination chemotherapy includes all of the following *except*

   (A) biochemical enhancement of effect.
   (B) rescue of normal cells.
   (C) overcoming or preventing resistance.
   (D) biochemical nullification of effect.
   (E) cytotoxic to both resting and dividing cells.

3. All of the following chemotherapy agents can be administered intrathecally *except*

   (A) methotrexate.
   (B) cytarabine.
   (C) hydrocortisone.
   (D) thiotepa.
   (E) vincristine.

4. Hypersensitivity reactions have been commonly associated with all of the following agents *except*

(A) asparaginase.
(B) busulfan.
(C) carboplatin.
(D) etoposide.
(E) paclitaxel.

5. Which of these supportive agents may have a greater risk than benefit in patients with cancer when the goal is cure due to the potential increased risk of tumor progression?

(A) Antiemetics
(B) Colony-stimulating factors
(C) Corticosteroids
(D) Erythropoietin-stimulating agents
(E) Oprelvekin (IL-11)

6. How do antimetabolites exert their cytotoxic effect?

(A) Inhibiting DNA synthesis by sliding between DNA base pairs
(B) Inhibiting RNA synthesis by sliding between RNA base pairs
(C) Acting as false metabolites in the microtubules
(D) Acting as false substitutions in the production of nucleic acids
(E) Promoting microtubule assembly and stabilization

7. All of the following chemotherapy agents work through affecting microtubule function *except*

(A) docetaxel.
(B) vinblastine.
(C) mitoxantrone.
(D) vincristine.
(E) vinorelbine.

8. When does the neutrophil nadir associated with chemotherapy agents generally occur?

(A) During administration of the chemotherapy
(B) 1 to 2 days after therapy
(C) 10 to 14 days after therapy
(D) 1 month after therapy
(E) When the platelet count begins to rise

9. Which of the following statements describes hemorrhagic cystitis?

(A) It is caused by excretion of tumor cell breakdown products.
(B) It is associated with ifosfamide or cyclophosphamide administration.
(C) It is caused by the administration of mesna.
(D) It can be prevented or treated with acrolein.
(E) It can be treated with granulocyte colony-stimulating factor (G-CSF).

10. All of the following chemotherapy agents are vesicants *except*

(A) doxorubicin.
(B) mechlorethamine.
(C) vincristine.
(D) methotrexate.
(E) idarubicin.

Directions for questions 11–15: Each agent in this section is most closely associated with **one** of the following adverse effects. Each effect is used only **once**. Choose the **best** answer, **A–E**.

(A) Cardiotoxicity
(B) Conjunctivitis
(C) Diarrhea
(D) Pulmonary fibrosis
(E) Constipation

11. Vincristine

12. Irinotecan

13. Doxorubicin

14. Cytarabine

15. Bleomycin

Answers and Explanations

1. **The answer is B** *[see III.B]*.
BSA correlates with cardiac output, which determines renal and hepatic blood flow and thus affects drug elimination.

2. **The answer is D** *[see III.D.2]*.
Combination chemotherapy has been developed to have maximal cytotoxicity to tumor cells and minimal toxicity to normal cells. The drugs are dosed and scheduled such that maximal cell kill occurs, while sparing normal cells as much as possible. Combination regimens often contain agents with different spectrums of toxicity.

3. **The answer is E** *[see III.E.3]*.
Intrathecally administered vincristine is fatal. All syringes of vincristine must be labeled "Fatal if given intrathecally. For intravenous use only."

4. **The answer is B** *[see V.I]*.
Hypersensitivity reactions have been commonly associated with asparaginase, carboplatin, etoposide, and paclitaxel. Busulfan is not commonly associated with hypersensitivity reaction.

5. **The answer is D** *[see V.A.1.c]*.
Erythropoietin-stimulating agents (ESAs) have been found to increase the likelihood of tumor progression in certain patient populations and therefore should not be used in patients with cancer when the goal is cure.

6. **The answer is D** *[see IV.D]*.
Antimetabolites are structural analogs of naturally occurring substrates for biochemical reactions. They inhibit DNA synthesis by acting as false substitutions in the production of DNA.

7. **The answer is C** *[see IV.E]*.
Docetaxel is a taxane, which works by promoting microtubule assembly and stabilization, resulting in inhibition of cell division. Vincristine, vinblastine, and vinorelbine are vinca alkaloids, which work by preventing microtubule formation. Mitoxantrone is an antitumor antibiotic, which works by DNA intercalation.

8. **The answer is C** *[see V.A.2]*.
Bone marrow suppression, particularly of the neutrophils, usually is the most profound 10–14 days after chemotherapy.

9. **The answer is B** *[see V.K]*.
Hemorrhagic cystitis results from irritation of the lining of the bladder by acrolein, a metabolite of ifosfamide and cyclophosphamide. Mesna may be used to inactivate the acrolein, thus preventing hemorrhagic cystitis.

10. **The answer is D** *[see V.B.2]*.
Vesicant chemotherapy agents may cause local necrosis if extravasated outside the vein. Doxorubicin, idarubicin, mechlorethamine, and vincristine are all classified as vesicants.

11. **The answer is E** *[see V.C.3; V.E.–G]*.
Severe constipation and paralytic ileus is associated with the use of vincristine.

12. **The answer is C** *[see V.C.3; V.E.–G]*.
Severe diarrhea, requiring treatment with atropine and/or loperamide, is associated with irinotecan.

13. **The answer is A** *[see V.C.3; V.E.–G]*.
Cardiotoxicity is associated with cumulative doses of doxorubicin and other antitumor antibiotics.

14. **The answer is B** *[see V.C.3; V.E.–G]*.
Conjunctivitis occurs with high-dose cytarabine; patients receiving high-dose cytarabine should receive prophylaxis with steroid eye drops.

15. **The answer is D** *[see V.C.3; V.E.–G]*.
Pulmonary toxicity, including fibrosis, is associated with cumulative doses of bleomycin.

Pain Management

ALAN F. KAUL

51

I. INTRODUCTION

A. Definitions

1. **Pain** is an unpleasant sensory and emotional experience that is associated with actual or potential tissue damage or described in terms of such damage. It is a subjective, individual experience that has physical, psychological, and social determinants. There is no objective measurement of pain. In the United States alone, recurrent or persistent pain is experienced by more than 75 million individuals.

2. **Acute pain** lasts 30 days longer than the usual healing process for that type of injury, and occurs after muscle strains and tissue injury, such as trauma or surgery. The pain is usually self-limiting, decreasing with time as the injury heals. It is described as a linear process, with a beginning and an end. Increased autonomic nervous system activity often accompanies acute pain, causing tachycardia, tachypnea, hypertension, diaphoresis, and mydriasis. Increased anxiety also may occur.

3. **Chronic pain** is persistent or episodic pain of a duration or intensity that adversely affects the function or well-being of the patient and can persist after the resolution of an injury. Some define it as lasting more than 6 months.

   a. **Chronic nonmalignant pain** may be a complication of acute injury in which the healing process does not occur as expected or may be caused by a disease such as a rheumatological disorder (e.g., osteoarthritis, rheumatoid arthritis, fibromyalgia).

   b. The elderly are more likely to experience chronic pain because of the increased prevalence of degenerative disorders in this age group.

   c. The pain is constant, does not improve with time, and is described as a cyclic process (vicious circle).

   d. Compared to acute pain, there is no longer autonomic nervous system stimulation, so the patient may not appear to be in pain. Instead, the patient may be depressed; suffer insomnia, weight loss, and sexual dysfunction; and may not be able to cope with the normal activities of daily living, including family and job-related activities.

4. **Chronic cancer pain** occurs in 60% to 90% of patients with cancer. Its characteristics are similar to those of chronic nonmalignant pain. In addition to depression, prominent characteristics are fear, anger, and agony. The cause of chronic cancer pain can be related to the tumor or cancer therapy or can be idiosyncratic. Tumor causes of pain include bone metastasis, compression of nerve structures, occlusion of blood vessels, obstruction of bowel, or infiltration of soft tissue.

5. **Breakthrough pain** is the intermittent, transitory increase in pain that occurs at a greater intensity over baseline chronic pain. It may have temporal characteristics, precipitating factors, and predictability.

6. **Neuropathic pain** is a result of an injury or malfunction of the nervous system. Excluding patients with a progressive peripheral neuropathy or neuropathic pain associated with a cancer lesion, tissue damage is not ongoing. Neuropathic pain is described as aching, throbbing, burning, shooting, stinging, and tenderness or sensitivity of the skin.

7. **Migraine pain** is characterized by a severe headache generally associated with nausea and light and sound sensitivity. Migraine is a common disorder with a 1 year prevalence rate in Americans of approximately 13% ranging from 6% to 7% of men and 18% of women.

B. Principles of management
1. **Comprehensive pain assessment** should determine the characteristics of the patient's pain complaint, clinical status, and pain management history.
    a. Assessment of the pain complaint should include chronology and symptomatology of the presenting complaint such as information about onset, location, intensity, duration, quality, distribution, provocative factors, temporal qualities, severity, and pain history.
    b. Assessment of clinical status should include the extent of underlying trauma or disease. Also, the patient's physical, psychological, and social conditions should be determined.
    c. Assessment of pain management history includes drug allergies, analgesic response, onset, duration, and side effects.
2. **Appropriate pain management targets** should be established.
    a. The primary pain management goal is to improve patient comfort.
    b. For acute pain management, improved comfort can aid the healing and rehabilitation process.
    c. For chronic pain, the specific objectives are to break the pain cycle (i.e., erase pain memory) and minimize breakthrough pain.
    d. Other targets for chronic pain management include improvement of general well-being, sleep, outlook, self-esteem, activities of daily living, support, and mobility.
3. **Individualized pain management regimens** should be determined and initiated promptly.
    a. The optimal analgesic regimen, including dose, dosing interval, and mode of administration, should be selected.
    b. Additional pharmacological adjuncts and nonpharmacological therapies should be added if needed.
    c. The most common regimens for acute pain include intermittent (as needed) dosing, patient-controlled analgesia (PCA), or epidural infusions with narcotic or nonnarcotic agents.
    d. Nonnarcotic analgesics and nonpharmacological management usually are maximized. Narcotic use may be appropriate for certain patients being treated for chronic nonmalignant pain. Pain management specialists often include these agents in their plans.
    e. For chronic cancer pain, an individualized around-the-clock analgesic regimen is established, using a long-acting analgesic. An intermittent, as-needed regimen for breakthrough pain, using a short-acting analgesic, is also determined.
4. **Monitoring** the pain management regimen and **reassessment** of the patient's pain should occur on a continuous, timely basis. Any changes in analgesic, dose, dosing interval, or method of administration should be noted in the patient's medical record and carried out in a timely fashion.

II. ANALGESICS

A. **Nonnarcotic analgesics** include aspirin, other salicylates, acetaminophen, nonsteroidal anti-inflammatory drugs (NSAIDs), selective cyclooxygenase 2 (COX-2) inhibitors, disease-modifying antirheumatic drugs (DMARDs), and tumor necrosis factor α (TNF-α) inhibitors (*Table 51-1*). Aspirin products, acetaminophen, and some low-dose NSAIDs such as ibuprofen, ketoprofen, and naproxen sodium are available as over-the-counter (OTC) products.
1. **Mechanism of action.** Salicylates and NSAIDs are prostaglandin inhibitors and prevent peripheral nociception by vasoactive substances such as prostaglandins and bradykinins. Most NSAIDs inhibit both COX-1, which produces prostaglandins that are believed to be cytoprotective of the stomach lining, and COX-2, which produces prostaglandins responsible for pain and inflammation. Selective COX-2 inhibitors like celecoxib do not inhibit COX-1.

   Adalimumab, etanercept, and infliximab act by binding or capturing excess TNF-α, one of the dominant cytokines, or proteins, that play an important role in the inflammatory response. The exact mechanism of action of leflunomide, a novel drug used to treat rheumatoid arthritis, is not completely known but it is thought to inhibit pyrimidine synthesis.
2. **Therapeutic effects**
    a. The peripherally acting, nonnarcotic analgesics have several effects in common. These effects distinguish these agents from narcotic analgesics.
       (1) They are antipyretic.
       (2) They are anti-inflammatory (except acetaminophen).
       (3) There is a ceiling effect to the analgesia.

Table 51-1	NONNARCOTIC ORAL ANALGESICS AND NONSTEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDs)

Drug	Adult Dose Range (mg)	Dosing Interval (hr)	Maximum Dose/Day (mg)
Para-aminophenol derivatives			
Acetaminophen (Tylenol)	325–1000	4–6	4000
Salicylates			
Aspirin	325–1000	4–6	4000
Choline magnesium trisalicylate (Trilisate)	1000–1500	12	3000
Diflunisal (Dolobid)	250–1000	8–12	1500
Salsalate (Disalcid)	500–1000	8	3000
Arylpropionic acid derivatives			
Fenoprofen (Nalfon)	200	4–6	3200
Flurbiprofen (Ansaid)	50–100	6–12	300
Ibuprofen (Motrin)	300–800	6–8	3200
Ketoprofen (Orudis)	12.5–75.0	6–8	300
Naproxen (Naprosyn)	200–500	12	1250
Naproxen sodium (Anaprox)	275–550	12	1375
Oxaprozin (Daypro)	600–1200	12	1200
Heteroaryl acetic acid derivatives			
Diclofenac (Voltaren)	25–75	6–12	200
Ketorolac (intramuscular) (Toradol)	15–60	6	120
Ketorolac (oral)	10	4–6	40
Tolmetin (Tolectin)	200–600	6–8	1800
Indole and indene acetic acid derivatives			
Etodolac (Lodine)	200–400	6–12	1200
Indomethacin (Indocin)	25–50	8–12	200
Sulindac (Clinoril)	150–200	12	400
Anthranilic acid derivatives (fenamates)			
Meclofenamate	50–100	4–6	400
Mefenamic acid (Ponstel)	250	6	1000
Alkanone derivatives			
Nabumetone (Relafen)	1000	12–24	2000
Enolic acid derivatives (oxicams)			
Piroxicam (Feldene)	20	24	20
Cyclooxygenase 2 (COX-2) selective inhibitors			
Celecoxib (Celebrex)	100–200	12–24	400
Disease-modifying antirheumatic drugs (DMARDs)			
Leflunomide (Arava)	20	24	20[a]
Anakinra (Kineret)	100 mg SC	24	
Abatacept (Orencia)	500 mg for patients weighing less than 60 kg, 750 mg for patients weighing 60 to 100 kg, or 1 g for patients weighing over 100 kg	2 to 4 weeks after the first and then every 4 weeks	

Table 51-1 Continued.

Drug	Adult Dose Range (mg)	Dosing Interval (hr)	Maximum Dose/Day (mg)
Biological response modifiers (tumor necrosis factor α inhibitors)			
Adalimumab (Humira)	40 SC injection	Every other week	TBD
Etanercept (Enbrel)	25 SC injection	Once weekly	50 SC injection
Infliximab (Remicade)	3/kg IV infusion	Every 4 to 6 weeks	10/kg
Certolizumab (Cimzia)	200 mg SC	Every 2 weeks	
Adalimumab (Humira)	40 mg SC	Every other week	
Golimumab (Simponi)	50 mg SC (give with methotrexate)	Every month	
Others			
Tocilizumab (Actemra)	4 mg/kg IV infusion over 1 hr Max = 800 mg/infusion	Every 4 weeks	
Rituximab (Rituxan)	1000 mg IV (give with methotrexate)	Every 2 weeks × 2 doses	

aExcludes loading dose of 100 mg/day for 3 days.
IV, intravenous; *SC,* subcutaneous; *TBD,* to be determined.

      (4) They do not cause tolerance.

      (5) They do not cause physical or psychological dependence.

   b. The efficacy of nonnarcotics is compared to aspirin. Most drugs are comparable to aspirin; however, several NSAIDs have shown a superior effect to 650 mg of aspirin.

      (1) Diflunisal (500 mg)

      (2) Ibuprofen (200 to 400 mg)

      (3) Naproxen sodium (550 mg)

      (4) Ketoprofen (25 to 50 mg)

   c. The newer classes of drugs, in general, have not been compared to aspirin.

3. Clinical use

   a. Generally, the nonnarcotic analgesics are used orally to manage mild to moderate pain.

      (1) They are particularly suited for acute pain of skeletal muscle (orthopedic) or oral (dental) origin.

      (2) They are used to treat pain and inflammation associated with osteoarthritis and rheumatoid arthritis.

      (3) They are used in chronic pain and can have an additive effect with narcotic analgesics.

      (4) They also may be effective in managing pain owing to bone metastases.

      (5) They are used for mild to moderate migraine pain.

   b. The NSAID ketorolac is administered intramuscularly and is useful in moderate-to-severe pain, particularly in cases in which narcotics are undesirable (e.g., with drug addicts, excessive narcotic sedation, respiratory depression).

   c. The NSAID diclofenac epolamine is available as a topical patch (Flector Patch®) for treatment of strains, sprains, and contusions. One patch is applied to the most painful area twice a day (should not be applied to damaged or nonintact skin).

   d. Patients may vary in their response and tolerance to nonnarcotic analgesics. If a patient does not respond to the maximum therapeutic dose, then an alternate NSAID should be tried. Likewise, if a patient experiences side effects with one drug, then another agent should be tried.

   e. Several drugs (e.g., diflunisal, choline magnesium trisalicylate, naproxen, celecoxib, leflunomide, etanercept, infliximab, adalimumab) have long half-lives and, therefore, may be administered less frequently.

   f. The cost of nonnarcotic analgesics is highly variable and should be considered when an agent is selected. Pharmacotherapy with the COX-2 inhibitor celecoxib, the newer DMARDs like leflunomide or TNF-α inhibitors is significantly more expensive than older agents.

4. **Adverse effects**
    a. **Gastrointestinal (GI) effects.** Most nonnarcotic analgesics cause GI symptoms secondary to prostaglandin inhibition. At normal doses, acetaminophen and choline magnesium trisalicylate produce minimal GI upset. Because of their mechanism of action, the COX-2 inhibitors have a GI toxicity similar to placebo. Adalimumab, etanercept, infliximab, and leflunomide have been associated with GI side effects including nausea, abdominal pain, dyspepsia, constipation, vomiting, hematochezia, intestinal obduction, intestinal perforation, pancreatitis, peritonitis, peptic ulcer, and diarrhea.
        (1) The most common GI symptom is dyspepsia, but ulceration, bleeding, or perforation can occur.
        (2) Patients most predisposed to severe GI effects include the elderly, patients with a history of ulcers or chronic disease, and those who smoke or use alcohol.
        (3) To minimize GI effects, the lowest possible analgesic dose should be used. Aspirin, available as enteric-coated products, may minimize GI upset. Combination therapy with a GI "protectant" (e.g., antacid, H_2-antagonist, sucralfate, misoprostol) may be needed.
    b. **Hematological effects.** Most nonnarcotic analgesics inhibit platelet aggregation. The effect is produced by reversible inhibition of prostaglandin synthetase. Aspirin is an irreversible inhibitor. Acetaminophen and choline magnesium trisalicylate lack antiplatelet effects. TNF-α inhibitors have been associated with anemia, aplastic anemia, leukopenia, neutropenia, pancytopenia, and thrombocytopenia. Leflunomide has been associated with anemia and ecchymosis.
        (1) The effect of the NSAIDs correlates to the presence of an effective serum concentration.
        (2) Use of anticoagulants (e.g., heparin, warfarin [Coumadin]) is relatively contraindicated in combination with aspirin or NSAIDs.
    c. **Renal effects.** NSAIDs can produce renal dysfunction. Etanercept has not been shown to affect renal function.
        (1) The mechanism of NSAID-induced renal dysfunction includes prostaglandin inhibition, interstitial nephritis, impaired renin secretion, and enhanced tubular water/sodium reabsorption.
        (2) Many risk factors have been implicated, including congestive heart failure (CHF), chronic renal failure (CRF), cirrhosis, dehydration, diuretic use, and atherosclerotic disease in elderly patients.
        (3) Renal dysfunction is commonly manifested as abrupt onset oliguria with sodium/water retention. The effect reverses after discontinuation of the NSAID.
    d. **Malignancies and lymphoproliferative disorders.** Agents that block TNF-α may affect host defenses against malignancies because TNF-α mediates inflammation and modulates cellular immune response. Lymphomas have occurred more frequently in patients receiving TNF-α-blocking agents than in controls.
    e. **Infections.** Opportunistic and serious infections leading to sepsis and death have been associated with leflunomide and the TNF-α-blocking agents.
    f. **Miscellaneous effects**
        (1) Even in normal doses, acetaminophen can cause hepatotoxicity in patients with liver disease or chronic alcoholism. Hepatotoxicity has also been reported with the use of all NSAIDs, including the COX-2 selective inhibitors. Leflunomide and infliximab have also been shown to cause transient elevations in liver function tests such as aspartate aminotransferase (AST)—serum glutamic-oxaloacetic transaminase (SGOT)—and alanine aminotransferase (ALT)—serum glutamic pyruvic transaminase (SGPT).
        (2) Some patients exhibit acute hypersensitivity reactions to aspirin. Manifestations include either a rhinitis or asthma presentation or a true allergic reaction (e.g., urticaria, wheals, hypotension, shock, syncope). A cross-sensitivity to other NSAIDs may develop.
        (3) Some NSAIDs produce central nervous system (CNS) effects, including impaired mentation, headaches, and attention deficit disorder.
        (4) Leflunomide has received a **black box warning** because of its Category X pregnancy warning. It has also been associated with weight loss, alopecia, rash, and anemia.
        (5) TNF-α-blocking agents have been associated with reactions at the injection site and autoantibody production.
        (6) Celecoxib, a selective COX-2 inhibitor, has a **black box warning** U.S. Food and Drug Administration (FDA) warning from the because if its link to an increased risk for

cardiovascular events (heart attack and stroke). This increased risk has been demonstrated to be a drug class effect for all NSAIDs, excluding aspirin. Celecoxib is also contraindicated in patients with sulfonamide allergy.

NSAIDs for short- or long-term use are not advised in patients with established cardiovascular disease, particularly in those who have had a myocardial infarction (MI). A nationwide cohort study in patients > 30 years of age who were hospitalized with their first-time MI from 1997 to 2006 found that even short-term treatment with most NSAIDs was associated with an increased risk of death and recurrent MI. Among the NSAIDs studied, diclofenac was associated with the highest risk.

5. **Drug interactions.** Salicylates have two clinically significant drug interactions.
   a. **Oral anticoagulants.** Aspirin should be carefully monitored, if used, in anticoagulated patients because it inhibits platelet function and can cause gastric mucosal damage. This can significantly increase the risk of bleeding in anticoagulated patients. Also, doses of > 3 g/day of aspirin produces hypoprothrombinemia. Choline magnesium trisalicylate or acetaminophen can be used if a nonnarcotic is needed in an anticoagulated patient.
   b. **Methotrexate.** Salicylates may enhance the toxicity of methotrexate. The primary mechanism is blockage of methotrexate renal tubular secretion by salicylates. The resultant methotrexate toxicity has been reported as pancytopenia or hepatotoxicity. Salicylates should be avoided in patients receiving methotrexate.
   c. **TNF-α-blocking agents.** Anakinra (Kineret), a recombinant interleukin-1 (IL-1) receptor antagonist, has been observed to cause an increased risk of serious infections as neutropenia when used concomitantly with etanercept in patients with rheumatoid arthritis. Consequently, its use is not recommended concomitantly with any TNF-α-blocking agent.

B. **Narcotic analgesics** include the opioid drugs (*Table 51-2*). Because of their abuse potential, opioids are classified as controlled drugs. Special regulations control their prescribing.
   1. **Mechanism of action**
      a. Endogenous opiates afford the body self–pain-relieving mechanisms. These endogenous peptides include the endorphins, enkephalins, and dynorphins.

Table 51-2 SOME COMMONLY USED OPIOID ANALGESICS

Drug	Parenteral Dose (mg)[a]	Oral Dose (mg)[a]	Duration (hr)
Morphine	10	60	4–7
Morphine (CR) (MS Contin)	n/a	n/a	12–24
Hydromorphone (Dilaudid)	1.3	7.5	4–6
Oxymorphone (Numorphan)	1	—	4–6
Levorphanol (Levo-Dromoran)	2	4	4–7
Methadone (Dolophine)	10	20	4–6
Meperidine (Demerol)	75	300	3–6
Fentanyl (Sublimaze)	0.1	—	1–2
Fentanyl transdermal (Duragesic)	n/a	n/a	48–72
Codeine	130	200	4–6
Hydrocodone[b]	—	5–10	4–5
Hydromorphone ER (Exalgo)	—	16	24
Dihydrocodeine[b]	—	32	4–5
Oxycodone[b]	—	5–10	4–5
Oxycodone (CR) (OxyContin)	—	n/a	12–24
Nalbuphine (Nubain)	10	—	4–6
Butorphanol (Stadol)	2	—	4–6
Dezocine (Dalgan)	10	—	4–7
Buprenorphine	—	n/a	168

[a]Doses equivalent to 10 mg intramuscular or subcutaneous morphine.
[b]Doses for moderate pain not necessarily equivalent to 10 mg morphine.
CR, controlled release; *n/a*, not applicable, *ER*, extended-release.

b. Exogenous opiates are classified as agonists (stimulate opiate receptors), antagonists (displace agonists from opiate receptors), and mixed opiates (agonist–antagonist or partial agonist actions).

c. Opiate receptors are located in the brain and spinal cord. Several types of opiate receptors have been identified, including μ, κ, δ, σ, and ϵ.

d. Stimulation of μ-receptors produces the characteristic narcotic (morphine-like) effects.

    (1) Analgesia

    (2) Miosis

    (3) Euphoria

    (4) Respiratory depression

    (5) Sedation

    (6) Physical dependence

    (7) Bradycardia

e. The specific mechanism (central and spinal) of opiate agonist is alteration of the effects of nociceptive neurotransmitters, possibly norepinephrine or serotonin.

2. Clinical use

a. Opioid analgesics are used for the management of moderate-to-severe pain (acute or chronic pain) of somatic or visceral origin.

b. The use of narcotics should be individualized for each patient. The optimal analgesic dose varies from patient to patient. Each analgesic regimen should be titrated by increasing the dose up to the appearance of limiting adverse effects. Changing to another analgesic should occur only after an adequate therapeutic trial.

c. The appropriate route of administration should be selected for each patient.

    (1) Oral administration is the preferred route, particularly for patients with chronic, stable pain. Controlled-release morphine and oxycodone tablets are available for convenience in controlling continuous pain, particularly in those patients with cancer.

    (2) Intramuscular and subcutaneous administration are very commonly used in the postoperative period. Fluctuations in absorption may occur, particularly in elderly or cachectic patients.

    (3) Intravenous (IV) bolus administration has the most rapid, predictable onset of effect.

    (4) IV infusion is used to titrate pain relief rapidly, particularly in patients with unstable chronic pain. Morphine is most commonly used, often with supplemental IV bolus doses for breakthrough pain. A mechanical infusion device is necessary.

    (5) IV PCA is most often used for acute postoperative pain. It produces prompt analgesia with minimal side effects because small doses (e.g., 1 to 2 mg morphine) are delivered at frequent intervals (e.g., every 10 mins). It allows patient control of pain management. Morphine and meperidine are the most commonly used agents. A mechanical infusion device and properly trained patient and staff are necessary.

    (6) Epidural and **intrathecal administration** are used for acute postoperative pain and early management of chronic cancer pain. All drugs used epidurally or intrathecally must be preservative-free because of the neurotoxicity of parabens and benzyl alcohol when administered via these routes. Intrathecal doses are generally 1/10 of the corresponding drug's epidural dose.

        (a) Low opiate doses stimulate spinal opiate receptors and reduce the amount of narcotic reaching the brain. This results in delayed or minimal effects such as sedation, nausea, and respiratory depression. The opiate distribution that causes such effects depends on the site of spinal injection, water solubility of the opiate, and volume infused. For example, after lumbar administration of a more water-soluble opiate (morphine), severe respiratory depression can be observed 12 to 24 hrs after initial dosing.

        (b) Local side effects of intrathecal opiate administration are itching and urinary retention. Depending on the opiate used and the type of pain being treated, intermittent doses or continuous infusions (via a mechanical infusion device) can be used (*Tables 51-3* and *51-4*).

    (7) Rectal administration is an alternative for patients unable to take oral narcotics. Generally, poor absorption results in an unreliable analgesic response. It is an unacceptable route of administration for many patients.

Table 51-3 EPIDURALLY ADMINISTERED PRESERVATIVE-FREE OPIOIDS: INTERMITTENT DOSING

Drug	Dose (mg)	Onset of Action (min)	Time to Peak Effect (min)	Duration (hr)
Morphine	5–10	25	60	12–24
Fentanyl	0.1	5–10	20	6
Meperidine	50–100	5–10	15–30	7
Hydromorphone	1.0	10–15	20	12
Buprenorphine	0.3	30	40–60	8–9

(8) **Transdermal administration** is an alternative for patients with chronic pain who are unable to take oral narcotics. A controlled-release patch is available for fentanyl. Slow onset requires additional analgesia when starting treatment. The duration of analgesia is 48 to 72 hrs per patch. A slow reduction of effect follows removal of the patch and requires 24 to 36 hrs of monitoring.

d. Patients who have chronic pain or acute pain that is constant throughout the day should receive regularly scheduled (around-the-clock) doses of narcotics.

(1) Long-acting opiates (e.g., controlled-release morphine and oxycodone) are preferable.

(2) A supplement given as needed may be necessary to manage breakthrough pain, for which short-acting opiates (e.g., immediate-release morphine, hydromorphone) are preferable. If frequent supplements are required, then the around-the-clock regimen should be adjusted based on morphine equivalents (*Table 51-2*).

e. Although the analgesia and side effects of opiates are qualitatively similar, individual patients may respond differently. Analgesic selection is based on:

(1) Patient's past analgesia experience

(2) Need for a rapid onset of effect

(3) Preference for a long (or short) duration of action

(4) Preference for a particular mode of delivery

(5) Preference for a particular dosage form

(a) Controlled-release morphine or oxycodone for a long duration of action (8 to 12 hrs) may be preferable to opiates with long half-lives (e.g., methadone, levorphanol), which can accumulate and cause overdose symptoms (e.g., respiratory depression).

(b) Transdermal fentanyl can be used for patients who are unable to swallow.

(c) Rectal suppositories can be used for patients who are unable to swallow. They are available for morphine, hydromorphone, and oxymorphone.

(d) Concentrated hydromorphone injection (10 mg/mL) can be used for cachectic patients who require subcutaneous injections and in patients whose injection volumes must be minimized.

Table 51-4 EPIDURALLY ADMINISTERED PRESERVATIVE-FREE OPIOIDS: CONTINUOUS INFUSION

Drug	Initial Bolus Dose (mg)	Infusion Concentration (mg/mL)	Rate (mg/hr)
Morphine	2	0.05–0.25	0.2–1.5
Fentanyl	0.05–0.10	0.005–0.025	0.02–0.15
Meperidine	50–100	10–20	5–20
Hydromorphone	0.5–1.0	0.02–0.05	0.15–0.30

(6) Individual sensitivity to side effects, which includes nausea, euphoria, sedation, and respiratory depression

  (a) Partial agonists or mixed agonist–antagonists may be preferable for acute pain management in patients at risk for respiratory depression secondary to opiate agonists. These agents should not be used in patients who have received chronic doses of opiates because withdrawal symptoms will occur.

  (b) Epidural administration may be preferable for critically ill patients at risk for respiratory depression secondary to systemic narcotic administration.

3. Adverse effects. All narcotics can produce a variety of side effects that range from bothersome to life threatening.

a. Constipation occurs as a result of decreased intestinal tone and peristalsis. There is a patient variability, but generally most patients experience constipation after several days of therapy. Constipation may be more bothersome with certain types of opiates (e.g., codeine). It may occur sooner and be more problematic in hospitalized or bedridden patients or in patients who have received anesthesia or drugs with anticholinergic effects. Prophylaxis with a laxative/stool softener combination (e.g., bisacodyl/docusate [Gentlax-S]) and dietary counseling are warranted for patients who need chronic opiate therapy.

b. Nausea and **vomiting** occur owing to central stimulation of the chemoreceptor trigger zone. It is more problematic with one-time or intermittent parenteral dosing for acute pain. Occasionally, patients require concomitant therapy with an antiemetic (e.g., hydroxyzine, prochlorperazine); however, these agents may add to the sedative effects of opiates.

c. Sedation is a dose-related effect but sometimes is enhanced by concomitant use of other drugs with sedating effects (e.g., benzodiazepines, antiemetics). Most chronic pain patients become tolerant to this effect, but occasionally the addition of a CNS stimulant, such as dextroamphetamine or methylphenidate, is needed.

  (1) Patients starting therapy with narcotics should be warned about driving or operating machinery.

  (2) Sedation may be a sign of excessive dosing or accumulation. However, sedation should not be confused with physiological sleep in patients who have pain control difficulties. Patients in pain often develop insomnia. When pain is brought under control by appropriate narcotic titration, the patient initially may sleep for several hours.

d. Respiratory depression is the most serious adverse effect accompanying narcotic overdose. Respiratory depression may be a sign of an excessive dose, accumulation of long half-lived opiates (e.g., methadone, levorphanol), or accumulation of active morphine metabolites in renal failure patients.

  (1) Respiratory rate should be carefully monitored in patients receiving IV or epidural opiates, in neonates, in elderly patients, and in patients receiving other drugs that cause respiratory depression.

  (2) The opiate antagonists, naloxone and nalmefene, are administered intravenously to reverse life-threatening respiratory depression. Use of naloxone or nalmefene (Revex) in an opiate-dependent patient (e.g., a chronic cancer pain patient) can precipitate opiate withdrawal.

e. Anticholinergic effects, such as dry mouth and urinary retention, can be bothersome for some patients.

f. Hypersensitivity reactions, such as itching owing to histamine release, can occur secondary to opiate use, particularly with epidural or intrathecal administration. Wheals sometimes occur at the site of morphine injection. These reactions do not represent true allergy.

g. CNS excitation, such as myoclonus and other seizure-like activity, can be produced with the use of meperidine in renal failure. These symptoms have also been observed in patients with normal renal functions who receive high doses of meperidine (e.g., < 800 mg/day of intramuscular meperidine). The accumulation of the metabolite normeperidine is the cause.

4. Drug interactions

a. Narcotics have additive CNS depressant effects when used in combination with other drugs that also are CNS depressants (e.g., alcohol, anesthetics, antidepressants, antihistamines, barbiturates, benzodiazepines, phenothiazines).

b. Narcotics, particularly meperidine, can cause severe reactions such as excitation, sweating, rigidity, and hypertension in patients receiving monoamine oxidase (MAO) inhibitors. Meperidine should be avoided and other narcotics started at lower doses in patients being treated with MAO inhibitors.

5. Tolerance means that increasing doses of opiate are needed to maintain analgesia. Tolerance usually develops to the analgesic, sedative, and euphoric effects of opioids, but not to the pupillary-constricting and constipating effects. This is usually observed as a decreasing duration of analgesia in chronic pain patients. The addition of an NSAID may help delay or provide adequate analgesia in tolerant patients.

6. Dependence. The use of opiates for chronic pain may result in physical dependence, such that the abrupt discontinuation of the opiate results in the development of withdrawal symptoms.

a. Withdrawal symptoms include anxiety, irritability, insomnia, chills, salivation, rhinorrhea, diaphoresis, nausea, vomiting, GI cramping and diarrhea, and piloerection.

(1) The appearance and intensity of withdrawal symptoms vary according to the half-life of the opiate. For example, the withdrawal symptoms after discontinuation of chronic methadone may take several days to develop and may be less intense than those of withdrawal from morphine owing to its shorter half-life.

(2) The development of tolerance may be associated with withdrawal symptoms.

(3) The use of naloxone or a partial agonist–antagonist such as pentazocine in a patient receiving chronic opiate therapy produces acute withdrawal.

b. The development of physical dependence seen in chronic pain patients is not the same as psychological dependence or addiction. Also, the drug-seeking behavior observed in many acute pain patients (i.e., from postoperative pain) is not a sign of addiction, but rather a need for adequate pain relief. Studies suggest that the addictive rates for long-term treatment of noncancer pain are low in patients without a prior history of addiction. The analgesic needs of this type of patient should be reassessed and usually necessitates increasing the dose of opiate, changing to a longer duration drug, changing to a PCA, or adding an analgesic adjunct.

C. Adjuvant analgesics and miscellaneous analgesics. Adjuvant analgesics are drugs whose initial FDA-approved indication was for a condition other than pain. Other classes of drugs affect nonopiate pain pathways and may be useful in certain types of pain (e.g., neuropathic pain). These drugs often are used with other analgesics, and some may help manage narcotic side effects (*Table 51-5*).

1. Neuropathic pain agents include anticonvulsants (e.g., gabapentin, pregabalin, lamotrigine, carbamazepine), systemic local anesthetic agents—for example, 5% lidocaine (Lidoderm) patch—and tricyclic antidepressants—such as amitriptyline, nortriptyline, and desipramine. Gabapentin and systemic local anesthetic agents are considered first-line therapy in treating polyneuropathies. Anticonvulsant can be used for lancinating neurogenic pain (e.g., trigeminal neuralgia, phantom limb pain, posttrauma neurogenic pain). Tricyclic antidepressant and anticonvulsants are also used to treat migraine pain.

a. Mechanism of action

(1) Gabapentin and pregabalin may relieve neuropathic pain by the presynaptic binding of the α-2-δ subunit of voltage-sensitive calcium channels.

(2) Pregabalin may also modulate the release of the sensory neuropeptide substance P.

(3) Lamotrigine and carbamazepine are believed to block sodium channels at the site of ectopic discharge of damaged nerves.

(4) The use of local anesthetics allows for local pain relief without systemic toxicity, specifically by binding to the sodium channels in the damaged nerves.

(5) It is hypothesized that TCAs obtain their analgesic effects as a result of sodium channel blockade at the site of ectopic discharge in the peripheral nerves.

(6) All of these agents are recommended to aid in the reduction of neuronal hyperexcitability, whether it is peripherally or centrally.

b. Clinical use

(1) Data are available to give guidance on which agents to use to treat neuropathic pain, but they do not predict which agent will provide relief for each individual patient's pain.

Table 51-5	ANALGESIC ADJUNCTS AND MISCELLANEOUS ANALGESICS

Drugs	Dose	Maximum	Indications/Comments
Tricyclic Antidepressants			
Amitriptyline	10 mg/day	250 mg/day	Used at bedtime and started at low dose. Contraindicated in patients with urinary retention, glaucoma, and bundle branch block; severe anticholinergic effects and weight gain can be limited.
Nortriptyline	10 mg/day	125 mg/day	
Doxepin	10 mg/day	250 mg/day	
Clomipramine	10 mg/day	250 mg/day	
Desipramine	10 mg/day	200 mg/day	
Anticonvulsants			
Valproate	250 mg b.i.d.	500 mg t.i.d./q.i.d.	High teratogenicity incidence
Gabapentin	100 mg t.i.d. or 300 mg q.h.s.	300–1200 mg t.i.d.	No blood monitoring required
Pregabalin	100 mg t.i.d.	300 mg/day	This dose is for neuropathic pain.
Topiramate	25 mg/day	100 mg/day	Slow titration minimizes adverse events. Weight loss and metabolic acidosis are common.
Phenytoin	300 mg/day		Cosmetic side effects
Carbamazepine	100 mg/day	200–600 mg t.i.d.	Needs to monitor complete blood count (CBC) and liver function tests (LFTs)
Neuroleptics			
Fluphenazine	2–20 mg	30 mg/day	Refractory neurogenic pain; pain complicated by delirium or nausea (prochlorperazine)
Prochlorperazine	5–10 mg t.i.d./q.i.d.	10 mg q.i.d.	
Haloperidol	0.5–5.0 mg q 2–12 hrs	30 mg/day	
Corticosteroids			
Dexamethasone	1–4 mg b.i.d./q.i.d.	24 mg/day	From neural infiltration; pain associated with bony metastases
Antihistamines			
Hydroxyzine	25–100 mg q 4–6 hrs		Pain complicated by anxiety or nausea
Benzodiazepines			
Alprazolam	0.25–2.00 mg t.i.d./q.i.d.	4 mg/day	Pain complicated by anxiety or muscle spasm
Lorazepam	0.5–2.0 mg t.i.d./q.i.d.	10 mg/day	
Clonazepam	0.5–2.0 mg b.i.d./q.i.d.	4 mg/day	
Amphetamines and Amphetamine-Like Agents			
Dextroamphetamine	15 mg b.i.d./t.i.d.	5–60 mg/day	For excessive opiate-induced sedation in chronic pain patients
Methylphenidate	5 mg–20 mg b.i.d./t.i.d.	65 mg	

    (2) Typically, a **treatment algorithm** may recommend:
        (a) First line
          (i) Gabapentin
          (ii) Pregabalin
          (iii) 5% lidocaine patches
          (iv) TCAs
        (b) Second line
          (i) Other anticonvulsants (lamotrigine or carbamazepine)
          (ii) Other antidepressants (bupropion, citalopram, paroxetine, venlafaxine, imipramine)
        (c) Other
          (i) Capsaicin, clonidine
    c. Adverse effects. The most common adverse events associated with anticonvulsants are dizziness, headaches, and drowsiness. Lamotrigine has been associated with the development of Stevens–Johnson syndrome (SJS). It is recommended that lamotrigine be titrated up every 2 weeks to minimize the occurrence of SJS.

2. Tramadol (Ultram) is an oral, centrally acting analgesic with weak opiate activity. It has not been placed in a controlled drug schedule.
    a. Mechanism of action
        (1) Tramadol is a synthetic aminocyclohexanol that binds to opiate receptors, inhibiting norepinephrine and serotonin.
        (2) The analgesic effects are partially antagonized by naloxone.
    b. Clinical use
        (1) Tramadol is used for moderate to moderately severe pain.
        (2) The recommended dosage is 50 to 100 mg every 4 to 6 hrs, up to a maximum of 400 mg/day. The extended-release formulation (Ultram ER) is given at a dose of 100 to 300 mg/day.
        (3) At maximum dosage, tramadol appears no more effective than acetaminophen–codeine combinations.
    c. Adverse effects
        (1) GI effects include nausea, constipation, and dry mouth.
        (2) CNS effects include dizziness, headache, sedation, and seizures (overdose).
        (3) Diaphoresis
    d. Drug interactions
        (1) Tramadol can increase the sedative effect of alcohol and hypnotics.
        (2) Tramadol inhibits monoamine uptake and should not be used with MAO inhibitors.
        (3) Tramadol used with selective serotonin reuptake inhibitors (SSRIs) and other agents that increase serotonergic activity can cause "serotonin syndrome," which is characterized by irritability, anxiety, CNS excitation, and myoclonus.

D. Agents used to treat migraine (*see Table 51-6*)
1. Triptans include sumatriptan, zolmitriptan, naratriptan, rizatriptan, almotriptan, eletriptan, and frovatriptan.
    a. Mechanism of action. Triptans are 5-hydroxytryptamine (5-HT [1B/1D]) receptor agonists. One hypothesis for the efficacy of triptans in migraine is that activating 5-HT (1B/1D) receptors can lead intracranial blood vessels constriction.
    b. Clinical use. Triptans are effective for acute treatment of migraine but not used as a prophylaxis treatment. Triptans should be used as soon as possible after onset of migraine attack.
    c. Adverse effects
        (1) Cardiovascular (CV) effects include: rare but serious transient myocardial attack, coronary artery vasospasm, myocardial infarction, and atrial and ventricular arrhythmia.
        (2) Minor adverse events of sumatriptan injection: irritation at the injection site. However, orally administered triptans can cause paresthesias, flushing, feeling of pressure, tightness or pain in the chest, neck, and jaw.
        (3) Zolmitriptan has an incidence of recurrent headache similar to that seen with oral sumatriptan.
        (4) Naratriptan may have a lower risk of headache recurrence than other oral triptans, and has a lower incidence of side effects than sumatriptan and most other oral triptans.

Table 51-6	AGENTS USED TO TREAT MIGRAINE		

Drug	Initial Dose	Daily Maximum Dose	Comments
Serotonin Agonists (Triptan)			
Sumatriptan (subcutaneous)	6 mg SC	12 mg/day	• May repeat after 1 hr • Useful when non-oral route of administration is needed
Sumatriptan (oral)	25–100 mg PO	200 mg/day	• May repeat after 2 hrs • Maximum recommended monthly dose for migraine is 18 tablets (50 mg) or an equal amount.
Sumatriptan (nasal)	20 mg nasally	40 mg/day	• May repeat after 2 hrs • Similar speed of action and effectiveness to oral sumatriptan
Zolmitriptan	2.5 mg/day	10 mg/day	• Maximum monthly dose is 18 tablets (5 mg) each or equal amount.
Naratriptan	1.0–2.5 mg/day	5 mg/day	• Only triptan not contraindicated with MAO inhibitors
Rizatriptan	5–10 mg/day	30 mg/day	• Propranolol increase serum concentration of rizatriptan, which result in bradycardia; then use 5-mg dose; max = 15 mg/day
Almotriptan	6.25 or 12.5 mg/day	Two doses in 24 hrs	
Frovatriptan	2.5 mg/day	7.5 mg in 24 hrs	
β-Blockers			
Propranolol	60 mg/day	320 mg/day	• Benefits may lag 3 to 4 weeks.
Nadolol	40 mg/day	240 mg/day	
Timolol	10 mg/day	40 mg/day	
Atenolol	50 mg/day	150 mg/day	
Metoprolol	50 mg/day	300 mg/day	
Calcium-Channel Blockers			
Verapamil	120 mg/day	720 mg/day	• Widely used but weak evidence for efficacy
Nifedipine	30 mg/day	180 mg/day	• Benefits may be noted after 3–4 weeks on therapeutic dose.
Diltiazem	60 mg/day	360 mg/day	
Nimodipine	20 mg/day	60 mg/day	
Angiotensin-Converting Enzyme Inhibitors			
Lisinopril	10 mg/day for 1 week then 20 mg/day	40 mg/day	

    d. Contraindications
       (1) Triptans should be avoided in patients with familial hemiplegic migraine, basilar migraine, ischemic stroke, uncontrolled hypertension, ischemic heart disease, Prinzmetal angina, ischemic complications, cerebrovascular or peripheral vascular disease, and renal or hepatic disease.
    e. Drug interactions: Triptans are contraindicated in patients with near-term prior exposure to ergots alkaloid or other 5-HT agonists. Triptans, excluding eletriptan, frovatriptan, and

naratriptan, are contraindicated in combination with monoamine oxidase inhibitors (MAOIs). Because eletriptan is metabolized by cytochrome P450 3A4 enzyme (CYP3A4), it should not be used within 72 hrs of treatment with potent CYP3A4 inhibitors such as ketoconazole, itraconazole, nefazodone, troleandomycin, clarithromycin, nelfinavir, and ritonavir.

2. **β-Blockers.** Using β-blockers for prevention is effective in 60% to 80% of patients in reducing the severity and frequency of migraine attack by 50%. It is unclear how β-blockers prevent migraine, but their action is most likely related to inhibition of β1 receptors with secondary effects on serotonin. As serotonin plays an important role in the pathogenesis of migraine. β-Blockers with intrinsic sympathomimetic activity (ISA), such as pindolol and acebutolol, are less effective in the treatment of migraine. β-Blockers should not be used as initial therapy for migraine prophylaxis in patients over age 60 and in smokers. The use of β-blockers may be limited in patients with erectile dysfunction, peripheral vascular disease, Raynaud syndrome or disease, and in patients with baseline bradycardia or low blood pressure. They must be used cautiously in patients with diabetes mellitus, asthma, and those with cardiac conduction disturbances or sinus node dysfunction.

3. **Calcium-channel blockers (CCBs).** In treating migraines, CCBs are used prophylactically. They decrease the frequency of the attack, have minimal effect on headache severity and are, generally, not as effective as other agents. Also, the vasodilatory action of some calcium-channel blockers may induce or worsen migraine attacks. Their mechanism of action is unclear, but excessive levels of intracellular calcium under ischemic condition can cause neuronal damage and cell death. Among these agents, verapamil is frequently the first choice for prophylactic therapy because of ease of use and a favorable side effect profile. After 8 weeks of successful therapy with CCBs, tolerance may develop that can be overcome by increasing the dose or by switching to a different CCB. CCBs are contraindicated in patients with heart block, hypotension, heart failure, and atrial flutter and fibrillation.

4. **Angiotensin-converting enzyme inhibitors (ACEi) and angiotensin receptor blockers (ARBs).** Based on a double-blind, placebo-controlled, crossover study in patients with two to six migraine episodes, lisinopril (10 mg/day for 1 week, then 20 mg/day) significantly reduced the headache severity. ARB such as candesartan had similar results. ACE inhibitors are contraindicated in idiopathic and hereditary angioedema and hypersensitivity to lisinopril.

5. **Ergot (Ergotamine and Dihydroergotamine [DHE]).** Ergotamine and DHE bind to serotonin (5-HT 1B/1D) receptors similar to triptans. Various ergotamine preparations are available alone or in combination with caffeine and other analgesics for oral, sublingual, and rectal use, whereas DHE is available for intravenous, intramuscular, subcutaneous, and intranasal use. Based on clinical trials, oral ergotamine alone failed to show efficacy in migraine relief. Ergotamine tartrate can cause pruritus, muscle weakness, paresthesia, visual disturbance, vascular spasm, and cardiovascular system disorder (angina, MI, arrhythmia). In addition, ergotamine may worsen nausea and vomiting that associated with migraine. As a result, ergotamine is used in relatively few patients because issue of efficacy and side effects. It is used in patients with prolonged duration of attacks (e.g., greater than 48 hrs), and possibly frequent headache recurrence. Besides being a potent 5-HT (1B/1D) receptor agonist, DHE 45 is an alpha blocker that is a weaker arterial vasoconstrictor and more potent venoconstrictor than ergotamine tartrate. Also, it has fewer side effects than ergotamine tartrate. DHE is given intravenously for acute migraine in combination with antiemetic. Parenteral DHE 45 should not be used as monotherapy.

E. **Miscellaneous agents**

1. **Capsaicin**, a component of red peppers, causes the release of substance P from sensory nerve fibers, resulting in prolonged cutaneous pain transmission, histamine release, and erythema because of reflex vasodilation. Repeated local application depletes the peripheral sensory C-nerve fiber of substance P, resulting in pain inhibition. Topical capsaicin cream 0.025% or 0.075% has been shown to be useful in treating joint pain and tenderness in patients with arthritis. Other uses may include treating diabetic neuralgia, reflex sympathetic dystrophy, trigeminal neuralgia, notalgia paresthetica, psoriasis and psoralen (P), and long-wave ultraviolet radiation (UVA) induced skin pain, and postherpetic neuralgia. Local toxicity may include burning, stinging, erythema, pruritus, and superficial skin ulcers. Capsaicin 8% patch (Qutenza) administered for 1 hr can provide 3 months of relief for pain associated with postherpetic neuralgia. Significant dermal reactions have been associated with this formulation.

2. **Glucosamine sulfate and chondroitin sulfate** have been used with increasing frequency in the treatment of degenerative joint disease. Glucosamine sulfate appears to act as a substrate for and stimulant

to the biosynthesis of glycosaminoglycans and hyaluronic acid for forming proteoglycans found in the structural matrix of joints. Chondroitin sulfate provides additional substrates for the formation of healthy joint matrix. Short-term side effects associated with glucosamine include GI problems, drowsiness, skin reactions, and headache. Further research is needed to validate their roles.

F. **Nonpharmacological pain management.** Other therapeutic modalities for pain management include cognitive behavioral interventions and physical methods. These modalities are appropriate for interested patients, patients experiencing anxiety with their pain, patients who have incomplete relief from analgesic therapy, and patients who need to avoid or reduce analgesic use (e.g., those with chronic nonmalignant pain).

1. **Cognitive behavioral interventions** include education and instruction, simple relaxation, biofeedback, and hypnosis.

2. **Physical methods** include acupuncture, physical therapy, compression gloves, orthotic devices, heat and cold applications, massage, exercise, rest, immobilization, and transcutaneous electrical nerve stimulation (TENS).

Study Questions

Directions for questions 1–7: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. An emaciated 69-year-old man with advanced inoperable throat cancer is hospitalized for pain management. He is receiving a morphine solution (40 mg orally) every 3 hrs for pain. He complains of dysphagia and the frequency with which he must take morphine. An appropriate analgesic alternative for this patient would be

   (A) changing to a controlled-release oral morphine.
   (B) increasing the dose of the oral morphine solution.
   (C) changing to intramuscular methadone.
   (D) changing to transdermal fentanyl.
   (E) decreasing the frequency of oral morphine administration.

For questions 2–3: A 52-year-old woman with a diagnosis of ovarian cancer presents with complaints of pain. Her pain was reasonably well-controlled with two capsules of oxycodone every 4 hrs until 2 weeks ago, at which point she was hospitalized for pain control. She was placed on meperidine (75 mg) every 3 hrs but still complained about pain. Her meperidine dosage was increased to 100 mg every 2 hrs.

2. At this dosage of meperidine, the patient is likely to experience

   (A) excellent pain relief.
   (B) respiratory depression.
   (C) worsening renal function.
   (D) myoclonic seizures.
   (E) excessive sedation.

3. An appropriate next step in this patient's therapy would be to

   (A) add an NSAID.
   (B) discontinue the meperidine and convert her to a controlled-release oral morphine or oxycodone.
   (C) continue the present meperidine dosage because she will eventually get relief.
   (D) decrease the meperidine dose to avoid side effects.
   (E) consider hypnosis or relaxation techniques.

4. A 20-year-old victim of a motor vehicle accident is 3 days postsurgery for orthopedic and internal injuries. He has been in severe pain, and was placed on a regimen of intramuscular morphine (5 to 10 mg) every 4 hrs as needed for pain. A pain consultant starts the patient with a 20-mg intravenous morphine loading dose, and then begins a continuous intravenous morphine infusion with as-needed morphine boosters. About 2 hrs after this regimen is started, the patient is asleep. The nurse is concerned and calls the physician. The physician should

   (A) call for a psychiatric consult.
   (B) administer naloxone.
   (C) examine the patient, and reconfirm the dosage and monitoring parameters.
   (D) add an injectable NSAID.
   (E) add an amphetamine.

5. Potential adverse effects associated with aspirin include all of the following *except*

   (A) gastrointestinal ulceration.
   (B) renal dysfunction.
   (C) enhanced methotrexate toxicity.
   (D) cardiac arrhythmias.
   (E) hypersensitivity asthma.

6. All of the following facts are true about NSAIDs *except* which one?

(A) They are antipyretic.
(B) There is a ceiling effect to their analgesia.
(C) They can cause tolerance.
(D) They do not cause dependence.
(E) They are anti-inflammatory.

7. Which of the following narcotics has the longest duration of effect?

(A) Methadone
(B) Controlled-release morphine
(C) Levorphanol
(D) Transdermal fentanyl
(E) Dihydromorphone

Directions for questions 8–13: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E**.

(A) if **I only** is correct
(B) if **III only** is correct
(C) if **I and II** are correct
(D) if **II and III** are correct
(E) if **I, II, and III** are correct

8. Agents that are safe to use in a patient with bleeding problems include

(I) choline magnesium trisalicylate.
(II) acetaminophen.
(III) ketorolac.

9. Which of the following drugs bind or capture excess TNF-α?

(I) Adalimumab
(II) Etanercept
(III) Leflunomide

10. Leflunomide has been associated with

(I) diarrhea.
(II) alopecia.
(III) anemia.

11. Which of the following agents needs to be administered with: Dihydroergotamine (DHE 45):

(A) Ibuprofen.
(B) IV metoclopramide.
(C) Sumatriptan.
(D) Acetaminophen.
(E) Rizatriptan.

12. Which of the following should be done when eletriptan is administered with ketoconazole:

(A) Eletriptan should not be administered within 72 hrs of treatment with ketoconazole.
(B) Eletriptan should be used at the same time of ketoconazole administration time.
(C) Eletriptan should be administered within 2 hrs of ketoconazole administration time.
(D) None of the above.

Answers and Explanations

1. The answer is D *[see II.B.2.c.(8)]*.
Patients with throat cancer often cannot take oral analgesics. The patient described in the question is also having pain difficulties with an every 3-hr regimen. Transdermal fentanyl is a good alternative because, after titration, excellent analgesia can be produced without using oral or parenteral agents. Also, the frequency of analgesic use may be decreased when titration has occurred.

2. The answer is D *[see II.B.3.g]*.

3. The answer is B *[see II.B.2.c.(1); II.B.2.d.(1)]*.
Myoclonic seizures can occur after frequent, high-dose meperidine owing to the accumulation of the metabolite, normeperidine. Both oxycodone and meperidine have short durations of effect. In the chronic pain patient, an around-the-clock regimen, using a controlled-released oral morphine, would be an appropriate alternative. With titration, the patient should have good pain relief with an every 8- to 12-hr regimen.

4. The answer is C *[see II.B.3.c]*.
A patient suffering from pain cannot sleep properly. When the pain is adequately controlled, the patient may sleep initially for many hours. This usually is not oversedation owing to the narcotic. These patients should be monitored closely (e.g., respiratory rate), and other sedating drugs should be eliminated. Usually, no other intervention is needed.

5. The answer is D *[see II.A.4]*.
Aspirin has several adverse effects and drug interactions. However, cardiac arrhythmias are not induced by aspirin.

6. The answer is C *[see II.A.2]*.
Unlike the opiates, NSAID use is not associated with the development of tolerance.

7. The answer is D *[see Table 51-2]*.
Transdermal fentanyl is a controlled-release dosage form that is effective for up to a 72-hr period. All of the other drugs listed in the question are effective for periods of 1 to 8 hrs.

8. **The answer is C (I, II)** *[see II.A.4.b]*.
   Unlike aspirin and NSAIDs, acetaminophen and choline magnesium trisalicylate lack antiplatelet effects. Therefore, they are safe to use for patients with bleeding problems.

9. **The answer is C (I, II)** *[see II.A.1]*.
   Adalimumab, etanercept, and infliximab act by binding or capturing excess TNF-α, one of the dominant cytokines or proteins that play an important role in the inflammatory response. The exact mechanism of action of leflunomide, a novel drug used to treat rheumatoid arthritis, is not completely known, but it is thought to inhibit pyrimidine synthesis.

10. **The answer is E (I, II, III)** *[see II.A.4.a; II.A.4.f.(4)]*.
    Leflunomide has been associated with weight loss, diarrhea, nausea, alopecia, rash, anemia, and transient elevations in liver function tests.

11. **The answer is B** *[see II.D.5]*.
    Dihydroergotamine can cause nausea and vomiting. It needs to be administered with IV antiemetic. DHE 45 should not be used as monotherapy.

12. **The answer is A** *[see II.D.1.e]*.
    Because eletriptan is metabolized by cytochrome P450 enzyme CYP3A4, it should not be used within 72 hrs of treatment with potent CYP3A4 inhibitors such as ketoconazole, itraconazole, nefazodone, troleandomycin, clarithromycin, nelfinavir, and ritonavir.

Nutrition and the Hospitalized Patient

ROBERT A. QUERCIA, KEVIN P. KEATING

I. NUTRITIONAL PROBLEMS IN HOSPITALIZED PATIENTS

A. **Incidence.** It has been estimated that 30% to 50% of patients admitted to hospitals have some degree of malnutrition. As many as 75% of patients undergo a deterioration of nutritional status while hospitalized.

B. **Definitions**

1. **Malnutrition** is a pathological state, resulting from a relative or absolute deficiency or excess of one or more essential nutrients.

2. **Marasmus** is a chronic disease that develops over months or years as a result of a deficiency in total caloric intake. Depletion of fat stores and skeletal protein occurs to meet metabolic needs. Marasmic patients are generally not hypermetabolic and are able to preserve their visceral protein compartment as determined by measurements of serum albumin, prealbumin, and transferrin.

   a. Marasmus is a well-adapted form of malnutrition, and despite a cachectic appearance, immunocompetence, wound healing, and the ability to handle short-term stress are generally well preserved.

   b. Nutritional support in these patients should be initiated cautiously because aggressive repletion can result in severe metabolic disturbances, such as hypokalemia and hypophosphatemia.

3. **Kwashiorkor** is an acute process that can develop within weeks and is associated with visceral protein depletion and impaired immune function. It is the result of poor protein intake with adequate to slightly inadequate caloric intake; thus, patients usually appear well nourished. A hypermetabolic state (e.g., trauma, infection) combined with protein deprivation can rapidly develop into a severe kwashiorkor malnutrition characterized by hypoalbuminemia, edema, and impaired cellular immune function.

   a. In hospitalized patients, the development of kwashiorkor has been implicated in poor wound healing, gastrointestinal (GI) bleeding, and sepsis.

   b. Aggressive nutritional support to replete protein stores and decrease morbidity and mortality is indicated when the diagnosis of kwashiorkor is made.

4. **Mixed marasmic kwashiorkor** is a severe form of protein–calorie malnutrition that usually develops when a marasmic patient is subjected to an acute hypermetabolic stress, such as trauma, surgery, or infection.

   a. This condition results in depletion of fat stores, skeletal muscle protein, and visceral protein.

   b. Because of the marked immune dysfunction that develops in this state, vigorous nutritional support is indicated.

II. NUTRITIONAL ASSESSMENT AND METABOLIC REQUIREMENTS

A. **Nutritional assessment.** The most commonly used tools for nutritional assessment are as follows:

1. **Subjective global assessment (SGA)** relies heavily on the patient's history.

   a. SGA takes into account:

      (1) Recent weight change

      (2) Diet history

(3) Type and length of symptoms affecting nutritional status (e.g., nausea, vomiting, diarrhea)

(4) Functional status

(5) Metabolic demands of the current disease process

(6) Gross physical signs

    (a) Status of subcutaneous fat

    (b) Evidence of muscle wasting

    (c) Presence or absence of edema and ascites

b. Patients are then classified as being well nourished or moderately or severely malnourished.

2. Mini Nutritional Assessment (MNA) similar to the SGA, validated in elderly patients

  a. MNA takes into account:

    (1) Loss of appetite

    (2) Weight loss

    (3) Mobility

    (4) Psychological/physical stress

    (5) Neuropsychological problems

    (6) Body mass index (BMI)

  b. Patient is then assessed as being at no or increased nutritional risk. If at increased risk, a full nutritional assessment is undertaken

3. Nutritional Risk Index (NRI) similar to SGA and MNA

  a. 16-item questionnaire

  b. A modification exists for geriatric patients

4. Malnutrition Universal Screening Tool (MUST) uses standardized tables to score the following:

  a. Calculated BMI

  b. Unplanned weight loss

  c. Acute disease effect

  d. Add scores from a, b, and c and establish nutrition risk

5. Nutritional Risk Score (NRS) similar to the MUST, scores are assigned to the following:

  a. Weight loss

  b. Severity of disease

  c. Age

  d. Scores are totaled and nutritional risk assigned

6. Visceral Protein Markers (VPM) can be indicators of protein depletion if results are subnormal.

  a. Most commonly used VPM are:

    (1) Albumin

    (2) Prealbumin (transthyretin)

    (3) Transferrin

    (4) Retinol-binding protein

7. Total lymphocyte count—an indicator of immune competence—subnormal levels can be an indicator of malnutrition.

8. Anthropomorphics—skinfold measurements

  a. Values < 5th percentile can be indicators of fat and protein depletion

  b. Most commonly used:

    (1) Triceps

    (2) Biceps

    (3) Subscapular

    (4) Suprailiac

9. Multifactorial prognostic indicators

  a. Prognostic Nutritional Index (PNI) is derived from a formula that attempts to quantify a patient's risk of developing operative complications based on various markers of nutritional status, including:

    (1) Visceral protein markers

    (2) Anthropomorphics

    (3) Immune competence

  b. Prognostic Inflammatory Nutritional Index (PINI) is similar to the PNI but adds the inflammatory markers alpha 1 acid glycoprotein and c-reactive protein.

10. **Body composition analysis** assesses nutritional status by measuring and comparing the ratios of various body compartments.
    a. **Bioelectrical impedance.** The resistance to an electrical current is used to calculate lean body mass. The equipment is relatively inexpensive and easy to use. The results are inaccurate in critically ill patients and patients with fluid and electrolyte abnormalities.
    b. **Dual-energy x-ray absorptiometry (DEXA).** The differential attenuation of x-rays is used to measure fat and lean body mass. The equipment is expensive, and results are affected by hydration status.
    c. **Total body potassium** estimates lean body mass by using a whole body counter to measure a potassium isotope concentrated in lean tissue. This method of body composition analysis is impractical and available at only a few centers.
    d. **Total body water** estimates lean body mass from deuterium total body water measurements. This technique is clinically impractical.
    e. **In vivo neutron activation analysis.** Unlike other techniques, this analysis divides the body into several compartments. This technique requires a significant dose of radiation and is available at only a few research centers.
11. **Tests of physiological function** attempt to quantitate malnutrition based on the decrease in muscle strength caused by amino acid mobilization.
    a. **Maximum voluntary grip strength** is measured with isokinetic dynamometry. The results correlate well to total body protein. This test requires patient cooperation.
    b. **Electrical stimulation of the ulnar nerve** measures contractile function of the adductor pollicis muscle. This technique does not require voluntary patient effort and is inexpensive and easy to do. Its prognostic reliability is still under evaluation.

B. **Metabolic requirements**
1. **Energy requirements** are determined as **nonprotein calories (NPCs)**. It is important to avoid excess calories to minimize complications of nutrient delivery and to optimize nutrient metabolism. Energy requirements can be determined by the following three methods:
    a. **Indirect calorimetry or measured energy expenditure (MEE)** is the most accurate method of determining caloric requirements.
       (1) Oxygen (O_2) consumption and carbon dioxide (CO_2) production are measured directly.
       (2) Energy expenditure is related directly to oxygen consumption and is calculated from these measurements.
       (3) A respiratory quotient (RQ) can also be obtained from an MEE and is defined as the ratio of the amount of CO_2 produced to that of O_2 consumed during the course of oxidation of body fuels. The oxidation of carbohydrate results in an RQ of 1.0—that is, as much CO_2 is produced as O_2 is consumed. The oxidation of fat produces significantly less CO_2 and results in an RQ of 0.7. Normal mixed substrate oxidation results in an RQ of 0.8 to 0.9.
       (4) The provision of excess carbohydrate calories causes their conversion to fat (lipogenesis). Lipogenesis produces significantly more carbon dioxide than oxidation does. This can result in an RQ > 1.0, which is consistent with overfeeding. The determination of RQ can, therefore, indicate patterns of substrate use.
    b. **Estimated energy expenditure (EEE)** first requires the calculation of the **basal energy expenditure (BEE)** from the **Harris-Benedict equation**; the BEE is then multiplied by appropriate stress and activity factors.
       (1) **Men:** BEE = 66.5 + [13.8 × weight (kg)] + [5 × height (cm)] − [6.8 × age (years)]
       (2) **Women:** BEE = 65.5 + [9.6 × weight (kg)] + [1.8 × height (cm)] − [4.7 × age (years)]
       (3) **Stress factors:** uncomplicated surgery 1.00 to 1.05, peritonitis 1.05 to 1.25, and sepsis or multiple trauma 1.25 to 1.50
       (4) **Activity factors:** bed rest 0.95 to 1.10 and ambulation 1.10 to 1.30
    c. **Simple nomogram.** The least accurate method of estimating caloric requirements, this technique is based on the patient's weight in kilograms. It is useful when the other methods cannot be used. Patients with mild to moderate degrees of stress require approximately 25 to 30 kcal/kg/day, whereas the severely stressed patient (e.g., a patient with major burns) may require 35 kcal/kg/day or more.

2. **Protein (nitrogen) requirements** can be determined by several techniques, but nitrogen balance determinations and nomograms appear to be the most practical.

   a. **Nitrogen balance techniques.** The practitioner determines the patient's nitrogen output and develops a nutritional support program in which the protein administered results in a nitrogen input that exceeds losses.

      (1) Nitrogen balance = 24-hr nitrogen intake − 24-hr nitrogen output.

      (2) A 24-hr nitrogen intake = 24-hr total protein intake ÷ 6.25 (approximately 16% of protein is composed of nitrogen).

      (3) A 24-hr nitrogen output = [24-hr urine urea nitrogen (UUN) × 1.25 + 2, where 1.25 accounts for non-UUN losses (e.g., ammonia, creatinine) and two accounts for non-urine nitrogen losses (e.g., skin, feces). Total urinary nitrogen (TUN) determinations are currently available in some centers. Because TUN is a more accurate method of assessing urinary nitrogen losses, it should be used when available in place of a 24-hr UUN × 1.25 when calculating a nitrogen balance.

      (4) A positive nitrogen balance of 3 to 6 g is the goal.

      (5) This method cannot be used in renally impaired patients.

   b. **Nomogram method.** This method estimates protein needs based on lean body weight. Protein requirements are 1.5 to 2.0 g protein/kg/day for hospitalized patients.

   c. **Nonprotein calorie to nitrogen (NPC:N) ratio.** An NPC:N ratio of 125 to 150:1 generally has been recommended for the mildly to moderately stressed patient to achieve optimal nitrogen retention and protein synthesis. In the severely stressed patient, some studies indicate that ratios as low as 85:1 may be effective.

3. **Essential fatty acids (EFAs)** are those polyunsaturated fatty acids that cannot be synthesized by humans. EFAs affect immune responses by influencing energy production, eicosanoid synthesis, and cell membrane fluidity. They also affect levels of arachidonic acid in lymphocytes—especially monocytes, macrophages, and polymorphonuclear neutrophils (PMNs). Linoleic acid, an omega-6 polyunsaturated fatty acid (PUFA), is the principal EFA for humans. α-Linolenic acid, an omega-3 PUFA, also cannot be synthesized in vivo; its metabolic significance in humans continues to be investigated. It might be a conditionally essential fatty acid.

   a. Deficiency states of **linoleic acid** are characterized by diarrhea, dermatitis, and hair loss.

   b. The currently available lipid emulsions have a high linoleic acid content.

   c. Providing 4% to 7% of a patient's caloric requirements as linoleic acid from lipid emulsion prevents the development of essential fatty acid deficiency.

4. **Vitamins** are essential for proper substrate metabolism. Accepted daily allowances for oral administration have been established.

   a. **Vitamin A** (fat soluble). Normal stores can last up to 1 year but are rapidly depleted by stress. Vitamin A has essential functions in vision, growth, and reproduction. Recommended oral intake is 2500 to 5000 IU/day. **The recommended requirement is 3300 IU/day in parenteral nutrition (PN) formulations.**

   b. **Vitamin D** (fat soluble). In conjunction with parathormone and calcitonin, vitamin D helps regulate calcium and phosphorus homeostasis. Recommended oral intake is 100 to 400 IU/day. **The PN requirement is 200 IU/day.**

   c. **Vitamin E** (fat soluble) appears to function as an antioxidant, inhibiting the oxidation of free unsaturated fatty acids. Recommended daily oral allowances are 12 to 15 IU/day. **The requirement in PN formulations is 10 IU/day.** The presence of polyunsaturated fatty acids increases the requirement for vitamin E, which needs to be considered with the use of lipid system PN.

   d. **Vitamin K** (fat soluble) plays an essential role in the synthesis of clotting factors. The suggested oral intake is 0.7 to 2.0 mg/day. **The recommended PN requirement is 150 μg/day.**

   e. **Vitamin B_1 (thiamine**; water soluble) functions as a coenzyme in the phosphogluconate pathway and as a structural component of nervous system membranes. The development of its deficiency state (i.e., acute pernicious beriberi with high output cardiac failure) is well described in patients on PN receiving inadequate thiamine replacement. A prolonged deficiency state can cause Wernicke encephalopathy. Recommended doses are 0.5 mg/1000 oral calories/day and **6 mg/day in PN formulations.**

f. **Vitamin B$_2$ (riboflavin**; water soluble) functions as a coenzyme in oxidative phosphorylation. Essentially, no intracellular stores are maintained. Oral requirements are 1.3 to 1.7 mg/day. **The requirement in PN formulations is 3.6 mg/day.**

g. **Vitamin B$_3$ (niacin**; water soluble) functions as a coenzyme in oxidative phosphorylation and biosynthetic pathways. Pellagra is the well-described deficiency state. Oral requirements are 14.5 to 19.8 mg/day. **The recommended PN requirement is 40 mg/day.**

h. **Vitamin B$_5$ (pantothenic acid**; water soluble). The functional form of vitamin B$_5$ is coenzyme A, which is essential to all acylation reactions. Oral requirements are 5 to 10 mg/day. Intravenous (IV) requirements are 10 to 29 mg/day.

i. **Vitamin B$_6$ (pyridoxine**; water soluble) functions as a coenzyme in various enzymatic pathways. Deficiency states are accentuated by some medications, including isoniazid, penicillamine, and cycloserine. Oral requirements are 1.5 to 2.0 mg/day. **The recommended PN requirement is 6.0 mg/day.**

j. **Vitamin B$_7$ (biotin**; water soluble) functions in carboxylation reactions. It is synthesized by intestinal flora; therefore, deficiency states are rare. **The requirement in PN formulations is 60 μg/day.**

k. **Vitamin B$_9$ (folic acid**; water soluble) is involved in various biosynthetic reactions and amino acid conversions. Folate cofactors are necessary for purine and pyrimidine (DNA) synthesis. Stores usually last 3 to 6 months; however, rapid depletion is seen with metabolic stress. Deficiency of vitamin B$_{12}$ causes deficiency in folate. A megaloblastic anemia is classic in the deficiency state. Deficiency of folic acid in a pregnant mother can cause neural tube defects in the fetus. Oral requirements are 200 to 400 μg/day. **The recommended requirement in PN formulations is 600 μg/day.**

l. **Vitamin B$_{12}$ (cyanocobalamin**; water soluble) has various metabolic and biosynthetic functions. Because of large stores, deficiency states can take years to develop. Megaloblastic (pernicious) anemia is one manifestation of deficiency. Another manifestation of deficiency is peripheral neuropathy because B$_{12}$ is responsible for biosynthesis of the insulation sheet on nerves called myelin. Oral requirements are 2.0 μg/day. **The requirement in PN formulations is 5.0 μg/day.**

5. **Trace mineral deficiency** may develop during PN because of reduced intake, increased use, decreased plasma binding, or increased excretion.

a. **Iron** is necessary for hemoglobin and myoglobin production and is a necessary cofactor in various enzymatic reactions. Deficiency is classically demonstrated by a hypochromic, microcytic anemia as well as by the development of immune deficiency. Oral requirements are 16 to 18 mg/day. IV requirements are 0.5 to 1.0 mg/day.

b. **Zinc** is necessary for DNA and RNA synthesis and is a necessary cofactor in various enzymatic reactions. Zinc deficiency results in impaired wound healing, growth retardation, hair loss, dermatitis, diarrhea, anorexia, and glucose intolerance. Patients at high risk for developing zinc deficiency are those with long-term steroid therapy, malabsorption syndromes, fistulas, sepsis, and major surgery. Oral requirements are 10 to 15 mg/day. IV requirements are **3.0 to 5.0 mg/day.**

c. **Copper** is necessary for heme synthesis, electron transport, and wound healing. Deficiency that develops during PN usually manifests as anemia, leukopenia, and neutropenia. Oral requirements are 30 μg/kg/day. **IV requirements are 0.5 to 1.5 mg/day.**

d. **Manganese** is involved in protein synthesis and possibly glucose use. Oral requirements are 0.7 to 22.0 mg/day. **IV requirements are 150 to 300 μg/day.**

e. **Selenium** is important in antioxidant reactions. Deficiency during PN has been associated with muscle pain and cardiomyopathy. **IV requirements are 40 to 60 μg/day.**

f. **Iodine** is a component of the thyroid hormones. Deficiency manifests as a goiter. Recommended intake is 1 μg/kg/day.

g. **Chromium** is important in glucose use and potentiates the effect of insulin. Signs of deficiency include hyperglycemia and abnormal glucose tolerance. Oral requirements are 70 to 80 μg/day. IV maintenance requirements are 0.14 to 0.20 μg/kg/day (10 to 15 μg/day). **Suggested IV requirements for deficiency and severe glucose intolerance are 150 to 200 μg/day.**

h. **Molybdenum** is essential to xanthine oxidase. Oral requirements are 2.0 μg/kg/day.

III. METHODS OF SUPPORT

A. PN is also called **total parenteral nutrition (TPN)** and **hyperalimentation**. It is used to meet the patient's nutritional requirements when the enteral route cannot accomplish this.

1. **Indications.** When the enteral route cannot be used because of dysfunction or disease states (e.g., acute pancreatitis, inflammatory bowel disease, complete bowel obstruction), PN is instituted.

2. **Initiation** of PN should be undertaken within 1 to 3 days in moderately to severely malnourished patients when the inadequacy of enteral support is anticipated for more than 5 to 7 days. In healthy or mildly malnourished patients, PN should be initiated within 5 to 7 days if enteral support has not been initiated.

3. **Routes of administration**
   a. **A central venous route** is used with hypertonic PN formulations (i.e., dextrose concentrations > 10%). Most commonly, dextrose concentrations of 25% are used centrally, and the osmolarity exceeds 2000 mOsm/L. Such highly osmolar solutions must be infused into a large-diameter central vein (e.g., superior vena cava), where they are rapidly diluted by high flow rates.
   b. **A peripheral venous route** can be used when the dextrose concentration is 10% or less.
      (1) Solutions with 10% dextrose, amino acids, electrolytes, and trace minerals have a resulting osmolarity of 900 to 1000 mOsm/L. Higher osmolarity is associated with a higher incidence of thrombophlebitis.
      (2) The major reason for use of the central venous PN rather than the peripheral route is the development of thrombophlebitis. Maintaining the osmolality of the peripheral PN solution < 900 mOsm/kg and preferably between 600 and 800 mOsm/kg with IV lipid emulsion administered concurrently over 24 hrs minimizes the incidence of thrombophlebitis. Also, the development of new peripheral fine-bore catheters made from polyurethane or silicone has been shown to be significantly less thrombogenic. In addition, the use of low-dose heparin (1 unit/mL) and hydrocortisone (5 mg/L) delivered in the PN solutions has been shown to protect against thrombophlebitis.
      (3) **Glyceryl trinitrate** patches (5 mg), when applied over the area where the tip of the catheter is expected to lie, have been shown to significantly reduce peripheral PN infusion failure caused by phlebitis. With the use of this new catheter technology and new techniques for infusion, it is now feasible to administer peripheral PN in selected patients for short-term therapy (7 to 10 days) with a low incidence of peripheral vein thrombophlebitis.

4. **NPC sources**
   a. **Dextrose monohydrate** is the form of dextrose used for parenteral administration. It yields 3.4 kcal/g. It is the component in PN formulas that contributes the most to osmolarity. It is available commercially in concentrations up to 70%.
   b. **IV lipids** are commercially available as 10% or 20% emulsions derived from soybean oil (intralipid) or a combination of soybean oil and safflower oil (Liposyn II).
      (1) Both the 10% and 20% emulsions are isotonic (280 and 340 mOsm/L, respectively) and can be administered via the peripheral vein with a low incidence of phlebitis; these emulsions provide 1.1 and 2.0 kcal/mL, respectively. They contain 1.2% egg yolk phospholipids as the emulsifying agent and 2.25% to 2.50% glycerol to make the emulsions isosmotic.
      (2) Lipid emulsions can be given as part of the daily NPC requirement or two to three times per week to prevent essential fatty acid deficiency. Both types of lipid emulsion contain particles of 0.4 to 0.5 μm, which prevents the use of 0.22 μm bacterial retention filters.

5. **Protein (nitrogen) source**. **Synthetic crystalline amino acids** are currently used as the nitrogen source in PN formulations.
   a. **These formulations are available commercially without electrolytes and dextrose in concentrations of 5.5% (Travasol), 8.5% (Travasol), 10% (Aminosyn II, Travasol), 15% (Aminosyn II, Clinisol), and 20% (Prosol).**
   b. These formulations yield 4 kcal/g.
   c. These solutions generally contain a mixture of free essential and nonessential L-amino acids.
   d. Specialized amino acid formulations are available for specific disease states.

6. **Systems of PN**
   a. **Glucose system PN**
      (1) **Definition.** The glucose system PN is a parenteral formulation in which dextrose is used exclusively as the NPC source. Nitrogen is provided as crystalline amino acids. Electrolytes, vitamins, and trace minerals are added to the formulation as needed.
      (2) **Administration.** The glucose system PN formulations usually have dextrose concentrations of 25% or greater and must be administered by the central venous route. These formulations are also referred to as two-in-one formulations because the dextrose and amino acids are usually mixed in one container with electrolytes, vitamins, and trace minerals.
         (a) Because of the high dextrose concentration, initial administration should be at low hourly rates (e.g., 50 mL/hr) and increased gradually over 24 hrs to avoid hyperglycemia (> 200 mg/dL).
         (b) To avoid reactive hypoglycemia (< 70 mg/dL), discontinuation should be gradual over several hours.
         (c) Lipid emulsions should be administered for **essential fatty acid replacement** in a dose that provides 4% to 7% of required calories as linoleic acid. This can be accomplished by the administration of 250 mL of 20% or 500 mL of 10% emulsion, two to three times weekly.
   b. **Lipid system PN**
      (1) **Definition.** The lipid system PN is a parenteral formulation in which lipid is administered daily to provide a substantial proportion of the NPC. Nitrogen is provided as crystalline amino acids. Electrolytes, vitamins, and trace minerals are added to the formulation as needed.
      (2) **Administration.** The lipid system PN is administered peripherally when the dextrose concentration is less than or equal to 10% and centrally when the dextrose concentration is more than 10%.
         (a) **Piggyback method.** The solution with amino acids, dextrose, electrolytes, trace minerals, and vitamins is infused concurrently with a separate bottle of lipid emulsion through a Y site on the intravenous administration set.
         (b) **Total nutrient admixture (TNA) method**—three-in-one, all-in-one. Lipids, amino acids, dextrose, electrolytes, trace minerals, and vitamins are mixed in one container and administered by the central or peripheral route, depending on dextrose concentration.
            (i) **Advantages** include simplification of administration and decreased training time for home PN patients.
            (ii) **Disadvantages** include the inability to inspect for particulate matter in the opaque admixture, the inability to use 0.22-μm bacterial retention filters, and stability problems.
            (iii) Because the presence of lipid emulsion in TNAs obscure the presence of a precipitate and may present a life-threatening hazard to patients, the U.S. Food and Drug Administration (FDA) suggests that the piggyback method be used to administer lipid emulsion. If a TNA is deemed medically necessary, then specific admixture guidelines recommended by the FDA should be followed. Also, a particle filter (i.e., 1.2 μ) should be used with TNA administration.
         (c) **Lipid dosage**
            (i) Lipid calories should not exceed 60% of total daily calories, including protein calories.
            (ii) Maximum dosage of lipids for adults is 2.5 g/kg/day.
            (iii) Baseline and weekly serum triglycerides must be monitored in patients on lipid system PN.
      (3) **Adverse effects** of lipids are uncommon. The most frequent adverse effects include fever, chills, sensation of warmth, chest pain, back pain, vomiting, and urticaria (overall incidence $< 1\%$). Severe hypoxemia has been reported with rapid infusion of lipid emulsion.

7. **Additives**
   a. **Electrolytes.** PN formulations must include adequate amounts of sodium, magnesium, calcium, chloride, potassium, phosphorus, and acetate. The intracellular "anabolic" electrolytes—potassium, magnesium, and phosphate—are essential for protein synthesis. Requirements vary widely, depending on a patient's fluid and electrolyte losses; renal, hepatic, and endocrine status; acid–base balance; metabolic rate; and type of PN formula used. The electrolyte composition of the PN formula must be adjusted to meet the needs of the individual patient.
   b. **Vitamins and trace minerals.** Vitamins are usually added to PN solutions in the form of commercially available multivitamin preparations. The current adult multiple vitamin infusion formula available (Infuvite Adult, MVI-Adult) meets the amended requirements of the FDA for adult parenteral multivitamins.
      (1) The new FDA requirements are based on the prior multivitamin formulation recommended by the Nutrition Advisory Group of the Department of Foods and Nutrition of the American Medical Association (NAG-AMA) but with increased dosages of vitamins B_1, B_6, C, and folic acid and the addition of vitamin K.
      (2) The FDA also approved the same multivitamin formulation without vitamin K (MVI-12; multivitamin infusion without vitamin K) for those patients who receive warfarin-type anticoagulant therapy. Because of stability problems, one vial of Infuvite Adult and MVI-Adult contains vitamins A, D, E, B_1, B_2, B_3, B_5, B_6, and K. MVI-12 contains the same vitamins in one vial without vitamin K. The second vial for both preparations contains vitamins B_{12}, biotin, and folic acid.
      (3) Trace minerals may be added individually or as a commercially available multielement preparation. Precise requirements for trace minerals have yet to be determined.
   c. **Insulin** may be required for patients receiving PN formulations (especially glucose system PN) to maintain blood glucose levels $<$ 200 mg/dL. If insulin is required, it is best provided by the addition of an appropriate amount of regular insulin to the PN formulation at the time of admixture. Although a small amount of insulin (5 to 10 U per bag) may be adsorbed to the container and tubing, such losses can be overcome by appropriate titration of the dose. The addition of insulin to the PN formulation has the advantage of changes in the rate of PN infusion being automatically accompanied by appropriate changes in the rate of insulin infusion.
   d. **Miscellaneous drugs.** Several medications have been successfully admixed with PN formulations for continuous infusion. The H_2-receptor antagonists are the most common drugs used in this way. The routine addition of medications to PN formulations remains controversial because of:
      (1) **Questions of stability** over the wide range of PN component concentrations
      (2) Possible **therapeutic inadequacy** or toxicity secondary to PN rate changes and loss of peak and trough levels
      (3) Increased **potential for waste** with dose changes
8. **Complications** with the use of PN can be serious and potentially life threatening but can be avoided by careful management. Complications can be divided into mechanical, infectious, and metabolic.
   a. **Mechanical** complications generally relate to the central venous catheter or its placement and include pneumothorax, catheter occlusion, and venous thrombosis.
   b. **Infectious** complications usually are related to the central venous catheter. This line-related sepsis is secondary to multiple catheter manipulations, contamination during insertion, or contamination during routine maintenance. Hyperglycemia and IV lipids also have been implicated. Maintaining blood sugars $<$ 200 mg/dL has been shown to significantly reduce septic complications in certain subsets of patients.
   c. **Metabolic** complications are the most common. These include hyperglycemia, hypoglycemia, hypokalemia, hypomagnesemia, hypophosphatemia, metabolic acidosis, respiratory acidosis, prerenal azotemia, and zinc deficiency. A transient self-limited hepatic dysfunction is also seen with long-term PN.

B. **Enteral nutrition (EN).** Use of the GI tract to achieve total nutritional support or partial support in combination with the parenteral route should be attempted whenever possible in the face of inadequate oral intake. Theoretical advantages include maintenance of normal digestion, absorption, and gut mucosal barrier function.
   1. **Contraindications** to EN include complete intestinal obstruction, high-output intestinal fistulas, severe acute pancreatitis, severe acute inflammatory bowel disease, and severe diarrhea.

2. Routes of administration. Tube feedings can be administered via nasogastric, nasoduodenal, nasojejunal, gastrostomy, and jejunostomy tubes.

3. EN formulations can be classified as being standard (complete) or modular.

    a. Standard formulas generally contain carbohydrates, fats, vitamins, trace minerals, and a nitrogen source. They are further classified according to their nitrogen source.

        (1) Monomeric formulas contain crystalline amino acids as their nitrogen source. These formulas are usually marketed commercially for specific indications (e.g., ileus, pancreatitis, hepatic coma).

        (2) Short-chain peptide formulas contain dipeptides and tripeptides from hydrolyzed protein or de novo synthesis as their nitrogen source. They are currently marketed for the metabolically stressed patient.

        (3) Polymeric formulas contain either intact proteins or protein hydrolysates as their nitrogen source. Most patients can be managed with these formulas.

    b. Modular formulas consist of separate modules of specific nutrients that can be combined or administered separately. They are used for supplemental use or to custom design an EN formula to meet a specific clinical situation.

        (1) Carbohydrate modules differ in the type of carbohydrate present (e.g., polysaccharides, disaccharides, monosaccharides).

        (2) Protein modules contain either intact protein, hydrolyzed protein, or crystalline amino acids.

        (3) Fat modules contain either long-chain triglycerides (LCTs) prepared from vegetable oils or medium-chain triglycerides (MCTs) prepared from coconut oil. MCTs are more water soluble and more easily absorbed than LCTs. (Bypassing the intestinal lacteal and lymphatic system, MCTs are transported directly to the portal system.) MCTs are, however, relatively expensive and contain no essential fatty acids.

4. Complications. The two **most common** complications of EN are diarrhea and improper tube placement.

    a. Diarrhea in patients receiving EN is usually secondary to concomitant administration of medication (e.g., antibiotics and sorbitol-containing liquids). Infectious causes should be eliminated (e.g., *Clostridium difficile*), after which antidiarrheal medications may be beneficial. Reducing the rate or concentration may also be effective.

    b. A **feeding tube improperly placed** into the tracheobronchial tree can have disastrous consequences. Tube feedings should never be initiated without radiological verification of tube position.

    c. Aspiration

IV. MONITORING SUPPORT

A. PN. In addition to appropriate general medical and nursing care, patients receiving PN initially require daily and weekly laboratory monitoring to assess nutritional progress and metabolic status.

    1. Electrolytes

        a. Initially, **potassium**, **sodium**, and **chloride** should be determined daily. Potassium is used intracellularly; thus, hypokalemia is not an uncommon finding.

        b. Calcium, **magnesium**, and **phosphate** are primarily intracellular electrolytes, serum levels of which become depleted during protein synthesis. Serum levels generally do not fall as rapidly as potassium; therefore, monitoring two to three times a week is recommended initially until the patient is stabilized, then weekly thereafter.

        c. Bicarbonate should be monitored to assess acid–base balance. Hyperchloremic metabolic acidosis may develop in patients on PN. This imbalance can be corrected by providing the potassium and sodium as acetate (converted to bicarbonate in the serum) rather than as the chloride salt. After initial correction, provision of one-half the sodium and potassium requirements as the acetate salt and one-half as the chloride salt may be beneficial.

    2. Serum glucose should be monitored daily, particularly in central glucose systems. Maintaining a blood glucose concentration between 100 to 200 mg/dL is generally recommended.

    3. Weights obtained on a daily or every other day basis track optimum lean body weight gain of 0.25 to 0.50 lb/day. Weight gain in excess of 0.5 lb/day generally indicates fluid overload or fat deposition.

4. **Visceral proteins** (e.g., albumin, prealbumin, transferrin) are important indicators of the adequacy of nutritional support.
   a. **Albumin** is useful in the initial assessment of nutritional status, but its long half-life (18 to 21 days) limits its utility as a short-term marker of nutritional repletion.
   b. **Prealbumin** has a short half-life (2 to 3 days) and is a more sensitive and early indicator of the adequacy of nutritional support. Its serum value is falsely elevated in renal failure.
   c. **Transferrin** has an intermediate half-life (7 to 10 days), which makes weekly monitoring useful. Transferrin may be falsely elevated in iron-deficiency states.
   d. **Retinol-binding protein** has an ultrashort half-life (12 hrs). Values are affected by injury and metabolic stress.
5. **Serum creatinine** and **blood urea nitrogen (BUN)** should be obtained at least weekly. Evidence of renal impairment may require modification of the PN formula. Elevation of the BUN in the absence of renal impairment may be secondary to the PN formula (e.g., excess nitrogen, low NPC:N ratio) and appropriate adjustments need to be made.
6. **Liver function tests**—aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, lactate dehydrogenase (LDH), and bilirubin—require baseline and periodic monitoring because of potential toxicity from the PN formulation (i.e., fatty infiltration of the liver). Abnormal liver function studies may necessitate changes in the PN formulation.
7. **Serum triglycerides** should be measured for a baseline and weekly thereafter for patients on lipid system PN. It is not necessary to monitor triglycerides on a weekly basis for patients receiving lipids two to three times per week for essential fatty acid replacement.
8. **A 24-hr UUN** should be obtained weekly to determine nitrogen balance for patients in whom nitrogen requirements are uncertain. These are usually highly stressed, severely ill, or injured patients in an intensive care unit (ICU) setting.
9. **Serum iron** levels should be obtained weekly to determine deficiency and to allow appropriate interpretation of serum transferrin levels.
B. **EN** generally requires less intense laboratory monitoring. Specific laboratory guidelines for monitoring EN support vary from institution to institution.

V. SUPPORT OF SPECIFIC STATES

A. **Conditionally essential nutrients**
1. **Glutamine.** Because of its instability, glutamine is currently not a component of commercially available standard PN amino acid solutions and is found in free form in relatively few EN formulas. A relative deficiency has been shown to occur in critical illness. It is known to be used as a primary fuel source by enterocytes and may exert a trophic effect on the gut mucosa. It is most widely used as a PN component for bone marrow transplant patients and short gut syndrome. Glutamine-containing dipeptides that are stable and highly soluble are being investigated as a source of glutamine in PN. At present, glutamine must be added to the PN solution at the time of compounding. Increasing evidence supports glutamine supplementation in critical illness.
2. **Arginine** has been shown experimentally and clinically to enhance immune function. EN formulas enriched with arginine are available commercially. Recently, the efficacy of exogenously administered arginine to subsets of critically ill patients, specifically septic patients, has come into question.
3. **Antioxidant formulations.** Oxidant production occurs as part of the normal inflammatory response and has been implicated in reperfusion injury. The body also produces antioxidant defenses to limit oxidant damage to healthy tissue. These defenses rely on adequate intake of dietary nutrients, such as the sulfur-containing amino acids, vitamin E, vitamin C, selenium, and zinc.
4. **Tyrosine**, **cysteine**, and **taurine** are either absent or present in low concentrations in commercially available PN formulas. They are believed to be conditionally essential amino acids by some investigators.
5. **Omega-3 polyunsaturated fatty acids** are derived from fish oils and are currently found in some EN formulations. These fatty acids have been shown experimentally to enhance immune response, protect against tumor growth, and inhibit some of the proinflammatory effects of omega-6 fatty acids. In addition, they have been shown to lower cardiovascular risk factors by decreasing platelet activation, lowering blood pressure, and reducing triglycerides.

6. Commercially available enteral formulas supplemented with various combinations of the afore-mentioned agents are advocated for appropriate patient populations, i.e., major elective surgery, trauma, burns, head and neck cancer, and critically ill patients on mechanical ventilation. In particular, patients on mechanical ventilation with adult respiratory distress syndrome (ARDS) should be given an enteral formula rich in omega-3 polyunsaturated fatty acids and antioxidants.

B. **Nutritional support for renal failure.** The goal of nutritional support in acute renal failure (ARF) is to meet the patient's NPC requirements while minimizing volume, protein load, and potential electrolyte imbalance.

1. **PN formulations** used in ARF are low-nitrogen, high-caloric density formulas (e.g., 2% amino acid/47% dextrose), resulting in NPC:N ratios of approximately 500:1.

2. **Commercial renal failure formulations** (e.g., NephrAmine, Aminosyn RF) containing primarily essential amino acids have shown no clinical advantage over less expensive, low-concentration standard amino acid formulations.

3. **Standard glucose system formulations** (4.25% amino acid/25% dextrose) can generally be used in renal failure patients receiving hemodialysis or continuous renal replacement therapy (CRRT) on a regular basis. This formulation is particularly useful in critically ill ICU patients because it can provide adequate protein to attain positive nitrogen balance, which is not possible with renal failure PN. ICU patients with ARF almost always have preexisting comorbidities and other complications and should be provided adequate protein to attain positive nitrogen balance. Dialysis therapy should not be avoided or delayed to provide these patients adequate protein doses of 1.5 to 2.5 g/kg/day to achieve positive nitrogen balance.

4. **Monitoring transferrin** is a more sensitive and accurate visceral protein marker compared to albumin and prealbumin for assessing nutritional progress in these patients.

5. **Enteral formulations** that are low in nitrogen and calorie dense (1.7 to 2.0 NPC/mL) are available for patients with renal failure.

C. **Nutritional support for hepatic failure.** Patients with hepatic failure have altered protein metabolism, resulting in decreased serum levels of branched-chain amino acids (i.e., leucine, isoleucine, valine) and increased levels of aromatic amino acids (i.e., phenylalanine, tyrosine, tryptophan), methionine, and glutamine. A similar amino acid profile can exist in the cerebrospinal fluid (CSF) and is thought to contribute to hepatic encephalopathy. Fluid and electrolyte disturbances are frequently associated with hepatic failure as well.

1. **PN and EN formulations** enriched in branched-chain amino acids and low in aromatic amino acids (e.g., HepatAmine, Hepatic-Aid 11) have been **used to improve** mental status in patients with altered serum amino acid profiles and hepatic encephalopathy. However, studies have not demonstrated definitive clinical differences in morbidity and mortality with these more expensive formulations compared to standard formulas. These enriched branched-chain amino acid formulations should be reserved for the rare encephalopathic patient who is refractory to standard treatment with luminal acting antibiotics and lactulose.

2. EN is recommended whenever feasible as the optimal route of nutrient delivery for ICU patients with acute and/or chronic liver disease. EN has been shown to improve nutritional status, reduce complications, and prolong survival in liver disease patients.

3. Protein requirements in ICU patients should not be restricted as a clinical management strategy to reduce the risk of developing hepatic encephalopathy. The protein dose should be determined in the same manner as the general ICU patient. In patients with encephalopathy, a protein intake of 0.8 to 1.2 g/kg/day is warranted.

D. **Nutritional support for respiratory failure.** The type and amount of substrate administered as NPC can have an effect on a patient's ventilatory status. Overfeeding with resultant lipogenesis and increased carbon dioxide production can be a cause of respiratory acidosis and/or increased minute ventilation and therefore should be avoided. Even in the presence of appropriate amounts of NPC administered as carbohydrate, the normal carbon dioxide load generated by glycolysis may be excessive for the patient with underlying pulmonary dysfunction—for example, chronic obstructive pulmonary disease (COPD).

1. **PN lipid system formulations** (e.g., 4.25% amino acid/15% dextrose with daily lipid emulsion), where the lipid component constitutes 40% to 50% of the total NPC, may be beneficial in reducing the ventilatory demands in respiratory failure patients because lipolysis generates less carbon dioxide than glycolysis.

2. **EN formulations** containing similar amounts of fat can be prepared from standard EN formulas with the use of lipid modules (i.e., MCT oil, corn oil). More expensive commercial pulmonary formulas are also available.

3. **Oxepa**, a low-carbohydrate enteral formula containing antioxidants, eicosapentaenoic acid, and γ-linolenic acid, is currently available for adult respiratory distress syndrome (ARDS). It modulates the phospholipid fatty acid composition of inflammatory cell membranes, decreases the synthesis of the proinflammatory eicosanoids of lung injury, and attenuates endotoxin-induced increases in pulmonary microvascular protein permeability.

E. **Nutritional support for cardiac failure.** The goal in these patients is to meet metabolic needs while restricting fluid and sodium intake.

1. **PN formulations** that provide protein and calories in as high a concentration as possible is the goal of nutritional therapy. This can be accomplished with both central glucose and lipid system PN formulations (e.g., 5% amino acid/35% dextrose; 7% amino acid/21% dextrose/20% lipid emulsion).

2. **Serum electrolyte monitoring** and **adjustment** are imperative in cardiac failure patients receiving PN, particularly when potent diuretics are used concurrently.

3. **EN formulations** with high nutrient density are available for oral supplementation or tube feedings. Infusion of enteral tube feedings should begin at one-third to one-half the strength, with a gradual increase in concentration, while maintaining a slow infusion rate (30 to 50 mL/hr) to avoid rapid increases in fluid load, cardiac output, heart rate, and myocardial oxygen consumption.

F. **Nutritional support in pancreatitis.** Severe acute pancreatitis is a hypercatabolic state that without nutritional support renders the patient a poor surgical candidate and at increased risk of infection.

1. Early initiation of enteral feeding via the gastric or jejunal route is advocated for these patients. Elemental or small peptide-based formulas that are nearly fat-free or contain medium chain triglycerides are well tolerated. If intolerance to gastric feeds occurs, more distal feeding should be attempted.

2. PN should be reserved for the patient with severe acute pancreatitis who is intolerant to enteral feeding.

G. Thermal injury is one of the most hypermetabolic conditions observed in the critical care setting.

1. Methods for estimating the calorie requirements in this patient population are conflicting owing to differences in bias and precision. One of the more accurate unbiased methods reported for estimating energy requirements in thermal injury is

$$\text{Kcal} = (1000 \text{ kcal} \times \text{BSA}) + (25 \times \%\text{BSAB})$$

where BSA is body surface area and BSAB is body surface area burned.

2. Protein requirements in thermally injured patients are high at 2.0 to 2.5 g/kg/day because of the significant degree of catabolism associated with this injury.

3. The increased dermal losses of nitrogen from their burn wounds renders the use of the conventional nitrogen balance formulas less accurate in assessing nitrogen requirements, especially with thermal injuries > 40% of BSA. The UUN plus the insensible loss factor can differ significantly from total nitrogen losses in this patient population.

H. **Hyperglycemia** and **insulin resistance** are common occurrences in critically ill patients. Previous recommendations in critically ill ICU patients were to provide intensive insulin therapy (IIT) to maintain blood glucose levels between 80 to 110 mg/dL to reduce morbidity and mortality in this patient population. Based on the results of a recent systematic evidence review of the literature on ITT in hospitalized patients, the American College of Physicians (ACP) provided the following practice guideline for the management of glycemic control in medical intensive care unit (MICU) and surgical intensive care unit (SICU) patients.

1. ACP recommends not using IIT to normalize glucose in SICU/MICU patients with or without diabetes mellitus

2. ACP recommends a target blood glucose level of 140 to 200 mg/dL if insulin therapy is used in SICU/MICU patients.

3. The ACP also noted the following clinical considerations:
   a. Critically ill medical and surgical patients who are hyperglycemic have a higher mortality rate.
   b. Most clinicians agree that prevention of hyperglycemia is an important intervention.

     c. The range of optimal glucose level is controversial. A few studies show that IIT improves mortality, whereas most have shown that patients who receive IIT have no reduction in mortality and have a significantly increased risk for severe hypoglycemia.

I. **Nutritional support in pregnancy.** Nutritional support in pregnancy can have a significant effect on fetal outcome. Weight gain throughout pregnancy is the primary indicator of the adequacy of the nutritional state of mother and child. A weight gain of 11.5 to 16.0 kg should be the desired goal in women with normal prepregnancy BMI. PN and EN have both been used successfully during pregnancy, with both modalities demonstrating adequate maternal weight gain, appropriate fetal growth, and term delivery. The calories required to achieve appropriate weight gain throughout the entire pregnancy per the World Health Organization recommendations are an additional 300 kcal/day above the estimated basal energy expenditure (based on the pregravid weight) during all trimesters. The recommended daily protein intake during a normal pregnancy is approximately 1 g/kg/day. This amount represents the normal recommended daily allowance for females plus an additional 10 g/day. In pregnant patients with moderate-to-severe stress, both calories and protein requirements need to be adjusted in the same manner as for other hypermetabolic nonpregnant patients.

    1. PN glucose system and lipid system formulations can both be used successfully to meet the nutrient requirements of pregnant patients. PN is most commonly used during pregnancy in patients with severe hyperemesis gravidarum.

    2. Essential fatty acids (EFAs) are required by both mother and fetus. They are necessary for prostaglandin synthesis and normal fetal lipid development. The provision of at least 4.5% to 7.0% of calorie requirements as EFAs has been estimated to meet the minimum requirements during pregnancy.

    3. The **daily vitamin requirements** in a normal pregnancy based on the 1999 dietary reference intakes (DRIs) can be met with the parenteral vitamin infusion Infuvite Adult and MVI-Adult. If MVI-12 is used as the parenteral vitamin preparation, an additional 65 μg of vitamin K needs to be added to the daily PN formulation to meet the daily DRI requirements.

    4. Prealbumin appears to be the preferred biochemical marker to assess protein status in pregnancy, because albumin is falsely depressed and transferrin is falsely elevated in pregnant patients.

    5. EN may be useful during pregnancy for patients with less severe hyperemesis gravidarum. The composition of polymeric formulas should be adequate for meeting the nutritional requirements of most pregnant patients.

    6. Blood glucose levels should be kept at approximately 100 mg/dL during prolonged continuous PN or EN infusion because chronically elevated maternal glucose levels can result in fetal anomalies, increased risk of miscarriages, and stillbirth.

J. **Nutritional support in inflammatory bowel disease (IBD).** IBD is associated with weight loss, hypoalbuminemia, anemia, electrolyte imbalance, and vitamin/mineral deficiencies (especially zinc)

    1. PN has no role as primary therapy.

    2. PN has a role with high-output fistulae.

    3. Polymeric and elemental enteral formulas seem equally tolerated.

K. **Nutritional support in short bowel syndrome (SBS).** A loss of bowel from resection or dysfunction can result in reduced absorption of fluid, electrolytes, macronutrients and micronutrients. Specific deficiencies are related to the regions of lost absorption (e.g., free water and iron deficiency are associated with jejunal loss, vitamin B_{12}, bile salt, and fat-soluble vitamin deficiency are associated with ileal loss). Complications include dehydration; weight loss; deficiencies of electrolytes, mineral, and trace elements; metabolic bone disease; cholelithiasis; nephrolithiasis; gastric acid hypersecretion and D-lactic acidosis. Intestinal adaptation begins to occur after resection and is promoted by enteral feeding.

    1. PN is not uncommonly required for the short-term and is usually required for the long-term in massive small bowel resection.

    2. Hypersecretion of gastric acid should be treated with H2-blockers.

    3. D-lactic acidosis is caused by fermentation of an increased carbohydrate load delivered to the colon. Treatment is aimed at decreasing enteral carbohydrates.

    4. Fat-soluble vitamins should be monitored and replaced.

    5. Stool volume should be monitored and treated with antidiarrheal agents if greater than 2 L/day.

    6. Oral calcium and magnesium supplementation needed when enteral feeding achieved.

7. Intestinal adaptation in patients with massive resection may be hastened/improved by the provision of glutamine (enteral and/or parenteral) recombinant human growth hormone and high-carbohydrate, low-fat feeds.

L. **Nutritional support in bariatric surgery.** Bariatric surgeries are divided into restrictive (vertical banded gastroplasties and silastic ring vertical gastroplasties), restrictive/malabsorptive (Roux-en-Y gastric bypass), and malabsorptive procedures (biliopancreatic diversion). Since restrictive procedures retain the use of the entire GI tract, nutritional deficiencies are less common than in malabsorptive procedures. The primary nutrients affected by bariatric surgery include:

1. Iron—one of the most frequent deficiencies after bariatric surgery. Occurs in both restrictive and malabsorptive procedures. Deficiency is secondary to reduced areas of absorption in the small bowel with malabsorptive procedures and reduced production of hydrochloric acid in the stomach for both types of bariatric procedures. The result is a reduction in iron reduced to the absorbable ferrous state. Prevention/treatment is with oral iron supplementation combined with ascorbic acid to acidify the stomach and facilitate absorption.

2. Vitamin B_{12} deficiency—common after gastric bypass surgery. Absorption is dependent on intrinsic factor produced in the parietal cells of the stomach, and hydrochloric acid is required to cleave vitamin B_{12} from protein foodstuffs in the stomach. Prevalence after Roux-en-Y procedure is estimated at 12% to 33%. Prevention/treatment: oral B_{12} formulations of 350 to 1000 mcg/day or monthly injections of 2000 mcg in those patients who do not respond to the oral supplements.

3. Folate deficiency—less frequent than B_{12} deficiency. Folate absorption occurs preferentially in the proximal intestines, but with adaptation after gastric bypass surgery, absorption can occur throughout the small bowel. Prevention/treatment: 1 mg folate PO/day.

4. Thiamine deficiency—uncommon. Seen with postoperative hyperemesis syndromes. Prevention: 50 to 100 mg IV or IM thiamine at 6 weeks postop in patients with hyperemesis.

5. Zinc—depends on fat absorption. Deficiency observed with malabsorptive surgery. Standard daily supplementation of zinc is recommended after malabsorptive surgery.

6. Selenium deficiency and a life-threatening cardiomyopathy have been reported in patients after malabsorptive surgery. Supplementation of selenium at 40 to 80 mcg/day is recommended in patients undergoing malabsorptive bariatric surgery.

7. Fat-soluble vitamins (A, D, E, K)—malabsorptive bariatric surgery results in a high incidence of vitamin A, D, and K deficiency with altered calcium metabolism (vitamin E, to a lesser extent). Patients undergoing malabsorptive surgery require long-term annual measurements of fat-soluble nutrients. There is no proven regimen for vitamin supplementation after malabsorptive surgery, but lifelong daily supplementation of fat-soluble vitamins has been recommended at the following dosages: 10,000 IU vitamin A; 1200 IU vitamin D; 300 mcg vitamin K, and 1800 mg calcium citrate.

VI. TECHNICAL ASPECTS OF PN PREPARATIONS

A. PN formula preparation is performed **aseptically** in the pharmacy under a laminar flow hood that filters the air, removing airborne particles and microorganisms. PN is especially at risk of contamination because it is a mixture of multiple additives and is an excellent growth medium for microorganisms. An expert committee of the *United States Pharmacopeia* (*USP*) developed Chapter <797>, the first official monograph containing medication standards that must be followed and are enforceable by regulatory agencies concerning the procedures and requirements for pharmacy prepared sterile products. The *USP* Chapter <797> provides evidence-based instructions for pharmacy design, washing, garbing, quality assurance, and personnel training and evaluation to improve compounding practices for sterile products including PN. PN is classified as a medium-risk level compounded sterile product (CSP) when it is prepared from injectable amino acids, dextrose, lipid emulsions, electrolytes, trace elements, and sterile water. When PN is compounded using powdered amino acids, it is classified as a "high-level" CSP because its preparation involves the use of nonsterile ingredients and carries the highest risk for contamination by microbial, chemical, or physical matter. PN solutions prepared for inpatient administration have a beyond-use date of 30 hrs based on storage at room temperature and a medium risk level. In the home care setting, the beyond-use date can be extended to 9 days, but the PN admixture must be stored under refrigeration at 36° to 46°F until use. The 30-hr time limit still applies once PN is initiated.

B. **Compatibility** of the various components of PN formulations is determined by several factors, including their concentration, solution pH, temperature, and the order of admixture. The **most common** compatibility concern is in regard to the addition of calcium and phosphate salts to PN solutions. Dibasic calcium phosphate is very insoluble, whereas monobasic calcium phosphate is relatively soluble. At low pH, a greater amount of monobasic calcium phosphate predominates. The pH of the PN solutions is determined primarily by the concentration and type (brand) of amino acids. PN solutions containing higher concentrations of amino acids have a lower pH that allows for greater solubility of calcium and phosphate. The type (brand) of amino acid solutions commercially available differ in their pH. Thus, the choice of amino acid preparation as well as the concentration of amino acids may allow for more or less calcium and phosphate to be administered in PN solutions. An increase in the temperature of PN solutions increases the dissociation of calcium. This increases the amount of calcium ion available to complex with phosphate and results in a decrease in calcium and phosphate solubility. Therefore, lower PN solution temperatures may allow for a greater amount of calcium and phosphate to be solubilized. The order of calcium and phosphate addition to PN solutions can also affect the solubility of these electrolytes. It is recommended that phosphate be added and diluted in the PN solution prior to the addition of calcium.

C. After admixture of the various components, the PN solution should be **visually inspected** for precipitate or particulate matter. After labeling and final checking, the PN solution should be refrigerated until delivery to the nursing unit.

D. A statistically valid, continuous **sterility testing program** should be an essential component of quality control in preparing PN solutions.

VII. HOME PARENTERAL NUTRITION (HPN).
HPN has become a widely accepted and useful technique for provision of complete nutritional requirements in the home setting. When used appropriately, this modality benefits the patient medically and psychologically, with a decreased cost to the health care system.

A. **Indications** for HPN include SBS, severe IBD, radiation enteritis, enterocutaneous fistulae, and selected malignancies.

B. **Candidate selection** requires a multidisciplinary approach to determine if the patient and family can assume the responsibility and training needed for safe and successful HPN.

C. **Administration.** HPN is infused through a central venous silastic catheter (e.g., Hickman, Broviac), which allows for prolonged PN with low clotting and infection rates. The PN solution is generally infused over a 12- to 15-hr period at night. This type of cycling program allows the patient to be free from the infusion pump during the day, allowing for a more normal lifestyle.

D. **Clinical monitoring** and follow-up are done periodically, depending on the needs of the individual patient. Long-term HPN patients generally are seen by the physician on a monthly basis after initial stabilization.

VIII. MISCELLANEOUS

A. **Soluble fiber** is present in some commercially available EN formulas. This fiber is fermented by normal large intestinal flora to short chain fatty acids that are used by colonocytes as a fuel source. These short chain fatty acids also seem to have a trophic effect on the large intestinal mucosa.

B. **Growth factors.** The use of recombinant human growth hormone, insulin-like growth factor, and anabolic steroids, in combination with nutritional support to improve nitrogen balance and reduce hospital length of stay in select patient populations, is currently under investigation. To date, recombinant growth hormone (Humatrope) is available for nutritional support in children with cystic fibrosis, sickle-cell anemia, and thalassemia and in adults with AIDS-related cachexia. Oxandrolone is a synthetic anabolic steroid with FDA approval for increasing weight gain in patients with chronic infection, major surgery, and severe trauma. It also has established efficacy in alcoholic cirrhosis (improved survival and liver function), burns (improved nitrogen balance, wound healing, and weight gain), and in AIDS cachexia (improved weight gain). Usual dose is 2.5 to 20.0 mg orally (80 mg in alcoholic cirrhosis) in divided doses daily for up to 4 weeks.

Study Questions

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A 32-year-old, well-nourished man involved in a motor vehicle accident was admitted to the surgical intensive care unit with multiple long bone fractures and abdominal injuries with no nutritional support for 4 days. This patient is most likely

   (A) suffering from moderate-to-severe kwashiorkor malnutrition.
   (B) at low risk for hospital-acquired infection and other complications.
   (C) not suffering from protein or calorie malnutrition.
   (D) suffering from severe marasmus malnutrition.
   (E) not a candidate for aggressive nutritional support.

2. A patient in the ICU on a ventilator was placed on a glucose system PN formulation providing 2040 kcal/day and 98 g protein/day. A measured energy expenditure (MEE) of 2038 kcal and RQ of 1.1 were subsequently obtained. Which of the following is correct based on this information?

   (A) The patient is receiving adequate glucose calories, and an adjustment in the program is not necessary.
   (B) The daily protein intake has to be decreased to reduce the patient's RQ.
   (C) The PN formulation should be switched to a lipid system formulation to reduce the carbon dioxide load.
   (D) The patient is retaining oxygen from the glucose calories in the PN formulation.
   (E) Lipid emulsion should be added to the current PN formulation to enhance lipogenesis.

3. Total nutrient admixture (TNA)

   (A) is more complicated to administer for home parenteral nutrition patients.
   (B) should be filtered with a 1.2-μ filter.
   (C) consists of glucose, amino acids, electrolytes, and trace minerals mixed in one container.
   (D) is the method recommended by the FDA to administer lipid system PN.
   (E) can be visualized for particulate matter.

4. The calorie requirements of a moderately hypermetabolic hospitalized patient are best estimated by using the

   (A) nomogram method.
   (B) nitrogen balance method.
   (C) (EEE) method.
   (D) PNI.
   (E) SGA method.

5. Lipid system PN

   (A) can be administered by peripheral vein if the glucose concentration is less than 15%.
   (B) requires daily serum triglyceride monitoring.
   (C) is contraindicated in patients with elevated carbon dioxide levels.
   (D) requires daily lipid administration to provide a portion of the patient's nonprotein calorie requirements.
   (E) can be administered with a maximum lipid dosage of 4.5 g/kg/day.

6. Commercial PN formulations for hypermetabolic critically ill patients

   (A) are enriched in branched-chain amino acids and contain low concentrations of aromatic amino acids.
   (B) contain primarily essential amino acids.
   (C) have not demonstrated a positive clinical outcome benefit in this patient population.
   (D) are the preferred PN formulation used in this clinical setting.
   (E) are enriched with arginine to enhance immune function.

7. Which of the following methods of parenteral nutritional support would be most appropriate in a severely protein calorie malnourished patient with acute renal failure?

   (A) 2% amino acid/47% dextrose.
   (B) 4.25% amino acid/25% dextrose.
   (C) 4% essential amino acid/47% dextrose.
   (D) 4.25% amino acid/25% dextrose with dialysis on a regular basis.
   (E) 2% amino acid/47% dextrose/20% lipid emulsion.

8. Which of the following statements regarding the monitoring of nutritional support is true?

 (A) Prealbumin is not the optimal marker to follow for short-term nutritional progress.
 (B) Transferrin is falsely depressed in patients with iron deficiency.
 (C) Albumin is falsely elevated in renal failure.
 (D) A positive nitrogen balance of 3 to 6 g of nitrogen daily is optimal.
 (E) A weight gain of 1.5 to 2.0 lb/day indicates optimal lean body weight gain.

9. Patients with end-stage liver disease

 (A) generally have increased levels of branched-chain amino acids and decreased levels of aromatic amino acids.
 (B) should be placed on a low-branched chain, high-aromatic amino acid PN solution.
 (C) should not have their protein restricted in the ICU as a clinical management strategy to reduce the risk of developing hepatic encephalopathy.
 (D) require glutamine-enriched amino acid solutions.
 (E) can tolerate standard glucose system formulations 4.25% amino acid/25% dextrose with regular dialysis.

For questions 10–12: A 67-year-old white female presented to the attending physician with a 3-month history of progressive difficulty swallowing and a 10-kg weight loss. She is currently 160 cm tall and weighs 50 kg. She has just undergone a distal esophagectomy and proximal gastrectomy for distal esophageal cancer. At the time of surgery, she had a feeding jejunostomy tube inserted.

10. The dieticians who are adept at using the Harris-Benedict equation have gone home for the day, and the surgeon calls you for your best guess at what the hourly goal rate for this patient should be using isotonic enteral formula, which provides 0.85 nonprotein calories (NPCs)/mL. Your answer should be

 (A) 65 mL/hr.
 (B) 75 mL/hr.
 (C) 85 mL/hr.
 (D) 95 mL/hr.
 (E) 50 mL/hr.

11. The enteral formulation the surgeon has selected is enriched with fish oils. He is hoping this additive will

 (A) prevent diarrhea.
 (B) prevent dermatitis.
 (C) prevent hyperglycemia.
 (D) improve immune function.
 (E) improve neurological function.

12. On the 5th postoperative day, the feeding jejunostomy tube becomes clogged and unusable. The patient will be NPO an additional 5 days to ensure the integrity of her surgical anastomosis. The most appropriate course at this time is

 (A) start the patient on a lipid-based peripheral PN program.
 (B) keep the patient NPO and without PN support.
 (C) have a central venous catheter inserted, and initiate a lipid-based PN program.
 (D) start the patient on a glucose-based peripheral PN program.
 (E) have a central venous catheter inserted, and start the patient on a high branched-chain amino acid parenteral program.

For questions 13–14: RJ is a 28-year-old pregnant woman. She is in the 9th week of her pregnancy and is diagnosed with hyperemesis gravidarum. Her pregravid weight was 57 kg, and her height is 5 ft., 5 in. She has lost 7 kg (12.3%) during her pregnancy. She was placed on a central glucose PN program.

13. Which one of the following represents the best estimate of her daily caloric requirements?

 (A) 1675 kcal
 (B) 1790 kcal
 (C) 2261 kcal
 (D) 2062 kcal
 (E) 1925 kcal

14. MVI-12 is used as the parenteral vitamin preparation in the PN formulation. Which of the following vitamin(s) need to be supplemented in the daily PN formulation to meet the daily requirements during pregnancy?

 (A) Vitamin K
 (B) Thiamine (B_1)
 (C) Folic acid
 (D) A and C
 (E) Pyridoxine (B_6)

For questions 15–17: A 55-year-old male with multiple traumatic injuries and type II diabetes was admitted to the surgical ICU. He was placed on mechanical ventilation and initiated on glucose system PN. After 3 days of PN therapy his blood glucose levels have ranged from 250 to 285 mg/dL over the past 24 hrs with 80 U of insulin/L in his PN formulation. He is on no other insulin supplementation at this time.

15. The nutritional support service recommends an insulin drip with the goal of achieving a blood glucose level of

 (A) 180 to 225 mg/dL.
 (B) 200 to 215 mg/dL.
 (C) 140 to 200 mg/dL.
 (D) 65 to 100 mg/dL.
 (E) 70 to 105 mg/dL.

16. What parenteral trace mineral therapy may be an effective adjunct if the insulin drip fails to achieve the glucose level goal?

(A) 20 to 40 mg zinc/day
(B) 150 to 200 μg chromium/day
(C) 0.5 to 1.5 mg copper/day
(D) 150 to 400 mcg manganese/day
(E) 40 to 60 μg selenium/day

17. The recommended ACP guideline for management of glucose levels in this patient population has shown that:

(A) The range of optimal glucose level is definitive.
(B) Hyperglycemia results in decreased duration of PN therapy.
(C) Most patients receiving intensive insulin therapy have no reduction in mortality but have a significantly increased risk for severe hypoglycemia.
(D) Length of time on the ventilator is decreased.
(E) A & C.

For questions 18–19: A 35-year-old female with severe morbid obesity (BMI = 51 kg/m^2) of more than 12 years duration and refractory to conventional obesity treatment was entered into a bariatric surgery program. The patient underwent a Roux-en-Y procedure without any major postoperative complications.

18. The patient was readmitted to the hospital 3 months after discharge with intolerance to solid and liquid foods and persistent hyperemesis. She also presented with generalized paresthesia, ataxis, and mental confusion. Which of the following nutrients is most likely deficient in this patient?

(A) Selenium
(B) Vitamin D
(C) Calcium
(D) Thiamine
(E) Vitamin E

19. This patient should be placed on which of the following nutrient supplementations to prevent potential cardiomyopathy?

(A) Folate (1 mg/day)
(B) Vitamin B$_{12}$ (350 to 1000 mcg/day)
(C) Selenium (40 to 80 mcg/day)
(D) Vitamin A (10,000 IU/day)
(E) Vitamin K (300 mcg/day)

For questions 20–22: A pharmacist managing the PN department of an IV home infusion company decided to review all technical aspects of PN preparation with the pharmacy staff in an effort to update procedures and educate pharmacy staff on current standards of PN admixtures.

20. There is some confusion among the staff as to where to obtain the most current document on medication standards for pharmacy prepared sterile products that provides evidence-based instructions for pharmacy design, quality assurance, washing, garbing, and personnel training and evaluation to improve compounding practice for PN admixtures. The most appropriate source to obtain this information is the

(A) ASHP 2015 Initiative.
(B) ASPEN Practice Guidelines.
(C) *USP* Chapter <797> Monograph.
(D) National IV Therapy Association.
(E) FDA Intravenous Compounding Guidelines.

21. In reviewing their procedures for storage of prepared PN admixtures, they found a beyond-use date of 14 days under refrigeration until PN is initiated in the home setting. Based upon the most current standards for pharmacy prepared sterile products, which one of the following is the correct beyond-use date for storage of PN admixtures prepared for home use?

(A) 30 hrs under refrigeration
(B) 3 days under refrigeration
(C) 14 days under refrigeration
(D) 24 hrs at room temperature
(E) 9 days under refrigeration

22. In compounding PN for home patients, there are several patients with SBS for whom physicians are prescribing the addition of the amino acid glutamine to the PN formulation. The pharmacists must use nonsterile glutamine powder to compound these PN formulations. In updating their procedure manual, what would be the risk-level for compounding these specialty PN formulations based on the most current document on medication standards for pharmacy prepared sterile products?

(A) Intermediate-risk level
(B) High-risk level
(C) Low-risk level
(D) Medium-risk level
(E) Minimum-risk level

For questions 23–24: A 28-year-old white male involved in a motor vehicle accident was admitted to the SICU with severe abdominal and head injuries. The patient is fluid restricted because of his head injury and was subsequently placed on a concentrated glucose system PN. His calcium and phosphate serum levels are quite low and because of his fluid restriction, they want to add as much calcium and phosphate to the PN formulation to correct these electrolyte deficiencies.

23. Which of the following strategies would allow for the best calcium and phosphate solubility?

(A) Use a brand of amino acids that has the lowest pH.

(B) Calcium should be added and diluted in the PN prior to the addition of phosphate.

(C) The amino acid concentration should be kept as low as possible.

(D) The temperature of the PN solution should be kept as high as tolerable.

(E) The pH of the PN solution should be increased by the addition of 0.1N sodium hydroxide.

24. The form of calcium phosphate that is most soluble in PN solutions is

(A) dibasic.

(B) divalent.

(C) monobasic.

(D) trivalent.

(E) tribasic.

Answers and Explanations

1. The answer is A *[see I.B.3]*.
A hypermetabolic state (e.g., trauma, infection) combined with protein deprivation can rapidly develop into a severe kwashiorkor malnutrition characterized by hypoalbuminemia, edema, and impaired cellular immune function.

2. The answer is C *[see V.D.1]*.
Even in the presence of appropriate amounts of NPCs administered as carbohydrate, the normal carbon dioxide load generated by glycolysis may be excessive for the patient with underlying pulmonary dysfunction. PN lipid system formulations, in which the lipid component constitutes 40% to 50% of the total NPCs, may be beneficial in reducing the ventilatory demands in respiratory failure patients because lipolysis generates less carbon dioxide than glycolysis.

3. The answer is B *[see III.A.6.b.(2).(b).(iii)]*.
A particle filter (i.e., 1.2 μ) should be used with TNA administration.

4. The answer is C *[see II.B.1]*.
Energy requirements are determined as nonprotein calories by indirect calorimetry, estimated energy expenditure, and the simple nomogram method. The nomogram method is the least accurate method of estimating caloric requirements.

5. The answer is D *[see III.A.6.b.(1)]*.
The lipid system PN is a formulation in which lipid is administered daily to provide a substantial portion of the NPCs.

6. The answer is C *[see V.C.1]*.
PN formulations enriched in branched-chain amino acids have been made available with the rationale that, being the preferred fuel source in this patient population, it would enhance protein synthesis, decrease protein catabolism, and improve the patient's clinical outcome. However, these more expensive branched-chain amino acid formulations have not been shown to favorably influence clinical outcomes in critically ill patients.

7. The answer is D *[see V.B.3]*.
Standard glucose system formulations (4.25% amino acid/25% dextrose) can generally be used in renal failure patients who are being dialyzed on a regular basis. This formulation is particularly useful in severely malnourished patients because it can provide adequate protein to attain positive nitrogen balance, which is not possible with renal failure PN.

8. The answer is D *[see II.B.2.a.(4)]*.
A positive nitrogen balance of 3 to 6 g is the goal.

9. The answer is C *[see V.C.3]*.
Protein requirements in ICU patients should not be restricted as a clinical management strategy to reduce the risk of developing hepatic encephalopathy.

10. The answer is B *[see II.B.1.c]*.
Use the nomogram of 30 kcal/kg to determine the NPCs/day, and divide that by the NPCs/mL of the enteral formula to determine the volume of formula per day, which is divided by 24 hrs to yield the hourly goal rate.

11. The answer is D *[see V.A.5]*.
Omega-3 polyunsaturated fatty acids are derived from fish oils and are currently found in some enteral formulations. These fatty acids have been shown experimentally to enhance immune response.

12. **The answer is A** *[see III.A.3.b]*.
    With the use of new catheter technology and new techniques for infusion, it is now feasible to administer peripheral PN in selected patients for short-term therapy (7 to 10 days) with a low incidence of peripheral vein thrombophlebitis. This method of PN administration avoids the potential of more serious complications associated with central venous route administration.

13. **The answer is A** *[see V.I]*.
    The estimated basal energy expenditure is calculated using the pregravid weight in the Harris-Benedict equation. An additional 300 kcal/day is added to the basal energy expenditure to provide the required calories per day during pregnancy.

14. **The answer is A** *[see V.I.3]*.
    An additional 65 μg of vitamin K needs to be added to the daily PN formulation when MVI-12 is used as the parenteral vitamin preparation to meet the daily requirements during pregnancy.

15. **The answer is C** *[see V.H.2]*.
    ACP recommends a target blood glucose level of 140 to 200 mg/dL if insulin therapy is used in SICU/MICU patients

16. **The answer is B** *[see II.B.5.g]*.
    Suggested IV requirements of chromium for deficiency and severe glucose intolerance are 150 to 200 μg/day.

17. **The answer is C** *[see V.H.3.c]*.
    A few studies show that IIT improves mortality, whereas most have shown that patients who receive IIT have no reduction in mortality and have a significantly increased risk for severe hypoglycemia.

18. **The answer is D** *[see V.L.4]*.
    Thiamine deficiency is not common after bariatric surgery but is seen in patients with postoperative hyperemesis syndromes.

19. **The answer is C** *[see V.L.6]*.
    Selenium deficiency and a life-threatening cardiomyopathy have been reported in patients after malabsorptive surgery. Supplementation of selenium at 40 to 80 mcg/day is recommended in patients undergoing malabsorptive surgery.

20. **The answer is C** *[see VI.A]*.
    The *USP* Chapter <797> provides evidence-based instructions for pharmacy design, washing, garbing, quality assurance, and personnel training and evaluation to improve compounding practices for sterile products, including PN.

21. **The answer is E** *[see VI.A]*.
    In the home care setting, the beyond-use date can be extended to 9 days, but the PN admixture must be stored under refrigeration at 36° to 46° F until use.

22. **The answer is B** *[see VI.A]*.
    When PN is compounded using powdered amino acids, it is classified as a "high-level" CSP because its preparation involves the use of nonsterile ingredients and carries the highest risk for contamination by microbial, chemical, or physical matter.

23. **The answer is A** *[see VI.B]*.
    The pH of the PN solutions is determined primarily by the concentration and type (brand) of amino acids. PN solutions containing higher concentrations of amino acids have a lower pH that allows for greater solubility of calcium and phosphate. The type (brand) of amino acid solutions commercially available differ in their pH.

24. **The answer is C** *[see VI.B]*.
    Dibasic calcium phosphate is very insoluble, whereas monobasic calcium phosphate is relatively soluble.

53 Immunosuppressive Agents in Organ Transplantation

DAVID I. MIN

I. ORGAN TRANSPLANTATION

A. **Definition.** Replacement of a diseased vital organ with a viable organ from a living or deceased donor. Solid organ transplantation has become the therapy of choice for many patients with end-organ failure (i.e., heart, liver, lung, and kidney disease). However, it generally requires immunosuppression to overcome the immunological barrier between donor and recipient, except in syngeneic (i.e., identical twins) or autologous transplantation.

B. **Classification**

1. **Solid organ transplantation**

   a. **Life-saving transplantation** (e.g., heart, heart–lung, lung, and liver transplantation). There is no alternative life-sustaining method available.

   b. **Non–life-saving transplantation** (i.e., kidney, pancreas, face, hand, and cornea transplantation). There are alternative life-sustaining methods available, such as dialysis or external insulin injection. In these cases, transplantation will improve the patient's quality of life or long-term survival significantly.

2. **Hematopoietic stem cell (bone marrow) transplantation** is used mainly for hematological malignancy or aplastic anemia.

II. GRAFT REJECTION

A. **Transplant immunology** (see *Chapter 56*)

1. **Graft rejection.** The body's immune system recognizes the allograft (transplanted organ) as a foreign antigen, and it initiates the immune response to remove or destroy the transplanted graft. This reaction is called "rejection." The degree of the reaction depends on the genetic similarities or differences between the organ of the donor and the immune system of the recipient.

2. **Histocompatibility.** The antigen determining the compatibility between the donor and the recipient is called a **histocompatibility antigen**, the gene being located on chromosome 6. In many transplants (e.g., bone marrow or kidney transplant), this histocompatibility matching is an important factor for determining the long-term survival of the graft. However, more selective, potent immunosuppression may alleviate the importance of tissue matching between donor and recipient (exception: in hematopoietic stem cell transplantation, the tissue matching is still important).

3. **Other factors.** Another group of substances that also plays an important role is the **ABO blood group system** of red blood cells. The donor and recipient must be ABO-compatible; otherwise, immediate graft destruction occurs. Some patients may have preformed antibody for unspecified donors because of multiple blood transfusions or other reason. In this case, patients may destroy the transplanted organ immediately. To detect the preformed antibody, the recipient's serum will be tested immediately before the transplantation (cross-match).

B. Types of graft rejection

1. **Types of graft rejection according to the time course**
   a. **Hyperacute rejection.** Immediate destruction (within minutes or hours) of the transplant organ by a preformed antibody or complement system. Today, this is extremely rare. It occurs only in an ABO-mismatched organ or a cross-match positive (preformed antibody) organ. There is no adequate treatment available.
   b. **Acute rejection** occurs within a few days to several months after transplantation. It is mediated mainly by T lymphocyte (acute cellular rejection), but occasionally, it is mediated by antibody (antibody-mediated rejection) and this rejection can be reversible by steroids or antibody therapy such as muromonab/CD3 or antithymocyte globulin (acute cellular rejection) or intravenous immunoglobulin (IVIG; antibody-mediated rejection).
   c. **Chronic rejection** occurs several months to several years after transplantation. The exact mechanism of this reaction is unknown, but it is thought to be mediated by B lymphocyte (antibody), and there is no adequate treatment available.

2. **Graft versus host**, **host versus graft.** In most solid organ transplants, rejection occurs as the host immune system rejects or attacks the transplant organ (host vs. graft). However, in hematopoietic stem cell (bone marrow) transplant, the host is generally immune deficient and the transplanted graft is immune competent and attacks host tissues (graft vs. host).

III. PROPHYLAXIS AND TREATMENT OF GRAFT REJECTION (*Table 53-1*)

A. Calcineurin inhibitors

1. **Cyclosporine (Neoral®, Sandimmune®, Gengraf®, others)**
   a. **Mechanism of action.** Cyclosporine binds an intracellular receptor, cyclophilin. This complex inhibits calcineurin, an intracellular phosphatase that involves activation of the promoter region for the gene-encoding cytokine, such as interleukin-2. This results in inhibiting T-cell activation in the early stage of immune response to a foreign antigen such as a graft.
   b. **Dosing and monitoring.** Cyclosporine pharmacokinetics is unpredictable, and many factors such as age, time after transplant, different oral formulation (Neoral® or Sandimmune®), or drugs affect it. Oral bioavailability is about 30%. Generally, 8 mg/kg/day of oral cyclosporine as two divided doses is used in solid organ transplantation and adjusted according to the blood levels. Serum creatinine should be monitored with the blood levels of cyclosporine. The blood levels are useful in the clinical monitoring.
   c. **Side effects. Nephrotoxicity** is the major side effect. Neurotoxicity and hepatotoxicity are also common. Hirsutism and gingival hyperplasia are also cumbersome side effects. Numerous drug interactions have been reported (*Table 53-2*).

2. **Tacrolimus (Prograf®, and generics)**
   a. **Mechanism of action.** It is very similar to cyclosporine (*III.A.1.a*).
   b. **Dosing and monitoring.** Tacrolimus pharmacokinetics is also variable, and oral bioavailability is about 25%. Blood levels are useful in clinical monitoring.
   c. **Side effects. Nephrotoxicity** is the major side effect. Neurotoxicity and posttransplant diabetes are more common than with cyclosporine. Hair loss is also a common side effect.

B. Antimetabolites

1. **Azathioprine (Imuran®)**
   a. **Mechanism of action.** It is converted to 6-mercaptopurine in the body and is a non-specific purine synthesis inhibitor. It interferes with DNA and RNA synthesis so that it may reduce both cell-mediated and humoral immune responses.
   b. **Dosage and monitoring.** An initial dose of 3 to 5 mg/kg/day is administered preoperatively. Immediately after transplantation, the dose is usually tapered to a maintenance dose of 1 to 3 mg/kg/day or titrated to the patient's white blood cell (WBC) count. The WBC count is generally maintained greater than 3000/mm³.
   c. **Side effects. Bone marrow suppression** (leukopenia, thrombocytopenia) is the major side effect. In addition, a xanthine oxidase inhibitor, allopurinol, inhibits azathioprine metabolism. When these drugs are used concurrently, the azathioprine dose should be reduced by 80%. Otherwise, the patient may develop severe leukopenia due to azathioprine overdose.

Table 53-1 CURRENT IMMUNOSUPPRESSIVE AGENTS USED IN ORGAN TRANSPLANTATION

Classification	Drug	Usual Initial Dose	Major Side Effects	Monitoring
Calcineurin inhibitors	Cyclosporine (Neoral, Sandimmune, Gengraf)	10 mg/kg/day	Nephrotoxicity	Blood concentrations and serum creatinine concentrations monitoring
	Tacrolimus (Prograf and others)	0.1–0.3 mg/kg/day	Neurotoxicity	
Antimetabolites	Azathioprine (Imuran)	1.5–3.0 mg/kg/day	Bone marrow suppression	WBC count monitoring
	Mycophenolate mofetil (CellCept)	1 g twice daily	Bone marrow suppression and GI side effects	WBC monitoring and GI symptoms
	Mycophenolate sodium (Myfortic)	720 mg twice daily	Same as above	Same as above
	Methotrexate	15 mg/m^2 on day 1; 10 mg/m^2/day on days 3, 6, and 11	Same as above	Same as above
mTOR inhibitor	Sirolimus (Rapamune)	6–15 mg loading dose and 2–5 mg once daily	Hyperlipidemia, leukopenia, and thrombocytopenia	Blood trough concentrations and WBC, platelet, and lipid profile monitoring
	Everolimus (Zortress)	0.75 mg twice daily	Same as above	Blood trough concentrations and WBC, platelet, and lipid profile monitoring
Alkylating agent	Cyclophosphamide (various)	3–4 mg/kg/day for 4 days, followed by reduction to 1 mg/kg/day for treatment of rejection	Hemorrhagic cystitis	WBC count
Antibody products	Thymoglobulin	1.5 mg/kg/day for 7–14 days	Leukopenia and thrombocytopenia	T-cell count
	Antithymocyte globulin (Atgam)	15–20 mg/kg/day for 7–14 days	Same as above	Same as above
	Basiliximab (Simulect)	For adults, two doses of 20 mg each (day 0 and day 4)	No significant side effects reported	No special monitoring required
Corticosteroids	Prednisone (Deltasone or others) or methylprednisolone (Solumedrol)	500 mg IV on the day of surgery and rapidly tapering to 10 mg daily at 1 month	Fluid retention, psychosis, cataracts, osteonecrosis	Signs and symptoms

GI, gastrointestinal; IV, intravenous; mTOR, mammalian target of rapamycin; WBC, white blood cell.

Table 53-2	MAJOR DRUG INTERACTIONS OF CYCLOSPORINE, TACROLIMUS, SIROLIMUS, OR EVEROLIMUS WITH OTHER DRUGS AND THEIR MANAGEMENT

Drugs	Mechanism	Effects	Management
Antiepileptic drugs Phenytoin Phenobarbital Carbamazepine	Increased metabolism by inducing cytochrome P450 enzyme	Cyclosporine or tacrolimus trough levels drop within 48 hrs after initiation of these drugs	Increase cyclosporine dose or tacrolimus with frequent monitoring of blood levels
Rifampin or isoniazid	Same as above	Same as above	Same as above
Azole antifungal agents Ketoconazole Fluconazole Itraconazole	Inhibition of liver cytochrome P450 enzyme by these drugs	Significant increase of cyclosporine or tacrolimus levels	Reduce cyclosporine or tacrolimus dose with frequent monitoring of levels
Macrolide antibiotics Erythromycin	Inhibition of liver and GI cytochrome P450 enzyme	Increase AUC ($\times$ 2) and cyclosporine or tacrolimus trough levels ($\times$ 2–3)	Same as above
Calcium-channel blockers Verapamil Diltiazem Nicardipine	Same as above	Same as above	Reduce cyclosporine or tacrolimus dose or use nifedipine, isradipine
Antiviral agents Indinavir Ritonavir Saquinavir	Same as above	Same as above	Reduce cyclosporine or tacrolimus dose or use nifedipine, isradipine
Grapefruit juice	Inhibition of GI cytochrome P450 enzyme	Increase AUC and peak concentrations of cyclosporine and possibly tacrolimus and increase variability of blood levels	Avoid grapefruit juice

AUC, area under the curve, *G.I.,* gastrointestinal.

2. **Mycophenolic acid (CellCept® and generics, Myfortic®)**
   a. **Mechanism of action.** Two forms are available. Mycophenolate mofetil (CellCept®) is a pro-drug that is converted to mycophenolic acid in the body, which is the active form. Myfortic® is an enteric formulation of mycophenolic acid. In the body, mycophenolic acid inhibits *de novo* purine synthesis pathway by inhibiting inosine monophosphate dehydrogenase. As a result, it inhibits DNA and RNA synthesis in immune cells such as lymphocytes.
   b. **Dosing and monitoring.** A dose of 2 g/day (CellCept®) or 1440 mg/day (Myfortic®) is administered as two divided doses. The WBC and GI symptoms should be monitored.
   c. **Side effects. Bone marrow suppression** (leukopenia, thrombocytopenia) is the major side effect, as in azathioprine. In addition, GI side effects such as nausea, gastric pain, or diarrhea are more common than with azathioprine.
3. **Methotrexate.** This agent is used mainly in autoimmune disease and preventing graft versus host disease in hematopoietic stem cell transplant patients.
   a. **Mechanism of action.** It prevents dihydrofolic acid from converting to tetrahydrofolic acid by inhibiting the enzyme dihydrofolate reductase. As a result, DNA and protein synthesis are inhibited.
   b. **Dosing and monitoring.** Dosage regimens in BMT patients usually consist of 15 mg/m^2/day on day 1 after transplant and 10 mg/m^2/day on days 3, 6, and 11 with other agents such as cyclosporine.
   c. **Side effects. Bone marrow suppression** (leukopenia, thrombocytopenia) is the major side effect as in azathioprine. In addition, diarrhea and mucositis are common.
C. **mTOR (mammarian Target of Rapamycin) inhibitors** are specific for inhibiting a kinase called mammarian target of rapamycin, resulting in halting cell proliferation.
   1. **Sirolimus (Rapamune®)**
      a. **Mechanism of action.** Sirolimus binds intracellular receptor, FKBP-12 (FK binding protein-12). This complex inhibits the mTOR, which is a key regulatory kinase. This results

in inhibiting T-cell activation in a later stage of immune response to foreign antigens, such as a graft.

    b. Dosing and monitoring. A dose of 2 to 10 mg/day is administered as a once-daily dose. Usually, a loading dose of 6 to 15 mg with a maintenance dose of 2 to 5 mg once daily is used. Blood levels are useful in clinical monitoring. The serum lipid profile, WBC count, and GI symptoms should be monitored.

    c. Side effects. Hyperlipidemia is the major side effect. In addition, leukopenia, thrombocytopenia, and GI side effects are common.

  2. Everolimus (Zortress®)

    a. Mechanism of action. Similar to sirolimus, but it has a short half-life.

    b. Dosing and monitoring. A dose of 1.5 mg/day is administered as two divided doses. Usually, without loading dose, 0.75 mg twice daily is given and after 4 to 5 days, the dose should be adjusted according to the blood levels. Blood levels are useful in clinical monitoring and 3 to 8 ng/mL of trough level is a therapeutic target. The serum lipid profile, WBC count, and GI symptoms should be monitored.

    c. Side effects. Hyperlipidemia is the major side effect. In addition, anemia, leukopenia, thrombocytopenia, and GI side effects are common.

D. Alkylating agent. Cyclophosphamide is the alkylating agent mainly used for hematopoietic stem cell transplant patients. Rarely, it is used as a substitute agent for azathioprine in solid organ transplantation.

  1. Mechanism of action. It is converted to the active metabolite, phosphoramide mustard in the liver, which inhibits the cross-linking of DNA, leading to cell death.

  2. Dosing and monitoring. Doses of cyclophosphamide up to 3 to 4 mg/kg/day for 4 days followed by a reduction to 1 mg/kg/day to treat graft rejection. The dosage should be titrated to maintain a WBC count greater than 4000/mm^3.

  3. Side effects. Hemorrhagic cystitis and **bone marrow suppression** (leukopenia, thrombocytopenia). In addition, nausea, vomiting, and diarrhea are common.

E. Antibody products

  1. Antithymocyte globulin (Thymoglobulin®, Atgam®)

    a. Mechanism of action. It is a purified polyclonal immunoglobulin from rabbits (Thymoglobulin®) or horses (Atgam®) that binds to the human T cells. However, it may have cross-reactivity against the red blood cells, platelets, and granulocytes.

    b. Dosing and monitoring. The dosage is 1.5 mg/kg (Thymoglobulin®) or 15 to 20 mg/kg (Atgam®) infusion daily through a central line for 7 to 14 days for prevention or treatment of rejection. The T-lymphocyte counts are monitored and maintained less than 100/mm^3. Generally, premedications such as acetaminophen, diphenhydramine, and corticosteroid are required to reduce the infusion-related side effects (e.g., fever, chills). For the infusion of these drugs, the central venous line is a preferred route, rather than a peripheral vein.

    c. Side effects. Antithymocyte globulin may cause fever, chills, erythema, leukopenia, thrombocytopenia, and anaphylactic reaction or serum sickness.

  2. Basiliximab (Simulect®)

    a. Mechanism of action. It is a chimeric (murine/human) monoclonal antibody (IgG1), produced by recombinant DNA technology, that binds to block the interleukin-2 receptor on the surface of activated T lymphocytes, and as a result, it prevents T-lymphocyte activation, thus preventing acute rejections.

    b. Dosing and monitoring. It is indicated only for the prevention of acute rejection. The usual recommended dosage for the adult patient is two doses of 20 mg each at day 0 and day 4 after kidney transplantation. No special monitoring is required.

    c. Side effects. Based on results of clinical trials, no cytokine release syndromes have been noticed.

  3. Other antibody agents

    Alemtuzumab (Campath®) or rituximab (Rituxan®) are indicated for hematologic malignancy and not approved for the organ transplantation, but are occasionally used in the organ transplantation for prevention of acute rejection or intractable antibody-mediated rejection.

F. Corticosteroids. Prednisone (Deltasone®) and **methylprednisolone** (Solumedrol®) are the major corticosteroid products used for transplant patients.

  1. Mechanisms of action. Corticosteroids have multiple pharmacological effects in various cells. Corticosteroids bind with intracellular glucocorticoid receptors, which results in altering DNA

and RNA translation. As a result, corticosteroids cause a rapid and profound drop in circulating T lymphocytes. They have potent anti-inflammatory effects by inhibiting arachidonic acid release and macrophage phagocytosis.

2. **Dosing and monitoring.** They are used in both preventing and treating graft rejection and acute graft versus host disease. In general, prophylactic doses in solid organ transplantation are in the range of 1 to 2 mg/kg/day and tapered over months to 0.1 to 0.3 mg/kg/day. In the case of treatment, the dosage is 500 mg of methylprednisolone IV for 3 to 5 days or 1 to 2 mg/kg/day of oral prednisone, which should be tapered rapidly.

3. **Side effects.** In the long-term, corticosteroids cause more troubling side effects. They include psychological disturbances (i.e., euphoria, depression), adrenal axis suppression, hypertension, sodium and water retention, myopathy, impaired wound healing, increased appetite, osteoporosis, hyperglycemia, and cataracts.

IV. COMPLICATIONS OF IMMUNOSUPPRESSION

A. **Infections**

1. **Risk.** Transplant patients have a high risk of acquiring an infection due to patient factors such as diabetes mellitus, hepatitis, or uremia. In addition, immunosuppressive agents can cause various effects, such as leukopenia, lymphopenia, or T-cell dysfunction, that inhibit adequate immune response to the infection.

2. **Time course.** The risk of infection is greatest during the first 3 months after transplantation, when higher doses of immunosuppression are used, and again after a rejection episode is treated. This risk correlates with the overall level of immunosuppression.

3. **Types of infections** include bacterial, fungal, viral, and protozoan.

4. **Prevention**

   a. **Trimethoprim-sulfamethoxazole** (Bactrim® and others). One single- or double-strength tablet daily for 6 months significantly reduces *Pneumocystis carinii* pneumonia and bacterial urinary tract infection. After 6 months, three times a week is effective.

   b. **Herpes and cytomegalovirus (CMV) infection.** Oral acyclovir (200 mg b.i.d. for normal renal function, with doses adjusted according to renal function) for herpes prophylaxis. For CMV prophylaxis, various prophylaxes can be used. High doses of acyclovir (800 mg q.i.d for normal renal function, with doses adjusted according to renal function), valganciclovir (Valcyte®) 450 mg to 900 mg daily, or high-titer CMV immunoglobulin are effective in reducing the incidence of CMV infection and invasive CMV disease.

   c. **Polyoma virus infection.** In kidney transplant patients, polyoma virus infections such as BK virus nephropathy can be an important cause of kidney dysfunction or graft loss after transplantation. In many cases, reactivation of polyomavirus after transplantation causes kidney dysfunction and reduction of immunosuppression and leflunomide (Arava®) therapy shows some effectiveness.

   d. **Nystatin solution**, **clotrimazole troche**, **or fluconazole** reduces oral candidiasis (thrush).

B. **Increased risk of malignancy**

1. **Cause.** Continuous immunosuppression interferes with normal immune surveillance and function for malignancy. In addition, some of the immunosuppressive drugs may be directly carcinogenic or activate oncogenic virus, such as Epstein–Barr virus (EBV).

2. **Characteristics.** Cancers that occur most frequently in the general population (e.g., lung, breast, colon) are not increased among transplant patients. However, various cancers uncommon in the general population are often more prevalent in transplant patients: lymphomas, squamous cell carcinomas of the lip and skin, Kaposi's sarcoma, and other sarcoma.

3. **Posttransplant lymphoproliferative diseases (PTLDs).** The incidence of lymphoma appears to correlate with the intensity of immunosuppression. It is especially well documented that T-cell specific agents, including OKT3, cyclosporine, and tacrolimus, increase the incidence of lymphoproliferative diseases.

4. **Treatment.** In case of nonvital organ transplant, immunosuppression should be reduced or stopped. If EBV-related lymphoma occurs, acyclovir or ganciclovir therapy appears to be effective; the B-cell–specific monoclonal antibody, rituximab (Rituxan®), is also used.

C. Hypertension. Many immunosuppressive agents cause hypertension. Cyclosporine and tacrolimus clearly increase the arterial blood pressure, and steroids may exacerbate hypertension after transplantation from fluid and sodium retention. Treatment usually requires the use of multiple agents, including diuretics and calcium-channel blockers.

D. Posttransplant diabetes mellitus. Many immunosuppressive agents increase blood glucose levels. Corticosteroids, cyclosporine, and tacrolimus increase blood glucose. Some patients develop a new onset of diabetes after transplantation, which increases morbidity and mortality and reduces graft and patient survivals. Careful monitoring of blood glucose and patient counseling are essential.

Study Questions

Directions: Each of the numbered items 1–6 is based on the case. The remaining questions (7–10) are based on the statement, not based on the case. Select the **one** lettered answer or completion that is **best** in each question.

Case: A 28-year-old white female patient was admitted to the hospital for a kidney transplant from a deceased donor who had died 12 hrs earlier. She had a history of type I diabetes mellitus since 8 years old. She started chronic hemodialysis 2 years ago. She was blood typed and the final cross-match was negative. She underwent a successful renal transplant.

Lab at admission: Na 130 mEq/L (135–145), K 5.1 mEq/L (3.5–5.0), Cl 99 mEq/L (98–110), CO_2 18 mEq/L (22–28), Cr 9.5 mg/dL (0.8–1.2), BUN 65 mg/dL (5–15), hemoglobin 9.5 gm/dL (13–15), and glucose 185 mg/dL (60–100).

Virus serology: CMV and EBV titer negative and donor positive for CMV and EBV, Hepatitis A, B, & C serology negative.

Vital signs: BP 150/90 mm Hg, pulse 65/min, RR 12/min, Temp. 98.6°F.

Physical exam: Pale, slightly edematous.

Allergy: no known allergy

Medications on admission: Human NPH/regular insulin, 35/10 units in the morning and 10/5 units in the evening; calcium carbonate 1250 mg t.i.d., calcitriol 0.5 mcg orally daily, enalapril 5 mg b.i.d., metoclopramide 10 mg q.i.d., and erythropoietin 10,000 units sq per week

1. The patient received Simulect® with cyclosporine, mycophenolate, and prednisone. The nurse asked about Simulect®. Which of the following is an appropriate response?

(A) Simulect® is useful, but patient's weight gain should be less than 3% from the dry weight before therapy.

(B) Simulect® is useful agent to treat rejection, but chest x-ray and monitoring of patient's fluid status are required before this therapy.

(C) Simulect® is a chimeric IgG with specificity against IL-2 receptor, and it is useful for prevention acute cellular rejection.

(D) Simulect® is a humanized IgG product against IL-2 receptor, and it is useful in preventing acute humeral rejection.

(E) Simulect® is a rabbit serum against human T cells, and it is useful for prevention and treatment of rejection.

2. On day 7, her serum creatinine was 1.4 mg/dL and BUN 28 mg/dL. Her urine output was excellent and her blood cyclosporine level was 250 ng/mL (200–300). She was discharged to her home. Several days later, she developed a worsening hypertension of 170/105 mm Hg. Which of the following medication(s) she is taking worsened her hypertension?

I. Cyclosporine
II. Prednisone
III. Mycophenolate

(A) **I** only
(B) **III** only
(C) **I** and **II**
(D) **II** and **III**
(E) **I**, **II**, and **III**

3. Due to her worsening hypertension, her local physician wants to start Cardizem® CD 240 mg daily. What is your advice for this hypertension therapy?

   (A) Cardizem® CD will decrease cyclosporine metabolism, so please reduce the cyclosporine dose by 25% and check cyclosporine level twice a week.
   (B) Cardizem® CD will decrease cyclosporine metabolism, so please increase cyclosporine dose by 25% and check cyclosporine level twice a week.
   (C) Cardizem® CD will increase cyclosporine metabolism, so please switch cyclosporine to tacrolimus.
   (D) Cardizem® CD will decrease cyclosporine metabolism, so please switch cyclosporine to tacrolimus.
   (E) Cardizem® CD will increase cyclosporine metabolism, so please switch cyclosporine to azathioprine.

4. Which of the following is most appropriate regarding prophylactic regimen for her infections?

   I. Co-trimoxazole s.s. daily for PCP prophylaxis
   II. Nystatin for prophylaxis of fungal infection
   III. Valcyte® for CMV disease

   (A) **I** only
   (B) **III** only
   (C) **I** and **II**
   (D) **II** and **III**
   (E) **I**, **II**, **and III**

5. Which of the following is correct regarding Myfortic®?

   I. It is an enteric-coated formulation of mycophenolic acid.
   II. Its major side effect is leukopenia.
   III. It causes severe hyperlipidemia.

   (A) **I** only
   (B) **III** only
   (C) **I** and **II**
   (D) **II** and **III**
   (E) **I**, **II**, and **III**

6. The patient's urine output decreased, her creatinine rose to 2.2 mg/dL (baseline: 1.4 mg/dL) and her feet had +2 edema. Her cyclosporine dose was 150 mg twice daily and her trough level was 450 ng/mL (200 to 300). She felt shaky and subsequent physical exam revealed a mild hand tremor. Acute rejection was ruled out by kidney biopsy. Which of the following is the appropriate adjustment of her immunosuppression?

   (A) Increase cyclosporine dose to 175 mg b.i.d. and prednisone 10 mg q.d.
   (B) Reduce cyclosporine dose to 125 mg b.i.d. and monitor cyclosporine trough level.
   (C) Increase prednisone from 10 mg to 20 mg daily.
   (D) Switch cyclosporine to tacrolimus.
   (E) Stop cyclosporine and start thymoglobulin.

   End of the case

7. A 38-year-old woman came to your clinic and complained of hair loss and did not want to take an immunosuppressant anymore. Which of the following is an appropriate advice for her problem?

   (A) Switch mycophenolate mofetil to sirolimus
   (B) Stop her prednisone and add methylprednisolone
   (C) Switch her tacrolimus to cyclosporine
   (D) Switch her mycophenolate mofetil to Myfortic
   (E) Add azathioprine to her regimen

8. Which of the following is *not* a side effect of corticosteroid therapy?

   (A) Osteoporosis
   (B) Leukopenia
   (C) Moon faces
   (D) Poor wound healing
   (E) Hypercalcemia

9. Which of the following is likely to decrease tacrolimus blood concentration when it is used concomitantly?

   (A) Grapefruit juice
   (B) Erythromycin
   (C) St. John's wort
   (D) Voriconazole
   (E) Verapamil

Answers and Explanations

1. **The answer is C** *[see III.E.2]*.
   Simulect® (basiliximab) is a chimeric monoclonal antibody against the Interleukin-2 receptor. This drug can be used as prevention of an acute cellular rejection. The dose for rejection treatment is 20 mg on day 0 and day 4. It occasionally causes mild fever, but it does not cause any serious side effects. (A) Orthoclone (OK3) requires < 3% weight gain. (B) Simulect® does not require for monitoring fluid status by x-ray. (D) Simulect® does not prevent acute humeral rejection. (E) Simulect® is used only for prevention of rejection, not for the treatment of rejection.

2. The answer is C *[see III.A.1; III.F]*.

Cyclosporine and prednisone increase the blood pressure. Cyclosporine (Neoral®) promotes the vasoconstriction and causes renal dysfunction, which contributes to hypertension. Prednisone (Deltasone®) increases fluid and sodium retention, which contributes to hypertension. Mycophenolate mofetil (CellCept®) is an antimetabolite inhibiting DNA synthesis and cell proliferation. Its side effects include leukopenia and thrombocytopenia, and it does not cause hypertension.

3. The answer is C *[see Table 53-2]*.

Cardizem® CD (diltiazem) CD is a cytochrome P450 enzyme inhibitor that decreases cyclosporine metabolism. When cyclosporine is used concurrently with diltiazem, it is necessary to decrease cyclosporine dose by 25% in order to prevent the toxicity. Frequent monitoring of cyclosporine blood levels and the cyclosporine dose adjustment should be made based on the blood levels.

4. The answer is E *[see IV.A]*.

All of these drugs are required for posttransplant infection prophylaxis. Co-trimoxazole (Bactrim) single strength (s.s.) once daily for pneumonitis jirovecci, nystatin 5 mL swish and swallow four times daily for fungal infection, and valganciclovir (Valcyte) 450 to 900 mg daily for CMV are important prophylactic regimen.

5. The answer is C *[see III.B.2.a]*.

Myfortic® is an enteric-coated formulation of mycophenolate sodium that inhibits inosine monophosphate dehydrogenase. Its major side effects include gastrointestinal side effects (e.g., nausea, vomiting, or diarrhea) and leukopenia. It does not cause hyperlipidemia, but sirolimus does.

6. The answer is B *[see III.A.1]*.

This is a typical symptom of cyclosporine toxicity, which is confirmed by her high blood level (therapeutic level, 200 to 300 ng/mL) with tremor, acute renal dysfunction (serum creatinine 2.2 mg/dL from baseline 1.4 mg/dL), and +2 edema. The dose of cyclosporine should be reduced by 25 mg (There are 25 mg and 100 mg capsules), and the blood levels as well as signs and symptoms should be closely monitored.

7. The answer is C *[see III.A.2]*.

Tacrolimus causes alopecia (hair loss) and cyclosporine causes hirsutism.

8. The answer is E *[see III.F]*.

All of the above are side effects of corticosteroid therapy except hypercalcemia. The corticosteroid use causes calcium loss by kidney resulting in hypocalcemia.

9. The answer is C *[see Table 53-2]*.

All of the above except St. John's wort are CYP3A inhibitors, which increase tacrolimus blood concentrations. St. John's wort is a CYP3A inducer, which decreases tacrolimus levels.

Outcomes Research and Pharmacoeconomics

ALAN H. MUTNICK

I. GENERAL CONCEPTS

A. **Outcomes research (OR)** is used to describe the study of health care interventions (treatment modalities such as drug therapies, surgery, and palliative therapy), care delivery processes, and health care quality that are evaluated to measure the extent to which optimal and desirable outcomes can be reached. Generally speaking, OR is research: it evaluates effectiveness as compared to efficacy; utilizes observational studies that balance generalizability with confounding/bias; is used to supplement rather than replace randomized, controlled clinical trials; and is more extensive than "pharmacoeconomics."

1. The **Economic**, **Clinical**, **Humanistic Outcome (ECHO) model** provides a framework for comprehensive evaluation of outcomes. Three areas of outcomes identified by Kozma and Reeder (1998) are economic outcomes, clinical outcomes, and humanistic outcomes.

2. **Outcomes research methodologies** include retrospective chart review, prospective clinical trials, meta-analysis, observational studies, and computer modeling studies.

3. **Examples of outcomes measures**

a. **Economic outcomes** include acquisition costs associated with care, labor costs associated with care, costs to treat adverse drug reactions, costs of treatment failure, costs of hospital readmission, and costs of emergency room and clinic visits.

b. **Clinical outcomes** include length of hospital stay, adverse drug reactions, hospital readmission costs, emergency room/clinic costs, and death.

c. **Humanistic outcomes** include patient satisfaction, functional status as measured by a validated instrument, and quality-of-life assessment.

B. **Pharmacoeconomics (PE)**, a division of health economics, is designed to provide decision makers with information about the value of the different pharmacotherapies. Pharmacoeconomics balances the costs with the consequences or outcomes of pharmaceutical therapies and services.

II. COST

A. **Definitions**

1. **Total cost.** All expenses directly and indirectly necessary to provide a product or service

2. **Average cost.** The average cost per unit of output (total cost divided by quantity)

3. **Fixed cost.** Costs that do not vary with the quantity of output for a short-run production (e.g., rent, fixtures, fixed salary, depreciation, administrative costs)

4. **Variable cost.** Costs that vary with the level of output (e.g., wages, supplies)

5. **Marginal cost.** The extra cost of producing *one extra* unit of output

6. **Incremental cost.** Additional costs when comparing one alternative to another

7. **Direct cost.** Costs directly related to producing/providing a specific quantity of services or output (e.g., salary, drug cost, supply cost for the provision of pharmacy services)

8. **Indirect cost.** Costs that are allocated to the area(s) that produce/provide a specific quantity of services or output (e.g., overhead cost)

9. **Allowable cost.** A cost that is eligible to claim for purposes of reimbursement as necessary and relevant to the delivery of a unit of output

10. **Opportunity cost.** The cost of the benefit of pursuing an alternative course of action

11. **Operating cost.** Any cost that supports the operations to provide the output

B. **Cost and charge**

1. The meaning of the term *cost* depends on the perspective for the analysis. The following examples show differing perspectives.

2. Providers may include hospitals, physician offices, or ambulatory surgery centers, and the term *cost* means the total costs for providing the specific service(s).

3. Payors may include third-party providers such as insurance companies, Medicare, or Medicaid, and the term *cost* means the price that they have to pay to obtain the service (i.e., charges by providers).

4. Charges do not equal the payment to providers. Depending on the contractual terms, many providers receive only a percentage of the charges for payment. These are called discounted charges. Many providers today receive a lump-sum amount of dollars for each episode of care, for example, diagnosis-related groups (DRGs) or case rate payment. This may also apply to both inpatient and outpatient treatments.

5. During recent years, reimbursement for various health-related services have transitioned from the more traditional "fee for service" to a more "prospective reimbursement" process, where rates are established through contracts prior to patients needing such services. This change has resulted in the need to minimize additional consequences of health care services because reimbursement is not necessarily increased due to such consequences, and providers may actually be rewarded financially for "improvements" of the quality of services being provided.

6. Contractual terms are rarely reviewed and vary with different insurance carriers. This creates additional confusion as to the costs associated for various services or therapies.

7. A recognizable way to resolve these hurdles is to use the cost to charge (RCC) ratio for the cost estimation. Multiply the RCC by the patient's charge to yield the estimated cost. RCC can be obtained from the individual hospital's Centers for Medicare and Medicaid Services (CMS) yearly cost report.

C. **Basic steps in assessing cost**

1. Define the units of service or output
2. Determine the number of service or output units provided
3. Determine cost drivers of these units of service or output
4. Calculate total costs, direct or indirect, related to the provision of this output or service
5. Calculate the average cost and incremental cost

III. ELEMENTS OF A GOOD STUDY

A. **Sound objective(s).** The study has well-defined objective(s) and answerable question(s).

B. **Perspective(s).** There is a defined perspective for analysis (e.g., patient, payer, provider, society). In many cases, study perspective determines the cost-effectiveness of an intervention. Most of the published PE guidelines suggest that societal perspective be considered as an additional perspective for analysis.

C. **Patient population** chosen must be within the scope of analysis. Patient selection criteria that are too stringent pose a threat to external validity. Patient selection criteria that are too liberal are a threat to internal validity. Consideration is also given to comorbidity and multiple treatment modalities.

D. **Possible comparators and their effectiveness.** All relevant alternatives for comparison are identified. Chosen comparator(s) should be reasonable and is the current preferred standard treatment. In some instances, no treatment (placebo) is considered as an alternative.

E. **Metrics for costs and consequences.** Measures chosen for costs and consequences can affect the results of the analysis. Biases can be introduced into the analysis if units of measures are not clearly defined. This may pose a problem with a multi country study in the aggregation of the final costs and consequences because currency exchange rates may fluctuate from time to time.

F. **Inclusion of relevant costs and consequences in the analysis** are based on the perspective chosen. The computation of costs and consequences should be transparent to readers. The key is reproducibility. Readers should be able to use the published computation methods with the local data to validate the findings.

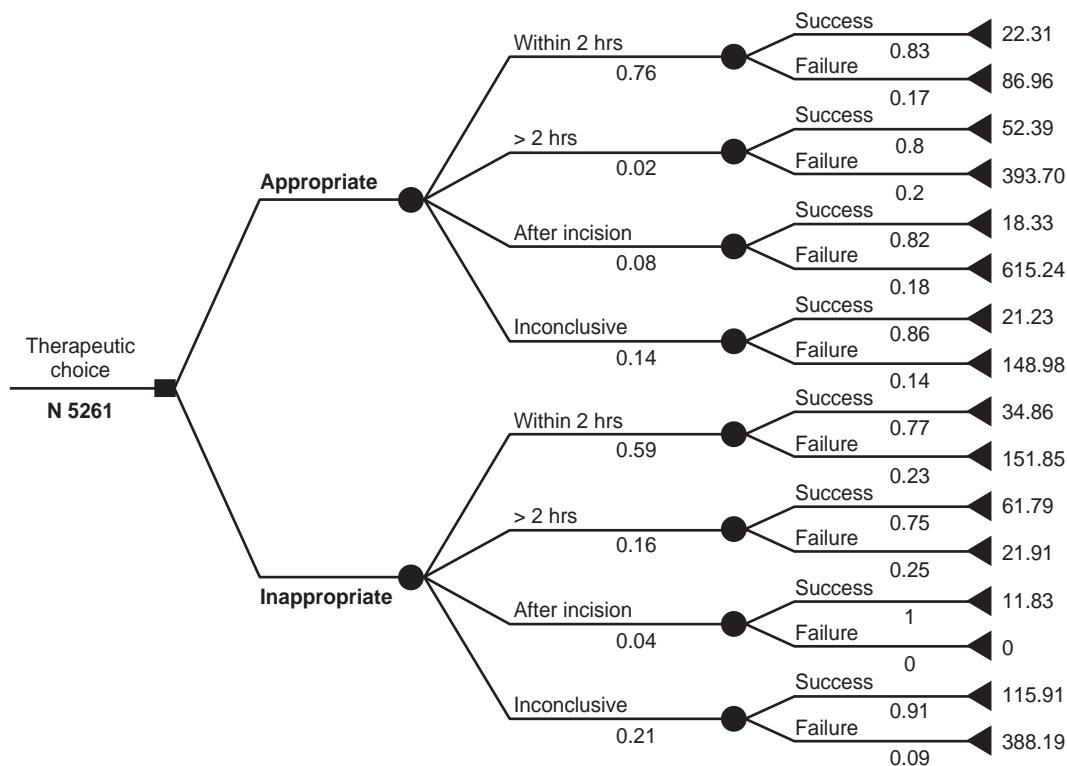
G. **A valid data source.** Depending on the design of the study, data can come from clinical trials, observational studies, health care claim databases, chart reviews, and epidemiological data. Each of the sources of these data was designed for some other purpose than economic analysis. Limitations are listed in VIII.

H. **Discounting for costs and consequences.** Much discussion has been devoted to the appropriateness of discounting costs and consequences as well as the discount rate. The consensus at this time is to discount both costs and consequences. The discount rate normally is the opportunity cost of using resources. Many researchers have used the government bond rate. Regardless, the researcher must offer the justification for the chosen discount rate(s).

I. **Incremental analysis** provides an insight on the comparison for cost generated from one alternative to another alternative, and the additional benefit yielded from the increased cost.

J. **Sensitivity analysis** should include all the plausible values and their justification for the key parameters.

K. **Time horizon of the analysis** covers the full duration of treatment for the disease process. For example, the time horizon for the cholesterol-lowering agent's treatment should be the life span from the start day of treatment to the end of life.

L. **Appropriateness and comprehensiveness of presentation and discussion of the study results.** Similar to clinical studies, the presentation of study results should not be biased. Interventional alternatives and study limitations must be addressed. Generalizability and applicability are also discussed.


IV. PHARMACOECONOMIC METHODOLOGIES

A. **Cost of illness (COI)** is the evaluation and assessment of the resources used in treating an illness. This technique is used to obtain the baseline cost information before the introduction of a new intervention. Costs are measured in terms of dollars. Like any PE analysis, the evaluator needs to define the analysis perspective. A different perspective will change the cost structure. For example, from a patient's perspective, the cost of illness will include the transportation to and from the treatment site. Time duration of the disease can be critical in determining the cost and may be a source of bias. No comparison is made in this type of analysis.

B. **Cost-benefit analysis (CBA)** is a tool used to determine priority for the resource allocation. The technique can be applied to the comparison of health care programs and with non-health care programs, such as social welfare programs. For example, one can compare the costs and benefits of a coronary risk factor reduction program and the childhood immunization program and the domestic violence prevention program. This technique consists of identifying all of the benefits that accrue from the program and converting them into dollars in the year that they accrue. The stream of costs and benefits are then discounted to present value at the selected discount rate. Net benefit is computed for each program and can then be compared with other programs.

C. **Cost-minimization analysis (CMA).** The underlying assumption for this type of analysis assumes that consequences are equivalent. Therefore, only cost is compared. The cheapest intervention will be chosen for implementation. Equivalent outcomes may not necessarily be equal. One needs to determine the key outcome of each comparator. For example, two drugs may have the equivalent therapeutic value but different side effect profiles. In such cases, consequences may not be equivalent, and this technique is not appropriate. CEA should be used instead.

D. **Cost-effectiveness analysis (CEA)** is a technique to assist the decision maker in identifying a preferred choice among possible alternatives within similar consequences (e.g., same therapeutic category) in terms of health improvement created (e.g., life year gained, clinical cures). It is not to be used to compare different consequences for each alternative, such as blood pressure reduction to degree of cholesterol lowering. Consequences can be intermediate outcomes or surrogate outcomes such as the reperfusion time of the vessel after thrombolytic therapy. Generally, the incremental cost of a program or an intervention from a specified perspective is compared to the incremental health effects. An example is the cost per unit of blood pressure reduction with each antihypertensive agent compared. The results of the analysis normally are stated in terms of cost per unit of effectiveness.

E. **Cost-utility analysis (CUA).** Unlike CEA, CUA measures the consequences in terms of the quality-adjusted life year (QALY) gained. The results of the analysis are normally expressed as a cost per QALY. The metric of QALY incorporates both the improvement in quantity of life, quality of life, and the preference (utility value) of the health state. There are three sources of obtaining utility values for health states in CUA: judgment to estimate the utility values, values from the literature, or values elicited from a sample of subjects. Common techniques for eliciting utility values are rating scale (visual analog scale), standard gamble, and time trade-off. Five circumstances have been summarized that detail when CUA may be the appropriate technique to apply.

1. When quality of life is the only outcome
2. When quality and quantity of life are health outcomes
3. When the intervention affects both mortality and morbidity and a combined unit of outcome is desired
4. When the intervention being compared has a wide range of potential outcomes and a common unit of outcome is needed
5. When the objective is to compare a gold standard intervention that already has the cost per QALY. QALY is calculated by multiplying the utility values obtained for the specific health state with the quantity of life years spent in that specific health state. Comparison can then be made for the program and intervention.

F. **Multiattribute utility theory (MAUT) or analysis (MAUA)** is another technique available in assessing utilities. In this situation, several attributes can be included, such as clinical, financial, and quality of life. It is possible to preferentially weigh the decision based on what the priorities are for the decision maker, and then apply the weights to identify the most preferable therapy, service, and so on. As evidenced from the following three examples, the individual's perspective will have a major effect on the final decision made, based on the levels of priority chosen for evaluation.

1. A physician may view clinical outcome to represent 70% of his or her decision, followed by patient's quality of life (20%), and last being therapy costs (10%).
2. A hospital administrator may view the financial outcomes (70%) as a major priority, followed by the clinical outcome (20%), and last, the quality of life (10%).
3. A patient with health insurance might view the clinical outcome (45%) and quality of life (45%) as the top priorities and have minimal concern for the financial outcomes (10%) of such a decision, especially with adequate insurance coverage.

G. **Willingness to pay (WTP)** technique is used to assess the perceived value or benefit of a product and service. The WTP values can be obtained through two approaches:

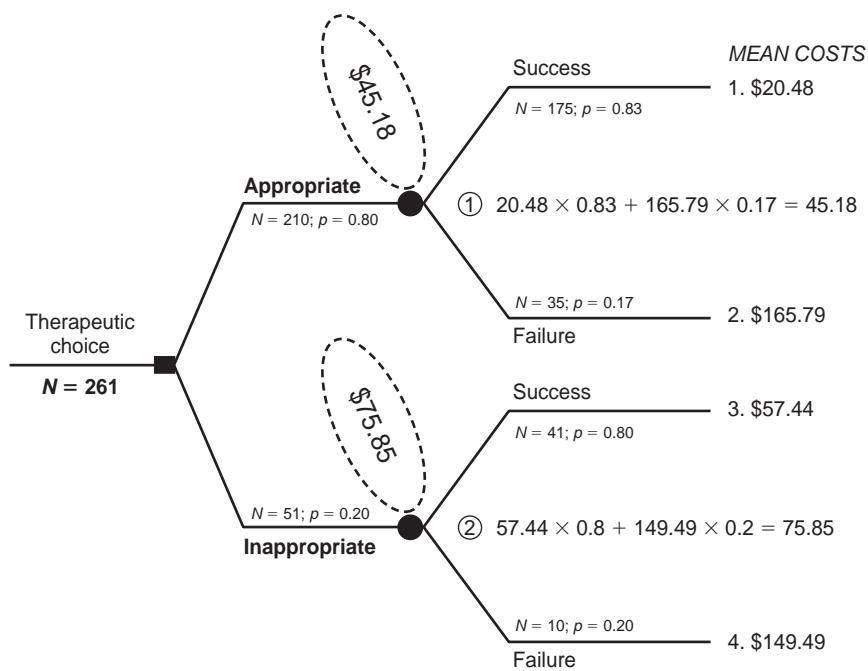
1. Indirect measurement, which examines in actual payments previous real-world decisions that involve trade-offs between money and expected outcomes.
2. Direct measurement, which uses survey methods to elicit stated dollar on the perceived benefits. In this second approach, researchers are seeking to provide sufficient background information to create within the respondent's mind a hypothetical market in which the person provides a judgment of the value of the proposed service.
3. The challenge of using contingent valuation is to present within the questionnaire sufficient, clearly organized information to allow this judgment to occur. Basic facts need to be given at the appropriate time. Unlike CBA, WTP takes into consideration the psychological aspects of the illness as well as the physical deterioration. The use of WTP as an outcome measure is theoretically consistent with welfare economics. It also provides a means to assign dollar values to health outcomes.

V. DECISION ANALYSIS.

Is a systematic approach to decision making under conditions of uncertainty. It is a tool for helping the decision makers identify options that are available, predict the consequences and value of each option based on the probabilities assigned to each option, and choose the option that has the best payoff. Decision analysis can be incorporated into a pharmacoeconomics evaluation. Steps in performing a decision analysis are as follows:

A. **Identify and bound the decision.** All the ground rules such as analysis perspective, comparators selection, time span, and decision rules are identified and clarified.

B. **Develop a decision tree** (*Figure 54-1*). The decision maker will structure the decision in the form of a tree with branches from left to right. Each branch is a segment of a path that leads to an outcome.

Figure 54-1. Decision tree with probabilities included.


The process of setting up the tree helps the decision maker put thoughts on paper and provides an evaluation for each option that occurs.

C. **Assess and assign probabilities.** Probability related to each branch is assessed and assigned. Probabilities can be obtained from the published literature, an expert panel, or clinical trials.

D. **Value outcomes.** For each of the outcome possibilities, assign a value. This can be in the form of monetary or utility values.

E. **Calculate the expected value.** Using the averaging-out and folding-back method, start from the right and work backward to the left, and calculate the expected value by multiplying the outcome value to each assigned probability (*Figure 54-2*).

F. **Choose the preferred course of action.** Depending on the ground rules set in the beginning of either optimization or minimization, choose the best course of action.

G. **Perform a sensitivity analysis.** Assign different values to all plausible outcomes and resolve the decision tree to identify the robustness of the data and/or results.

VI. **PATIENT-REPORTED OUTCOMES (PRO).** PRO refers to any outcomes based on data provided by patient or patient proxy. It includes health-related quality of life data. PRO data can be collected during the clinical trial. Examples of PRO data include patient satisfaction with treatment and providers, functional status, psychosocial well-being, treatment compliance/adherence, and disease symptoms. There is a growing amount of interest in adding PRO data into the drug review and evaluation process.

A. **Health-related quality of life (HRQOL).** Although quality of life focuses on all aspects of life, HRQOL focuses only on a patient's nonclinical information such as functional status, well-being, perception of health, return to work from an illness, and other health outcomes that are directly affect by health status. Standardized questionnaires are used to capture HRQOL data in various research settings. Data are obtained either by telephone interview, self-administration, personal face-to-face interview, observation, or mail-in survey. Such standardized questionnaires can also be divided into general health status instruments—for example, Short-Form 36 (SF-36), Short-Form 12, SF-10 for Children, SF-8 Health Surveys, sickness impact profiles (SIPs)—or disease-specific instrument

Figure 54-2. Completed decision tree after averaging out and folding back.

(e.g., McGill Pain Inventory, Beck Depression Scale, Functional Living Index—Cancer). The general health status instruments measure the global health status, whereas the disease-specific instruments target the disease-specific issues.

B. Short form surveys are the most frequently used general health status instruments. There are a variety of dimensions available, depending on the chosen short form instrument. The original SF-36 includes physical functions, social functions, emotional role, physical role, bodily pain, mental health, general health, and vitality. Other survey instruments may contain only some of these dimensions. Interested readers can explore the following Web site: http://www.qualitymetric.com for more information.

C. At the time of this update, the entire set of rules and regulations of the recently approved, Patient Protection and Affordable Care Act (PPACA) have not been finalized. However, a key aspect of the act besides working to ensure health care for all U.S. citizens is to begin creating a venue where "quality-performing" health care providers and institutions will be able to recapture health care dollars by demonstrating improvements in patient outcomes. This will include patient satisfaction with the services received and quality clinical therapies provided as a way to improve outcomes (β-blockers after myocardial infarctions, correct antibiotics for designated infections, appropriate surgical procedures to minimize negative outcomes, etc.). Health care providers will become incentivized to improve in quality as a way to capture maximal amounts of reimbursements. Bad performances will result in poor reimbursements.

D. Psychometric properties. Before using any instrument, the researcher must understand the psychometric properties of the chosen instrument. The psychometric properties consist of the reliability and validity information of the instrument. In addition, the sensitivity and specificity of the instrument are also important.

1. **Reliability** is a measure of consistency. Can we reproduce the same score under the same conditions with the same individual? Statistical methods of measuring reliability are Cronbach's α, Pearson's r coefficient, and the κ statistic.

2. **Validity** is a measure of accuracy. Is the instrument measuring what it is supposed to measure? Types of validity are content validity, construct validity, criterion validity, and convergent/divergent validity.

3. **Use of the instrument.** The psychometric properties preclude "mixing and matching" sections of established questionnaires or selection of a section of an established questionnaire for administration without recalibrating the instrument's psychometric properties.

VII. MODELING STUDIES. Mathematical modeling is widely used today in the economic evaluation of medications and health care technologies.

A. The goal for modeling is to assemble evidence of costs and outcomes in a form that can project long-term consequences. Model-based evaluations are great tools for health care decision makers.

B. Mathematical models provide the cost-consequence estimates that cannot be revealed by randomized control trials or epidemiological studies because of the duration required for long-term studies (10 to 20 years).

C. Results derived from modeling assist decision makers in making informed decisions. However, the quality of the decision is based completely on the truthfulness of the projected results, which in turn depends on the input information and assumptions imposed for each model.

D. The International Society of Pharmacoeconomics and Outcomes Research (ISPOR) recommends the following criteria for assessing the quality of models: model structure, data used as inputs for the model, and model validation.[1]

VIII. 1997 FDA MODERNIZATION ACT, SECTION 114, HEALTH CARE ECONOMIC INFORMATION

A. "Health care economic information provided to a formulary committee, or other similar entity, in the course of the committee or entity carrying out its responsibilities for the selection of drugs for managed care or other similar organizations, shall not be considered to be false or misleading under this paragraph if the health care economic information directly relates to an indication approved . . . for such drug and is based on competent and reliable scientific evidence." (From the FDA's Modernization Act of 1997, http://www.fda.gov/cder/guidance/s830enr.txt)

B. Health economic information means any analysis that identifies, measures, or compares the economic consequences including the costs of the represented health outcomes, or the use of a drug to the use of another drug, or to another health care intervention, or to no intervention.

C. **Key concepts of the act**
   1. A venue for the pharmaceutical industry to provide OR and/or PE research studies to decision makers
   2. Economic information can be provided in the form of CMA, CBA, CUA, COI, and cost quality of life.
   3. Competent and reliable scientific information pertaining to an approved indication
   4. Standard of competent and reliable scientific information has not been addressed.

IX. PRACTICAL ISSUES IN INTERPRETING OUTCOMES RESEARCH AND PHARMACOECONOMIC STUDIES

A. **Comparisons between economic study and randomized clinical trials (RCTs)**
   1. Economic studies are carried out in an observational environment, whereas RCTs depend on rigorous experimental design with strict inclusion/exclusion criteria.
   2. RCTs rely on highly controlled and artificial clinical settings to demonstrate clinical efficacy. Clinical and economic end points of the study may not be the same. In addition, RCTs tend to have additional protocol costs (e.g., extra tests) and inflated benefits (e.g., medication compliance, appropriateness of utilization).
   3. Economic studies have large sample sizes, whereas RCTs are limited to a relatively small sample size.
   4. Economic studies are generalizable to the broader patient population, whereas RCTs are limited to those included within the stringent entry criteria, which might not represent the typical patient receiving the tested therapy.
   5. Economic studies are usually involved in evaluating "effectiveness" as compared to RCTs, which evaluate "efficacy."

B. **Multiple countries' OR and PE studies**
   1. There are significant differences in physician practice patterns and care delivery systems among different countries.

---

[1]Weinstein MC, O'Brien B, Hornberger J, et al. ISPOR Task Force on Good Research Practices. Principles of good practice for decision analytic modeling in health-care evaluation. *Value Health*. 2003;6(1):9–17.

2. Different methods of funding health care and allocating health expenditures make it almost impossible to calculate costs.

3. Patients' concerns and beliefs are different.

C. **Budgetary constraints.** Decision making should not be solely based on the information from the PE analysis because most published PE studies do not impose budgetary constraint as part of the analysis. *Cost-effective* does not equal *affordable*. In addition, one should also consider the implementation costs of the program. In many instances, implementation costs may exceed the benefits or effectiveness of the program.

D. **Reproducibility**

1. Often, owing to journal space limitation, lengthy cost computations are eliminated from the published article. Such practice creates an impossible auditing mechanism for the derivation and computation of costs. Critical assessment of this section of the published article is necessary to ensure the validity and reliability of the results.

2. Modeling is an appropriate method when the disease and treatment in question has a lengthy time span and ethical dilemma of withdrawing treatment. However, assumptions and input values to these models are not transparent to readers.

3. Both issues make it almost impossible to reproduce the study results using the local data.

E. **Limitations of claim data studies.** Claim data studies are designed for billing purposes. There is no differentiation between comorbid conditions and complications in coding data. This can pose a problem in quality benchmark studies. In addition, coding practice may be different from one institution to another, a threat to reliability.

Study Questions

Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The underlying assumption of cost-minimization analysis (CMA) is

   (A) calculation of cost minimization ratio.
   (B) consequences or outcomes are equivalent.
   (C) costs are equivalent.
   (D) patient satisfaction is equivalent
   (E) no more than two comparators in any analysis.

2. Which one of these statements is *not* true for the differences between economic studies and randomized clinical trials (RCTs)?

   (A) Generalizability and applicability of the results differ between economic studies and RCTs.
   (B) Clinical end point and economic end point are identical.
   (C) RCTs tend to have inflated benefits and additional protocol-driven costs.
   (D) Sample size of the economic study is normally larger than in the RCT.
   (E) Clinical efficacy assessment through the RCTs as compared to clinical effectiveness through the economic study.

3. In choosing an instrument to measure the health-related quality of life (HRQOL), which of the following is *not* a key component of the assessment?

   (A) Reliability as a sign of consistency for the instrument.
   (B) Validity of the instrument in order to assure its accuracy.
   (C) Incorporate similar questionnaires into a single instrument after calibration.
   (D) Sensitivity and specificity of the instrument.
   (E) Length of the instrument.

4. In choosing a study perspective, the current pharmacoeconomic guidelines have suggested which one of the following perspectives to be included?

   (A) Society
   (B) Payers
   (C) Patients
   (D) Providers
   (E) Practitioners

Directions for questions: The questions and incomplete statements for questions 5–6 in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, **A–E.**

(A) if **I only** is correct
(B) if **III only** is correct
(C) if **I and II** are correct
(D) if **II and III** are correct
(E) if **I, II, and III** are correct

5. When interpreting outcomes research amongst multiple countries, what issues needs special attention?

(I)   Cost computations
(II) Health care funding and cost-allocating mechanisms
(III) Patients' variations and beliefs

6. Which one of these pharmacoeconomic techniques does not address both cost and consequences?

(I)   Cost-benefit analysis
(II) Cost-effectiveness analysis
(III) Cost of illness

7. Which of the following is an example of a clinical outcome indicator?

(A) Dollars spent treating acute myocardial infarction
(B) Resources used in diagnosing the presence of medical errors
(C) Duration of hospitalization and mortality versus discharge rate for ventricular fibrillation patients treated with amiodarone
(D) Functional capacity of patients treated with ramipril in the presence of cardiovascular risk factors
(E) Patient satisfaction survey upon discharge

Answers and Explanations

1. **The answer is B** *[see IV.C]*.
   CMA assumes all consequences compared are equivalent. Patient satisfaction would represent a humanistic outcome and is not considered in a CMA. For this reason, only the cost of each alternative is compared with the least expensive alternative being chosen.

2. **The answer is B** *[see IX.A]*.
   Clinical and economic end points are generally not equal. In the sequence of the study events, efficacy should come before effectiveness and is routinely a key outcome associated with the RCTs as compared to effectiveness being associated with the economic or outcomes study.

3. **The answer is C** *[see VI.D.1–3]*.
   A key process involved in each instrument used to assess quality of life is the need to "calibrate" and "recalibrate" the psychometric properties in order to make sure it is adequately assessing the instrument's intention. This would be of paramount concern when one incorporates items from one satisfactory instrument to that of another similar instrument. Both instruments on their own might meet all necessary purposes. However, when combining them, the process of recalibration is again necessary to adequately assure the reconfigured instrument's value.

4. **The answer is A** *[see III.B]*.
   The societal perspective must be included. It is critical in the health care environment to identify the perspective from which a decision is being made because that perspective directly affects the final decision. The decision to add a high-cost, moderately effective therapy for the treatment of hospitalized patient might be different if viewed from a hospital formulary committee (in-house budgetary concerns) than from the local community, national government (saving lives at whatever expense).

5. **The answer is E** *[see IX.B.1–3]*.
   All of the issues stated need special attention and play a major role in developing multinational economic evaluations to avoid carrying out a study that when completed cannot be generalized to the broad patient population.

6. **The answer is B** *[see IV.A]*.
   The cost of illness methodology is carried out as an assessment of the necessary resources that will be used to treat a designated illness. Resources are measured in terms of dollars, and there are no comparator groups in the evaluation.

7. **The answer is C** *[see I.A.3]*.
   Clinical outcomes include the following: length of hospital stay, adverse drug reactions, hospital readmission, and death. These are definable measures of a patient's response to a given treatment, such as amiodarone used for the treatment of ventricular fibrillation.

55 Drug Product Development in the Pharmaceutical Industry

GURVINDER SINGH REKHI, LEON SHARGEL

I. INTRODUCTION

A. **Active pharmaceutical ingredient (API)**
1. A **drug substance** is the API or component that produces pharmacological activity.
2. The API may be **produced by** chemical synthesis, recovery from a natural product, enzymatic reaction, recombinant DNA technology, fermentation, or a combination of these processes. Further purification of the API may be needed before it can be used in a drug product.
3. A **new chemical entity (NCE)** is a drug substance with unknown clinical, toxicologic, physical, and chemical properties. In addition, the U.S. Food and Drug Administration (FDA) considers an NCE as an API that has not been approved for marketing in the United States.
4. The **identity**, **strength**, **quality**, and **purity** of a drug substance depend on proper control of the manufacturing and synthetic process.

B. **Drug product**
1. A drug product is the **finished dosage form** (e.g., capsule, tablet, injectable) that contains the API, generally in association with other excipients, or inert ingredients.
2. The excipients in the drug product may affect the functionality and performance of the drug product, including modifying the rate of drug substance release, improving drug stability, and masking the drug taste.
3. Different **approaches** are generally used to produce drug products that contain NCEs, product line extensions, generic drug products, and specialty drug products.

C. **New drug product development**
Drug products containing NCE are developed sequentially in the following phases:
1. **Preclinical**. Animal pharmacology and toxicology data are obtained to determine the safety and efficacy of the drug. Because little is known about the human and the therapeutic/toxicologic potential, many drug products will not reach the marketplace. No attempt is made to develop a final formulation during the preclinical stage. **Nonclinical studies** are nonhuman studies that may continue at any stage of research to obtain additional information concerning the pharmacology and toxicology of the drug.
2. **Phase I**
   a. An **investigational new drug (IND)** application for human testing is submitted to the FDA. Clinical testing takes place after the IND application is submitted.
   b. Healthy volunteers are used in phase I clinical studies to determine drug tolerance and toxicity.
   c. For oral drug administration, a simple hard gelatin capsule formulation containing the API is usually used for IND studies.
   d. Toxicologic studies—including acute, chronic, subchronic, and mutagenicity—and other such studies in various animal species are planned during this phase.

3. **Phase II**
   a. A limited number of patients with the disease or condition for which the drug was developed are treated under close supervision.
   b. Dose–response studies, bioavailability, and pharmacokinetics are performed to determine the optimum dosage regimen for treating the disease.
   c. Safety is measured by attempting to determine the **therapeutic index** (ratio of toxic dose to effective dose).
   d. A drug formulation having good physicochemical stability is developed.
   e. Chronic toxicity studies are started in two species; such studies normally last more than 2 years' duration.

4. **Phase III**
   a. Large-scale, **multicenter clinical studies** are performed with the final dosage form developed in phase II. These studies are done to determine the safety and efficacy of the drug product in a large patient population who have the disease or condition for which the drug was developed.
   b. Side effects are monitored. In a large population, new toxic effects may occur that were not evident in previous clinical trials.

5. Submission of a **new drug application (NDA)**. An NDA is submitted to the FDA for review and approval after the completion of clinical trials that show to the satisfaction of the medical community that the drug product is effective by all parameters and is reasonably safe as demonstrated by animal and human studies.

6. **Phase IV**
   a. After the NDA is submitted, and before approval to market the product is obtained from the FDA, manufacturing **scale-up** activities occur. Scale-up is the increase in the batch size from the clinical batch, submission batch, or both to the full-scale production batch size, using the finished, marketed product.
   b. The drug product may be improved as a result of equipment, regulatory, supply, or market demands.
   c. Additional clinical studies may be performed in special populations, such as the elderly, pediatric, and renal impaired, to obtain information on the efficacy of the drug in these subjects.
   d. Additional clinical studies may be performed to determine if the drug can be used for a new indication or additional labeling indications.

7. **Phase V**
   a. After the FDA grants market approval of the drug, product development may continue.
   b. The **drug formulation** may be modified slightly as a result of data obtained during the manufacturing scale-up and validation processes.
   c. Changes in **drug formulation** should always be within the scale-up and post-approval change (SUPAC) guidelines.

D. **Product line extensions** are dosage forms in which the physical form or strength, but not the use or indication, of the product changes. Product line extension is usually performed during phase III, IV, or V.
   1. Developing a transdermal patch when only tablets have been available, for example:
      - Progesterone
      - Nicotine
      - Estradiol
      - Nitroglycerin
   2. **Additional strengths**—as long as these strengths are within the total daily dose, for example:
      - Ibuprofen
   3. **Controlled-release or modified-release** dosage forms when only an immediate-release dosage form is available. This is an ongoing project for all brand companies; almost every NCE has or will eventually have a modified-release dosage form of the immediate-release product.

E. **Biologic products**
   1. A biologic product is any virus, serum, toxin, antitoxin, vaccine, blood, blood component or derivative, allergenic product, or analogous product applicable to the prevention, treatment, or cure of diseases or injuries.
   2. Biologic products are a **subset** of drug products, distinguished by their manufacturing processes (biologic vs. chemical). In general, the term *drugs* include biologic products.

3. **Biologic license application (BLA).** Biologic products are approved for marketing under the provisions of the Public Health Service (PHS) Act.

F. **Generic drug products**

1. After **patent expiration** of the API and/or brand drug product, a generic drug product may be marketed. A generic drug product is therapeutically equivalent to the brand-name drug product and contains the same amount of the drug in the same type of dosage form (e.g., tablet, liquid, injectable).

2. A generic drug product must be **bioequivalent** (i.e., have the same rate and extent of drug absorption) to the brand drug product. Therefore, a generic drug product is expected to give the same clinical response (**Chapter 6**). These studies are normally performed with healthy human volunteers.

3. Some generic products are not absorbed; for some others, bioequivalence is not a good marker. Under those conditions, **comparative clinical trials** or studies with **pharmacodynamic end points** are considered to measure the equivalence of two products. Inhalation products and non-absorbed drug products fall into this category.

4. The generic drug product may differ from the brand product in **physical appearance** (i.e., size, color, shape) or in the amount and type of excipients used in the formulation.

5. A generic drug product may not differ in both the qualitative and the quantitative compositions for liquids, injectables, semisolids, transdermal patches, inhalation products, and ophthalmic products, unless adequate safety studies have been performed.

6. Before a generic drug product is marketed, the manufacturer must submit an **abbreviated new drug application (ANDA)** to the FDA for approval. Because preclinical safety and efficacy studies have already been performed for the NDA-approved brand product, human bioequivalence studies, instead of clinical trials, are generally required for the ANDA. The chemistry, manufacturing, and control requirements for the generic drug product are similar to those for the brand-name drug product.

G. **Specialty drug products** are existing products developed as a new delivery system or for a new therapeutic indication. The safety and efficacy of the drug product were established in the initial NDA-approved dosage form. For example, the nitroglycerin transdermal delivery system (patch) was developed after experience with nitroglycerin sublingual tablets.

II. PRODUCT DEVELOPMENT. For each drug, various studies are required to develop a safe, effective, and stable dosage form.

A. **New chemical entities**

1. **Preformulation** is the characterization of the physical and chemical properties of the active drug substance and dosage form. The therapeutic indication of the drug and the route of administration dictate the type of drug product or drug delivery system (e.g., immediate release, controlled release, suppository, parenteral, transdermal) that needs to be developed.

   a. Preformulation activities are usually performed during the preclinical stage. However, these activities may continue into phases I and II.

   b. The following information is obtained during preformulation.

      (1) **Physical**, including particle size and shape, crystallinity, polymorphism, density, surface area, hygroscopicity (ability to take up and retain moisture), and powder flow

      (2) **Solubility**, including intrinsic dissolution, pH solubility profile, and general solubility characteristics in various solvents

      (3) **Chemical**, including surface energy, pH stability profile, pK_a, temperature stability (dry or under various humidity conditions), and excipient interactions

      (4) **Analytical** methods development, including development of a stability indicating method (measures both the API and the related substances), and cleaning methods

2. **Formulation development** is a continuing process. Initial drug formulations are developed for early clinical studies. When the submission of an NDA is considered, the manufacturer attempts to develop the final (marketed) dosage form. The dose of the drug and the route of administration are important in determining the modifications needed.

   a. **Injectable**

      (1) A final injectable drug product is usually developed in the preclinical phase.

      (2) Major concerns include the stability of the drug in solution and the sterility of the product.

      (3) Because few excipients are allowed in injectable products, the formulator must choose a final product early in the development process.

        (4) If the formulation is changed, bioavailability studies are not required for intravenous injections because the product is injected directly into the body.

        (5) Formulation changes may require acute toxicity studies.

   b. **Topical (for local application)** includes antibacterials, antifungals, corticosteroids, and local anesthetics.

        (1) The final dosage form for a topical drug product is usually developed during phase I because any major formulation changes may require further clinical trials.

        (2) The release of the drug from the matrix is measured in vitro with various diffusion cell models.

        (3) Significant problems encountered with locally acting topical drug products include local irritation and systemic drug absorption.

   c. **Topical (for systemic drug absorption)** includes drug delivery through the skin (transdermal), mucous membranes (intranasal), and rectal mucosa.

        (1) A prototype formulation is developed for phase I.

        (2) A final topical drug product is developed during phase III after the available technology and desired systemic levels are considered.

   d. **Oral**

        (1) Prototype dosage forms are often developed during the **preclinical phase** to ensure that the drug is optimally available and that the product dissolves in the gastrointestinal tract.

        (2) In the early stages of product development, **hard gelatin capsule** dosage forms are often developed for **phase I** clinical trials. If the drug shows efficacy, the same drug formulation may be used in phase II studies.

        (3) Final product development begins when the drug proceeds during phase II and before initiating phase III clinical studies.

 3. **Marketed product**. Considerations in the development of a final dosage form include the following:

   a. Color, shape, size, taste, viscosity, sensitivity, skin feel, and physical appearance of the dosage form

   b. Size and shape of the package or container

   c. Production equipment

   d. Production site

   e. Country of origin in which the drug is to be manufactured

   f. Country in which the drug will be marketed

B. **Product line extensions** are generally defined as drug products containing an NDA-approved drug in a different dosage strength or in a different dosage form (e.g., modified release, oral liquid).

 1. **Oral product line extensions**

   a. The simplest dosage form to develop is a different dosage strength of a drug in a tablet or capsule. Only bioequivalence studies are needed.

   b. A **modified-release** dosage form is more difficult to develop when only an immediate-release dosage form exists. Clinical trials are normally required.

   c. Considerations in developing these dosage forms are similar to those for the final drug product (see II.A.3).

   d. **Marketing** has a role in the choice of the dosage form.

   e. Because the original brand drug product information contributes to the body of knowledge about the drug, no preformulation is needed. All other factors considered for the original product are similar. If the relation between **in vitro** dissolution and **in vivo** bioavailability is known, the innovator can progress to a finished dosage form relatively quickly.

   f. **Regulatory approval** is based on the following:

        (1) Analytical and manufacturing controls

        (2) Stability information

        (3) Bioavailability and bioequivalence studies

        (4) Clinical trials (in the case of modified-release dosage forms)

   g. A new therapeutic indication for a drug requires new **efficacy studies** and a new **NDA**.

 2. **Liquid product line extensions**

   a. If the current marketed product is a liquid preparation, then the same factors as for the solid oral dosage forms are considered (see II.B.1.a–g).

   b. If the marketed product is a solid oral dosage form and the product line extension is a liquid, product development must proceed with caution because the rate and extent of absorption for liquid and solid dosage forms may not be the same.

      c. Regulatory approval requires
        (1) analytical and manufacturing controls;
        (2) stability information;
        (3) Bioavailability and bioequivalence studies
        (4) safety studies (e.g., depending on the drug substance, local irritation); and
        (5) clinical trials, if the rate and extent of drug absorption are drastically altered from the original dosage form.

C. Combination products are made up of two or more regulated components (e.g., drug/drug, drug/device, biologic/device, drug/biologic, or drug/device/biologic) that are physically, chemically, or otherwise combined or mixed and produced as a single entity.

    1. These may be two or more separate products packaged together in a single package or as a unit and may be composed of drug and device products, device and biologic products, or biologic and drug products.

    2. An **example** is an inhalation steroid (e.g., beclomethasone inhalation aerosol) in which the device component is important for delivery of the steroid.

III. PREAPPROVAL INSPECTIONS (PAIs)

A. The manufacturing facility is inspected by the FDA after an NDA, abbreviated antibiotic drug application (AADA), or ANDA is submitted and before the application is approved.

B. A PAI may also be initiated if a major change is reported in a supplemental application to an NDA, AADA, or ANDA.

C. During the PAI, the FDA investigator

    1. performs a general current good manufacturing practice (cGMP) inspection relating specifically to the drug product intended for the market;

    2. reviews the development report to verify that the drug product has enough supporting documentation to ensure a validated product and a rationale for the manufacturing directions;

    3. consults the chemistry, manufacturing, and control (CMC) section of the NDA, AADA, or ANDA and determines the capability of the manufacturer to produce the drug product as described;

    4. verifies the traceability of the information submitted in the CMC section to the original laboratory notebooks, electronic information, and batch records;

    5. verifies and ensures that all the quality systems are in place to manufacture the product so it retains the identity, strength, quality, and purity of the drug product that were approved by the center; and

    6. recommends approval for the manufacture of the drug product based on the status of the inspection.

IV. SCALE-UP AND POSTAPPROVAL CHANGES (SUPACs)

A. Purpose. These guidelines are intended to reduce the number of manufacturing changes that require preapproval by the FDA. The guidelines are published by the FDA on the Internet (http://www.fda.gov/Drugs/GuidanceComplianceRegulatoryInformation/Guidances/).

B. Function. These guidelines provide recommendations to sponsors of NDAs, AADAs, and ANDAs during the postapproval period when

    1. making slight changes in the amount of the **excipient** to aid in the processing of the product during scale-up,

    2. changing the **site** of manufacture,

    3. scaling up (increasing) or **scaling down** (decreasing) the batch size of the formulation, and

    4. changing the manufacturing **process** or **equipment**.

C. The FDA must be notified about a proposed change to a drug product through different **regulatory documentation**, depending on the type of change proposed.

    1. Annual report. Changes that are unlikely to have any detectable effect on formulation quality and performance can be instituted without approval by the FDA and reported annually. Examples of these changes include the following:

      a. Compliance with an official compendium

      b. Label description of the drug product or how it is supplied (not involving dosage strength or dosage form)

      c. Deletion of an **ingredient** that affects only the color of the product

      d. Extension of the **expiration date** based on full shelf-life data obtained from a protocol approved in the application

      e. **Container** and **closure system** for the drug product (except a change in container size for non-solid dosage forms) based on equivalency to the approved system under a protocol approved in the application or published in an official compendium

      f. Addition or deletion of an **alternate analytical method**

  2. **Changes being effected (CBE) supplement**. Changes that probably would not have any detectable effect but require some validation efforts require specific documentation, depending on the change. A supplement is submitted, and the change can be implemented without previous approval (**CBE-0**) by the FDA or, in some cases, the FDA has 30 days to review the change (**CBE-30**). The FDA may reject this supplement. Examples of reasons for submitting a supplement include the following:

      a. Addition of a **new specification** or test method or changes in methods, facilities, or controls

      b. **Label change** to add or strengthen a contraindication, warning, precaution, or adverse reaction

      c. Use of a **different facility** to manufacture the drug substance and drug product (the manufacturing process in the new facility does not differ materially from that in the former facility, and the new facility has received a satisfactory cGMP inspection within the previous 2 years covering that manufacturing process)

  3. **Preapproval supplement**. Changes that could have a significant effect on formulation quality and performance require specific documentation. This supplement must be approved before the proposed change is initiated. Appropriate examples for preapproval supplement are the following:

      a. Addition or deletion of an **ingredient**

      b. Relaxation of the limits for a **specification**

      c. Establishment of a **new regulatory analytical method**

      d. Deletion of a **specification** or regulatory analytical method

      e. Change in the method of **manufacture** of the drug product, including changing or relaxing an in-process control

      f. Extension of the **expiration date** of the drug product based on data obtained under a new or revised stability testing protocol that was approved in the application

D. When any change to a drug product is proposed, the manufacturer must show that the resultant drug product is **bioequivalent** and **therapeutically equivalent** to the original approved drug product (**see Chapter 6**).

  1. A **minor change** is a change that has minimal potential to have an adverse effect on the identity, strength, quality, purity, or potency of the product as they may relate to the safety or effectiveness of the product. If the proposed change is considered minor by the FDA, bioequivalence may be demonstrated by comparative dissolution profiles for the original and new formulations.

  2. A **major change** is one that has substantial potential to have an adverse effect on the identity, strength, quality, purity, or potency of a product as they may relate to the safety or effectiveness of the product. If the proposed change is considered major by the FDA, bioequivalence must be demonstrated by an in vivo bioequivalence study comparing the original and new formulations.

V. GOOD MANUFACTURING PRACTICES (GMPs) are regulations developed by the FDA. GMPs are minimum requirements that the industry must meet when manufacturing, processing, packing, or holding human and veterinary drugs. These regulations, also known as **cGMPs**, establish criteria for personnel, facilities, and manufacturing processes to ensure that the finished drug product has the correct identity, strength, quality, and purity characteristics.

A. GMPs are described in the Code of Federal Regulations (CFRs), title 21, sections 210 and 211.

B. **Drug product quality and drug product performance**

  1. Drug product quality relates to the biopharmaceutical and physicochemical properties of the drug substance and the drug product to the in vivo performance of the drug.

  2. Drug product performance is the release of the API from the drug product, leading to bioavailability of the API and achieving a desired therapeutic response.

      a. The performance of each drug product must be consistent and predictable to assure both clinical efficacy and safety.

      b. Drug product attributes and performance are critical factors that influence product quality.

      c. Each component of the drug product and the method of manufacture contribute to quality.

C. **Pharmaceutical development**
  1. **Quality by Design (QbD)** is a systematic, scientific, risk-based, holistic, and proactive approach to pharmaceutical development that begins with predefined objectives and emphasizes product and processes understanding and process control.
  2. The drug product and manufacturing method must be designed and developed with quality and the desired final product in mind.
  3. To achieve QbD objectives, product and process characteristics important to desired performance must be derived from a combination of prior knowledge and experimental assessment during product development.
  4. **Critical manufacturing attributes (CMAs)** and **critical process parameters (CPPs)**. A critical quality attribute is a physical, chemical, biological, or microbiological property or characteristic that needs to be controlled (directly or indirectly) to ensure product quality.
      a. The pharmaceutical manufacturer should identify critical manufacturing attributes (CMAs), CPPs, and sources of variability that ensures the quality of the finished dosage form.
      b. The critical quality attributes should be based on clinical relevance.

D. **Quality control (QC)** unit is the group within the manufacturer that is responsible for establishing process and product specifications.
  1. **Specifications** are the criteria to which a drug product should conform to be considered having acceptable quality for its intended use.
  2. The QC unit **tests** the product and verifies that the specifications are met. QC testing includes the **acceptance** or **rejection** of the incoming raw materials, packaging components, drug products, water system, and environmental conditions (e.g., heating, ventilation, air-conditioning, air quality, microbial load) that exist during the manufacturing process.

E. **Quality assurance (QA)** unit is the group within the manufacturer that determines that the systems and facilities are adequate and that the written procedures are followed to ensure that the finished drug product meets the applicable specifications for quality.

Study Questions

Directions: Each statement in this section can be correctly completed by **one or more** of the suggested phrases. Choose the **correct** answer, A–E:

  A   if **I** only is correct
  B   if **III** only is correct
  C   if **I** and **II** are correct
  D   if **II** and **III** are correct
  E   if **I, II**, and **III** are correct

1. Healthy human volunteers are used in drug development for
   I. phase I testing after the submission of an investigational new drug (IND) application.
   II. generic drug development for an abbreviated new drug application (ANDA) submission.
   III. phase III testing just before the submission of a new drug application (NDA).

2. The required information contained in a NDA that is *not* included in the ANDA consists of
   I. preclinical animal toxicity studies.
   II. clinical efficacy studies.
   III. human safety and tolerance studies.

3. A product line extension contains the NDA-approved drug in a new
   I. dosage form.
   II. dosage strength.
   III. therapeutic indication.

Directions: Each statement in this section can be correctly completed by **one** of the suggested phrases. Choose the **best** answer.

4. The regulations developed by the U.S. Food and Drug Administration (FDA) for the pharmaceutical industry for meeting the minimum requirements in the manufacturing, processing, packing, or holding of human and veterinary drugs are known as

(A) good manufacturing practices (GMPs).
(B) quality assurance (QA).
(C) quality control (QC).
(D) pre-approval inspection (PAI).
(E) scale-up and post-approval changes (SUPACs).

5. The unit within the pharmaceutical manufacturer that ensures that the finished dosage form has met all the specifications for its intended use is the

(A) analytical methods unit.
(B) marketing and sales unit.
(C) PAI unit.
(D) QA unit.
(E) QC unit.

6. Manufacturers may make a change in the formulation after market approval. If the change in the formulation is considered a minor change, the manufacturer needs to report the change to the FDA only in the

(A) annual report.
(B) preapproval supplement.
(C) IND submission.
(D) changes being effected supplement, 30 days (CBE-30).
(E) no report is required for a minor change.

Answers and Explanations

1. **The answer is C (I, II)** *[see I.C.2.b; I.F.2]*.
Phase I testing is the first set of human studies performed during new drug development. Phase I studies establish the tolerance and toxicity of the drug in humans. Bioequivalence studies for generic drug development are most often performed in healthy human volunteers. These studies establish the bioequivalence of the generic drug product against the brand drug product. Phase III testing entails large-scale, multicenter clinical studies performed in patients with the disease or condition to be treated. Phase III studies determine the safety and efficacy of the drug in a large patient population.

2. **The answer is E (I, II, and III)** *[see I.C.5; I.F.6]*.
The development of a new drug requires extensive toxicity and efficacy testing in animals and humans. The NDA documents all studies performed on the drug. The ANDA is used for generic drug product submissions. The generic drug product is similar to the original brand drug product that has already been marketed. Because the efficacy, safety, and toxicity of this drug product have been studied and documented, further studies of this nature are unnecessary.

3. **The answer is C (I, II)** *[see I.D]*.
Product line extensions are developed after further studies with the original NDA-approved drug product. From these studies, the manufacturer may develop a new dosage form (e.g., controlled-release product) or a new dosage strength. A new therapeutic indication requires an NDA.

4. **The answer is A** *[see V]*.
Quality control and quality assurance follow GMP regulations to ensure that the finished product meets all applicable specifications for quality. The FDA may inspect a manufacturing site (PAI) before the drug application is approved. In addition, the FDA must be notified about any proposed changes to an approved drug product.

5. **The answer is E** *[see V.D]*.
The QC unit performs the appropriate tests on the dosage form. PAI is performed by FDA compliance inspectors, who examine the pharmaceutical manufacturer and review the procedures and records for manufacturing the finished dosage form before the administration grants market approval. The analytical development unit develops the analytical methods used in testing the drug product.

6. **The answer is A** *[see IV.C.1]*.
All changes in the formulation must be reported to the FDA. A minor change is a change that has minimal potential to have an adverse effect on the identity, strength, quality, purity, or potency of the product as they may relate to the product's safety or effectiveness. Changes that are unlikely to have any detectable effect on formulation quality and performance can be instituted without approval by the FDA and need only to be reported in the annual report.

56 Microbiology

TERRI S. HAMRICK

I. SCOPE OF MICROBIOLOGY

A. Microbiology is the study of many diverse organisms, including archaea, bacteria, protozoa, algae, fungi, and acellular entities, nearly all of which are too small to be seen by the unaided eye. Prokaryotic organisms (bacteria and archaea) are single celled and lack internal membrane structures. Eukaryotic organisms may be single celled or multicellular, but all contain a true membrane-bound nucleus and other internal organelles.

B. **Domains of living organisms**

1. **Eukarya** (see section II) contains all members of the living world except for the prokaryotes. The microorganisms of the Eukarya domain include algae, fungi, and protozoa of which **fungi** and **protozoa** contain members of medical importance.

2. **Bacteria** (see section III) are unicellular, generally small in comparison to eukaryotic organisms, and very diverse in terms of cell shape, motility, metabolism, and oxygen requirements. Most bacteria do not cause human disease, but many diseases are due to bacteria.

3. **Archaea** have the same basic shape, size, and appearance of bacteria but have biochemical differences (e.g., structure of the cell wall), and they tend to inhabit extreme environments of heat, cold, pH, or salt concentration. Archaea are not a medically important domain of microorganisms and will not be further addressed in this chapter.

C. Nonliving but medically significant entities are the following:

1. **Viruses** (see section IV) lack many of the characteristics of living cells, including the ability to replicate without the assistance of host cell biosynthetic processes.

2. **Prions** are proteinaceous in nature and yet infectious (see section IV.B.4.b).

II. DOMAIN EUKARYA

A. **Fungi.** There are more than 50,000 species of fungi; however, only a few hundred have been implicated in human disease and most human mycotic infections can be attributed to a few dozen species.

1. **Taxonomy and nomenclature.** In addition to their vegetative growth as **yeasts** or **molds**, fungi can produce **spores** via asexual or sexual reproduction. The classification of fungi is based on the mechanism of production and morphology of spores that result from sexual reproduction. Fungi are named using the Linnaean or binomial system as a genus and species (e.g., *Homo sapiens* is the genus and species for humans).

2. **Structure.** Fungi are eukaryotic organisms that grow in two basic forms. **Molds** grow by forming branching tubules called **hyphae** or **mycelia** (multiple hyphae). **Yeasts** are unicellular fungi and typically reproduce by **budding**, although some species produce pseudohyphae (chains of yeast cells). Most fungi are either yeasts or molds, although some can assume either morphology (**dimorphic fungi**). There are a number of structural features of fungal cells that are noteworthy, particularly with respect to targeted antifungal therapy (see Chapter 36, "Infectious Diseases").

   a. The **fungal cell wall** is composed primarily of **chitin**, as opposed to bacterial cell walls, which are composed of peptidoglycan; thus, fungi are not sensitive to antimicrobials such as penicillin, which interfere with peptidoglycan synthesis.

   b. The predominant sterol in the fungal cell membrane is **ergosterol**, whereas human cell membranes contain cholesterol. Several antifungal agents target this difference between fungal and human cell structure.

3. **Fungal physiology.** Most fungi are **obligate aerobes**, although some are facultative anaerobes. None are obligate anaerobes. Fungi are dependent on a preformed organic source of carbon.

4. **Pathogenicity.** Healthy immunocompetent individuals have a high level of innate resistance to fungal infections.

   a. **Primary pathogens** are fungi that can infect normal, immunocompetent hosts (e.g., *Blastomyces dermatitidis*, *Histoplasma capsulatum*, *Coccidioides immitis*). All of the primary systemic fungal infections are **respiratory infections**.

   b. **Opportunistic fungi** are fungi that typically infect patients with impaired defenses. When normal host defenses are compromised, the host is more susceptible to certain fungal infections. Most fungal infections are opportunistic infections.

5. **Mechanisms of pathogenicity** and **important immune defenses** for selected fungal diseases.

   a. **Cutaneous mycoses. Dermatophytoses** are diseases caused by a group of related fungi in the genera *Trichophyton*, *Epidermophyton*, and *Microsporum*. These fungi are able to invade the skin, hair, and nails, owing in part to their ability to **break down keratin**. Penetration below the epidermis is rare. Various forms of dermatophytoses are referred to as ringworm or "**tineas**," being further defined by the affected anatomical site (e.g., tinea corporis of the body, tinea cruris of the groin, tinea pedis of the foot, tinea unguium of the nails, and tinea capitis of the scalp). Intact epithelium including chemical and bacterial factors (normal flora and bacterial metabolites) are important for inhibiting or preventing fungal growth (e.g., tinea pedis [athlete's foot] is often associated with damaged skin areas, moisture, specific skin chemistry, or heavy exposure to the fungi).

   b. **Systemic mycoses due to dimorphic fungi.** These primary systemic pathogens exist as a mold form in nature and as a yeast in infections. They are **inhaled** into the lungs from an environmental source and then disseminate to involve other tissues. Reduced cell-mediated immunity predisposes individuals to disseminated disease with *Histoplasma* and *Coccidioides*.

   c. *Candida* species, most commonly *Candida albicans*, are opportunistic fungal pathogens that can cause infections in **virtually any organ system** under the right circumstances. *Candida* are part of the normal flora of the gastrointestinal tract of many healthy individuals; therefore, the predominant source for infection is opportunistic spread of **endogenous** organisms (e.g., urinary tract infection of indwelling urinary catheter, pneumonia following aspiration, endocarditis of prosthetic heart valves, hematogenous infection following immunosuppression, *Candida* vulvovaginititis following antibiotic therapy).

   d. *Aspergillus* is a group of environmental fungi that can colonize the sinuses and upper respiratory tract following environmental exposure. A reduced number of neutrophils predispose patients to disseminated infections caused by *Aspergillus*. Inhalation of environmental *Aspergillus* can also lead to **hypersensitivity reactions** (e.g., **allergic bronchopulmonary aspergillosis**).

   e. A number of fungi produce powerful **toxins**. The aflatoxins are coumarin derivatives produced by *Aspergillus flavus*.

6. **Antifungal therapy** (discussed further in Chapter 36, "Infectious Diseases").

   a. **Azole drugs** (itraconazole, fluconazole, and ketoconazole) inhibit the synthesis of ergosterol, which is a structural part of the fungal cell membrane.

   b. **Polyene antifungals**, such as **amphotericin B**, associate preferentially with ergosterol in the fungal cell membrane and disrupt the cell membrane integrity. It is typically used for systemic mycoses, and resistance is rare. Nystatin is structurally related to amphotericin B although nystatin can only be used as a topical or oral suspension.

   c. **Echinocandins**, such as caspofungin (Cancidas), anidulafungin (Eraxis), and micafungin (Mycamine), interfere with the synthesis of the fungal cell wall by inhibiting the 1,3-β-glucan synthase.

B. **Protozoans** are unicellular, nonphotosynthetic eukaryotes. This chapter discusses some of the more common protozoan infections.

   1. **Taxonomy and nomenclature.** The protozoans are classified into phyla by mode of motility or life cycle, and then named by genus and species based on the degree of relatedness.

      a. **Flagellates**, which are distributed over four phyla, move by flagella—the arrangement of which can vary in different species (e.g., *Giardia*, *Trichomonas*, *Trypanosoma*, and *Leishmania*).

      b. **Amebas** (phylum, Amoebozoa) move by extrusion of pseudopodia (e.g., *Entamoeba* and *Acanthamoeba*).

    c. Ciliates (phylum, Ciliophora) move by coordinated motion of hairlike structures (cilia). (The ciliates contain no major contributors to human disease although *Balantidium* is considered a minor human pathogen.)

    d. Sporozoans (phylum, Sporozoa) have complex life cycles that include sexual and asexual reproduction phases, often involving invertebrate and vertebrate hosts (e.g., *Plasmodium*, *Toxoplasma*, and *Cryptosporidium*).

2. The **structure** of the protozoans varies with the organism and the stage of the life cycle. The life cycle of many protozoan parasites (e.g., amoebae, *Giardia*, cryptosporidia) consists of **two stages**: the motile **trophozoite**, which is found in the host, and the nonmotile **cyst**, which is transmissible and environmentally stable due to its thick cell wall. Protozoa that do not form cysts are transmitted person-to-person (e.g., *Trichomonas vaginalis*) or use an arthropod vector for transmission (e.g., *Plasmodium* species). Diagnosis of protozoan infections is often based on the morphology of the trophozoites or cysts in the clinical samples.

3. **Physiology.** The nutritional requirements of the parasitic protozoa are generally acquired by pinocytosis/phagocytosis or via simple diffusion. With respect to respiration, most are facultative anaerobes.

4. **Pathogenesis of selected protozoan infections**

    a. Intestinal and urogenital protozoa

        (1) *Entamoeba histolytica* causes amebic dysentery and liver abscess. It is acquired by the fecal–oral route in contaminated food or water. Other amoebae that infect humans tend to cause a mild, transient diarrhea.

        (2) *Giardia lamblia*, a flagellate, is responsible for giardiasis, which is a watery diarrhea that can persist for weeks or months and can be associated with malabsorption.

        (3) *Cryptosporidium* species are acquired via contaminated water, although person-to-person spread can occur. Infections of healthy people usually results in a mild, self-limiting diarrhea, although infections can last for months in immunocompromised individuals, resulting in major fluid loss or disseminated infections.

        (4) *T. vaginalis*, transmitted by sexual contact, causes vaginitis or urethritis, although many infections are asymptomatic.

    b. Blood and tissue protozoans

        (1) Malaria is caused by five plasmodia species (*Plasmodium vivax*, *P. ovale*, *P. malariae*, *P. falciparum*, and the newly described *P. knowlesi*), which are transmitted through the bite of an infected mosquito. Much of the pathology of malaria is due to the destruction of the red blood cells during the infection.

        (2) *Toxoplasma gondii* is usually acquired by ingestion of cysts in undercooked meat or ingestion of cat fecal contamination. Infections are usually mild, although, when acquired during pregnancy, can be transmitted to the fetus resulting in abortion, stillbirth, or neonatal disease (chorioretinitis, blindness, encephalitis, and hepatosplenomegaly).

5. **Therapy.** (Discussed in more detail in Chapter 36, "Infectious Diseases".) Drugs from the nitroimidazoles class, such as metronidazole (Flagyl) and tinidazole (Tindamax), tend to be the preferred treatment for most protozoan infections (*Giardia*, *Trichomonas*, and *Entamoeba*), although pyrimethamine and sulfonamides are often alternative therapies. Chloroquine has been the treatment of choice for malaria (*Plasmodium* species), although chloroquine resistance is common in some parts of the world. Recommendations for **chemoprophylaxis** and treatment of malaria vary depending on the profile of drug resistances in the area of travel, the species of *Plasmodium*, and the health status of the patient.

III. DOMAIN BACTERIA

    A. Taxonomy and nomenclature

      1. **Bacteria** (or Eubacteria) are grouped and named primarily based on **morphologic** and **biochemical characteristics** (e.g., the nature of the cell wall, staining characteristics, ability to use oxygen, ability to form endospores). DNA technology has led to the reclassification of some organisms based on DNA sequences and homology. Bacteria are named using the binomial Linnaean system as a genus and species; some species are classified with subspecies or strain designations.

2. **Morphology** is the classification of bacteria by shape and structure.
   a. Colony morphology is based on the size, color, shape, and texture of colonies that are grown in pure culture on an agar plate. Each colony originates from a colony-forming unit (CFU), consisting of a single cell or group of adherent cells.
   b. Microscopic morphology describes bacteria based on the size, shape, and arrangement of the cells (see section III.A.4).
3. **Stains.** Because of their small size and relative transparency, bacteria must be stained to be visible under the light microscope. Staining characteristics may be used in classification. The major types of staining reactions are the following:
   a. The **simple stain** uses a single dye (e.g., methylene blue, basic fuchsin, and crystal violet) to color the cells.
   b. The **gram stain** is a differential staining procedure in which the purple stain is retained in the thick peptidoglycan layer of the gram-positive bacteria, whereas the color is removed by an alcohol rinse from the thinner gram-negative walls. The gram-negative cells are then stained red by the counterstain.
   c. The **acid-fast stain** uses a procedure to stain cells that have an outer layer of a waxy lipid (acid-fast, stained red). This waxy layer prevents removal of the stain by an acid rinse. The stain is removed from cells that lack the waxy layer, which are then counterstained blue (non–acid-fast). Bacteria of the genus *Mycobacterium* are acid-fast bacilli (AFB) (see section III.B.4.b).
   d. The **endospore** stain involves a procedure that uses heat to help dye enter the endospore (see section III.B.6).
   e. The **capsule stain** is a colloidal suspension that is excluded from areas occupied by capsule and allows detection of the unstained capsular material.
4. **Bacterial cell shape and arrangement**
   a. **Cocci** are spherical and exist in chains (e.g., *Streptococcus* species), pairs/diplococci (e.g., *Neisseria gonorrhoeae*), and clusters (e.g., *Staphylococcus* species).
   b. **Bacilli** are cylindrical and rod-shaped organisms (e.g., pseudomonads, *Escherichia*).
   c. Coccobacilli are short, rounded rods (e.g., *Haemophilus*).
   d. **Spirochetes** and spirilla are helical like a corkscrew (e.g., *Treponema pallidum*).
   e. Vibrios are comma-shaped rods (e.g., *Vibrio cholerae*).
   f. Pleomorphic organisms exist in varied forms (e.g., *Legionella*, *Corynebacterium*).

B. **Structure of the prokaryotic cell**
   1. **Overview.** Prokaryotic cells (bacteria) are small and structurally different than eukaryotic organisms in a number of ways. Bacteria
      a. have a complex **cell wall structure**,
      b. **lack internal membrane-bound organelles** (e.g., nucleus, plastids, endoplasmic reticulum, vacuoles),
      c. multiply asexually by **binary fission** rather than by mitosis or meiosis,
      d. use 70S ribosomes rather than 80S ribosomes for protein synthesis, and
      e. possess a single supercoiled circular chromosome.
   2. **Cytoplasmic structures**
      a. **Bacterial ribosomes** are the sites of protein synthesis—the process whereby the messenger RNA (mRNA) code is translated into an amino acid sequence (see section III.E.2.b). In addition to being smaller (70S rather than 80S), bacterial ribosomes are significantly different from those of eukaryotic cells and are targets for antibacterial therapies. Bacterial ribosomes are not associated with membranes.
      b. The **bacterial chromosome** is typically a single, double-stranded, circular molecule that is contained within a discrete area of the cell known as the **nucleoid**.
      c. **Plasmids** are small, circular, extrachromosomal DNAs that are present in some bacteria. They often contain virulence genes, antibiotic resistance, or other genetic elements, such as transposons (see section III.E.3).
   3. The **cytoplasmic membrane** of bacteria is a phospholipid bilayer similar to eukaryotic membranes, except eukaryotic membranes contain sterols (e.g., cholesterol), whereas bacteria, with the exception of mycoplasmas, do not. The phospholipid arrangement creates a **permeability barrier** by establishing hydrophilic regions (glycerol phosphates) that flank a hydrophobic core

(fatty acids). The cytoplasmic membrane and the proteins embedded within are responsible for several important functions of the bacterium.

a. **Transport of nutrients** occurs by several mechanisms.

 (1) **Facilitated diffusion** is the passive diffusion of a substrate across the membrane using specific carrier proteins.

 (2) **Active transport** is the movement of molecules against a concentration gradient (from lower concentration outside of the cell to higher concentration inside the cell), which requires energy.

 (3) **Group translocation** is a variation of active transport in which the bacterial cell modifies the transported molecule such that the molecule can no longer leave the cell (e.g., phosphorylated glucose).

b. Energy production and the **electron transport chain** occur across the cytoplasmic membrane (see section III.D.4.b).

c. **Cell wall biosynthesis** occurs at the outer surface of the cytoplasmic membrane with the transport of cell wall precursors across the membrane for further assembly outside of the cytoplasm. Actinlike filaments may also line the cytoplasmic membrane for shape and septum formation during cell division.

d. **Secretion systems** that traverse the cytoplasmic membrane may be employed to translocate proteins across the cytoplasmic membrane to the outside of the bacterium (gram-positive bacteria) or to the periplasmic space (gram-negative organisms).

4. All bacteria have a **cell wall** composed of **peptidoglycan**, except mycoplasmas (see section III.F.3). The cell wall is a rigid structure that provides the general shape of the cell and functions to protect the cell from osmotic shock. The peptidoglycan of the cell wall is composed of repeating disaccharide units (a polymer of *N*-acetylglucosamine and *N*-acetylmuramic acid), with amino acid side chains that are covalently linked to amino acid side chains from disaccharide units elsewhere in the polymer, forming a stable **cross-linked structure**. The designations gram positive, gram negative, and acid fast are based on fundamental differences in the components of the cell wall and associated structures. Owing to the uniqueness and the importance of the cell wall to bacterial viability, it is the target of many antimicrobial agents (see Chapter 36, "Infectious Diseases").

a. **Gram-positive** organisms have a thick cell wall (approximately 40 layers thick), which is 90% peptidoglycan, with extensive cross-linking. **Teichoic acid** and lipoteichoic acid are polymers of glycerol or ribitol phosphodiesters that contribute to the structure of the gram-positive cell wall; lipoteichoic acid contains a fatty acid that anchors the cell wall to the cytoplasmic membrane. Additional cell wall–associated proteins and polysaccharides may serve as antigenic determinants.

b. **Acid-fast bacteria** (mycobacteria) have a thick peptidoglycan cell wall, which is surrounded by a waxlike coat of **mycolic acid** and glycolipids that is impermeable to many substances and imparts resistance to many disinfectants and antibiotics.

c. **Gram-negative** cell walls are more complex structurally and chemically, although they are thinner and do not contain teichoic or lipoteichoic acid.

 (1) Unique to gram-negative bacteria is an **outer membrane**, external to the cell wall, that acts as a permeability barrier to large molecules (e.g., lysozyme) and hydrophobic molecules (e.g., some antimicrobials). The outer membrane is an asymmetric bilayer, which consists of an inner leaflet with phospholipids much like those of the cytoplasmic membrane and an outer leaflet composed primarily of **lipopolysaccharide** (LPS). LPS, which is also known as **endotoxin**, is toxic to humans and is a potent activator of the immune response. LPS is responsible for many of the features of infections by gram-negative bacteria, including **inflammation**, **fever**, **and shock**. LPS is composed of three parts:

 (a) **Lipid A** consists of a disaccharide backbone with attached fatty acids. It is an integral component of the outer membrane and is responsible for the endotoxin activity.

 (b) **Core polysaccharide** is a branched polysaccharide of 9–12 sugars. Most bacteria within a genus will share conserved core polysaccharide structures.

 (c) The **O-antigen** portion, which consists of 50–100 repeating saccharide units, is attached to the core polysaccharide and extends away from the bacterial surface. The O-antigen composition and structure can vary within a bacterial species and is

often used to distinguish specific serotypes (e.g., O157, strains of enterohemorrhagic *Escherichia coli*).

(2) Specialized secretion systems used by gram-negative organisms translocate proteins from the cytoplasm across both membranes to the outside. The type III secretion system, which is a virulence factor used by many gram-negative pathogens, translocates proteins from the bacterial cytoplasm across both bacterial membranes and across nearby host cell membranes into the host cell cytoplasm to effect changes in the eukaryotic cell.

(3) Proteins associated with the outer membrane include receptors, structural proteins, and components of transport and secretory systems. **Porins** are transmembrane proteins that form pores to allow diffusion of small hydrophilic molecules through the outer membrane.

(4) The **periplasmic space**, an area between the cytoplasmic and outer membranes of gram-negative bacteria, contains components of transport systems (e.g., iron, sugars, metabolites) and hydrolytic enzymes (e.g., proteases, phospholipases, nucleases, and carbohydrate-degrading enzymes) for the breakdown of macromolecules. Enzymes for the breakdown of antimicrobials may also be located in the periplasmic space (e.g., β-lactamase).

5. External structures

a. Capsule is an adherent, usually polysaccharide surface coat (glycocalyx); however, the capsule of *Bacillus anthracis* is polypeptide. Not all bacteria are able to make a capsule, and those that do often do not continue to make the capsule upon culture in the lab. Antigenic differences among capsules can be used to identify strains within a single species of bacteria (e.g., *Streptococcus pneumoniae*, *Haemophilus influenzae* type b). The capsule is a major virulence factor owing to the following features:

(1) Acts as a barrier to toxic hydrophobic molecules

(2) Prevents phagocytosis of the organism by macrophages and neutrophils

(3) Aids in **adherence** of the organism to host cells and nonbiological surfaces

b. Flagella are threadlike appendages of helically coiled protein subunits (flagellin) that are used by some bacteria for **movement**. Flagella are anchored in the bacterial membrane and their rotation is driven by **proton motive force**. A bacterium may have one or more flagella anchored at different parts of the cell. The direction of the flagella rotation and thus the type of movement is influenced by chemoreceptors and signaling pathways that facilitate movement toward chemoattractants (**chemotaxis**) and away from repellants. Flagella express antigenic and strain determinants (typically the **H antigen** in strain designations). Periplasmic flagella, also called **axial filaments**, used by spirochetes, are positioned beneath the bacterial outer membrane. Movement of the axial filament leads to a corkscrew type of motion that facilitates movement through viscous environments.

c. Pili (fimbriae) are proteinaceous, hairlike structures on the outside of bacteria that promote **adherence** to surfaces, host cells, or other bacteria and are therefore an important virulence factor for some bacteria. **F pili** (sex pili), which are encoded by a plasmid (F), bind to other bacteria for the transfer of large segments of DNA between bacterial cells (see section III.E.4.b).

6. Endospores or bacterial spores are dehydrated multishelled structures formed by some gram-positive organisms (*Clostridium* and *Bacillus*) in response to **adverse conditions**. The endospore contains the bacterial DNA surrounded by a thick, keratin-like coat that imparts **resistance** to heat, dehydration, radiation, and chemicals. It is **not metabolically active and can remain dormant for years**. Upon exposure to water and nutrients, the endospore may once again become metabolically active, germinating into the vegetative state.

C. Microbial physiology

1. Nutritional requirements. Bacteria use a wide variety of nutrients to obtain energy and to construct new cellular components. The minimum requirement for growth is a source of carbon and nitrogen, an energy source, water, and various ions. Beyond these essentials, different bacteria have different requirements for exogenous sources of the elements for the construction of cellular components (DNA, carbohydrates, and proteins) and processes (enzymes). Most bacteria of medical importance would be considered **heterotrophs** in that they require an exogenous source for one or more essential metabolites. Growth requirements and metabolic by-products can be a means of identifying bacteria.

2. **Oxygen requirements**
   a. Aerobes have the ability to grow in the presence of atmospheric oxygen.
      (1) **Obligate aerobes** depend completely on oxygen for growth. Oxygen serves as the terminal electron acceptor in aerobic respiration.
      (2) **Aerotolerant** bacteria have the ability to grow with or without molecular oxygen, although they do not use oxygen for respiration.
   b. Anaerobes have the ability to grow without oxygen.
      (1) **Obligate anaerobes** do not tolerate the presence of oxygen and must grow in an environment free of oxygen. Many of these bacterial strains lack catalase and superoxide dismutase, enzymes that protect cells from the destructive oxidizing by-products normally produced under aerobic conditions (e.g., hydrogen peroxide, superoxide anions).
      (2) **Facultative anaerobes** do not require oxygen but grow better in its presence.
   c. **Microaerophiles** require oxygen levels below normal atmospheric pressures for growth (e.g., *Helicobacter pylori*).
3. Bacterial growth occurs by **binary fission** and can be measured as a doubling time or generation time. Growth can be plotted as the log of the cell number versus time to produce a curve with four distinct phases.
   a. The **lag phase** is a transition period during which the bacteria are replicating the chromosomal DNA and producing the enzymes needed for the new environment.
   b. During **logarithmic** (**log**) **phase**, division occurs at a constant and maximal rate, and the number of cells increases in a geometric progression. Under ideal growth conditions, the generation time varies among species over a range of minutes (15 to 20 mins for *Escherichia*) to hours (15 to 20 hrs for *Mycobacterium tuberculosis*). Because the cell wall is being synthesized rapidly, bacterial cells are most susceptible to cell wall inhibitors during this phase.
   c. In **stationary phase**, the growth rate tapers off such that growth and death rates are nearly equal, and a fairly constant population of viable cells results.
   d. **Death phase** occurs as the number of viable cells declines and the environment accumulates toxic wastes and autolytic enzymes.
D. **Metabolism and energy production**
   1. Microorganisms derive energy through the controlled breakdown of various organic substrates (carbohydrates, lipids, proteins) to produce usable energy, typically as **adenosine triphosphate** (ATP).
      a. **Substrate-level phosphorylation** is the process by which energy is directly transferred from an intermediate metabolic compound to generate ATP from adenosine diphosphate (ADP).
      b. **Oxidative phosphorylation** generates ATP through a series of oxidation reactions in which electrons from nicotinamide-adenine dinucleotide (NAD or its reduced form, NADH) or flavin adenine dinucleotide (FAD or its reduced form, $FADH_2$) are transferred through electron carriers, and ultimately to a final inorganic acceptor. This process creates a proton gradient that is used to fuel the generation of ATP. In the absence of oxygen, substrate level phosphorylation is typically the primary means of energy production; however, substrate level phosphorylation coupled with oxidative phosphorylation is a more efficient means of generating energy but requires a final inorganic electron acceptor (usually oxygen).
   2. The **glycolytic** (glycolysis) or **Embden-Meyerhof-Parnas** (EMP) pathway, the first step in fermentation and respiration, converts glucose into pyruvate, with the net yield of two molecules of ATP per glucose molecule produced by substrate level phosphorylation. The reduced form of NADH is also produced in this process. Glycolysis can occur in the presence or absence of oxygen.
   3. **Fermentation**, which does not require oxygen, is the process by which the pyruvate of glycolysis is converted into various end products (e.g., lactic acid, ethanol, butanol), depending on the individual bacterial species. These organic end products serve as electron acceptors to recycle the NADH from glycolysis, to NAD, which is necessary to continue the glycolytic process. Obligate aerobes are unable to use fermentative processes. Bacterial identification may be aided by the determination of fermentative end products (e.g., *Lactobacillus*, lactic acid; *Saccharomyces*, ethanol).

4. **Respiration** is an energy-producing, oxidative sequence of reactions in which inorganic compounds act as the final electron acceptor. This process includes glycolysis, the tricarboxylic acid (TCA) cycle, and the electron transport system, which yields ATP when coupled with oxidative phosphorylation.

   a. The **tricarboxylic acid** cycle further oxidizes the pyruvate produced from glycolysis and generates a substantial number of NADH (and $FADH_2$), which yield ATP through the electron transport chain.

   b. In the **electron transport chain**, which is located in the cytoplasmic membrane of bacteria, as opposed to the mitochondrial membrane of eukaryotes, electrons carried by NADH (or $FADH_2$) are passed through a series of donor–acceptor pairs (cytochromes, flavoproteins, and ubiquinones) and ultimately to a **final electron acceptor**, either oxygen (aerobic respiration) or another inorganic acceptor (anaerobic respiration) (e.g., nitrate, sulfate, carbon dioxide, ferric iron). Anaerobic organisms are less efficient at energy production than aerobic organisms, although anaerobic respiration is more efficient than fermentation alone.

5. **Catabolism** of proteins, polysaccharides, and lipids produces glucose, pyruvate, lipids, or other intermediates of the TCA cycle, which can then be directed toward energy production by entering the TCA cycle at various points.

E. **Genetics**

1. The genome of a typical bacterium consists of a **single**, **circular DNA molecule** (chromosome). Bacteria are haploid in that they have a single chromosome and therefore a single copy of each gene.

2. **Regulation and expression of genetic information**

   a. DNA has many functions.

      (1) It is duplicated for transfer to progeny during cell division.

      (2) It is transcribed into RNA, which can be translated into proteins.

      (3) It can be mutated to alter specific characteristics encoded by genes.

      (4) It can be duplicated and transferred to other bacterial cells in processes other than cell division (see sections III.E.3 and III.E.4).

   b. DNA replication, transcription, and translation

      (1) **Bacterial replication** involves accurate duplication of chromosomal DNA, which enables the formation of two identical daughter cells. Replication is initiated at a specific sequence in the chromosome (origin) and involves a number of enzymes. The two DNA strands unwind as the replication fork progresses, synthesizing new DNA, bidirectionally, with the original DNA strands serving as templates.

      (2) **Transcription** is the process by which the DNA sequence is copied into an RNA molecule that will then be used to produce necessary proteins. One gene can be transcribed into many copies of RNA. Simplistically, sigma factors bind to the promoter region of the gene and provide a docking site for the RNA polymerase. The area undergoes localized unwinding to allow RNA polymerase to transcribe the RNA (called mRNA) from the DNA template. The RNA is not processed, as in eukaryotes; there are no introns and exons; no capping of the beginning of the transcript (the 5′ end); and no polyadenine tails added to the terminus (the 3′ end) of the mRNA transcript.

      (3) **Translation** is the process of converting the genetic information contained in the mRNA into an amino acid sequence. As the transcript is being made, the 70S bacterial ribosome assembles at the 5′ end of the transcript with the transfer RNA (tRNA) for **formylmethionine** (fmet) at the start codon (AUG) of the mRNA. The ribosome contains two tRNA binding sites, each of which allows the codon of the mRNA to base-pair with the anticodon of the incoming, corresponding tRNA. The amino acid of the first tRNA is transferred to the adjacent amino acid on the new tRNA at the next codon (transpeptidase reaction); the empty tRNA (uncharged tRNA) is released, and the ribosome shifts to the next codon. This continues until the complete amino acid sequence (protein) is synthesized.

3. **Mechanisms of genetic change.** In addition to mutation, microorganisms can change their genetic constitution by the transfer of genetic material from a donor cell to a recipient cell. Transferred DNA can be integrated into the recipient chromosome, usually via **recombination**

between homologous segments (those DNA areas that have similar nucleotide sequences), or the DNA can be stably maintained as an extrachromosomal element (**plasmid**) or a bacterial virus (**bacteriophage**). **Transposons** are mobile genetic elements that, once they are inside of a bacterial cell, can transfer DNA within a cell, "hopping" from one place in the chromosome to another, or between the chromosome and a plasmid. Transposons carry the gene for the enzyme that mediates the insertion (transposase) and repeated sequence elements; transposons may also carry antibiotic resistance genes.

4. **Exchange of bacterial genetic material** can occur by three general mechanisms:
   a. **Transformation** involves a recipient cell taking up cell-free, fragmented (i.e., naked) DNA.
      (1) Transformation occurs naturally within only a few bacterial genera (e.g., *Neisseria*). Following uptake of the DNA, homologous recombination can incorporate the new sequences into the recipient genome.
      (2) Transformation is also associated with **recombinant DNA technology** or cloning. In this process, the bacterial cell walls are made leaky by chemical treatment or by electrical stimulus (electroporation). **Cloning** involves splicing a gene into a plasmid DNA (vector). All vectors share several common characteristics:
         (a) Typically small, well-characterized molecules of DNA.
         (b) Contain at least one replicon and can be replicated within the host even when the vector contains foreign DNA.
         (c) Code for a phenotypic trait that can be used to detect the presence of the foreign DNA, which can be used to distinguish parental from recombinant vectors.
         (d) Selectable markers (e.g., antibiotic resistance) to find cells that contain these vectors. This marker confers a selective advantage for the bacterial host, such that the plasmid will be stably maintained.
   b. **Conjugation** is the one-way transfer of DNA from a donor cell to a recipient cell through a sex pilus. Donor cells contain the F plasmid, which carries the genes for constructing the sex pilus and transferring the plasmid. Chromosomal DNA can transfer with the F plasmid in certain circumstances. If the F plasmid is integrated into the bacterial chromosome, the strain is designated Hfr (high-frequency recombination), which will transfer significantly more chromosomal DNA.
   c. **Transduction** is the transfer of genetic material by **bacteriophages**. During an infection, the bacteriophage may package fragments of the host DNA into bacteriophage particles, which may then be carried into the recipient bacterial cell at the time of infection. Bacteriophage can result in a **lytic infection** in which the bacteriophage enters the cell, replicates, and lyses the cell to release new progeny bacteriophage. **Lysogenic infections** incorporate the phage genome into the bacterial host DNA. Upon lysogenic conversion, the recipient cell can acquire traits that were carried with the bacteriophage genome. **Several toxins are encoded by bacteriophage**, for example, *Corynebacterium diphtheriae* (diphtheria toxin), *Streptococcus pyogenes* (erythrogenic toxin in scarlet fever), and *Clostridium tetani* (tetanus toxin). The lysogenic (temperate) phage may remain as part of the bacterial genome or can convert to a lytic infection. Transduction is considered **specialized** if the packaged bacterial DNA was adjacent to the integration site for the phage or **generalized** if the transferred DNA originated from random host sequences.

F. **Examples of unique bacteria**
   1. **Chlamydiae** (e.g., *Chlamydia trachomatis*, which causes blindness and sexually transmitted diseases) are obligate intracellular parasites that
      a. lack the ability to generate ATP, which they must obtain from the host cell, and
      b. have a two-phase life cycle.
         (1) The infectious form, or **elementary body** (EB), is a dense, nonreplicating cell that is resistant to drying in the environment.
         (2) The **reticulate body** (RB) forms from the EB after entry into the host cell. The RB is the metabolically active form that multiplies within the host cell vacuole. EBs form from the dividing RBs and will be liberated to infect new cells when the damaged host cell dies.
   2. Human pathogens in the family **Rickettsiaceae** (*Rickettsia*, *Ehrlichia*) are obligate intracellular parasites, most of which are transmitted by **arthropods** (e.g., *Rickettsia rickettsii*, which causes

Rocky Mountain spotted fever). They tend to invade endothelial cells, resulting in a rash, vasculitis, and fever.

3. **Mycoplasmas**, the smallest bacteria, are unique in that they **lack a cell wall** and are thus pleomorphic in shape. Unlike other prokaryotic organisms, mycoplasma plasma membranes contain sterols (e.g., *Mycoplasma pneumoniae*, which causes an atypical or walking pneumonia).

G. Mechanisms of pathogenicity

1. **Overview**. Although signs and symptoms of bacterial disease are often the result of the host response, microorganisms can damage tissue through the production of exotoxins and endotoxins and by the direct effects of the microbe growth.

   a. **Pathogens** are microbes that have mechanisms (virulence factors) to promote invasion or toxigenicity. The presence of these organisms is associated with disease.

   b. **Opportunists** are microbes that take advantage of preexisting conditions (e.g., immunosuppression, injury, reduced normal flora, organ dysfunction) to enhance the ability of the microbe to cause disease.

2. Determinants of bacterial pathogenesis are those features or components of the microbe that allow it to associate with the host or cause disease; **virulence factors** are the characteristics of an organism that allow it to either damage the host or evade host defenses.

3. **Mechanisms of disease**

   a. **Exotoxins** are polypeptides that are secreted by certain bacteria that alter specific host cell function (e.g., cholera toxin increases adenylate cyclase activity, leading to loss of fluid and electrolytes; diphtheria toxin prevents protein synthesis by the ribosome, resulting in cell death). They may be produced by gram-positive and gram-negative bacteria.

      (1) Exotoxins secreted into food or water that are then ingested by a host cause **intoxication** (e.g., botulism and staphylococcal food poisoning).

      (2) Exotoxins produced during an infection may interfere with cell function or physically damage the cell (e.g., *Bordetella pertussis*, *C. diphtheriae*, *V. cholerae*).

      (3) Exotoxins are **antigenic**; **toxoids** are exotoxins that have been modified (inactivated) to induce immunity without toxic effects (see Chapter 57, "Immunology").

   b. Infection is sufficient to cause disease for some microorganisms, especially when the presence of the bacteria elicits a strong **inflammatory response**. Bacterial infections often elicit host immune responses that are **pyogenic** (pus producing), involving neutrophils (e.g., streptococcal pharyngitis, gonococcal urethritis), or **granulomatous**, which elicit macrophages and T lymphocytes, resulting in an inflammatory lesion (granuloma) that can be important for diagnosis (e.g., tuberculosis). Rashes associated with many bacterial infections are often due to inflammation elicited by the presence of the bacteria (e.g., Rocky Mountain spotted fever, meningococcemia). In some cases, infection may be followed by toxin production (see section III.G.3.a), as in diphtheria.

   c. **Invasion of host tissues** and then growth in the tissue is often facilitated by bacterial enzymes (e.g., hyaluronidase, IgA protease, and hemolysin), which act on host tissues and immune defenses. **Intracellular bacteria** invade host cells to avoid immune responses (e.g., *Mycobacterium*, *Shigella*, and *Listeria*). Some bacteria (e.g., *Shigella* species, *Clostridium perfringens*) are able to produce toxins after the invasion of host tissue.

IV. VIRUSES

A. **Overview.** Viruses are **obligate intracellular parasites**. They are inert in the extracellular environment and depend on the intracellular machinery of the living host cells for replication. As such, reproduction of viruses occurs by assembly of the individual components rather than by binary fission.

B. **Taxonomy and nomenclature**. Viruses are classified into **families** (designated with the *-viridae* suffix), by genome structure, virion morphology, and means of replication. Further classification and naming of individual members within a family is often based on mode of transmission, associated disease, host range, and tissue or organ tropism.

1. **Viral structure**

   a. The virus particle (**virion**) consists of a nucleic acid genome packaged into a protein coat (capsid), which may be surrounded by a membrane (envelope). The virion may also contain

enzymes, nucleic acid–binding proteins, and other viral accessory proteins necessary for virion structure or initial replication of the virus within the host cell.

   b. The **genome** of the virus consists of either DNA or RNA, but not both. The DNA can be single or double stranded, linear or circular. The RNA can either be positive sense (like mRNA), negative sense, or double stranded. Additionally, RNA genomes may be segmented into pieces, with each piece containing a portion of the total genome.

   c. **Viral proteins and enzymes.** Structural proteins may be part of the **capsid** or associated with the nucleic acid or envelope. Nonstructural viral proteins are usually enzymes that are necessary to produce viral components important for viral replication (e.g., reverse transcriptase in retroviruses). Smaller viruses tend to be more dependent on host cell machinery than larger viruses, which tend to encode more viral enzymes in the viral genome and have more viral proteins packaged within the virion particle.

2. **Naked capsid (nonenveloped) viruses.** The capsid is a rigid protein structure and generally determines the overall shape of the virus. The capsid proteins assemble into repeating structural units (**capsomeres**) that have chemical features to allow them to fit together without complicated assembly processes, often arranging in icosahedral (20-sided) symmetry. The capsid proteins are important for binding of the virion to the receptor on the host cell in order to infect that cell. Naked capsid viruses are generally **more environmentally stable** and tend to be more resistant to drying, acid, detergents, gastric acid, and bile.

3. **Enveloped viruses** consist of the nucleocapsid as described earlier (usually icosahedral or helical in shape), surrounded by an **envelope**, which is a membrane composed of lipids, proteins, and glycoproteins. Virally encoded proteins and glycoproteins associated with the envelope include the matrix proteins, which line the inside of the envelope, and viral attachment proteins that project through the envelope (**spikes**). The envelope is easily disrupted, which makes most enveloped viruses **environmentally labile**, such that they typically must remain wet, cannot survive the gastrointestinal tract, and are easily inactivated by detergents, acid, and heat.

4. **Atypical virus-like agents**
   a. **Delta agents** (e.g., hepatitis D) have viral nucleic acid but require the presence of a helper virus (for hepatitis D, the helper virus is hepatitis B virus) in order to replicate.
   b. **Prions** are small **proteinaceous infectious particles** that, unlike viruses, do not have a virion structure or genome. Prions are resistant to a wide range of chemical and physical treatments, including disinfectants, formaldehyde, and heat up to 80°C. Human prion diseases tend to affect **neural tissue** following a long incubation period and are generally described as **transmissible spongiform encephalopathies** (TSEs) that can manifest as sporadic, genetic, or infectious diseases. The underlying feature of prion diseases appears to be a conversion of a host-encoded protein to a conformationally distinct isoform that is responsible for the consequences of the disease. Prions are transmitted by contact with infected tissue through transplantation, use of contaminated medical devices, or ingestion. Prion diseases of human importance include kuru, Creutzfeldt-Jakob disease (CJD), and variant CJD (vCJD), which is considered to have been transmitted to humans by ingestion of meat prepared from cattle affected by bovine spongiform encephalopathy (BSE).

C. **Viral replication.** The major steps in viral replication are similar for all viruses, although the individual features of each step can vary. The host cell machinery is commandeered to replicate the viral genome and synthesize viral proteins to assemble the progeny viruses; any processes not provided by the host cell must be encoded by the viral genome.

1. **Attachment.** Viral attachment proteins or glycoproteins (spikes) initiate attachment to the specific receptor on the host cell. The distribution of the host cell receptor determines the viral host range or tissue tropism (e.g., neurotropic, lymphotropic).

2. **Penetration and uncoating.** The mechanism for internalization (penetration) of the virus depends on the virion structure and cell type. Following attachment, a naked capsid virus enters the cell via **endocytosis**. An enveloped virus enters the cell either by **membrane fusion**, which delivers the capsid or nucleic acid directly to the cytoplasm, or by endocytosis followed by vesicle membrane fusion. Once internalized, the nucleic acid must be **uncoated** to make the viral genome accessible to begin the process of reproduction. The process of uncoating varies with the type of virus.

3. **Expression of viral genome and synthesis of viral components.** The next steps of viral replication depend on the type of virus.
   a. **DNA viruses** can use host cell transcription machinery to synthesize mRNA directly. For **positive sense RNA** viruses, the viral genome serves as the initial mRNA transcript. **Negative sense RNA** viruses need to generate mRNA from the viral RNA genome, which requires a virally encoded RNA polymerase. Upon entry into the host cell, **retroviruses** create a DNA copy of the RNA genome using the retroviral reverse transcriptase. mRNA is then made from the DNA copy as described earlier.
   b. **Early protein synthesis** by translation of the mRNA makes use of host cell translation processes, including ribosomes, tRNAs, and amino acids.
   c. Genome replication, like mRNA synthesis, depends on the type of viral genome.
   d. **Late protein synthesis** includes the synthesis of capsid and other structural proteins necessary for assembly of the progeny virions.
4. **Maturation and release.** Association of the viral genome with viral proteins (capsid and accessory proteins) to assemble the virion particle typically occurs in the cytoplasm, the nucleus, or at the cytoplasmic membrane. **Nonenveloped viruses** are usually released after the **host cell lyses**. **Enveloped viruses** assemble at a host cell membrane, usually the cytoplasmic membrane, and then exit the host cell by **budding** through the membrane, which creates the associated membrane envelope.

D. **Types of viral infections**
1. Infection of a cell by a virus may result in a **lytic infection** in which the host cell will die, often due to the interference of normal cellular function by the production of progeny virions.
2. Viral infections, such as measles, herpes simplex virus, and respiratory syncytial virus, can lead to fusion of neighboring cells, forming giant multinucleated cells (**syncytia**).
3. Host cells infected with a virus may also demonstrate **changes in appearance** that can assist with diagnosis (e.g., Negri bodies in brain tissue due to rabies infection).
4. **Persistent infections** in which virus persists in the host for a long period may take several forms.
   a. A **latent infection** occurs when the virus persists within the host cell but new virions are not synthesized. Latent infections may become active to allow viral replication (e.g., herpes simplex virus, varicella-zoster).
   b. A **chronic infection** is a state in which the host cell continues to replicate the virions (e.g., chronic hepatitis B infection).
   c. **Transforming** or **oncogenic** viral infections are persistent infections that stimulate uncontrolled growth or immortalization of the host cell (e.g., human papilloma virus associated with cervical cancer). Different oncogenic viruses have different means of immortalizing the cell.

E. **Mechanisms of pathogenicity**
1. Host cell damage and altered function can be the source of the symptoms of the viral infection.
2. **Immune responses**, specifically inflammatory reactions and hypersensitivities initiated by antiviral immunity, can contribute to the symptoms of a viral illness (e.g., interferon release associated with respiratory tract viral infections). Rashes (exanthems) are often due to the immune response directed to viral antigens and thus to infected cells (e.g., measles, parvovirus B19).
3. Some viruses **modulate the immune response**, resulting in increased susceptibility to secondary infections (e.g., measles virus infections, cytomegalovirus infections).

F. **Genetic variation**
1. **Mutations** occur spontaneously in viral genomes, creating new strains with different properties. In the context of an infection, individual viral strains or mutants with advantageous properties have a selective advantage and can quickly become the predominant strain. The high mutation rate of HIV promotes the development of antiretroviral drug-resistant strains after the initiation of treatment. Other changes that can result from genetic variation include changes in virulence, host range specificity, or tissue/cell tropism.
2. When two **segmented RNA** viruses infect the same host cell, the resulting progeny virions can be reassorted versions of the original two strains. Antigen shift in the influenza virus is an example of **reassortment** that leads to major antigenic changes.

V. TRANSMISSION OF INFECTIOUS AGENTS

A. Infectious agents are found in a number of different environments (**reservoirs**).
   1. Humans are reservoirs for diseases that are obligate human pathogens. When humans are the reservoir for the disease, they are said to be **carriers**.
      a. **Asymptomatic carriers** harbor an infection but have no symptoms. Some asymptomatic carriers carry the infectious agent as part of their normal flora (e.g., *S. pyogenes*).
      b. **Symptomatic carriers** have obvious signs and symptoms of disease.
   2. An animal reservoir exists when the primary host is an animal. Such animals may be wild (e.g., foxes, raccoons) or domesticated (e.g., livestock and pets). A **zoonosis** is an animal disease that can be transmitted to humans.
   3. Environmental reservoirs include soil, lakes, and plants.
B. The transmission of infectious agents depends on the source of infection. Many but not all diseases attributable to microbes are communicable (i.e., spread from person to person). For example, the common cold is communicable; botulism and tetanus are not. Diseases originating from other individuals can be acquired by a number of different mechanisms.
   1. **Contact**
      a. **Direct contact** requires physical contact between an infected individual and a susceptible individual (e.g., sexually transmitted diseases). Person-to-person spread of infection can occur from those infected with an obvious illness; those who are incubating the illness, but have not yet developed symptoms; those with asymptomatic or subclinical infections; and, in some cases, individuals with latent infections.
      b. **Indirect contact** involves a susceptible individual coming in contact with a contaminated surface. **Fomites** are objects that can transfer infectious agents when contaminated (e.g., doorknobs, tabletops and other surfaces, computer keyboards, toys).
   2. **Droplet transmission.** Infected droplets or aerosols are formed when an infected individual coughs or sneezes. The infected droplets transmit the disease to a susceptible individual when they come in contact with the mucous membranes of the individual's nose, mouth, or eyes.
   3. **Airborne transmission.** When small, contaminated dust particles or small infectious aerosol droplets (**droplet nuclei**) remain suspended in the air for long periods, they can transmit disease (e.g., influenza, tuberculosis). These small nuclei can infect both the upper and lower respiratory tracts.
   4. **Food and water contamination.** Food or water contaminated with bacteria or viruses from human or animal infectious material can lead to transmission of disease through the fecal–oral route (e.g., cholera, polio).
C. **Vectors** are living entities capable of transmitting diseases. The most common vector for infectious diseases is the mosquito (e.g., malaria, West Nile virus), although other insects (fleas, ticks, and flies) and mammals (dogs, mice, and rats) can also be vectors for infections (see *Tables 56-1 and 56-2*).
D. An infection is **epidemic** if it occurs with more frequency than usual, **pandemic** if the epidemic is distributed worldwide. An infection that occurs with regular frequency is **endemic**.
E. **Stages of infectious disease**
   1. **Incubation period** is the time between infection and appearance of symptoms.
   2. **Prodrome** is the period when nonspecific symptoms occur; not all infectious diseases have a prodromal period.
   3. **Specific illness** is when the characteristic features of the illness are present.
   4. **Recovery** is the period when the symptoms resolve and health is restored. This period may include a **convalescent phase**, where the agent associated with the disease is no longer detectable, but health is not yet restored.
   5. After the recovery phase, some infections are associated with **latent infections**, where the infection remains in the body in an inactive form, or a **chronic infection**, where the infectious agent continues to be produced.

VI. DISEASES CAUSED BY INFECTIOUS AGENTS

A. Selected major diseases caused by bacteria, fungi, and protozoa (*Table 56-1*).
B. Selected major diseases caused by viruses (*Table 56-2*).

Table 56-1	SELECTED IMPORTANT HUMAN PATHOGENS AND ASSOCIATED DISEASES

Organism	Major Virulence Factors	Route of Transmission[a]	Typical Infection
		Bacteria	
Gram-Positive Cocci: Aerobic and Facultatively Anaerobic			
Staphylococcus aureus	Capsule, protein A, various toxins, hydrolytic enzymes, antimicrobial resistances	Normal flora, person-to-person, ingestion of preformed exotoxin (food poisoning)	Cutaneous infections (impetigo, folliculitis, furuncles, carbuncles); disseminated infections (pneumonia, osteomyelitis, endocarditis, septic arthritis); toxin-mediated diseases (toxic shock syndrome, food poisoning); community-acquired infections
Staphylococcus species (coagulase negative)	Polysaccharide slime layer	Normal flora	Opportunistic infections; infections of foreign bodies (catheters, shunts, prosthetic joints, heart valves)
Streptococcus agalactiae (group B)	Similar to group A streptococci but no capsule	Asymptomatic colonization (genitourinary tract)	Neonatal disease (bacteremia, pneumonia, meningitis)
Streptococcus pneumoniae	Polysaccharide capsule, teichoic acid, immunoglobulin (Ig) A proteases, pneumolysin O	Asymptomatic colonization (nasopharynx or oropharynx), person-to-person (respiratory route)	Pneumonia, meningitis, endocarditis, bacteremia
Streptococcus pyogenes (group A streptococci [GAS])	Capsule, M proteins, pyrogenic exotoxins, streptolysins, streptokinase	Person-to-person (respiratory droplets)	Pharyngitis; scarlet fever; sinusitis; skin and soft tissue infections (impetigo, erysipelas, cellulitis, necrotizing fasciitis); toxic shock syndrome; rheumatic fever; glomerulonephritis
Gram-Positive Rods: Aerobic or Facultatively Anaerobic			
Bacillus anthracis	Capsule, edema toxin, lethal toxin, endospore formation	Endospores inoculated into skin lesions, ingested, or inhaled	Anthrax (cutaneous, gastrointestinal, inhalational)
Corynebacterium diphtheriae	Diphtheria toxin	Person-to-person spread (respiratory droplets or skin contact)	Diphtheria, cutaneous (wound) diphtheria
Listeria monocytogenes	Listeriolysin, adhesins, intracellular growth	Ingestion	Neonatal disease (meningitis, septicemia); spontaneous abortion or preterm delivery; flu-like illness; bacteremia or meningitis in patients with immunodeficiency
Acid-Fast Bacilli (AFB)			
Mycobacterium leprae	Ability to survive and replicate in macrophages	Person-to-person (respiratory aerosols or direct contact)	Leprosy
Mycobacterium tuberculosis	Ability to survive and replicate in macrophages; antibiotic resistances	Person-to-person (respiratory aerosols)	Tuberculosis (pulmonary, extrapulmonary)

Table 56-1 Continued.

Organism	Major Virulence Factors	Route of Transmission[a]	Typical Infection
		Bacteria	

Gram-Negative Cocci: Aerobic

Organism	Major Virulence Factors	Route of Transmission[a]	Typical Infection
Neisseria gonorrhoeae	Pili, adhesions, endotoxin, IgA protease, antigenic variation	Person-to-person (sexual transmission or direct contact for eye infections)	Gonorrhea, pelvic inflammatory disease, septic arthritis, ophthalmia neonatorum
Neisseria meningitidis	Polysaccharide capsule, endotoxin, antigenic variation	Person-to-person (respiratory droplets and secretions)	Meningitis, meningococcemia

Gram-Negative Rods: Aerobic and Facultatively Anaerobic

Organism	Major Virulence Factors	Route of Transmission[a]	Typical Infection
Bordetella pertussis	Pertussis toxin, adenylate cyclase toxin, adhesions, tracheal cytotoxin	Person-to-person (infectious aerosols)	Pertussis (whooping cough)
Campylobacter jejuni	Adhesins, invasion of intestinal mucosa	Ingestion (usually poultry)	Gastroenteritis
Escherichia coli—enteroaggregative (EAggEC)	Pili, cytotoxins	Ingestion	Diarrhea with mucus
E. coli—enterohemorrhagic (EHEC)	Shiga toxin, attaching and effacing factor	Ingestion; rarely, person-to-person	Watery diarrhea, hemorrhagic colitis, uremic syndrome
E. coli—enteroinvasive (EIEC)	Invasion and destruction of colonic epithelium	Ingestion	Watery diarrhea, hemorrhagic colitis
E. coli—enterotoxigenic (ETEC)	Pili, enterotoxins	Ingestion	Watery diarrhea
E. coli—meningitis associated	Capsule, adhesins	Normal flora	Acute meningitis (neonates)
E. coli—uropathogenic	Adhesins, hemolysin	Normal flora	Cystitis, pyelonephritis
E. coli—enteropathogenic (EPEC)	Specialized pili, attaching and effacing factor	Ingestion	Watery diarrhea and vomiting
Francisella tularensis	Capsule, low infectious dose	Zoonosis: arthropod bite, inoculation into skin lesions, inhalation, or ingestion	Tularemia
Haemophilus influenzae	Polysaccharide capsule, pili, adhesions	Asymptomatic colonization (oropharynx)	Meningitis, septicemia, epiglottitis, otitis media, sinusitis, bronchitis, pneumonia
Helicobacter pylori	Urease, cytotoxin	Person-to-person (fecal–oral)	Gastritis, peptic and duodenal ulcers, gastric cancer
Legionella pneumophila	Adhesins, cytotoxins, survival in macrophages	Infectious aerosols from contaminated water	Legionnaire disease (pneumonia), Pontiac fever (flu-like illness)
Pseudomonas aeruginosa	Capsule, exotoxins, phospholipase C, elastase, antimicrobial resistances	Opportunistic infection from environmental source: wounds, indwelling catheters, damaged cornea, lung infections	Skin infections, urinary tract infections, ear or eye infections, bacteremia, pulmonary infections (cystic fibrosis)
Salmonella enterica	Specialized secretion system, survival in macrophages	Ingestion of contaminated food, person-to-person, in children (fecal–oral); typhoid fever, person-to-person only	Diarrhea, enteric (typhoid) fever (ssp., typhi)

Table 56-1   Continued.

Organism	Major Virulence Factors	Route of Transmission[a]	Typical Infection
		Bacteria	
Shigella species	Specialized secretion system, intracellular spread, low infectious dose	Person-to-person (fecal–oral)	Bacillary dysentery
Vibrio cholerae	Cholera toxin, pili	Ingestion of contaminated food or water (person-to-person is rare)	Severe watery diarrhea
Yersinia pestis	Specialized secretion system, protein capsule, adhesins	Zoonosis, flea bites; person-to-person, inhalation of infected aerosols	Bubonic and pneumonic plague
Anaerobes			
Clostridium botulinum	Endospore formation, botulism toxin	Ingestion of preformed toxin, ingestion of spores, infant botulism	Botulism: foodborne, infant, wound
Clostridium difficile	Endospore formation, enterotoxin, cytotoxin	Asymptomatic colonization followed by reduced normal flora after antibiotic therapy	Antibiotic-associated diarrhea, pseudomembranous colitis
Clostridium perfringens	Endospore formation, many toxins, and hemolytic enzymes	Contamination with environmental spores (wounds), ingestion of preformed toxin (food poisoning)	Soft tissue infections (cellulitis, fasciitis, myonecrosis or gas gangrene); food poisoning; septicemia
Clostridium tetani	Endospore formation, tetanus toxin (tetanospasmin)	Inoculation of tissue with environmental spores	Tetanus
Unusual Bacteria			
Chlamydia trachomatis	Unknown	Sexual contact, ocular infections through direct contact, or fomite contact (especially flies)	Trachoma, neonatal conjunctivitis and pneumonia, urethritis, cervicitis, salpingitis, lymphogranuloma venereum
Chlamydophila pneumoniae	Unknown	Respiratory droplets and secretions	Pneumonia
Chlamydophila psittaci	Unknown	Zoonosis: inhalation of dried excrement or secretions from infected birds	Pneumonia
Coxiella burnetii	Intracellular survival, endospore-like structures	Zoonosis: inhalation	Q fever
Ehrlichia chaffeensis	Intracellular growth	Tick bite	Human monocytic ehrlichiosis
Mycoplasma pneumoniae	Adhesins	Inhalation of aerosolized droplets	Atypical pneumonia (walking pneumonia)
Rickettsia rickettsii	Intracellular survival, cell-to-cell spread	Tick bite	Rocky Mountain spotted fever
Spirochetes			
Borrelia burgdorferi	Adhesins	Tick bite	Lyme disease
Leptospira interrogans	Direct invasion through the skin, immune complex formation (glomerulonephritis)	Inoculation of skin through contaminated water	Leptospirosis
Treponema pallidum	Adherence factors, immune evasion	Sexual contact, congenital	Syphilis, congenital syphilis

(Continued on next page)

Table 56-1   Continued.

Organism	Major Virulence Factors	Route of Transmission[a]	Typical Infection
Bacteria			
Fungi			
Aspergillus species	Toxins, hypersensitivity reactions, enzymes	Inhalation	Mycotoxicosis (bleeding), allergic bronchopulmonary aspergillosis, pneumonia, organ abscesses (opportunistic mycosis)
Blastomyces dermatitidis	Survival in macrophages	Inhalation of aerosolized fungi from environmental source	Asymptomatic pulmonary infection, chronic skin and bone infections
Candida albicans	Normal flora	Opportunistic, endogenous infection, usually immunosuppressed individual	Oral thrush, vaginitis, chronic mucocutaneous candidiasis, systemic infections (opportunistic mycosis)
Cryptococcus neoformans	Mucopolysaccharide capsule	Inhalation of aerosolized environmental fungi	Pulmonary masses, chronic meningitis, cerebral masses, systemic spread (usually in immunocompromised patients)
Epidermophyton species, *Microsporum* species, *Trichophyton* species	Keratinase, elastase	Direct contact or fomite contact, environmental source, person-to-person	Dermatophytoses (tinea)
Histoplasma capsulatum	Survival in macrophages	Inhalation of aerosolized fungi from environmental source	Latent infections, acute pulmonary histoplasmosis, disseminated histoplasmosis
Pneumocystis jirovecii	Opportunistic infection	Airborne transmission (unknown source), immunosuppressed patients	Pneumocystis pneumonia (PCP) especially in AIDS patients
Protozoa			
Entamoeba histolytica	Cytotoxin, infective cyst, adhesin	Ingestion of cysts in contaminated water	Asymptomatic infection, intestinal amebiasis (colitis with diarrhea), amebic liver abscess
Giardia lamblia	Motility, infective cyst, attachment structure	Ingestion of cysts in contaminated water	Asymptomatic infection, acute watery diarrhea, chronic intermittent diarrhea with malabsorption
Plasmodium species	Mosquito vector, intracellular survival	Mosquito bite	Malaria
Toxoplasma gondii	Oocyst, intracellular survival	Ingestion of undercooked meat, ingestion of oocysts from contaminated cat feces, transplacental	Asymptomatic infection; spontaneous abortion stillbirth or severe neonatal disease (epilepsy, encephalitis, chorioretinitis, hydrocephalus)
Trichomonas vaginalis	Adhesion factors, motility	Sexual contact	Asymptomatic infection, vaginitis
Trypanosoma brucei	Tsetse fly vector, motility	Tsetse fly bite	African sleeping sickness

[a]Not all routes of transmission are described.

Table 56-2	IMPORTANT HUMAN VIRUS FAMILIES AND ASSOCIATED DISEASES

Family	Virion Morphology	Virus[b]	Transmission[c]	Major Associated Diseases
DNA Viruses[a]				
Poxviridae	Enveloped	Variola	Respiratory route	Smallpox
		Molluscum contagiosum	Direct contact (lesions, fomites)	Molluscum skin lesions
Herpesviridae	Enveloped	Herpes simplex virus 1 (HSV-1)	Close contact (saliva, vaginal secretions, vesicle fluid)	Fever blisters, cold sores, genital lesions
		Herpes simplex virus 2 (HSV-2)	Close contact (saliva, vaginal secretions, vesicle fluid); sexual contact	Genital lesions, oral lesions, neonatal HSV
		Varicella zoster	Respiratory route (respiratory droplets)	Chicken pox, shingles
		Epstein-Barr virus	Close contact (oral secretions)	Infectious mononucleosis, Burkitt lymphoma
		Cytomegalovirus (CMV)	Blood, organ transplants, close contact with secretions, transplacental	Chronic fatigue syndrome, mononucleosis syndrome, cytomegalic inclusion disease (congenital infection)
Adenoviridae	Naked capsid (nonenveloped)	Adenovirus	Direct contact via respiratory droplets, fecal–oral route (gastroenteritis)	Acute respiratory disease, pneumonia, conjunctivitis, gastroenteritis
Hepadnaviridae	Enveloped	Hepatitis B virus	Blood, sexual contact, neonatal	Hepatitis B (serum hepatitis), primary hepatocellular carcinoma
Papillomaviridae	Naked capsid (nonenveloped)	Human papillomavirus (HPV)	Direct contact (fomites), sexual contact	Skin warts, mucosal papillomas, anogenital warts, cervical cancer (certain HPV types)
Polyomaviridae	Naked capsid (nonenveloped)	JC virus	Respiratory route (probably)	Progressive multifocal leukoencephalopathy (immunocompromised patients)
Parvoviridae	Naked capsid (nonenveloped)	Parvovirus B19	Respiratory route (respiratory droplets), transplacental (fetal anemia)	Erythema infectiosum (fifth disease), fetal anemia
RNA Viruses[a]				
Paramyxoviridae	Enveloped	Parainfluenza	Respiratory route (droplet aerosols)	Cold-like illness, bronchitis, croup
		Measles virus (*Morbillivirus*)	Respiratory route (respiratory droplets)	Measles; pneumonitis; pneumonia; rarely, subacute sclerosing panencephalitis
		Mumps virus	Respiratory route (respiratory droplets)	Mumps
		Respiratory syncytial virus	Respiratory route (respiratory droplets)	Bronchiolitis, pneumonia (infants), common cold (older patients)
Orthomyxoviridae	Enveloped	Influenza viruses (A, B, and C)	Respiratory route (respiratory aerosols)	Classic flu, severe respiratory tract infection

Table 56-2   Continued

Family	Virion Morphology	Virus[b]	Transmission[c]	Major Associated Diseases
Coronaviridae	Enveloped	Corona virus	Respiratory route (respiratory aerosols)	Common cold
		Severe acute respiratory syndrome (SARS) virus	Respiratory route (respiratory aerosols)	Atypical pneumonia
Arenaviridae	Enveloped	Lassa fever and Machupo viruses	Zoonosis: inhalation of rodent aerosols	Hemorrhagic fever
Rhabdoviridae	Enveloped	Rabies virus	Zoonosis: saliva of infected animal (usually through a bite)	Rabies
Filoviridae	Enveloped	Ebola and Marburg viruses	Direct contact with infected blood or secretions	Hemorrhagic fever
Bunyaviridae	Enveloped	California encephalitis virus	Mosquito bite	Febrile illness, rash, encephalitis
		Hemorrhagic fever virus (e.g., Rift Valley fever)	Mosquito bite	Hemorrhagic fever, hemorrhagic pneumonia
		Hantavirus	Close contact with rodents, inhalation of rodent aerosols	Pulmonary edema, severe respiratory infection
Retroviridae	Enveloped	HIV (types 1 and 2)	Blood, sexual contact, perinatal	AIDS
		Human T-cell leukemia virus (types 1 and 2)	Blood, sexual contact, perinatal	Asymptomatic (usually), lymphocytic leukemia
Reoviridae	Nonenveloped, double capsid	Rotavirus	Fecal–oral route	Gastroenteritis
		Colorado tick virus	Tick bite	Hemorrhagic disease, meningitis, and encephalitis
Picornaviridae	Naked capsid (non-enveloped)	Rhinoviruses	Respiratory route; direct contact (secretions, fomites)	Common cold
		Polioviruses	Fecal–oral route	Asymptomatic or minor illness, paralytic poliomyelitis
		Echoviruses	Fecal–oral route	Febrile illness, carditis, aseptic encephalitis, meningitis
		Coxsackievirus	Fecal–oral route	Hand-foot-and-mouth disease, carditis, aseptic encephalitis, meningitis
		Hepatitis A and E viruses	Fecal–oral (ingestion of contaminated foods)	Acute hepatitis
Togaviridae	Enveloped	Rubella virus	Respiratory route, transplacental	Rubella (German measles), congenital defects

Table 56-2	Continued			
Family	**Virion Morphology**	**Virus**[b]	**Transmission**[c]	**Major Associated Diseases**
		Western, Eastern, and Venezuelan equine encephalitis viruses	Zoonosis (animals, insects)	Encephalitis
Flaviviridae	Enveloped	Yellow fever virus	Mosquito bite	Yellow fever (hepatitis, gastrointestinal hemorrhage)
		Dengue virus	Mosquito bite	Breakbone fever, hemorrhagic fever
		West Nile virus	Zoonosis (birds, mosquitoes)	Asymptomatic infection, encephalitis
		Hepatitis C virus	Blood	Acute or chronic hepatitis, cirrhosis
Caliciviridae	Naked capsid (non-enveloped)	Noroviruses (Norwalk virus)	Fecal–oral route (ingestion of contaminated food or water)	Gastroenteritis

[a]Arranged in order based on the size of the virus.
[b]Not all viruses within a family are represented.
[c]Not all routes of transmission are described.

Study Questions

Directions: Each question, statement, or item in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Which of the following is responsible for the acid-fast staining characteristic of mycobacteria?

   (A) The peptidoglycan
   (B) The polysaccharide capsule
   (C) The cytoplasmic membrane
   (D) The cell wall mycolic acid
   (E) The cell wall lipoteichoic acid

2. Of the following features, which is unique to gram-positive bacteria?

   (A) Cytoplasmic membrane
   (B) Endotoxin
   (C) Outer membrane
   (D) Peptidoglycan
   (E) Spore formation

3. Which structure is characteristic of a prokaryotic organism?

   (A) Nuclear membrane
   (B) 80S ribosome
   (C) Peptidoglycan
   (D) Electron transport chain
   (E) Segmented genome

4. Which of the following is an advantage for the bacterium that is attributable to the bacterial capsule?

   (A) It is antiphagocytic.
   (B) It is a source of nutrition.
   (C) It provides protection from dry, harsh environments.
   (D) It allows for the exchange of DNA between different bacteria.
   (E) It inactivates antimicrobials.

5. Which of the following is a protozoan infection that can lead to lesions in the eye if it is acquired congenitally (in utero)?

   (A) Malaria
   (B) Giardiasis
   (C) Cryptosporidiosis
   (D) Toxoplasmosis
   (E) Amebiasis

6. The envelope of an enveloped virus is derived from which of the following sources?

   (A) The viral capsomeres
   (B) The host cell membrane
   (C) The viral matrix proteins
   (D) The 80S ribosome
   (E) The retroviral reverse transcriptase

Answers and Explanations

1. **The answer is D** *[see III.A.3.c; III.B.4.b].*
   The acid-fast stain uses a procedure to stain cells that have an outer layer of a waxy lipid, which is composed of mycolic acid and glycolipids (acid-fast, stained red). This waxy layer prevents removal of the stain by an acid rinse. The stain is removed from cells that lack that layer; these cells are then counterstained blue (non–acid-fast). The peptidoglycan (and its thickness) has a greater effect on the staining properties of the gram stain. The polysaccharide capsule stain is a colloidal stain that is excluded from the area occupied by the capsule. Lipoteichoic acid is a feature of the gram-positive cell wall.

2. **The answer is E** *[see III.B.4.a; III.B.6].*
   Endospores or bacterial spores are dehydrated multishelled structures formed by some gram-positive organisms (*Clostridium* and *Bacillus*) in response to adverse conditions. All bacteria have a cytoplasmic membrane, and nearly all have peptidoglycan cell walls (except mycoplasma). The outer membrane and endotoxin are unique to gram-negative organisms.

3. **The answer is C** *[see III.B.1].*
   Eukaryotic organisms have membrane-bound organelles (nucleus and the associated nuclear membrane, Golgi apparatus, mitochondria, lysosome, etc.). The bacterial ribosome is 70S, whereas the eukaryotic ribosome is 80S. Aerobic and facultative anaerobic bacteria use the electron transport chain, although it is contained in the bacterial cytoplasmic membrane rather than in the membrane of the mitochondria, as it is in the eukaryotic cell. Peptidoglycan is a structure of most bacteria, but not found in eukaryotic cells. Some RNA viruses have a segmented genome.

4. **The answer is A** *[see III.B.5.a].*
   The capsule is antiphagocytic, provides some adherence properties, and is somewhat of a barrier to hydrophobic molecules. The sex pilus mediates the exchange of DNA. An endospore protects the bacterium from harsh environments. Specific enzymes (e.g., β-lactamase) inactivate antimicrobials.

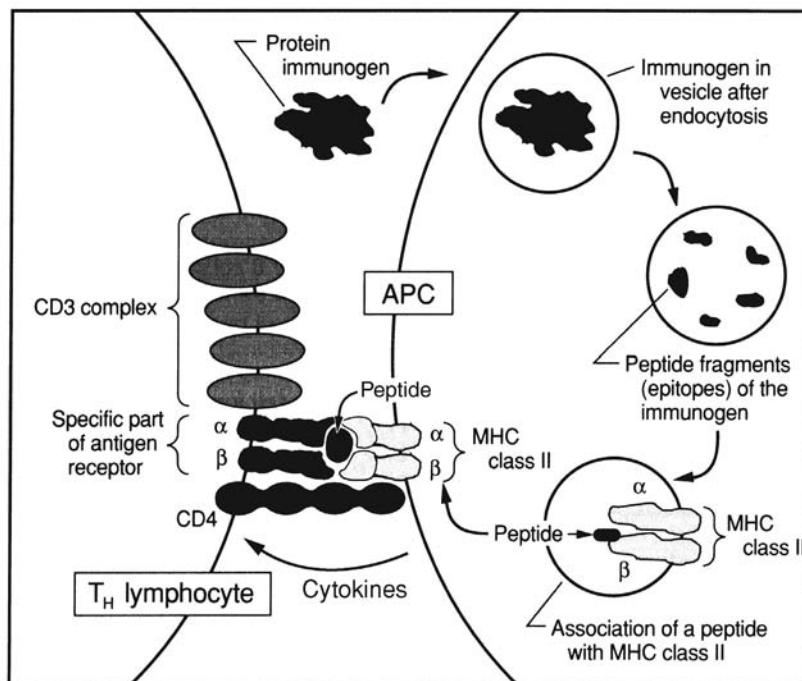
5. **The answer is D** *[see II.B.4.b.(2)].*
   Toxoplasmosis, the infection caused by *Toxoplasma gondii*, is usually mild, although, when acquired during pregnancy, can be transmitted to the fetus resulting in abortion, stillbirth, or neonatal disease (chorioretinitis, blindness, encephalitis, and hepatosplenomegaly). Malaria, associated with *Plasmodia* species, leads to a number of issues for the mother and infant when the infection is acquired during pregnancy, but after birth, the issues tend to be more related to the susceptibility to future infections with *Plasmodia* species Amebiasis is caused by *Entamoeba histolytica*. *Giardia lamblia* is responsible for giardiasis, which is a watery diarrhea. *Cryptosporidium* species infections usually result in a mild, self-limiting diarrhea.

6. **The answer is B** *[see IV.C.4].*
   Enveloped viruses assemble at a host cell membrane, usually the cytoplasmic membrane, and then exit the host cell by budding through the membrane, which creates the associated membrane envelope. Additional viral proteins and glycoproteins are added to the membrane to assist with the attachment of the virion particle to the next cell.

Immunology

TERRI S. HAMRICK, GILBERT A. STEINER

I. THE PHYSIOLOGY OF THE IMMUNE SYSTEM

A. **Immunogens, antigens, and haptens**
1. **Immunogens** are chemical compounds that cause a specific immune response.
2. **Antigens** are chemical compounds that interact with products of the adaptive immune response. An antigen may have several antigenic determinants (**epitopes**).
3. **Factors influencing immunogenicity of an antigen**
   a. In general, molecules recognized as "self" are not immunogenic.
   b. The most potent immunogens are usually large (> 5000 Da) proteins. Carbohydrates, lipids, and even nucleic acids can elicit an antibody response, although association with a protein improves immunogenicity (e.g., glycoproteins, lipoproteins, nucleoproteins).
   c. Some low-molecular-weight molecules (**haptens**) become immunogenic only when linked to a carrier protein. Certain drugs (e.g., penicillin) as well as some environmental substances (e.g., pentadecacatechol of poison ivy) are known to be haptens.
   d. **Adjuvants** are substances that enhance the immunogenicity of an antigen (section X.C.1.b).
4. In this chapter, the term *antigen* is used for compounds that are both immunogens and antigens.
B. The **cells of the immune system** are principally the white blood cells or leukocytes. These cells are derived from hematopoietic stem cells that originate in the bone marrow.
1. **Granulocytes** have prominent cytoplasmic granules containing reactive substances that kill microorganisms and stimulate other divisions of the immune response by activating inflammation.
   a. **Neutrophils** (also known as polymorphonuclear leukocytes or PMNs because of their multilobed nucleus) are the most numerous white blood cells in the blood. They are particularly good at **phagocytosis** (the process of capturing, engulfing, and killing microorganisms). Neutrophils are rapidly recruited to sites of **inflammation**. The mechanism of killing employed by neutrophils is detailed in section II.G.
   b. **Eosinophils** are granulocytes that are important for defenses against helminth worms and other intestinal parasites. They also play a role in allergies (hypersensitivity reactions) and asthma.
   c. **Basophils** also participate in the defense against parasites, although that process is less well understood.
2. **Monocytes** are leukocytes that circulate in the blood; as they migrate into the tissue, they become resident tissue **macrophages**. Macrophages are **phagocytic cells** that rid the body of dead cells, cellular debris, and serve as sentinel cells for the early detection of infection and tissue damage. They also produce cytokines that activate inflammation, recruit leukocytes such as neutrophils and additional macrophages to the site of the infection, and assist in activating the adaptive immune response by serving as antigen-presenting cells for T cells.
3. **Dendritic cells** are branched or dendritic-shaped cells that are very effective for initiating T-cell responses. Dendritic cells are resident within the tissues of the body, where they are phagocytic. They then enter the lymphatics to travel to the local secondary lymph tissue, where they express additional adhesins for interaction with T cells and present the antigens from the peripheral tissues.
4. **Mast cells** are resident in all connective tissues. They possess granules that contain a number of preformed inflammatory mediators, including histamine and tumor necrosis factor (TNF)-α. Together with IgE, they are involved in type I hypersensitivity reactions (section VI.B).


5. **Natural killer** (**NK**) **cells** are large, granular, lymphocyte-like cells that function in the targeted killing of cells such as virus-infected cells and tumor cells.

6. **Lymphocytes** are the primary cells of the adaptive immune response. All B and T lymphocytes are antigen specific via antigen receptors on the cell surface. Lymphocyte antigen receptors structurally consist of globular protein motifs know as immunoglobulin (Ig) domains. Ig domains are characteristic of many cell surface and secreted proteins of the immune system. In this chapter, the terms *B cell* and *T cell* are used instead of B lymphocyte and T lymphocyte.

   a. **B lymphocytes** (B cells) are primarily responsible for **humoral immunity** (antibody re–sponse). The antigen-specific receptor on the surface of the B cell is essentially a membrane-bound antibody molecule in association with accessory proteins (Igα and Igβ), which together make up the B-cell receptor (BCR). The antibody is roughly "Y" shaped with the transmembrane region positioned in the stem of the "Y" and the antigen-binding region at the ends of the arms. (Antibodies are further described in section IV.) Different B cells have different antigen specificity, but each B cell has only one specificity. Binding of the specific antigen stimulates the B cell for proliferation to form new B cells (**clonal expansion**) and differentiation into **plasma cells**, which secrete free-soluble antibody (*Figure 57-1*).

      (1) **Naive B cells** have antigen-specific immunoglobulin on the surface but have not yet interacted with a specific antigen.

      (2) **Memory B cells** are long-lived B cells that were selected as part of a previous immune response and are more rapidly activated if the antigen enters the body again.

   b. **T lymphocytes** (T cells) are responsible for **cell-mediated acquired immunity**. The T-cell receptor (TCR) consists of two membrane proteins (typically αβ or less often, γδ), which are responsible for the antigen specificity, and several other membrane and cytosolic proteins known as the *CD3 complex*, which is responsible for intracellular signaling. Different T cells

Figure 57-1. B cells: Antigen specificity and activation. During development in the bone marrow, progenitor cells give rise to a large number of B cells, each with different surface-expressed antibodies with different antigen specificity. Antibodies are able to bind antigens directly and do not require any processing of the antigen in order to bind to the corresponding epitope. During an infection, only those B cells with antibodies able to bind to the antigens are activated. Proliferation of pathogen-activated B cells and differentiation into antibody-secreting plasma cells will give rise to antibodies able to act in the adaptive immune response to the infection.

have different antigen specificity, but each T cell has only one specificity. Two major subsets of T cells exist: **helper T cells** (T$_H$ cells), which also express the coreceptor glycoprotein **CD4**, and **cytotoxic T cells** (T$_C$ cells), which express the coreceptor glycoprotein **CD8**.

(1) The TCR binds to a peptide fragment of an antigen that has been processed and presented with **major histocompatibility complex** (MHC, also known as human leukocyte antigens or HLAs) on the surface of another cell. The coreceptors, CD4 and CD8, assist with the recognition of the MHC presenting the antigen. MHC proteins involved in antigen presentation are divided into two classes.

   (a) **Class I MHC.** Peptides that originate from inside the host cell (e.g., viral antigens) are processed via a cytosolic pathway and presented on the surface with class I MHC. Class I MHC is present on **all nucleated cells** and presents peptides to T$_C$ cells. The class I MHC genes are known as *HLA-A, -B*, and *-C*.

   (b) **Class II MHC.** Peptides that originate from outside of the host cells are engulfed via phagocytic, endocytic, or pinocytic processes, degraded and then complexed with class II MHC in specific membranous vesicles prior to presentation on the cell surface. Class II MHC is typically only expressed on **"professional" antigen-presenting cells** (B cells, macrophages, and dendritic cells), which then present peptides to T$_H$ cells (*Figure 57-2*). The class II MHC genes are known as *HLA-DP, -DQ*, and *-DR*.

   (c) Each person inherits one set of MHC genes (haplotype) from each parent, and all inherited genes are expressed simultaneously on the appropriate cell types. HLA type is important for transplantation and is discussed further in section IX.

Figure 57-2. Helper T-cell (T$_H$ cell) antigen recognition. During development in the bone marrow and thymus, T-cell precursor cells give rise to a large number of T cells with different T-cell receptors (TCRs). The TCR consists of conserved signaling proteins (CD3 complex) and αβ-glycoprotein chains with different antigen specificity. Different T cells have different antigen specificity, but each T cell has only one specificity. Antigens that originate from outside of the host cells are engulfed via phagocytic, endocytic, or pinocytic processes and degraded into smaller peptides that are then complexed with class II MHC prior to presentation on the surface of the APC. The TCR only recognizes the complex formed by peptides bound to major histocompatibility complex (MHC) proteins on the surface of host cells. The CD4 molecule on the T$_H$ cell assists in recognizing the class II MHC on the APC. *MHC*, major histocompatibility complex; *APC*, antigen-presenting cell (B cell, macrophage, or dendritic cell).

(2) Naive T cells are those that are mature but have not yet encounter the specific antigen for activation.

(3) Binding of the specific antigen in the right context activates the T cell for proliferation to form new T cells (**clonal expansion**) and differentiation into **effector T cells**. The effector activity of the T cell depends on the type of T cell and the environment of the activation. The activity of the T cell is accomplished through the cytokines (see *Table 57-1*) that the T cell produces and via contact with nearby cells (further developed in section III). **T_H effector cells** can be divided into two functional groups: type 1 T_H cells (T_H1) and type 2 T_H cells (T_H2).

Table 57-1 MAJOR PROPERTIES OF SELECTED CYTOKINES

Cytokine	Sources of Secretion[a]	Major Actions
CXC chemokine (IL-8)	T_H1, macrophages	Attracts (chemotactic factor) and activates macrophages, neutrophils, and appropriate T cells
GM-CSF	T_H1	Proliferation of granulocytes, macrophages, and dendritic cells from bone marrow
IFN-γ	T_H1, CTL	Increased production of IgG, inhibition of T_H2 cells, activates macrophages and neutrophils, stimulates NK cytolytic activity, increases generation of T_H1 cells, increased expression of MHC (class I and II) on APCs and other cells
IL-1	Macrophages	Activates vascular endothelium, T cells and APCs; promotes B-cell growth and antibody production, proinflammatory
IL-2	T_H0, T_H1	Proliferation of activated T cells
IL-3	T_H1, T_H2	Growth factor for hematopoietic cells
IL-4	T_H2, T_{REG}	Proliferation of activated B cells, increased expression of class II MHC on B cells, production of IgG4 and IgE Ab, inhibits macrophage activation, increase in growth of mast cells, increased production of T_H2 cells
IL-5	T_H2	Activates eosinophils, proliferation and maturation of B cells, increased production of IgA
IL-6	T_H2, macrophages	Growth of B cells, production of IgG; induces fever and production of acute-phase proteins[b]; proinflammatory
IL-7	Bone marrow stromal cells	Stimulates growth and proliferation of developing B cells
IL-10	T_H2, T_{REG}	Decreases expression of class II MHC on macrophages, inhibits T_H1 production, inhibits cytokine release by macrophages, increases mast cell proliferation, anti-inflammatory
IL-12	Macrophages	Increased production of T_H1, activates NK cells
IL-13	T_H2, T_{REG}	Inhibits macrophage activation
TGF-β	T_H2, T_{REG}	Suppresses the activity of inflammatory cells and inflammation (especially in the presence of IL-6), anti-inflammatory, increased production of IgA (especially in the presence of IL-10)
TNF-α	T_H1, macrophages	Together with IFN-γ, activates macrophages and neutrophils; localized release, initiates inflammation; systemic release leads to fever and shock; proinflammatory

[a]Not all sources are listed.
[b]Acute-phase proteins include C-reactive protein, mannose-binding lectin, and fibrinogen.
Ab, antibody; *CTL*, cytotoxic T lymphocyte; *CXC*, a protein structure motif, typified by a cysteine (C), another amino acid (X), and a cysteine (C); *IL*, interleukin; *IFN*, interferon; *APC*, antigen-presenting cell; *GM-CSF*, granulocyte-macrophage colony-stimulating factor; *MHC*, major histocompatibility complex; *NK*, natural killer; *TGF*, transforming growth factor; T_H, T-helper lymphocyte; T_H0, newly activated T-helper cell; *TNF*, tumor necrosis factor.

   (4) T_H1 cells are primarily involved in **cell-mediated immunity**. The main cytokines of T_H1 cells (interleukin [IL] 2, interferon-γ [IFN-γ], and others) lead to inflammation, macrophage activation, and the production of opsonizing antibodies (those that assist with phagocytosis).

   (5) T_H2 cells are primarily involved in **humoral immunity** and **anti-inflammatory** immune defenses. The main cytokines produced by T_H2 cells include IL-4 and IL-5.

   (6) T_C cells become cytotoxic effector cells (cytotoxic T lymphocytes or **CTLs**) either directly via antigen presented by the dendritic cell or with the help of activated T_H cells. The naive T_C cell requires strong signals to become a CTL. The effector function of the CTL is to kill target cells that express the peptide: MHC, usually virus-infected cells or tumor cells (further described in section III.B.2.b). The target cell dies by apoptosis (programmed cell death).

   (7) T regulatory (T_{REG}) CD4+ T cells are autoreactive T cells whose function is to suppress activity of effector T cells and prevent the activation of naive autoreactive CD4+ and CD8+ T cells. This is accomplished through direct contact and through the expression of immunosuppressive and anti-inflammatory cytokines (IL-4, IL-10, and transforming growth factor [TGF]-β).

C. Organs of the immune system

 1. Primary immune organs (thymus and bone marrow) are the sites of lymphocyte development and maturation. The creation of the antigen-specific receptors of the lymphocytes occurs during development in the primary organs before the lymphocyte encounters antigen. **B-cell** development occurs in the **bone marrow**; **T-cell** development begins in the **bone marrow** and finishes in the **thymus**.

 2. Secondary immune tissues are the sites throughout the body where antigen-specific lymphocytes contact antigens. Antigens enter the different types of secondary lymph tissues via different mechanisms. Both B and T cells circulate throughout the body, passing through the secondary lymphoid tissue. Lymphocyte circulation is influenced by chemokines and cell surface receptors. Each secondary lymph tissue has T- and B-cell zones for activation and differentiation of lymphocytes. Upon immune stimulation, activation of appropriate B and T cells will lead to the formation of **germinal centers**, which are areas of intense B-cell proliferation and differentiation.

  a. Lymph nodes throughout the body are connected via **lymphatic vessels**. Fluid (**lymph**) from extravascular spaces is collected in the lymphatic vessels and returned to the circulation via the left subclavian vein. The naive lymphocytes enter the lymph node via the blood vessels and migrate to their respective B- and T-cell zones. Free antigens from the tissue, dendritic cells (with processed antigen), and immune complexes enter the lymph node in the lymph. Lymphocytes that recognize specific antigens (either free antigens in the case of B cells or presented with appropriate MHC in the case of T cells) will proliferate and differentiate into effector lymphocytes (further described in sections III and IV).

  b. The **spleen** is primarily responsible for **surveillance of the blood**. Antigens that arrive in the blood activate B cells and T cells for proliferation and differentiation in the same manner as for the lymph node.

  c. The mucosal epithelium of the respiratory and the gastrointestinal tracts are particularly vulnerable to infection and contain specialized secondary lymph tissue broadly referred to as **mucosa-associated lymphoid tissue** (MALT). Gut-associated lymphoid tissues (GALTs) include the tonsils, adenoids, and Peyer patches. Antigens are delivered across the mucosa and into the MALT by specialized epithelial cells, such as **M cells** (microfold cells).

II. INNATE IMMUNITY

A. Overview. Innate immunity includes defenses (physical, chemical, and cellular) that are poised to either prevent an infection or **act rapidly** to an infection. Innate defenses do not need prior exposure to an antigen to respond.

B. Anatomic and mechanical barriers to infection are designed to prevent infectious agents from accessing the body and include the **skin**, which is covered by protective layers of keratinized cells; **mucus**, which provides a mechanical and chemical barrier to infection; and **chemical and molecular factors**, such as surfactants, low pH, high salt, and acids. Some of these factors (low pH, high salt, surfactants, and acid) interfere directly with microbial life, whereas others recognize features of microbes that are common to some or all microbes (e.g., the enzyme lysozyme, which is found in tears, saliva, gastric secretions, and lysosomal granules of phagocytes, cleaves peptidoglycan of bacterial cell walls).

Defensins and **cathelicidins** are small cationic antimicrobial peptides that have direct antimicrobial activity, are found at mucosal surfaces, and are produced by many immune cells. **Interferons**, which interfere with viral replication, are released by host cells or immune cells in response to the presence of intracellular viruses. **Biological factors** such as normal flora bacteria (especially on the skin and gastrointestinal tract surfaces) provide a defense against infection by physically preventing access to the surfaces of the body, producing metabolites that create an inhospitable environment for pathogens, and consuming available nutrients.

C. **Phagocytosis** is the process by which microbes are engulfed and destroyed by immune cells, usually neutrophils or macrophages. Phagocytes can recognize some microbes directly (further discussed in section II.G).

D. **The complement system** consists of approximately 30 circulating and membrane-expressed proteins that serve as an effector system of both the innate and antibody-mediated adaptive immune responses. Most of the complement components are synthesized in an inactive form by the liver, and then activated, in a cascade manner, when needed. **Complement activation** occurs through three different pathways: alternative, classical, and lectin. Complement is responsible for increases in the inflammatory response, opsonization to enhance phagocytosis, lysis of cells, and immune complex clearance. Regardless of the mechanism of activation, all three pathways converge at C3, which is the most abundant complement protein in the blood.

1. **Complement activation**
   a. The **alternative pathway** of complement activation is triggered by the carbohydrates, lipids, and proteins that are often found on foreign surfaces, particularly bacteria and fungi. The precipitating event involves spontaneous hydrolysis of complement C3 followed by C3b covalently binding to nearby surfaces. Other complement components then associate to continue the cascade of activation.
   b. The **classical pathway** is initiated by the association of complement component C1 with immune complexes containing IgG or IgM. Alternatively, C1 can bind to several pentraxin proteins that are synthesized in response to infection, including pentraxin 3 (PTX3) and the **acute-phase proteins**—C-reactive protein (CRP) and serum amyloid P-component (SAP). Binding of C1 then activates other complement components to continue the cascade of activation.
   c. The **lectin pathway** is activated when the **mannose-binding lectin** (MBL) binds to the carbohydrate moieties found on the surface of many bacteria, fungi, and parasites. Binding of MBL induces a conformational change such that MBL-associated proteins are active to continue the cascade of activation.

2. **Defensive functions of complement.** In the initial stages of the complement cascade, individual components are cleaved into fragments (typically designated by lowercase letters) that sequentially generate biologically active molecules. Because one active complement molecule can act on multiple subsequent complement molecules, initially small-initiating signals can be rapidly amplified.
   a. **Opsonins** produced by complement, chiefly C3b, are covalently attached to the target surface. Phagocytic cells that have receptors for C3b include neutrophils and resident tissue macrophages.
   b. **Anaphylatoxins** (potent activators of inflammation) are peptides (C3a and C5a) that exert their effects by binding to receptors present on a number of different cell types. Anaphylatoxins act as **chemoattractants** for phagocytes, stimulate **vasodilation** and smooth muscle contraction, and induce **histamine release** and **oxidative burst** in mast cells and neutrophils, respectively.
   c. The **membrane attack complex** (MAC), formed by complement components C5b678 and polymerized subunits of C9, **lyses target cells** by forming a pore in the target cell membrane.
   d. Complement activation through the classical pathway is an important feature of immune complex clearance. Small immune complexes, consisting of antigen–antibody (IgG or IgM) and C3b, are efficiently bound to the complement receptors present on erythrocytes and are then removed from the surface of the erythrocyte in the liver and spleen.
   e. **Regulatory proteins** present on the membrane of the host cell (complement receptor 1, membrane co-factor protein, decay accelerating factor, and CD59) or as soluble proteins in the plasma (factor I and factor H) act at different steps of the complement cascade to prevent the inappropriate activation of complement on host cells and tissues.

E. The **acute-phase response** (APR) is a coordinated response to a number of triggers, including pro-inflammatory cytokines and bacterial LPS. During the APR, the hepatic production of a number of proteins is increased, including complement factors such as C3, MBL, and C-reactive protein; coagulation factors such as fibrinogen, plasminogen, and tissue plasminogen activator; transport and metal-binding proteins; and immunomodulatory agents such as granulocyte colony-stimulating factor and IL-1 receptor antagonist.

F. **Inflammation** is a collection of events that rapidly occurs following tissue injury or infection. There are several inflammatory pathways; many of the individual steps of inflammation are controlled by cytokines or other small regulatory molecules that are often referred to as **inflammatory mediators**. The inflammatory response is largely protective, although in certain circumstances, such as hypersensitivity reactions and autoimmune diseases, inflammation can be the major mechanism of harm to the body. The hallmark signs of inflammation are **pain**, **redness**, **swelling**, **and heat**, most of which can be attributed to vasodilation of the local blood vessels, increased local vascular permeability (edema), and the inflammatory mediators that assist with leukocyte transmigration from the circulation to the tissue.

G. **Phagocytic cells** (neutrophils and monocytes/macrophages) are important cells of the innate immune defense system.

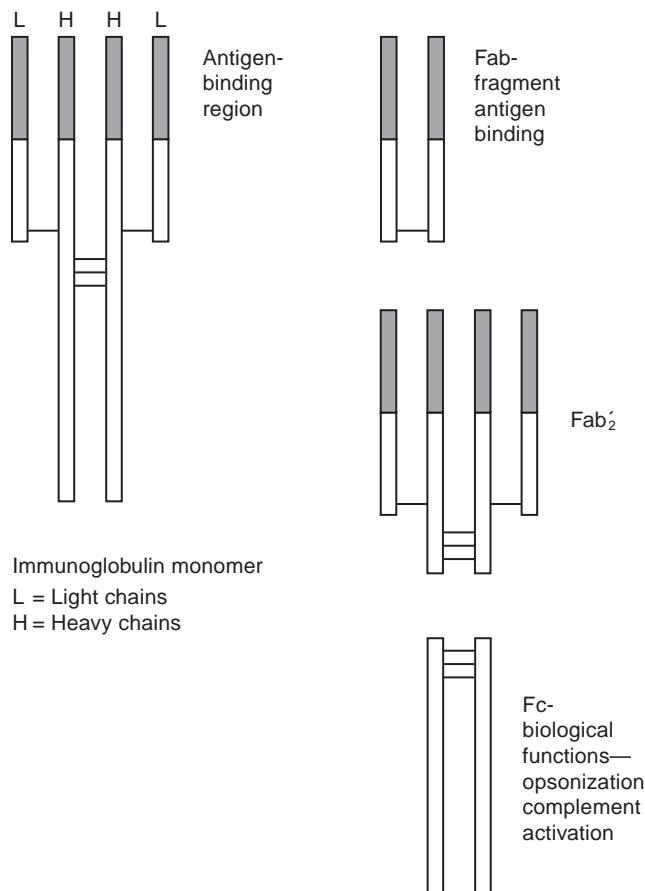
1. The phagocytes are recruited to sites of inflammation by adhesions that are expressed on local endothelial cells. The phagocytes then migrate to the site of the infection by following the concentration of inflammatory mediators.

2. Phagocytic cells can engulf bacteria, cellular debris, and other particulate matter via a number of recognition mechanisms. Neutrophils and macrophages also have a number of **pattern recognition receptors** (PRRs) that can bind directly to **pathogen-associated molecular patterns** (PAMPs) such as lipopolysaccharide, peptidoglycan, lipoteichoic acids, and mannans, which are widely expressed by microbial pathogens as repetitive motifs but are not present on host cells or tissues. Phagocytes also have receptors to bind to opsonins, such as antibody and complement.

3. Components that have been engulfed by a neutrophil or macrophage are initially contained within a membrane-bound vesicle, which then fuses with cytoplasmic **granules** containing defensins, lysozyme, lactoferrin, proteases, and other enzymes. The cell also **acidifies the vesicle** by actively pumping hydrogen ions into the interior. Phagocytes also synthesize a number of powerful **oxidizing agents** (superoxide anion, hydrogen peroxide, and hydroxyl radicals) via oxidative pathways (**respiratory burst or oxidative burst**).

H. **Toll-like receptors** (TLRs) are a family of pattern-recognition receptors of innate immunity that are present on many types of leukocytes, especially macrophages, dendritic cells, and neutrophils. Each type of TLR is specific for a different type of common pathogen component, such as lipopolysaccharide, teichoic acid, flagellin, and double-stranded RNA. TLRs share structural homology to each other and are membrane associated, being associated with either the outer membrane or internal membrane structures, depending on the PAMP that they recognize. Upon binding, TLRs induce phagocyte activation, enable the initiation of the adaptive immune response, and elicit the production of various cytokines for further immune function.

III. FUNCTIONAL BRANCHES OF THE ADAPTIVE IMMUNE RESPONSE: T-CELL–MEDIATED IMMUNE RESPONSES (CELL-MEDIATED IMMUNITY)

A. **T-cell activation.** Upon activation by antigen, signals from the TCR and coreceptors alter the pattern of gene transcription for proliferation and differentiation into effector T cells (T_H1, T_H2, or CTL). The effector activity of the T cell is accomplished through the cytokines that the T cell produces (see *Table 57-1*). TCR binding to antigen and initial T-cell activation involves a cascade of signaling events that include the transcription factors NF κB, nuclear factor of activated T cells (NFAT), and activator protein 1 (AP-1). The production of **IL-2** in response to T-cell activation is important for the initial proliferation and differentiation of the T cell. The immunosuppressive drugs cyclosporine A and tacrolimus (also called FK506) disrupt the signals from the TCR, thereby inhibiting the production of IL-2. Rapamycin inhibits the signaling from the IL-2 receptor.


B. **T-cell effector functions**
   1. **Nonviral intracellular parasites** such as mycobacteria, *Listeria*, and certain protozoa are primarily eliminated by T-cell–macrophage immunity. Antigen-specific T_H1 cell activation with the release of IFN-γ and other macrophage-activating factors enhances effective immunity to these bacterial intracellular pathogens.
   2. **Viruses** must be eliminated from both extracellular sites and infected cells.
      a. **Antibodies** neutralize virus particles in blood and tissue fluids to prevent further infection of host cells. These antibodies also serve as opsonins to assist with phagocytosis. Antibodies are generally ineffective against infected cells.
      b. **CTL cells** recognize infected cells via class I MHC presentation of viral peptides. The CTL then directly kills the infected cells in an antigen-specific manner and secretes lymphokines, such as IFN-γ. Cytotoxic granule release (granulolysin, perforin, and granzymes) by the CTL is focused toward the infected cell, which is triggered to die by apoptosis; healthy, nearby cells are not affected. In addition, CTLs can induce apoptosis via FAS ligand binding to FAS on the target cells.
      c. **NK cells** kill infected (and tumor) cells in a non–antigen-specific manner by binding to MHC-like molecules using a variety of receptors. NK cells kill their target cells using mechanisms similar to those used by CTLs.
      d. **IFN-γ** (secreted by CTL, NK, and T_H1 cells) and **IFN-α** and **IFN-β** (secreted by fibroblasts and other cells) provide additional antiviral immunity by binding to receptors on nearby uninfected cells to induce the synthesis of kinases and endonucleases (i.e., antiviral proteins), which inhibit viral and cellular growth. Interferons also upregulate MHC protein expression, which makes infected cells more visible to T cells.
   3. **Tumors** are modified host cells and must be eliminated by the immune system, usually by cell-mediated immunity via CTL and NK cells (discussed in section VIII).
   4. **Graft rejection** (see section IX)
C. **T-cell memory.** T-cell immune responses give rise to long-lived immunological memory (memory cells) and protective immunity.

IV. FUNCTIONAL BRANCHES OF THE ADAPTIVE IMMUNE RESPONSE: HUMORAL IMMUNITY

A. **Overview.** The production of antibodies is the major focus of the B-cell portion of the immune system. The function of an antibody is to recognize and bind to its corresponding foreign antigen in order to prevent that antigen from functioning (neutralization) or to target the antigen to other components of the immune system. Most antibody responses involve the activation of both B and T_H cells. **T-independent responses** to certain antigens do not require T_H cells. These antigens tend to either interact with other PRRs (e.g., bacterial LPS) or are highly repetitive antigens (e.g., bacterial cell wall carbohydrates). T-cell–independent responses generally produce only IgM and do not produce a memory B-cell response.
B. **Primary immune response.** The first time a specific antigen is encountered, only **naive B cells** and **naive T_H cells** are present to respond to the antigen. In the secondary lymph tissue, B cells and T cells are closely associated with each other such that proliferation and differentiation of antigen-specific B and T cells can occur simultaneously. Germinal centers develop in secondary lymph tissue as a result of the lymphocyte proliferation during an immune response. Activated lymphocytes differentiate into short-lived **effector cells** and **long-lived memory cells**. Some of the activated B cells differentiate into plasma cells secreting IgM of low affinity. Later in the immune response, under the direction of the T_H cells, B cells will undergo isotype switching such that plasma cells producing other classes of antibody will develop. The primary humoral immune response is detected in the serum after 4 days and peaks at 7 to 14 days.
C. **Affinity maturation.** Under the influence of T_H cells, B cells undergo somatic hypermutation, which introduces point mutations into the immunoglobulin genes such that the expanding population of B cells will produce BCRs with altered antigen-binding sites. Only those B cells that have produced immunoglobulins with a greater affinity for the antigens, as demonstrated by the ability to interact with antigen present in the lymph tissue, will be allowed to mature. In this way, the antibody response matures to produce antibodies with increasing binding affinity.

D. Isotype switching. After B-cell activation, T_H cells secrete cytokines to direct isotype switching to produce different classes (isotypes) of antibody. Antigen binding is unaffected by the isotype change. T_H2 cytokines, chiefly IL-4, IL-5, and TGF-β, lead to the production of IgA and IgE, as well as weakly opsonizing antibody, such as IgG2 and IgG4. T_H1 cells direct the production of opsonizing antibodies, chiefly IgG1 (see *Table 57-1*).

E. Memory immune responses. The creation of memory B and T cells establishes **immunological memory**. Long-lived memory B cells retain surface immunoglobulin with the selected antigen affinity and of the selected isotype, in the event the same antigen is encountered again. Memory cells more rapidly respond to the presence of the antigen (2 to 3 days after reencountering the antigen), and the absolute amount of specific antibody is greater. For some immune responses, but not all, memory is lifelong.

F. Immunoglobulins: Antigen binding and class-specific functions. In this chapter, the terms *antibody* and *immunoglobulin* are used interchangeably.

1. **Structure.** The standard immunoglobulin unit has four polypeptide chains that are held together by disulfide bonds: two identical light (L) chains and two identical heavy (H) chains. Each chain can be divided into a **C-terminal constant region** and an **N-terminal variable region** of amino acids (*Figure 57-3*). The N-terminal variable regions formed from the H- and L-variable domains combined are responsible for antigen binding by the immunoglobulin. The C-terminal constant regions of the H chain (Fc, or fragment crystallizable) determine the class of the immunoglobulin. The mechanism for generating diversity in the variable portion of the H and L chains is based on the requirement for gene rearrangement of the antibody gene segments during lymphocyte development. The germ line H and L chain genes are nonfunctional until gene segments are rearranged during B-cell development to create a functional gene. The number of different immunoglobulin gene segments, coupled with junctional and insertional variability during DNA recombination, accounts for an enormous number of different potential immunoglobulin sequences, and thus antigen binding for antibodies.

Figure 57-3. Immunoglobulin (or antibody) molecule. The four glycoprotein chains that make up the antibody are two identical heavy chains (designated by H) and two identical smaller light chains (designated by L). Each arm of the antibody is made up of the complete L chain paired with a portion of the H chain. The stem of the antibody consists of the paired carboxyl-terminal portions of the two H chains. The polypeptide chains of different antibodies have regions that vary greatly in amino acid sequence (Variable or V regions, designated by *gray shading*). The variable regions of the H and L chains are aligned at the ends of each arm of the antibody molecule and account for the diversity of antigen-binding specificities among different antibodies. Proteolytic cleavage of the antibody molecule with the enzyme papain results in three fragments corresponding to the two arms (shown as Fab-fragment antigen binding) and the stem (fragment crystallizable, shown as Fc-biological functions). Digestion of IgG with the enzyme pepsin degrades the Fc region and retains the Fab'2 molecule (shown as Fab'2). *Fc*, fragment crystallizable.

2. **Class.** There are five general heavy-chain, constant-region amino acid sequences. These determine the **five general classes of immunoglobulins**: **IgM**, **IgG**, **IgE**, **IgA**, and **IgD**. Within some classes, variants of heavy-chain amino acid sequence yield subclasses: IgG1–4 and IgA1–2. The class of an immunoglobulin defines the transport of the antibody throughout the body, as well as the ability of the antibody to interact with other components of the immune system.

   a. **IgM** is the first antibody produced in response to a new infection. The IgM is present on the surface of the mature naive B cells as a monomer, whereas IgM is secreted from the plasma cell as a pentamer. As the first antibody produced, IgM tends to have low binding affinity; however, it is able to bind strongly because it has 10 antigen-binding sites. IgM is present in the blood and tissues, although it does not penetrate tissues well because of its large size. IgM is the most potent **activator of the complement system** via the classical pathway (section II.D). Its serum half-life is 9 to 11 days.

   b. **IgD** is produced on the surface of mature naive B cells simultaneously with IgM and serves as a marker for maturation. It is present in very small amounts in the serum and does not appear to be produced as a secreted antibody by plasma cells.

   c. **IgG** is the predominant serum immunoglobulin secreted at the end of the primary immune responses and during memory responses. There are four subclasses of IgG in humans, each with differences in function. IgG has the longest lasting serum half-life (21 days for most subclasses) and is the most plentiful antibody in the serum. IgG (especially IgG3) is able to **activate complement** via the classical pathway. IgG1, IgG2, and IgG3 are **opsonic** and enhance the phagocyte's ability to engulf the pathogen when it is coated in IgG. The FcRn receptor transports IgG across endothelial cells into the tissues and can also selectively **transport IgG across the placenta** into the fetus during the last trimester of pregnancy.

   d. **IgA** can be expressed as either a monomer (in the blood and tissues) or a dimer (at mucosal surfaces). Dimeric IgA is **secreted in large quantities across mucosal surfaces** into gastrointestinal, respiratory, lachrymal, mammary, and genitourinary secretions, where it **protects the mucosa from colonization**.

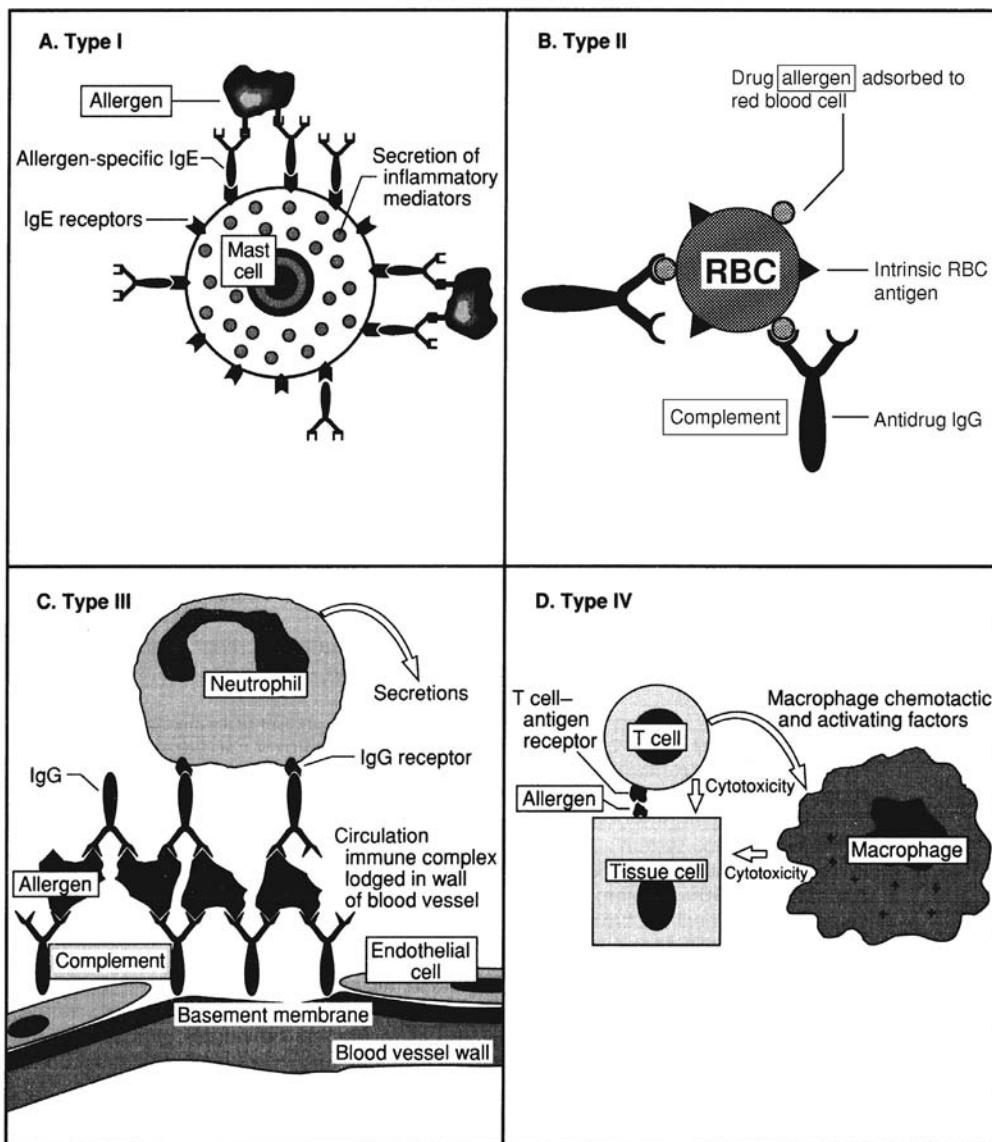
   e. **IgE** is the least plentiful antibody in the serum. IgE is made in small quantities and is rapidly bound irreversibly to the high affinity FcεRI receptors present on mast cells, basophils, and eosinophils. Antigen binding to the IgE on the surface of the mast cell signals activation and degranulation of the mast cell (section VI.B).

3. **Specificity.** The specificity of each immunoglobulin for antigen binding resides in the two identical antigen-binding sites, each formed by the combination of the variable regions of heavy and light chains.

4. **Quantitation of immunoglobulin: Antigen binding and cross-reactivity.** Between 10^8 and 10^{11}, unique immunoglobulins with different antigen-binding specificities are formed by the immune system. B cells are constantly being replaced at a rate of about 2.5 billion per day in a healthy, young adult by production in the bone marrow.

   a. **Cross-reactive antibodies** are those that are able to bind to different, but closely structurally related, antigens. Cross-reactivity may also occur through the sharing of some, but not all, antigens by two strains of bacteria, viruses, or other microorganisms.

   b. Each antigen has the potential to activate multiple B cells, and microorganisms have several antigens; therefore, each immune response will elicit the production of multiple antibodies with unique specificities. This response is known as a **polyclonal response**.

V. IMMUNODEFICIENCIES


A. **Primary immunodeficiencies** are inherited or congenital, and are generally rare.

   1. **Phagocytic cell defects.** Patients with defects in phagocytic cells have frequent bacterial infections.

      a. **Chronic granulomatous disease** (CGD) is a group of disorders that involves the inheritance of defects in the NADPH (nicotinamide adenine dinucleotide phosphate) oxidase, which is essential for the production of the reactive oxygen species during the respiratory burst that accompanies phagocyte activation. Patients with CGD experience severe recurrent bacterial and fungal infections, often resulting in the formation of granulomas that can obstruct the gastrointestinal and urogenital systems. Early diagnosis and treatment, typically with prophylactic antibacterial and antifungal agents, as well as administration of IFN-γ, can be effective, although at present, the only long-term cure is allogenic hematopoetic cell transplant (bone marrow transplantation).

b. **Leukocyte adhesion deficiency** (LAD) is a group of rare inherited disorders that is due to a defect in adhesion molecules of neutrophils, and often other leukocytes, that are necessary for leukocytes to enter the tissue from the blood. LAD patients should receive early antimicrobial therapy; allogenic hematopoietic stem cell transplantation has been successful in many LAD patients.

2. **Complement system deficiencies**

   a. Complement component C3 is common to all pathways of complement activation, and as such, deficiencies in C3 have the most dramatic effect. Patients with **C3 deficiency** suffer from **recurrent**, **and often severe**, **bacterial infections** involving the upper respiratory tract, meninges, and bloodstream. Patients lacking the fluid phase control proteins (factor H and factor I) experience a similar pattern of recurrent infections due to the uncontrolled activation and thus depletion of C3.

   b. Patients with immunodeficiencies in the **lectin pathway** of complement activation experience recurrent bacterial infections, typically in early childhood, prior to establishing an efficient antibody repertoire.

   c. Lacking the early components of the **classical pathway** leads to an increase in the incidence of immune complex diseases and some autoimmune diseases, such as systemic lupus erythematosus and glomerulonephritis.

   d. Patients lacking the **late-acting complement components** (C6–C9) are unable to form the MAC; however, they are competent for opsonic function, immune clearance, and initiating inflammation via the complement cascade. Lacking any of these terminal complement components increases the patient's susceptibility to infections with *Neisseria*.

   e. **Treatment.** Complement deficiencies that lead to recurrent bacterial infections should be managed with antimicrobial therapy. Supplementation with purified complement components has had some success, although the half-life of most complement components is short, and frequent infusions would be required.

3. **Antibody-related deficiencies**

   a. **X-linked agammaglobulinemia** (XLA) is due to mutations in the Bruton tyrosine kinase gene, which is important for BCR signaling. XLA patients lack mature B cells, plasma cells, and all five classes of antibody. Patients with XLA have recurrent infections usually beginning at 5 to 6 months of age, when maternal antibody transferred prior to birth is waning. Treatment involves antimicrobial therapy as well as periodic injections of intravenous immunoglobulin containing large amounts of IgG (see section X.B.1.b).

   b. **Selective IgA deficiency** is the most common primary immunodeficiency disorder and is characterized by a **reduced level of IgA** in the presence of normal levels of the other antibody isotypes. Many patients are asymptomatic or experience a slight increase in the frequency of respiratory tract infections. The genetic basis for selective IgA deficiency is not yet defined and is likely to be a heterogeneous group of genetic abnormalities. The foundation of treatment for IgA deficiency is the treatment of the associated infections, and no specific immunotherapy is required.

   c. **X-linked hyper-IgM** (XHIM) syndrome is characterized by **high levels of serum IgM** and very low levels of serum IgG, IgA, and IgE. The B cells from these patients are functionally normal; however, their T-helper cells lack a ligand (CD40 ligand) that is important for signaling to the B cells to undergo isotype switching and generate memory B cells. The CD40 ligand is also important for T-cell interaction with dendritic cells and macrophages. XHIM presents with recurrent bacterial infections; some patients also have recurrent neutropenia and anemia. It is important to treat the associated bacterial infections; the infusion of immunoglobulin for intravenous use (IVIG) is the traditional therapy (see section X.B.1.b). Bone marrow transplantation can be performed in certain situations and will reconstitute the immune system with functional T cells, thereby improving antibody and leukocyte function.

4. **T-cell–associated immunodeficiencies**

   a. **DiGeorge syndrome** or congenital **thymic aplasia** is a T-cell deficiency that is due to the failure of the thymus to develop normally during embryogenesis. Cell-mediated immune responses are undetectable in DiGeorge patients, and they present with multiple recurrent or chronic infections with viruses, bacteria, fungi, and protozoa. Additional features of DiGeorge patients include cardiac anomalies, renal anomalies, eye anomalies, hypoparathyroidism, and skeletal defects. Patients with partial hypoplasia often recover thymic function and need no immunologic treatment. Transplantation of postnatal allogeneic cultured thymus tissue has successfully reconstituted immune function in DiGeorge patients with severe T-cell deficiency.

  b. Severe combined immunodeficiency (SCID) is a phenotypic term for a wide range of congenital and inherited immunologic defects that include the loss of both B- and T-cell systems. Most patients experience severe, recurrent infections that begin in the first few months of life. Some of the genetic defects result in defective T-cell signaling through cytokine receptor mutations or kinases involved in cytokine signaling (JAK3 kinase). Still other defects are in genes important for TCR complex signaling (CD3) or genes encoding recombinase enzymes required for gene rearrangement in TCR and BCR generation. Mutations in genes that control class II MHC expression result in a condition known as bare lymphocyte syndrome, which functionally presents as SCID, because class II MHC expression is necessary for T_H cell development in the thymus. Most SCID patients will not survive the first year of life unless the immune system is reconstituted by hematopoietic stem cell transplantation.

B. Secondary immunodeficiencies. Defects in immunity that are secondary to another cause are more common than primary causes.

  1. **Malnutrition** is the most common cause of immunodeficiency disorders worldwide, and malnourished individuals often experience an increased incidence of infectious diseases, an impaired response to vaccination, defects in cell-mediated immunity, and defective phagocyte function, all of which reverse following adequate nutritional support.

  2. Patients with **lymphoproliferative diseases**, such as leukemia and myeloma, are also prone to infection. These patients experience varying degrees of hypogammaglobulinemia and impaired antibody responses; some lymphoproliferative diseases also lead to defective cell-mediated immune function.

  3. In developed countries, immunodeficiency is often due to specific **medical treatment**. Therapeutic agents such as x-rays, cytotoxic drugs, and corticosteroids can have dramatic effects on the immune system. Immunosuppressive drugs, such as used to prevent organ transplant rejection or used to suppress autoimmune reactions, can also affect lymphocyte and neutrophil activity.

  4. Some **microorganisms** suppress the immune response, particularly cytomegalovirus, measles, rubella, Epstein-Barr virus, and some bacterial infections, such as tuberculosis, leprosy, and syphilis.

  5. **AIDS** is a late stage of a progressive infection with **HIV**. HIV (either HIV-1 or HIV-2, although HIV-1 is more common in the United States) selectively infects CD4-bearing cells leading to a gradual depletion of T_H cells. AIDS is defined by the presence of certain opportunistic infections and cancers including *Pneumocystis* pneumonia; disseminated cryptococcosis; histoplasmosis; toxoplasmosis; mycobacterial disease; persistent, ulcerative herpes simplex virus infection; Kaposi sarcoma; and disseminated cytomegalovirus infection. There are many specific targets for antiretroviral therapy, including reverse transcriptase inhibitors, protease inhibitors, integrase inhibitors, and fusion inhibitors (reviewed more specifically in Chapter 36, "Infectious Diseases"). Early intervention using a combination of drugs, while monitoring CD4+ cell count and viral load, allows for tailored treatment regimens to achieve the best results for individual patients (i.e., highly active antiretroviral therapy or HAART). There are no known cures and no effective vaccines available for HIV, although there are clinical vaccine trials ongoing.

VI. HYPERSENSITIVITIES

A. Overview. Under some circumstances, immune responses produce damaging and sometimes fatal results, known collectively as *hypersensitivities*. Hypersensitivity reactions differ from protective immune responses in that they are exaggerated or inappropriate and damaging to the host. Hypersensitivity reactions are classified by the immune mechanism (*Figure 57-4*).

B. Type I hypersensitivity reaction (also known as immediate hypersensitivity) occurs upon the reaction of allergen (an antigen that elicits an allergic response) with specific IgE antibody that is bound to high affinity receptors on the surface of mast cells and basophils.

  1. **Sensitization phase.** Initial contact with the allergen leads to proliferation and differentiation of the specific T_H and B-cell populations. This is known as sensitization and does not generate allergic symptoms. After sensitization, IgE associates with mast cells and allergic reactions can be elicited upon reexposure to the allergen. All normal individuals can make IgE specific for a variety of different antigens; however, some individuals (atopic) are more prone to developing IgE and experiencing allergic responses. The tendency to develop IgE-mediated responses does appear to have a genetic component. The pattern of inheritance is not yet understood, although MHC-linked genes appear to be involved in some cases.

Figure 57-4. The four main types of hypersensitivity reactions. **A. Type I** hypersensitivity is mediated by allergen-specific IgE antibody bound to the mast cell by virtue of the IgE Fc receptors. When allergen binds to the IgE, the mast cell is activated to release the inflammatory mediators contained within the mast cell granules. **B. Type II** hypersensitivities are mediated by the presence of a foreign antigen adsorbed to a host cell or tissue, in this case a red blood cell. IgG binds to the associated allergen, and immune reactants (i.e., complement) mediate damage to the host cell. **C. Type III** hypersensitivities are due to the accumulation of antigen–antibody complexes that lodge in the body and mediate damage within the tissue and vasculature via complement and phagocytic cells (neutrophil). **D. Type IV** hypersensitivity reactions are mediated by T cells (T_H1, T_H2, or CTL), which also often activate macrophages through the production of cytokines. *RBC*, red blood cell.

2. **Activation phase.** Cross-linking and clustering of the mast cell–bound IgE by the presence of allergen leads to the rapid release of mast cell granules containing many preformed inflammatory mediators (histamine, proteases, and TNF-α) and the synthesis of longer acting agents (leukotrienes, prostaglandins, and cytokines) that mediate the late phase response. The initial degranulation occurs within minutes, whereas the late phase response usually begins within 4 to 6 hrs and can last 24 hrs. Direct activation of mast cells via non–IgE-mediated events can also lead to the clinical features resulting from rapid mast cell degranulation. Complement components (C3a and C5a) act directly on mast cells, as do some food additives and certain drugs (e.g., aspirin, angiotensin-converting-enzyme [ACE] inhibitors, opioids) in some sensitive patients.

3. **Effector phase.** The symptoms of the type I hypersensitivity reactions are due to the inflammatory mediators released by the activated mast cells.

   a. **Histamine** binds rapidly to a variety of cells via histamine receptors; H_1 and H_2 receptors are chiefly involved in the type I hypersensitivity reaction. Histamine binds to **H_1 receptors** on smooth muscles (airway constriction, gastric muscular contractions) and endothelial cells (vascular permeability). Binding of histamine to **H_2 receptors**, chiefly present at mucosal surfaces, results in increased mucous secretion and increased gastric acid production.

   b. **Cytokines and chemotactic factors** are important for the growth and differentiation of leukocyte cell types, such as T_H2s and eosinophils, as well as recruitment of leukocytes, including eosinophils and neutrophils.

   c. **Leukotrienes** and **prostaglandins**, which are both synthesized as part of the late phase response, lead to prolonged constriction of smooth muscle (bronchoconstriction) and continued vascular permeability.

4. **Clinical presentations of type I hypersensitivities**

   a. **Allergic rhinitis** is the most common atopic disorder worldwide. Airborne allergens react with IgE-sensitized mast cells in the nasal mucosa and conjunctiva, resulting in degranulation of these mast cells, increased mucous secretion, localized vasodilation, and increased vascular permeability. Typical respiratory allergens include grass, tree, and weed pollens; fungal spores; dust mite allergens; and pet dander.

   b. **Asthma** is a syndrome characterized by a generalized but reversible **airway obstruction**, **bronchial hyperresponsiveness**, **and airway inflammation**. Asthma cannot be explained solely based on IgE-mediated mast cell processes; however, most cases occur in patients who also show immediate hypersensitivity to defined environmental allergens. Airway inflammation plays a major role in the pathogenesis of asthma; recruitment of inflammatory cells, particularly eosinophils, can ultimately lead to remodeling of the respiratory tissue (further described in Chapter 41, "Asthma and Chronic Obstructive Pulmonary Disease").

   c. **Food allergies** are caused by the intake of certain foods that then interact with sensitized mast cells of the GI tract. Mast cell degranulation and mediator release leads to smooth muscle contraction (nausea and vomiting) and increased mucous and acid secretion. Typical food allergens include nuts, eggs, milk, and shellfish. In some cases, the food can be absorbed systemically, leading to mast cell degranulation in the skin (hives or atopic urticaria) or anaphylaxis from systemic mast cell degranulation.

   d. **Anaphylaxis** is due to a generalized degranulation of IgE-sensitized mast cells following allergen exposure and is characterized by bronchospasm and cardiovascular collapse. Common allergens associated with anaphylaxis include bee and wasp stings, certain foods, and drugs (most notably, penicillin).

5. **Clinical tests for allergies and intervention.** Sensitivity is normally assessed by the introduction of small amounts of allergen into the skin either via **skin prick (scratch test) or intradermal injection**, followed by assessment for the wheal and flare (swelling and redness) reaction within 30 mins. Alternatively, allergen-specific **serum IgE** can be measured by radioallergosorbent test (RAST) or the enzyme-linked immunosorbent assay (ELISA). Skin tests and antigen-specific IgE blood tests are not always an accurate assessment for food allergies.

6. **Treatments**

   a. For some patients, the easiest means to control allergies or asthma is to **avoid exposure** to known allergens or asthma triggers.

   b. Modulation of the immunologic response or **desensitization** by injection of small amounts of allergen can lessen the hypersensitivity reaction to those specific allergens. Desensitization is thought to occur via a stimulation of T_H1 cells rather than T_H2 cells and, in some cases, a production of increased amounts of IgG rather than IgE. Recent desensitization clinical trials using oral introduction of allergen shows promise, particularly with respect to food allergies, and is thought to occur via the stimulation of T_{REG} cells. Sublingual immunotherapy (SLIT, currently used in Europe for desensitization to environmental allergies) and specific oral tolerance induction (SOTI, used in investigational studies) are not currently approved by the U.S. Food and Drug Administration (FDA) and are considered experimental.

  c. Another strategy in the treatment of severe, persistent, allergic asthma uses an **anti-IgE monoclonal antibody** (omalizumab) to inhibit the binding of IgE to the mast cell.

  d. **Mast cell stabilization.** Cromolyn sodium (sodium cromoglycate) renders mast cells more resistant to triggering and activation.

  e. **Mediator antagonists.** Antihistamines (ethanolamines, most notably diphenhydramine) are H_1-receptor competitive antagonists of histamine. Cimetidine and ranitidine competitively inhibit histamine H_2 receptors. Specific treatments for asthma are discussed in Chapter 41, "Asthma and Chronic Obstructive Pulmonary Disease." Epinephrine acts through its α-agonist and β-agonist effects and is the most important drug for the treatment of anaphylaxis.

C. **Type II hypersensitivities** are antibody mediated and are due to the production of IgM or IgG antibodies directed to foreign antigens associated with cell surfaces. The targeted cell is either damaged or destroyed by complement activation, either direct lysis or opsonization; antibody-dependent, cell-mediated cytotoxicity via NK cells or eosinophils; or opsonization by antibody, followed by phagocytosis by neutrophils and macrophages. Certain drugs, as well as blood group antigens (e.g., ABO incompatible transfusion reactions or Rh hemolytic disease), may act as type II hypersensitivity antigens (ABO transfusion reactions will be further discussed in section IX.B).

  1. **Type II drug reactions.** Drugs acting as haptens may become associated with cells or other components of the body and initiate antibody formation. When associated with the surface of red blood cells, drugs (e.g., penicillins, cephalosporins, and quinidine) can result in hemolytic anemia. Other drugs (e.g., quinine) more often attach to platelets and produce thrombocytopenia. The sensitization phase of a type II hypersensitivity reaction to a drug requires approximately 7 to 10 days after the initiation of drug therapy, at which point, antibody production will be sufficient for cell lysis and inflammation. Subsequent exposure to the drug will result in symptoms more rapidly (approximately 3 days or less). Withdrawing the drug typically resolves the symptoms.

  2. The **Rhesus blood group** (Rh antigen) is a protein antigen, most often the D polypeptide; anti-Rh antibodies are the leading cause of **hemolytic disease of the newborn** (HDN). During pregnancy of an Rh-negative mother with an Rh-positive child, the mother may become sensitized to the D antigen of the child's blood. Sensitization usually occurs at or near delivery and does not affect the source child. However, subsequent Rh-positive children may develop HDN when maternal IgG, including anti-D antigen antibodies, are passed across the placenta into the neonate during the third trimester. Rh-negative women are administered RhoD immune globulin (RhoGAM) during the latter part of pregnancy and within 72 hrs of delivery of an Rh-positive child in an effort to prevent sensitization. The passive immunization with the anti-RhoD antibodies acts by binding fetal blood cells that may be in the maternal circulation.

D. **Type III hypersensitivity** reactions are mediated by **immune complexes** of foreign antigen together with IgG, or occasionally IgM antibodies. The presence of the immune complexes results in activation of complement, including the generation of chemotactic and vasoactive factors. The classic immune complex allergic disorders include the Arthus reaction, serum sickness, and hypersensitivity pneumonitis (farmer's lung).

  1. **Arthus reactions** are localized cutaneous inflammatory reactions due to the immune complexes and inflammation that form in dermal blood vessels following the **localized injection** of large amounts of antigen into a sensitized individual. Antigen sources for Arthus reactions include drug injections (e.g., β-lactam–based antibiotics, heparin, incidental foreign proteins in injectable products such as fetal calf serum), vaccines, insect stings, and spider bites. Arthus reactions are characterized by an **edematous and erythematous reaction**, occurring within 3 to 8 hrs at the site of the antigen injection. The reaction will resolve without intervention, although hemorrhagic ulceration at the site is not uncommon. A limited form of Arthus reaction occurs commonly at the site of allergy desensitization and usually subsides in less than 24 hrs.

  2. **Serum sickness** is a systemic immune complex reaction that occurs after injection of large quantities of foreign material. The antigen–antibody complexes deposit in small blood vessels, where complement-generated inflammation gives rise to the clinical features: **fever**, **joint pain**, **urticaria**, and **splenomegaly**. Typical antigens for serum sickness include heterologous antiserum (e.g., antivenin for snake, scorpion, and spider bites), antitoxins, intravenous human gamma globulin, and intravenous drugs. After initial injection, symptoms of primary serum sickness begin to appear as the antibody response develops (usually 7 to 10 days). In patients already sensitized to

the antigen, symptoms appear more quickly (usually 2 to 4 days after injection). Complications of serum sickness are rare, and the symptoms usually resolve as the antibody response increases and the immune complexes are more efficiently removed from the body. Treatment is largely symptomatic.

3. **Inhalation of antigenic particles** or fumes can result in a hypersensitivity pneumonitis due to antigen–antibody complexes and the subsequent inflammation that forms in the lungs. Inhalation of environmental fungal spores or other organic particles, especially *Aspergillus* spores in **farmer's lung**, appears to generate both **IgE and IgG** to the inhaled antigens as well as T_H1 **cells**. The combination of the IgE- and IgG-mediated reactions, together with the action of proinflammatory cytokines, leads to tissue damage, inflammation, and the typical symptoms, which could be described as **asthma symptoms superimposed with fever**, **cough**, **and sometimes chronic lung damage**. Avoidance of antigen exposure is an important feature of management; repeated episodes lead to bronchial wall weakening and pulmonary fibrosis. High-dose systemic corticosteroid therapy is necessary to resolve the acute allergic inflammation and prevent long-term lung damage.

E. **Type IV hypersensitivities** (**delayed-type hypersensitivities**) are mediated by specific effector **T cells**. Examples of type IV hypersensitivities include the immune response to some infections (tuberculosis) and contact dermatitis, most often associated with metals or haptenic chemicals.

1. One of the best known examples of a type IV hypersensitivity is the **tuberculin skin test** (Mantoux skin test). Injection of purified protein derivative (PPD) into the skin of an individual previously infected with *Mycobacterium tuberculosis* recruits and activates those cells currently or previously employed in response to the tubercule bacillus (i.e., T cells and macrophages). A positive tuberculin skin test will present with **redness** and **a palpable induration at 48 to 72 hrs** after administration.

2. Many chemical substances, natural and synthetic, can be the source of **contact hypersensitivity**, which is typically a type IV hypersensitivity reaction. Common allergens include metals (nickel and chromate), plastics, rubber, lanolin, latex, plant chemicals, and medications such as neomycin and phenothiazines. The plant oil urushiol is the immunogenic hapten that is responsible for the contact dermatitis associated with **poison ivy**. The reaction is characterized by a red rash within a few days of contact, bumps, patches of weeping blisters on the skin, swelling of the area, and intense itching. Effective treatment focuses on suppressing the T-cell response: topical steroids such as triamcinolone or clobetasol. If the affected area involves more than 20% of the body or is particularly severe, systemic corticosteroid therapy may be required. Inhalation of the allergen when the plants are burned can lead to severe allergic respiratory issues.

3. **Celiac disease**, also known as **gluten-sensitive enteropathy**, is considered an autoimmune disorder that is triggered by a cell-mediated, adaptive immune response to ingested gluten, such as that found in wheat gluten and related proteins in rye and barley. In genetically susceptible individuals (i.e., HLA-DQ2 or -DQ8), gliadin, gluten's main antigen, associates with host proteins. Development of the symptoms of the disease is associated with T_H **and** T_C **lymphocytic** infiltration in the gut epithelial membrane and lamina propria, expression of proinflammatory cytokines, and production of IgA and IgG antibodies directed against the gluten as well as host components (e.g., tissue transglutaminase). **Inflammation**, **villous atrophy**, **and crypt hyperplasia** in the small intestine are all characteristic of celiac disease. Extraintestinal symptoms can include bone and skin disease, anemia, endocrine disorders, and neurological deficits. Gluten-free diet is the only effective intervention for celiac disease.

VII. AUTOIMMUNITY is an immune response that is directed against self-antigen(s); autoimmune diseases are conditions where the autoimmune response is responsible for the tissue or organ damage.

A. **Mechanisms of breakdown in tolerance.** Autoimmunity requires a breakdown in the mechanism of self-tolerance. During the development of the lymphocyte repertoire in the bone marrow and thymus, T and B cells with self-reactive receptors are eliminated or rendered anergic (unresponsive) to prevent immune system self-reactivity. Additional mechanisms of peripheral tolerance are also involved in controlling self-reactive lymphocytes.

1. **Genetic factors.** Autoimmune diseases tend to run in families. The genetic contribution to autoimmune diseases often involves multiple genes; however, there are some genetic components

that are associated with increased risk for the development of certain autoimmune disorders. Many of the strongest and best characterized **genetic associations with autoimmune disorders** involve different variants of MHC/HLA: HLA-B27 and increased risk of ankylosing spondylitis, HLA-DR3 or -DR4 and increased risk of insulin-dependent diabetes mellitus (IDDM), HLA-DR4 or -DR1 and increased risk of rheumatoid arthritis, and HLA-DR2 and a protective effect for the development of IDDM.

2. **Hormonal influences.** There is a general trend for autoimmune disease to occur more frequently in women than in men, probably due to differences in hormone profiles. The precise mechanism is unknown.

3. **Infection. Molecular mimicry**, or shared/similar epitopes in pathogen antigens and self-antigens, can elicit autoimmune disorders (e.g., immune reactivity to group A streptococcal M proteins and the development of rheumatic fever). Additionally, infection in a target organ induces the expression of co-stimulatory molecules and the presentation of pathogen and self-antigens through the action of IFN-γ.

B. **Organ-specific autoimmune disorders** usually affect a single organ, most often an endocrine gland.

1. **Hashimoto thyroiditis** involves the infiltration of mononuclear cells, including lymphocytes, macrophages, and plasma cells, into the thyroid, resulting in destruction of follicular cells and a general breakdown in the architecture of the thyroid. The immune mechanisms involve antibody and cell-mediated components. The resulting **hypothyroidism** is treated with synthetic thyroid hormone replacement (levothyroxine sodium also known as Synthroid, Levoxyl, Levothroid, or Unithroid).

2. **Graves disease** is the result of antibodies that act as agonists of thyroid-stimulating hormone (TSH) by binding to the TSH receptor and stimulating the release of thyroid hormones. The resulting **hyperthyroidism** is treated by antithyroid drugs (e.g., propylthiouracil or methimazole) or thyroid ablation by radiation or surgical removal, which would then be treated with synthetic thyroid hormone replacement therapy.

3. **Rheumatic fever** is due to the production of antibodies directed against the M proteins of group A streptococci (GAS), which are cross-reactive to antigens present in the heart. Early identification and antimicrobial treatment during an infection with GAS is important to prevent the formation of the antibodies. Repeated streptococcal infections can lead to further damage to the heart tissue (rheumatic heart disease).

4. **Autoimmune-hemolytic anemia** (erythrocyte), **-thrombocytopenia** (platelet), **-neutropenia** (neutrophil), and **-lymphopenia** (lymphocyte) are mediated by antibodies directed against antigens intrinsic to the cell surface of the affected blood cell. It is important to discriminate between type II hypersensitivity-mediated cellular destruction, which is often due to the transient presence of extrinsic antigens on the surface of the cell, and autoimmune disease, which would be due to immune activity toward self-antigens. Autoimmune responses may need immunosuppressant therapy to halt the destruction, whereas hypersensitivity is often self-limiting and resolves when the extrinsic antigen is no longer present. For autoimmune hemolytic anemia, transfusions may be required. **Plasmaphoresis** to remove self-reactive antibodies or splenectomy can slow the erythrocyte destruction in severe cases.

5. With **myasthenia gravis**, antibodies are directed against the **acetylcholine receptor** (Ach-R) on the motor end plates of the muscle cells, blocking the binding of acetylcholine and mediating complement-dependent damage to the receptor and cell membrane. The patient experiences variable **skeletal muscle weakness**, often appearing first as drooping eyelids, double vision due to an impairment of extraocular eye muscles. Acetylcholinesterase inhibitors, neostigmine (Prostigmin), pyridostigmine (Mestinon and Regonol), and others are the first line of treatment, followed by corticosteroids for long-term control, or other immunosuppressants (e.g., cyclosporine or azathioprine) for more severe cases.

6. **Insulin-dependent diabetes mellitus** (IDDM or type I diabetes) is caused by the selective destruction of the islets of Langerhans of the pancreas. Destruction involves T cells and often antibodies directed against antigens in the pancreatic β-cell, the primary producer of insulin. Disease symptoms appear when the destruction is nearly complete and the insulin levels are low. Increased risk of developing IDDM is associated with HLA-DR3 and -DR4. Current therapy targets the replacement of the insulin (see Chapter 46, "Diabetes Mellitus"). Immunotherapeutic approaches to consistently and safely prevent or reverse IDDM have not been developed in humans.

7. **Goodpasture syndrome** is characterized by **progressive glomerulonephritis** and frequently, pulmonary hemorrhage (particularly in those who smoke). The tissue damage is due to the production of antibodies directed against antigens of type IV collagen, which is present in the basement membrane in the lungs and glomeruli. The risk of developing Goodpasture's is strongly associated with certain variants of HLA-DRB1. Patients are treated by plasmaphoresis, followed by systemic corticosteroids, and often cyclophosphamide.

8. **Multiple sclerosis** (MS) is an inflammatory, demyelinating **neurodegenerative**, autoimmune disease of the central nervous system. The exact immune mechanism is not completely understood; however, T_H1 cells and the inflammatory cytokines that they secrete (e.g., IFN-γ) are strongly implicated. The clinical features, which include sensory disturbance and motor dysfunction, can be highly variable and dependent on many factors, such as the sites of pathological lesions and the rate of new lesion formation. Treatment strategies focus on reducing the inflammation within the CNS, and include interferon β-1b (Betaseron and Extavia), interferon β-1a (Avonex and Rebif), glatiramer acetate, mitoxantrone, fingolimod, and natalizumab.

C. **Non-organ specific or systemic autoimmune diseases** affect multiple organs, usually associated with antigens found throughout the body.

1. **Sjögren syndrome** (SjS) is a complex, chronic autoimmune disease, which is characterized by mononuclear cell infiltration of **exocrine glands** resulting in reduced or loss of secretory function. SjS may present as either primary SjS or as secondary, occurring in association with other autoimmune diseases, such as rheumatoid arthritis, systemic lupus erythematosus, or other connective tissue disorders. The precise immune mechanism is not completely understood. Mild cases are treated with artificial tears, medications for dry eyes (cyclosporine ophthalmic emulsion and hydroxypropyl cellulose ophthalmic inserts), medications for dry mouth (cevimeline, and pilocarpine hydrochloride), and frequent drinking of water. Systemic manifestations often require immunosuppressive therapy, such as systemic corticosteroids, to treat internal organ manifestations or severe flares.

2. **Rheumatoid arthritis** (RA) is a chronic, recurrent, systemic inflammatory disease that principally involves the joints. It is characterized by the presence of rheumatoid factors (autoantibodies directed against the Fc portion of IgG) in the serum and synovium, infiltration of lymphocytes and activated macrophages into involved joint synovium, and local production of TNF-α and other proinflammatory cytokines in involved synovium. Therapy is generally aimed at reducing synovial inflammation in order to improve symptoms and preserve joint function. Specific therapeutic interventions are discussed further in Chapter 42, "Osteoarthritis and Rheumatoid Arthritis."

3. **Systemic lupus erythematosus** (SLE) is a systemic autoimmune disorder directed to self-antigens that are present in all or nearly all cells of the body, most typically nuclear components, such as nucleic acids and nucleoprotein particles. The immune complex formation initiates inflammatory reactions leading to cell and tissue destruction. **Symptoms are variable depending on the site of immune complex formation** and may be intermittent, which complicates diagnosis. Joint pain and swelling are the most common symptoms. Other symptoms include fatigue, fever with no other cause, malaise, hair loss, mouth sores, skin rashes (described as a butterfly rash on the face in some patients), sensitivity to sunlight, and swollen lymph nodes. For individual patients, the course of the disease is highly variable in terms of severity, the organs and tissues involved, and the progression of the disease. Mild disease may be treated with nonsteroidal anti-inflammatory drugs (NSAIDs) and corticosteroid creams for the skin rashes. Hydroxychloroquine (Plaquenil, an antimalarial medication) is sometimes useful in patients whose symptoms have not improved with other interventions. Belimumab (Benlysta), a monoclonal antibody inhibitor of B cells, is a newly FDA-approved drug for use in SLE. More severe cases of SLE are often treated with high-dose corticosteroids or cytotoxic drugs (e.g., cyclophosphamide). When flares have subsided, the dose can often be lessened to reduce side effects. Drug-induced lupus erythematosus is similar to SLE in terms of the clinical presentation; however, it is caused by a hypersensitivity reaction to a medication (e.g., chlorpromazine, hydralazine, isoniazid, methyldopa, penicillamine, procainamide, quinidine, and sulfasalazine). Symptoms tend to occur after taking the drugs for at least 3 to 6 months, and they tend to resolve when the medication is discontinued.

VIII. TUMOR IMMUNOLOGY involves the antigenic properties of the transformed cell, the host immune response to the tumor cells, the effect of the growth of the tumor may have on the body, and the potential manipulation of the immune response to eradicate the tumor.

A. **Overview. Cancer** results from a single cell that has undergone multiple mutations that lead to **uncontrolled cell growth**. Tumors can be **benign** (encapsulated, local, and limited in size), **malignant** (continually increasing in size and encroaching on adjacent tissues), or **metastatic** (spreading out from the primary tumor to form secondary tumors often at distant sites). Exposure to chemicals, radiation, viruses, or accumulated errors during replication can facilitate the malignant transformation.

B. **Immune recognition of cancers**

1. Malignant tumors express molecules that may be recognized by the immune response. Tumor-specific antigens are expressed on tumor cells, but not on normal cells (e.g., viral proteins). Tumor-associated antigens are expressed on tumor cells but can also be found on normal cells, although often in smaller amounts or on cells of a different developmental stage (e.g., p53 and CT antigens).

2. **MHC class I chain-related** (**MIC**) **proteins** are stress-induced proteins that are often expressed on the surface of transformed epithelial cells, which can then be recognized by **NK cells** and **CTLs**. Tumor cells that express tumor antigens via class I MHC are recognized and killed by CTLs. Tumor cells that alter gene expression to reduce class I MHC presentation are recognized and killed by NK cells.

3. Several types of cancers are associated with chronic viral infections. By preventing infection, vaccinations protect against cancers caused by those viruses (e.g., human papillomavirus vaccine and hepatitis B vaccine).

C. Monoclonal antibodies directed against tumor antigens can be used for diagnosis and therapy, either alone via typical antibody-mediated mechanisms or conjugated to cytotoxic drugs or radioactive isotopes. Examples include rituximab (Rituxan), trastuzumab (Herceptin), and ibritumomab (Zevalin, conjugated to ^{111}I). Additional specific chemotherapy agents are discussed in Chapter 50, "Cancer Chemotherapy."

IX. TRANSPLANTATION is complicated by the antigenic differences between donor and recipient, the most important of which are antigenic differences in the HLA class I and class II molecules (also known as transplantation antigens).

A. **Autograft** is transplantation of tissue from one site to another on the same person, as might be used for the treatment of severe burns, and does not require immunosuppressive therapy. A **syngeneic transplant** (or isograft) is a transplant between genetically identical individuals and also does not require immunosuppressive treatment. **Allograft** (or allogeneic transplant) is a transplant between two genetically different individuals and often requires immunosuppressive therapy due to alloreactions (either graft rejection or graft versus host reaction, depending on the type of tissue transplanted). Specific immunosuppressant therapy is discussed further in Chapter 53, "Immunosuppressive Agents in Organ Transplantation."

B. **Transfusion** is a form of "living transplant" whereby blood is removed from one person for infusion into another. Human erythrocytes lack HLA classes I and II molecules. Major antigenic determinants of erythrocytes include the ABO glycolipids and the Rhesus (Rh) erythrocyte antigens. In routine ABO blood grouping, if antigens are absent from a person's erythrocytes (A or B carbohydrates), then antibodies, usually IgM, that recognize those antigens naturally develop due to structural similarities between the A and B carbohydrates and the carbohydrates present in gut bacteria. As such, persons of blood type O would make anti-A and anti-B antibodies, whereas blood type AB would make neither set of antibodies. If the recipient of a blood transfusion is making antibodies that recognize antigens found on the transfused blood, then the newly transfused erythrocytes will be lysed by complement and phagocytes. Patients experience fever and chills associated with the hemolysis of the transfused blood. The Rh blood antigen (most typically, the D antigen) is a protein antigen; Rh-positive individuals have the protein antigen, and Rh-negative individuals do not. The production of antibodies does not occur until the D antigen is introduced into the body and recognized as foreign by Rh-negative individuals (Rh immunization). Anti-Rh antibodies are the leading cause of HDN (discussed in section VI.C.2).

C. **Transplantation of solid organs.** Common solid organ transplants are kidney, heart–lung (in combination or separately), pancreas, and liver (with or without intestine segment).

1. **Hyperacute rejection** is the result of preformed antibodies against ABO blood group antigens or HLA antigens. These preformed antibodies act with complement, which leads to immediate destruction of the tissue and occlusion of the graft blood vessels, usually within minutes or hours of transplantation. Once established, no treatment is available to reverse the effects. ABO incompatible kidney transplants have been successfully performed in investigational studies in Japan, Europe, and the United States by performing plasmaphoresis of the recipient before and after transplantation.

2. **Acute rejection** is caused by effector T cells that are responding to HLA differences between donor and recipient. Acute rejection takes days to develop and can be reduced or prevented by the use of immunosuppressant drugs prior to and after transplantation.

3. **Chronic rejection** occurs months or years after transplantation and is characterized by a gradual thickening of the vasculature of the transplanted tissue. As the lumen of the vessel walls narrow, the blood supply to the grafted tissue is eventually reduced, causing ischemia and tissue death.

4. Matching of donor and recipient HLA class I and class II allotypes improves the outcome of organ transplantation. The need for HLA matching and immunosuppressive therapy varies with the organ transplanted. The cornea of the eye can be transplanted without consideration of HLA type or immunosuppressive therapy because the cornea is not vascularized, and the immunological environment of the cornea suppresses inflammation. Liver cells express very low levels of HLA class I and class II antigens. Good HLA match between donor and recipient for liver transplantation can reduce the incidence of acute rejection; however, it does not appear to influence the overall graft outcome. Bone marrow transplantation is the most sensitive to HLA mismatches.

D. **Hematopoietic stem cell transplantation** (bone marrow transplantation). Bone marrow transplantation is often used as a treatment for many genetic diseases that affect cells of the hematopoietic system, including many immunodeficiencies, and some cancer treatments, particularly those with immune system cancers. Hematopoietic stem cells are infused into the patient whose own bone marrow has been weakened or destroyed due to the immunodeficiency or cancer treatment. The grafted bone marrow cells repopulate the hematopoietic system of the recipient. Recipient rejection of the graft bone marrow is less of a concern because the recipient immune system is typically immunodeficient; however, the donor marrow is immunocompetent and can lead to **graft versus host disease** (GVHD). In GVHD, mature T cells (T_H or T_C) that are present in the donor graft respond to the recipient HLA allotypes. The donor T-cell response can occur in any tissue, although the skin, intestines, and liver are principally involved. Almost all bone marrow transplant recipients experience some degree of GVHD, although the severity tends to correlate with the degree of HLA mismatch. In addition to reducing the incidence of GVHD, it is important that the donor and recipient match for at least one HLA class I and one HLA class II allotype in order to reconstitute the immune system.

X. VACCINATION

A. **Overview. Passive vaccination** is the introduction of antibody, either whole serum, concentrated immune (gamma) globulin that is mostly IgG, or purified IgG, to provide immediate protection. Passive immunization is useful for patients who cannot form antibodies (immunodeficient) or for the patients who might develop disease before active immunization could stimulate antibody production. Passive immunization is temporary, lasting several weeks to several months for each administration. **Active vaccination** is the intramuscular, subcutaneous, or oral introduction of antigen(s) to stimulate a specific immune response. Protection through memory varies with the vaccine, but immunity is long lasting.

B. **Passive vaccination** (*Table 57-2*)

1. **Human immune globulin** is prepared from pooled plasma, usually from thousands of adult donors. The antibody preparation is mostly IgG and reflects the immunity of the donor pool. Although rare, contamination by viruses is possible. Three different preparations are available: **immune gamma globulin for intramuscular** use (IGIM), **immune gamma globulin for**

intravenous use (IVIG or IGIV), and **specific immune globulins** with a high content of antibody against a particular antigen (for intravenous or intramuscular use).

a. **Standard human serum immunoglobulin for intramuscular use** (**IGIM**) is a polyclonal immune globulin preparation from pooled plasma of donors and is typically used to prevent or reduce the severity of certain viral diseases, such as hepatitis A, measles, varicella, and rubella, or for IgG deficiency in adults and children. Adverse reactions include angioedema, pain, and inflammation at the site of the injection, urticaria, and, in rare instances, anaphylaxis. IGIM should never be administered intravenously due to the presence of high-molecular-weight immunoglobulin aggregates that can lead to serious systemic reactions.

b. **Immune globulins for intravenous use** (**IVIG**) are prepared from pooled human serum and modified to minimize antibody aggregation. There are many preparations of IVIG, which are supplied either as a lyophilized powder or sterile solution. The concentration, rate of administration, and dosing interval varies with the preparation and the underlying reason for treatment. The advantage of IVIG is the ability to administer large doses of immune globulin

---

Table 57-2   SELECTED PASSIVE VACCINES[a]

Vaccine Name	Description (Source)[b]	Typical Use
Black widow spider antivenin	Antiserum (equine)	Prophylaxis, therapy
Botulinum antitoxin	Botulism antiserum (equine) to trivalent toxin	Prophylaxis, therapy
Cytomegalovirus immune globulin (CMV-IGIV) for intravenous use (CytoGAM)	Anti–CMV-enriched serum product (human)	Prophylaxis of CMV disease associated with transplantation of kidney, lung, liver, pancreas, and heart
Hepatitis B (HepB) immune globulin (HBIG), intramuscular use	Anti–HepB-enriched serum product (human)	Prophylaxis
Immune globulin for intramuscular use (IGIM)	Polyclonal, pooled immunoglobulin, mostly IgG (human)	Prophylaxis (hepatitis A[c], measles, varicella, and rubella); therapy for IgG deficiency
Immune globulin, human, for intravenous use (IVIG)	Polyclonal, pooled immunoglobulin, mostly IgG (human)	Preferred therapy for IgG deficiency; therapy for idiopathic thrombocytopenic purpura; prophylaxis (hepatitis A[c], measles, varicella, and rubella)
Rabies immune globulin (RIG) for intramuscular and/or subcutaneous use[d]	Anti-rabies enriched, pooled plasma (human)	Prophylaxis
Respiratory syncytial virus (RSV-MAb, palivizumab) for intramuscular route[e] (Synagis)	Anti-RSV monoclonal antibody (humanized)	Prophylaxis in high-risk populations
RhoD immune globulin (RhoGAM)	Anti–Rho(D)-enriched serum product (human)	Prophylaxis during pregnancy and after delivery of Rh+ by Rh− mother
Snake bite antivenin	Crotalidae polyvalent antiserum (equine)	Prophylaxis, therapy
Tetanus immune globulin (TIG) for intramuscular use	Anti-tetanus toxin enriched serum product (human)	Prophylaxis
Varicella zoster immune globulin for intramuscular use	Anti-varicella zoster enriched serum product (human)	Prophylaxis, therapy in immunocompromised patients

[a]Not all passive vaccines nor approved uses included.
[b]Valence indicates the number of antigenic types included in synthesis of the vaccine preparation.
[c]Hepatitis A active vaccination within 2 weeks of exposure is preferred over IGIM prophylaxis for those < 40 years of age; IGIM should be used for children aged < 12 months, adults > 40 years, immunocompromised persons, and persons with chronic liver disease.
[d]Administered into the depth of and around the bite wound if possible; remainder administered IM.
[e]RSV-MAb (monoclonal antibody) is preferred over human immune globulin (RSV-IGIV).

and a more rapid onset of action. IVIG is particularly valuable as replacement therapy for the **management of primary immunodeficiency disorders** and for the management of idiopathic thrombocytopenic purpura and Kawasaki disease. Side effects include fever, nausea, abdominal pain, and vasoactive phenomena (usually vasodilation), although slow administration reduces these side effects. Patients with IgA deficiency may develop severe anaphylactic reactions after IVIG infusion due to the trace amounts of IgA in the IVIG preparations.

    c. **Special preparations of human immune globulin** are serum products that contain high specific antibody content. Most are available in the intramuscular form; a few are for intravenous use.

    d. **Animal antisera.** Equine (horse) antisera prepared from hyperimmunized horses are used in certain situations. Antibody derived from animals can produce an immune response in humans that leads to rapid clearance of protective antibodies and the risk of allergic reactions, particularly **serum sickness** or **anaphylaxis**. Animal serum should not be given without inquiring about prior exposure or allergy to animal products. When administering animal-derived antiserum, epinephrine should be available.

  2. Rationales for passive vaccination

    a. **Prophylaxis of infectious disease.** Antibodies are given prophylactically to prevent or reduce clinical symptoms of a viral or bacterial infection, particularly in a patient without previous exposure and therefore without immunologic memory. The vaccine protects the recipient during the incubation period for infection. For example:

      (1) **Tetanus immune globulin** (**TIG**) is used to prevent tetanus following injury in patients whose immunization is uncertain or incomplete.

      (2) **Hepatitis B immunoglobulin** (**HBIG**) is administered to a newborn child of a woman with hepatitis B or to nonimmune individuals as soon as possible after exposure to hepatitis B.

    b. **Prophylaxis or therapy** prevents or attenuates the effects of infection in special populations. Examples are **varicella zoster immunoglobulin** (**VZIG**) is given to patients with leukemia or immunocompromised patients who have been exposed to the varicella zoster virus; cytomegalovirus human immune globulin is used for the prophylaxis of CMV disease for recipients of kidney, lung, liver, pancreas, and heart transplants. IVIG or IGIM, pooled sera containing a broad spectrum of IgG specificity, is often administered following exposure to some viral illnesses (see *Table 57-2*).

    c. **Treatment of antibody deficiency.** Individuals who are deficient in antibody production, either because of primary immunodeficiency (see V.A.3) or as a result of chronic lymphocytic leukemia, receive IVIG or IGIM every 2 to 4 weeks to maintain humoral immunity. IVIG is generally preferred.

    d. **Other situations.** IVIG is used for idiopathic (autoimmune) thrombocytopenia purpura. Intramuscular RhoD immunoglobulin (RhoGAM) is used prophylactically for Rh disease (see section VI.C.2). Muromonab-CD3 (OT3) is a mouse-derived monoclonal antibody that binds to CD3 on the surface of T cells. T cells become opsonized with bound muromonab-CT3 and are targeted for destruction in the liver. Muromonab-CD3 is used in the treatment of acute renal graft rejection and in some circumstances, acute rejection of liver and heart transplants.

C. Active vaccination is the administration of an antigen to elicit a protective immune response. (**Specific vaccines** in common use and recommended administration schedules are listed in *Table 57-3*.) The anamnestic response when reencountering antigen is both stronger and faster, and provides potential protection.

  1. Overview

    a. **Contents.** Active vaccines contain one or more subunits of a pathogen or whole pathogenic organisms but may also contain preservatives, low doses of antibiotics, and other compounds that do not affect the immune response.

    b. **Administration.** Active vaccines are administered subcutaneously, intramuscularly, intradermally, orally, or intranasally. Some are introduced adsorbed to aluminum hydroxide or aluminum phosphate adjuvants. An **adjuvant** is a vaccine addition that increases the antigenicity of the vaccine.

Table 57-3	COMMONLY ADMINISTERED IMMUNIZATIONS FOR INFANTS, ADOLESCENTS, AND ADULTS[a]

Vaccine	Vaccine Antigen	Target Population[b]	Number of Doses	Schedule
Viral Vaccines				
Hepatitis A (HepA)	Inactivated, whole virus	Children < 2 years[c]	2	12–24 months
Hepatitis B (HepB)	Recombinant, HBsAg subunit	All	3	Birth, 1–2 months, 6–18 months[d]
Human papillomavirus (HPV)	Viral subunits; HPV4, quadravalent, HPV2, bivalent	Adolescent females[e]	3	11–12 years
Inactivated polio (IPV)	Inactivated, whole virus[f]	Children < 5 years	4	2, 4, 6–18 months, 4–5 years
Influenza[g]	TIV, trivalent, inactivated; LAIV, live, attenuated, influenza	All, annually	2 for first use; single dose annually, thereafter	LAIV for use 2–49 years only; minimum age of 6 months for TIV
Measles, mumps, rubella	Live, attenuated, whole viruses	Children, < 5 years[h]	1, with 1 booster	15–18 months, 4–6 years
Rotavirus (live oral)	Live, attenuated virus	Infants < 6 months old	3	2, 4, and 6 months
Varicella	Live, attenuated, whole virus	Children, < 5 years; others at-risk	1, with 1 booster	15–18 months, 4–6 years
Zoster	Live, attenuated virus	> 60 years	1	> 60 years
Bacterial Vaccines				
Diphtheria, tetanus, pertussis (DTaP, Tdap for one-time adolescent and adult use[i])	Diphtheria and tetanus toxoids, acellular pertussis containing 2–4 purified bacterial components	Infants and children, < 6 years; boost for adolescents and adults	5	2, 4, 6, 15–18 months, and 4–5 years
Haemophilus influenzae[b]	Type b-polysaccharide—protein conjugate, usually tetanus toxoid	Infants, children < 2 years	4	2, 4, 6, 12–15 months
Meningococcal	MCV4, 4-valent, polysaccharide conjugate; MPSV4, 4-valent, polysaccharide	Adolescents; also, certain "at-risk" populations[j]	1, with 1 booster	11–12 years, 16 years
Pneumococcal	PCV, 13-valent, pneumococcal polysaccharide conjugate; PPSV, 23-valent, pneumococcal polysaccharide[k]	Infants, children, adults > 65[l] years		
Tetanus (Td)	Tetanus and diphtheria toxoids	All	3, with boosters	Every 10 years[l]

[a]The recommended immunizations and schedules are approved annually by the Advisory Committee on Immunization Practices (ACIP). Updates and complete schedules, including catch-up schedules and special indications for vaccination, can be found at http://www.cdc.gov/vaccines/recs.
[b]The entire target population is not listed in all cases.
[c]HepA is also recommended for older children at greater risk for hepatitis A infection.
[d]HepB can be administered as a "catch-up" vaccine for adolescents and adults.
[e]HPV may be administered as a catch-up vaccination for females up to age 26; HPV4 is recommended for administration to adolescent males.
[f]Live, attenuated, oral polio vaccine (OPV) is no longer used in the United States.
[g]Both TIV and LAIV are trivalent influenza vaccines, selected annually; certain medical conditions may preclude the use of LAIV.
[h]Additional two-dose series of MMR is recommended for adults in certain situations.
[i]Tdap should be substituted for Td one time for adolescents and adults.
[j]Younger children at risk may receive MCV4 at 2 years; MPSV4 is preferred for those > 55 years.
[k]Children < 2 years should receive the PCV13 vaccine; PPSV is recommended for adults.
[l]The pneumococcal vaccination is also recommended for adult smokers and those with certain medical conditions (e.g., asthma).

c. **Seroconversion.** For many active vaccines, the success of the series of vaccinations is indicated by seroconversion of the patient. Seroconversion indicates that a person who previously did not have specific serum antibodies (i.e., seronegative) now has these antibodies (i.e., seropositive). Seroconversion does not necessarily indicate established immunity, especially in the case of live vaccines.

d. **A schedule of active vaccination.** Successful vaccination can be affected by the age of the patient; therefore, the timing of childhood immunizations is driven largely by the efficacy of the vaccine in the age population. Newborns have poorly developed immune systems and rely chiefly on passively acquired maternal antibodies for the first few months of life. With the exception of the hepatitis B vaccine, which is administered at birth, most immunizations are deferred until the child is 2 months old. The rotavirus vaccine is the only currently administered live, attenuated vaccine for use in infants. Some vaccines are intended for use primarily in noninfant populations.

e. Most vaccines require **a series of vaccinations** to achieve adequate immunity, whereas others are effective with a single vaccination. For those that require a series, intervals between vaccinations greater than those recommended do not generally diminish protection. The duration of memory varies with each vaccine, and **booster vaccinations** are often necessary.

f. **Side effects** include inflammation at the site of vaccination, malaise, mild fever, chills, headache, myalgia, and arthralgia. More severe side effects include febrile illness, somnolence, seizures, or anaphylactic hypersensitivity to vaccine antigens or accessory components (e.g., antibiotic, chicken protein). Severe reactions contraindicate continuation of a series.

2. **Types of active vaccines**

a. **Live**, **attenuated vaccines** consist of whole organisms, usually viruses. These organisms multiply after vaccination but are attenuated to reduce their pathogenicity.

(1) A small dose produces a **strong**, **long-lasting immune response** because the antigen concentration increases when the organism multiplies. Some vaccines elicit lifelong immunity in one or two doses (e.g., the measles, mumps, rubella [MMR] vaccine).

(2) **Live**, **attenuated viral vaccines** are not recommended for pregnant women or those intending to become pregnant within 3 months of vaccination. Vaccines made from attenuated agents (e.g., MMR, varicella) have the potential for causing disease in immunocompromised patients and are generally not advised for use in these patient populations or those with other underlying illness.

b. **Inactivated vaccines** may contain whole, inactivated (killed) bacteria or viruses, or any antigenic fraction isolated from either. Fractional vaccines are either protein based or polysaccharide based. **Toxoids** (inactivated bacterial toxins) and **viral subunit vaccines** (e.g., hemagglutinin of influenza or capsid proteins of papilloma) are protein-based vaccines. The acellular pertussis vaccine is also a protein-based subunit vaccine, containing two or more antigens for *Bordetella pertussis*. Some subunit vaccines are produced by recombinant DNA technology typically in yeast cells (e.g., hepatitis B surface antigen, human papillomavirus [HPV] vaccine). Most polysaccharide vaccines are **capsular polysaccharide** antigens, which tend to elicit a poor immune response in children. **Conjugate polysaccharide vaccines** contain the capsular polysaccharide antigen, chemically linked to a protein carrier, which elicits a better immune response (e.g., *Haemophilus influenzae* type b). The *Neisseria meningitidis* and *Streptococcus pneumoniae* vaccines are both available as pure polysaccharide and polysaccharide conjugate vaccines.

(1) Inactivated vaccines are not able to replicate and **cannot cause disease** from infection, even in an immunodeficient person. Inactivated vaccines are typically safe to administer during pregnancy, with the exception of the HPV vaccine, which should not be administered during pregnancy.

(2) Inactivated vaccines **require multiple doses** and typically only produce humoral immunity. Antibody titer to inactivated vaccine antigens diminishes over time and may require periodic repeated vaccination to increase or "boost" antibody titers. Pure polysaccharide vaccines tend to be T-cell–independent antigens and often do not elicit a memory response that is boosted with subsequent doses.

D. **Simultaneous administration of active and passive vaccines.** Sometimes active and passive vaccines against a pathogenic organism are administered simultaneously to maximize postexposure prophylaxis. The immunoglobulin offers immediate protection, and the active vaccine stimulates a lasting immune response. These vaccines are given at separate sites to prevent antibody (passive) and antigen (active) from reacting and inactivating one another.

    1. **HBV and HBIG.** Infants who are born to mothers with a hepatitis B infection are significantly protected from becoming chronic carriers by the combined prophylaxis.

    2. **Tetanus.** Combined prophylaxis is sometimes used, depending on the type of wound and the patient's history of active vaccination. Recommended guidelines are as follows:

       a. **A tetanus-prone wound** is one that produces anaerobic conditions (e.g., deep puncture) or one in which exposure to *Clostridium* or its spores is probable (e.g., contaminated with animal feces). If the patient's history of active vaccination is uncertain or includes fewer than three doses, both TIG and Td are administered. The patient returns to complete the toxoid series.

          (1) If the wound is tetanus-prone but the patient received a full series of active vaccination, no treatment is necessary if the last Td dose was received within the last 5 years.

          (2) If the last dose was received more than 5 years ago, Td, but not TIG, is given to boost memory immunity and antibody production.

       b. For a **clean**, **minor wound**, if the patient's history of active vaccination is uncertain or includes fewer than three doses, Td is administered.

          (1) If the patient received a full series of active vaccinations, no treatment is necessary if the last Td dose was received within 10 years.

          (2) If the last dose was received more than 10 years ago, Td, but not TIG, is given to boost memory immunity and antibody production.

XI. IMMUNIZATION PRACTICE FOR THE PHARMACIST

A. **Background.** Since the 1970s, there has been a growing interest in using pharmacists for the administration of immunizations. In 1994, the secretary of U.S. Department of Health and Human Services sought the aid of the American Pharmacists Association to improve immunization rates in the United States. As a result, certificate programs were developed to ensure the knowledge and capabilities of pharmacists to administer vaccines. Currently, **all 50 states** offer some level of pharmacist-provided immunizations.

B. **Legal and regulatory issues**

    1. **State law.** Although pharmacists are authorized to immunize in every state, the requirements to be authorized and the scope and restrictions on immunization practice vary from state to state. Please refer to your state's Pharmacy Practice Act to determine specifics. Limitations and requirements include education and/or certification requirements, age of patients who can be immunized, scope of vaccines allowed, CPR requirements, continuing education requirements, vaccine administration authorizations (prescription, collaborative practice agreements, protocols, standing orders), approved routes of administration, and student pharmacist provisions.

    2. **Liability issues.** Federal law requires that all patients immunized be provided with the most current **Vaccine Information Statement** (VIS) for the particular vaccine being given. These are available on the Centers for Disease Control and Prevention (CDC) Web site (http://www.cdc.gov/vaccines). It is paramount that the immunizing pharmacist stays within the state's Pharmacy Practice Act. Pharmacists may only offer vaccines that are on the state's list of vaccines approved for pharmacist administration and only to the designated age population.

    3. The pharmacist must have **adequate training to immunize** and keep that training up to date.

    4. **Vaccine Injury Compensation Program** (VICP) is a national program that protects manufacturers and providers (including pharmacists) from vaccine injury claims for adverse effects listed on the Vaccine Injury Table (see Web site at http://www.hrsa.gov/vaccinecompensation/default.htm) while maintaining a fund from which injury claims could be paid.

C. Pharmacies that provide immunizations must adhere to **Occupational Safety and Health Administration** (OSHA) safety regulations to minimize risks to their employees and document compliance with each of the OSHA regulations.

1. OSHA regulations include required training regarding potential exposure to **blood-borne pathogens**, which must be provided at the outset of any immunization program, at the time an employee is assigned to immunization duties and annually thereafter. This training must be offered at no cost to the employee and during regular working hours.

2. An employer must provide the **hepatitis B series** to any employee who will be at risk of exposure to blood-borne disease.

3. OSHA requires the use of **needles**, **syringes**, **and/or safety devices** attached to needles and syringes to minimize injury with any such contaminated device.

4. The employer is required to maintain a log of all incidents of percutaneous injury by contaminated sharp equipment. The log needs to list the type and brand of equipment involved, the area where the injury occurred, and a description of how it happened.

D. **Vaccine storage and management.** Vaccines, like most biologicals, are sensitive to changes in temperature. All vaccines currently available in the United States must be stored under controlled temperature conditions, as described for each vaccine formulation.

E. **Record keeping**

1. **Patient immunization records** should be maintained by the patient's medical provider; however, patients can benefit by pharmacists maintaining these records and providing a copy to the patient.

2. **Vaccine administration record.** The immunizing pharmacist is required by the National Vaccine Injury Compensation Program to document and maintain certain information for all vaccines administered: administration date; vaccine manufacturer; lot number and expiration date; name, address, and title of administering pharmacist; and VIS—date printed on VIS and date given to patient.

3. Vaccine administration records must be permanent and readily retrievable. They may be stored as paper files or electronically. The length of time these records must be kept may vary by state. Usually, however, records must be maintained for at least the life of the patient.

F. **Vaccine resource materials for the immunizing pharmacist.** Immunization practice is a constantly changing field. New vaccines, changes in administration schedules, and adverse reaction alerts are only a few of the topics that require the pharmacist to maintain competence.

1. **Basic reference.** Centers for Disease Control and Prevention. *Epidemiology and Prevention of Vaccine-Preventable Diseases.* 12th ed. Washington, DC: Public Health Foundation; 2011. http://www.cdc.gov/vaccines/pubs/pinkbook/default.htm. Accessed May 12, 2011.

2. **Web sites**

a. Centers for Disease Control and Prevention. Vaccines and Immunizations. http://www.cdc.gov/vaccines

b. Immunization Action Coalition. http://www.immunize.org

c. American Pharmacists Association. Pharmacist Immunization Center. http://www.pharmacist.com/AM/Template.cfm?Section=Pharmacist_Immunization_Center1&Template=/TaggedPage/TaggedPageDisplay.cfm&TPLID=126&ContentID=20733

G. **Clinical issues**

1. **Identifying the patient's needs.** Determining the patient's vaccine needs requires an immunization history, which can be provided by the patient and possibly contacting the medical provider.

2. **Screening the patient.** Each year, the Advisory Committee on Immunization Practices (ACIP) of the CDC reviews and updates the use of vaccines. Recommendations are published in schedules designated for particular populations (http://www.cdc.gov/vaccines/recs/schedules/default.htm). The ACIP guidelines for administration should be consulted to ensure the appropriate vaccine is administered.

3. **Contraindications and precautions.** Contraindications are conditions that greatly increase the chance of an adverse reaction. According to the CDC, there are two permanent contraindications to vaccine administration: severe allergic reaction to a previous dose and encephalopathy occurring within 7 days of pertussis vaccination (for which no other cause is identified). Mild illness, current antimicrobial therapy, breastfeeding, and having a pregnant or immunosuppressed person living in the household are not considered to be valid contraindications. If, however, the patient describes symptoms for which you would normally refer to a physician, defer immunization until the illness resolves. Live vaccines and HPV should not be given to pregnant women, but deferred

till afterward. The tetanus, diphtheria, and acellular pertussis booster vaccine (Tdap) should also be deferred until the latter half of the pregnancy, whereas the standard tetanus and diphtheria booster (Td) can safely be given if needed during pregnancy. Live vaccines should not be given to severely immunosuppressed individuals. Inactivated vaccines may be given to people such as these, although response may be muted. Please refer to the CDC Web site for a more thorough discussion of precautions. When in doubt, refer the patient to a physician.

4. **Adverse events**
   a. **Local reactions** at the injection site are most commonly seen following administration of inactivated vaccines. Patients should be advised to take an anti-inflammatory and/or apply a cool compress to control these symptoms.
   b. **Systemic vaccine-related reactions** following live vaccine administration represent a mild form of the disease and are usually no cause for alarm. Patients experiencing a more severe response should be referred to their medical provider.
   c. **Vasovagal syncope** is a temporary loss of consciousness that sometimes occurs following injections of any kind. Most occur within 15 mins of the injection and resolve quickly. Patients may complain of being dizzy or light-headed, may appear pale and sweaty, and have cold hands and feet. Occasionally, the patient may experience nausea. If affected, patients should be kept in a supine position with legs elevated. The blood pressure and pulse should be monitored. If blood pressure falls or the patient does not regain consciousness quickly, call 911. Because of the possibility of aspiration, water or other fluids should not be offered to a patient experiencing syncope.
5. **Allergic reactions** can occur within a few minutes or up to an hour after vaccination. Mild allergy can result in pruritis, erythema, hives, and urticaria. These symptoms can generally be controlled with antihistamines. If the patient does not respond to the antihistamine or if the condition continues to progress, the patient should immediately contact a medical provider. The patient should always report any allergic reaction to the primary care physician.
6. **Anaphylaxis** is a severe, life-threatening allergic reaction (see section VI.B.4.d) that requires immediate intervention (see next discussion) while summoning emergency care (911). Symptoms can include those seen in mild allergic reactions, but more importantly, include angioedema (swelling of the lips, tongue, and throat), bronchospasm, shortness of breath, and cramping. This often progresses to shock and cardiovascular collapse.

H. **Emergency preparedness.** Procedures for handling emergency situations should be detailed in a policy and procedure manual and any standing order or protocol, including the use of emergency drugs. Any adverse reaction requiring a response should be reported via the **Vaccine Adverse Event Reporting System** (VAERS) available at http://vaers.hhs.gov/index.
   1. Patients should be advised to remain in an area where they can be observed for **15 mins** following vaccination.
   2. Because of the potential for syncope, the pharmacist should administer vaccines to patients who are sitting in an open area. This will allow the pharmacist to support the patient while he or she is being lowered to the floor.
   3. **Antihistamines** should be accessible in the event a patient begins to experience allergic reactions following immunization. Typically, diphenhydramine elixir 25 to 50 mg should be given orally at the first sign of symptoms.
   4. **Epinephrine** should be available for use in apparent anaphylaxis reactions. Vaccines should never be administered if epinephrine is not available. Multiple doses should be available in case of a delayed emergency medical services response.
      a. **Dosage forms**
         (1) Vial at 1:1000 w/v equivalent to 1 mg/mL
         (2) Autoinjector
            (a) Epi-pen 0.3 mg/pen
            (b) Epi-pen Jr 0.15 mg/pen
      b. **Dose**
         (1) Vial: 0.01 mL/kg
         (2) Autoinjector: 1 pen
      c. **Route**: IM (preferred) has faster onset than SQ
      d. Repeat every 5 to 15 mins if needed

Study Questions

Directions: Each question, statement, or item in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A man was ill 10 days ago with a viral illness. Laboratory analysis of the patient's blood reveals that the patient's antiviral antibodies have a high ratio of IgM/IgG. What does this tell you?

   (A) It is unlikely that the patient had encountered this virus before his recent illness.
   (B) The patient is predisposed to IgE responses to this virus.
   (C) This information is unrelated to the recent viral illness.
   (D) This patient's response is due to a memory response.
   (E) It is likely that this patient is developing an autoimmune disorder.

2. Which class of antibody has the longest serum half-life and opsonizes antigens for phagocytosis through two different pathways?

   (A) Immunoglobulin A (IgA)
   (B) Immunoglobulin D (IgD)
   (C) Immunoglobulin E (IgE)
   (D) Immunoglobulin G (IgG)
   (E) Immunoglobulin M (IgM)

3. Urticaria that appears rapidly after the ingestion of food usually indicates which type of hypersensitivity reaction?

   (A) Type I
   (B) Type II
   (C) Type III
   (D) Type IV

4. The mechanism of pathogenesis for which of the following autoimmune disorders is due to widely distributed immune complexes?

   (A) Systemic lupus erythematosus (SLE)
   (B) Insulin-dependent diabetes mellitus (IDDM)
   (C) Graves disease
   (D) Hashimoto thyroiditis
   (E) Multiple sclerosis

5. A patient receives long-term, high-dose therapy with penicillin. After approximately 2 weeks of therapy, the patient has a low-grade fever, rash, and muscle and joint pain. Which type of hypersensitivity accounts for these symptoms?

   (A) Type I
   (B) Type II
   (C) Type III
   (D) Type IV
   (E) This is unlikely to be due to a hypersensitivity

6. The treatment of multiple sclerosis (MS) might include which of the following agents?

   (A) Neostigmine
   (B) Cyanocobalamin
   (C) Omalizumab
   (D) Propylthiouracil
   (E) IFN-β-1b

7. The therapeutic role of muromonab-CD3 in acute renal graft rejection is probably based on

   (A) activation of T-cell function and increased secretion of cytokines.
   (B) destruction of T cells by complement.
   (C) opsonization of T cells for phagocytosis.
   (D) apoptosis of activated T cells.
   (E) activation of T_{REG} cells.

8. Which is a current clinical application of intravenous human immunoglobulin (IVIG)?

   (A) Prophylaxis after hepatitis B virus (HBV) exposure
   (B) Treatment of humoral immunodeficiency
   (C) Prophylactic infant immunization for respiratory syncytial virus (RSV)
   (D) Prophylaxis for Rh disease by infant immunization
   (E) Treatment for snake bites

For questions 9 and 10: An 18-year-old college student has a deep puncture wound. The student is unsure of his history of vaccination.

9. If no other information is available, what should the physician recommend?

   (A) No vaccination
   (B) Tetanus immunoglobulin (TIG)
   (C) Tetanus toxoid (Td)
   (D) Both TIG and Td at separate sites
   (E) Administer IVIG and Tdap

10. If the student had received a full series of diphtheria, pertussis, tetanus (DTaP) vaccinations as a child, and received the Tdap prior to entry into college last year, what should the physician recommend?

(A) No vaccination
(B) Tetanus immunoglobulin (TIG)
(C) Tetanus toxoid (Td)
(D) Both TIG and Td at separate sites
(E) Administer IVIG and Tdap

11. CD4$^+$ T cells specifically recognize antigens in which form?

(A) Bound to major histocompatibility complex (MHC) class I molecules on the surface of any nucleated cell
(B) In free, soluble form in extracellular fluids
(C) Bound to MHC class II molecules on the surface of special antigen-presenting cells (APCs)
(D) Bound to complement receptors on professional antigen-presenting cells (APCs)
(E) Associated with class II MHC on the surface of T$_C$ cells

12. The normal consequence of complement activation by either the lectin or alternative pathway includes all of the following EXCEPT?

(A) Acute inflammation
(B) Immune complex clearance
(C) Cytolytic action
(D) Recruitment of leukocytes
(E) Opsonization of microbes

13. In antiviral immunity, what directly recognizes and kills viral-infected cells?

(A) Complement
(B) Antiviral antibodies
(C) Interferons
(D) Eosinophils
(E) Cytotoxic T cells (CTLs)

14. A patient was skin tested with purified protein derivative (PPD), which was administered to determine previous exposure to *Mycobacterium tuberculosis*. The patient developed redness and induration at the skin test site 48 hrs after inoculation. Histologically, the reaction at this site would most probably show

(A) plasma cell infiltration.
(B) eosinophils.
(C) neutrophils.
(D) acid-fast bacilli.
(E) T cells and macrophages.

15. Graft versus host disease (GVHD) is associated primarily with which type of transplantation?

(A) Kidney
(B) Heart
(C) Bone marrow
(D) Cornea
(E) Autografts

16. The prophylactic use of cyclosporine in graft rejection is probably based on its ability to

(A) competitively inhibit the IL-2 at the IL-2 receptor.
(B) inhibit synthesis of antibodies, thereby preventing hyperacute rejection.
(C) inhibit activation of B cells, thereby preventing acute rejection.
(D) block transcription of the IL-2 gene and synthesis/secretion of IL-2.
(E) induce apoptosis in activated T cells.

17. Which statement about pneumococcal and meningococcal vaccines is true?

(A) They are both available as a purified polysaccharides or conjugated polysaccharide.
(B) They are both recommended for children < 2 years of age.
(C) Each vaccine formulation contains all serotypes of disease-causing organisms.
(D) They are live attenuated, requiring only a single dose to be effective.
(E) They should not be administered during pregnancy.

18. A patient currently taking methyldopa develops hemolytic anemia, which resolves shortly after the drug is withdrawn. The most probable explanation is that the patient was experiencing

(A) an atopic hypersensitivity.
(B) a type II hypersensitivity.
(C) immune complex hypersensitivity.
(D) cell-mediated hypersensitivity.
(E) a type IV hypersensitivity.

19. Infliximab (Remicade) is a chimeric monoclonal antibody that binds directly to TNF-α. Patients taking this medication should be advised that they are

(A) more susceptible to infections because TNF-α is important for synthesizing IgM.
(B) more susceptible to infections because they will generate more lymphocytes in the absence of TNF-α.
(C) less susceptible to infections because T$_H$1 responses will predominate in the absence of TNF-α.
(D) more susceptible to infections because the initiation of inflammation will be less efficient without TNF-α.
(E) less susceptible to infections because they will not initiate an acute-phase response without TNF-α.

20. What would be the typical time frame for the appearance of a type IV hypersensitivity reaction in a person already sensitized to the antigen?

(A) Within a few minutes
(B) Within a few hours
(C) Within a few days
(D) Within a few weeks
(E) Within a few months

21. For a patient who was experiencing a type I hypersensitivity, including difficulty breathing and loss of consciousness, which of the following would be the most appropriate medical intervention?

(A) injection of epinephrine
(B) injection of nonsteroidal anti-inflammatory drugs
(C) injection of antihistamines
(D) injection of corticosteroids
(E) administer an oral H_2-receptor inhibitor

Answers and Explanations

1. The answer is A *[see IV.B]*.
The primary immune response to an infection is characterized by the initial production of IgM beginning 4 to 6 days and peaking 9 to 14 days after introduction of the antigen. Under the influence of T_H cells, activated B cells will undergo isotype switching to produce antibodies that might be more effective (e.g., IgG, longer lasting, opsonic, distributed well in tissues; IgA, high concentrations in mucous; IgE, parasitic infections and mast cell activation). Memory responses maintain the isotype effective from the previous immune response.

2. The answer is D *[see IV.F.2.c]*.
IgG has the longest lasting serum half-life (21 days for most subclasses) and is the most plentiful antibody in the serum. Antigen bound by IgG is opsonized for phagocytosis by neutrophils and macrophages via phagocyte Fc receptors; however, IgG is also able to activate complement, which will lead to the addition of covalently bound C3b to the microbe surface. C3b is also an opsonin for which phagocytes have receptors that will assist with phagocytosis.

3. The answer is A *[see VI.B.4.c]*.
Food allergies are usually type I reactions. In a patient with mast cells already associated with IgE specific to a food allergen, the allergic response usually occurs shortly after ingestion. Mast cell activation and degranulation in the gastrointestinal tract leads to smooth muscle contraction (vomiting) and increased mucous and acid secretion. Allergen absorbed into the circulation may lead to mast cell degranulation in the skin (e.g., urticaria) or anaphylaxis.

4. The answer is A *[see VII.C.3]*.
In SLE, persistent circulating immune complexes (typically containing nuclear antigens, such as nucleoproteins and nucleic acids) are responsible for much of the pathology. In Graves disease, an antibody acting as a TSH agonist hyperstimulates the thyroid. In IDDM, T-cell cytotoxicity, and potentially antibody production, leads to the destruction of the beta islet cells in the pancreas. In Hashimoto thyroiditis, antibodies and CTLs (and macrophages) infiltrate the thyroid. With multiple sclerosis, T_H1 cells and the resulting inflammatory responses are thought to be responsible for the demyelination.

5. The answer is C *[see VI.D.2]*.
One of the most common causes of a type III hypersensitivity reaction is the response to drugs, often when they are used long term at a high dose and delivered intravenously. The treatment is to discontinue the drug.

6. The answer is E *[see VII.B.8]*.
Treatment with IFN-β-1b reduces the frequency of MS flare-ups. The precise mechanism of action is currently unknown but may involve the activation of suppressor T cells and reduced production of proinflammatory cytokines. Neostigmine is used as an anticholinergic agent in myasthenia gravis. Cyanocobalamin is administered in autoimmune pernicious anemia to replace nonabsorbed vitamin B_{12}. Propylthiouracil is used as an antithyroid medication in Graves disease. Omalizumab is a monoclonal antibody that targets IgE.

7. The answer is C *[see X.B.2.d]*.
Muromonab-CD3 is a mouse anti-CD3 monoclonal antibody that binds to all T cells because CD3 is a constant part of the antigen receptor of each T cell. The binding of muromonab-CD3 opsonizes the T cells for phagocytosis, chiefly in the liver, and the overall effect is a reduction in the total number of T cells. A later secondary phase of activity seems to involve antigenic modulation of the T cells such that the CD3 is removed from the surface, rendering those T cells incapable of signaling antigen binding. Mouse antibodies are inefficient at activating human complement. Some T-cell activation with cytokine secretion occurs, but it is an undesirable side effect of muromonab-CD3 administration.

8. The answer is B *[see X.B.1.b; Table 57-2]*.

IVIGs are used to replace antibodies in immunodeficient individuals. Each of the other choices is a formulation of passive transfer of antibodies; however, they are either enriched for specific antibodies or monoclonal antibodies (in the case of the RSV prophylaxis). Hepatitis B immunoglobulin (HBIG) is administered intramuscularly. Anti-Rh antibody is also administered intramuscularly to the mother immediately postpartum (sometimes during pregnancy) but not to the infant. Snake bite antivenin is derived from sera produced in horses.

9. The answer is D *[see X.D.2.a]*.

A patient with an uncertain history of vaccination and a tetanus-prone wound requires both active and passive vaccination. TIG provides immediate protection if the individual does not have memory. Td begins the series that leads to the establishment of memory. A tetanus-prone wound in an individual with a full series of active vaccinations requires no treatment if the last vaccination in the series was administered less than 5 years earlier. These recommendations are general guidelines.

10. The answer is A *[see X.D.2.a.(1)]*.

Even if the wound is a tetanus-prone wound, booster vaccination within 5 years obviates the need for additional tetanus vaccination.

11. The answer is C *[see I.B.6.b.(1).(b)]*.

CD4$^+$ (helper) T cells have TCRs that recognize fragments (epitopes) of immunizing antigens (immunogens) only when the peptide fragments are bound to MHC class II molecule on the surface of APCs (B cells, macrophages, or dendritic cells). CD8$^+$ T cells recognize peptide fragments bound to MHC class I molecules. As a result, T cells cannot be activated inappropriately by soluble antigens.

12. The answer is B *[see II.D.2.d]*.

The four functions of complement are inflammation, opsonization, cell lysis, and immune complex clearance. The classical pathway of complement activation is responsible for immune complex clearance because the antibody associated with the complexes initiates the classical pathway. When complement is activated, regardless of the pathway of activation, the complement components have functions that lead to all three of the other actions. Acute inflammation allows greater movement of plasma proteins and phagocytes from blood to tissue. Opsonization of immune complexes enhances their phagocytosis. Cytolysis of microorganisms by the membrane attack complex often results in their killing.

13. The answer is E *[see III.B.2.b]*.

Antiviral antibodies are important in extracellular immunity to viruses by neutralizing them for infection of additional cells and targeting the viruses for opsonization by complement. Interferons are secreted from viral-infected and other cells (e.g., macrophages, T cells) and, after binding to receptors, induce the appearance of antiviral proteins in other cells. CTLs recognize viral-infected cells and cause direct cytotoxicity.

14. The answer is E *[see VI.E.1]*.

Type IV hypersensitivity reactions are delayed after the introduction of antigen because antigen-specific T cells become activated and attract other cells, such as macrophages, to the site of antigen introduction (e.g., the epidermis of the skin in contact sensitivity, the lungs in tuberculosis). Inflammation is primarily caused by tissue damage and secretion of proinflammatory cytokines by the infiltrating cells. Although histamine release from local mast cells can also occur, H$_1$-antagonists of histamine usually do not have significant effects because T cell and macrophage activation, migration, and secretion are not greatly affected by these drugs.

15. The answer is C *[see IX.D]*.

In bone marrow transplantation, marrow containing mature lymphocytes is transplanted to a generally immunosuppressed host. The greatest problem is an immune response by the graft lymphocytes against HLA and other tissue antigens of the host. In renal and cardiac transplantation, the greatest problem is rejection of the foreign organ by the immune system of the host. Corneal transplants do not elicit rejection nor do autograft transplants (transplants from one part of the body to another on the same individual).

16. The answer is D *[see III.A]*.

Cell-mediated immune mechanisms are central in acute graft rejection, and the inhibition of T-cell activation appears to be the key element in immunosuppression. Responding T cells require signaling from IL-2 to reach full activation and progress to cell division. IL-2 is produced by activated T cells and can act in an autocrine manner. Cyclosporine blocks the cascade of signals that occur when T cells encounter specific antigen. The T-cell signaling is important for the transcription of the IL-2 gene. Inhibiting those signals inhibits the synthesis of IL-2 and prevents full T-cell activation and division. Its effects are limited to activated T cells. Because it has no direct effect on antibody synthesis, it is not useful in the hyperacute rejection phenomena, which is based on antibody-mediated mechanisms. Hyperacute rejection is essentially untreatable because it depends on the presence of antibodies in the graft recipient.

17. The answer is A *[see X.C.2.b; Table 57-3]*.

The pneumococcal and meningococcal vaccines are multivalent and contain purified polysaccharide (PPSV23 and MPSV4, respectively) from a number of different serotypes (indicated by the number associated with each vaccine designation above). However, these vaccines do not contain polysaccharide from all of the relevant infectious agents. The pneumococcal and meningococcal vaccines are also formulated as a conjugate vaccine (MCV4 and PCV13, respectively). The pneumococcal vaccine is recommended for infants and children, beginning at 2 months. The minimum age for administration of the meningococcal vaccine is 2 years, although the recommended age dosing is 11 to 12 years.

18. The answer is B *[see VI.C.1]*.

This patient was experiencing a type II hypersensitivity reaction, which is characterized by antibody-mediated lysis of host cells (in this case, erythrocytes) due to the presence of exogenous antigen (methyldopa). An atopic hypersensitivity (type I, IgE mediated) would have exhibited atopic symptoms, such as urticaria. Immune complex hypersensitivity symptoms would include a skin rash, fever, and joint pain.

19. The answer is D *[see Table 57-1]*.

TNF-α is involved in inflammation and T_H1 responses. Inflammation is particularly important for responses to bacterial infections. Infliximab is prescribed for a number of autoimmune disorders that involve inflammatory mechanisms.

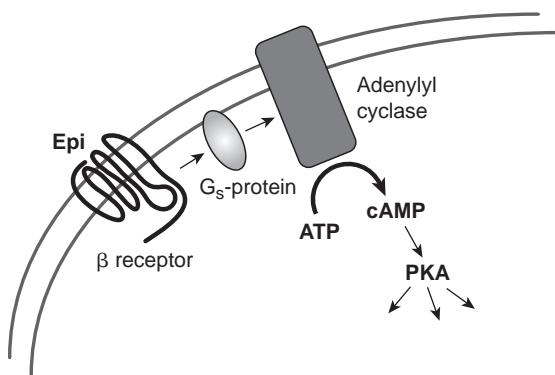
20. The answer is C *[see VI.E]*.

Type IV hypersensitivity reactions are mediated by T cells (T_H1, T_H2, and CTL) and the inflammation associated with the T-cell activity. As such, the recruitment of the T cells typically takes 48 to 72 hrs after the introduction of the antigen. The classic example of a type IV hypersensitivity reaction is the tuberculin skin test.

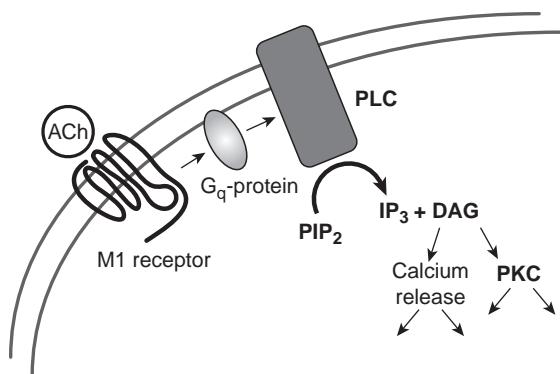
21. The correct answer is A *[see VI.B.6.e]*.

Many of the interventions will act on the allergic responses associated with a type I hypersensitivity reaction; however, this patient is experiencing a severe reaction. Epinephrine more immediately reverses the airway constriction.

58

Principles of Pharmacology and Medicinal Chemistry


S. THOMAS ABRAHAM, MICHAEL L. ADAMS

I. INTRODUCTION. A complete understanding of the pharmacological actions of drugs requires an appreciation of their pharmacokinetic and pharmacodynamic properties, as well as the complexity of the biological responses modulated by these agents. This chapter will focus on the pharmacodynamic aspect of drugs with an emphasis on the mechanisms and consequences of drug–receptor interactions. Additionally, the chemical characteristics of pharmacological agents that influence their interactions with specific receptors will be addressed.


II. RECEPTORS. Currently, we understand that receptors are unique protein or glycoprotein structures that are responsible for the reception and transmission of information that ultimately alters the behavior of cells, organs, or even the entire organism. It is generally understood that endogenous hormones, neurotransmitters, or growth factors interact with specific receptors to modify cellular behavior.

    A. Cell surface receptors and their signal transduction

        1. The seven transmembrane G protein–coupled receptors are localized in the plasma membranes of cells in such a manner as to have seven transmembrane domains, with multiple extracellular and intracellular domains. This group of receptors is the most heterogeneous of the cell surface receptors and communicates with intracellular components by activating specific guanine nucleotide-binding (G) protein intermediates.

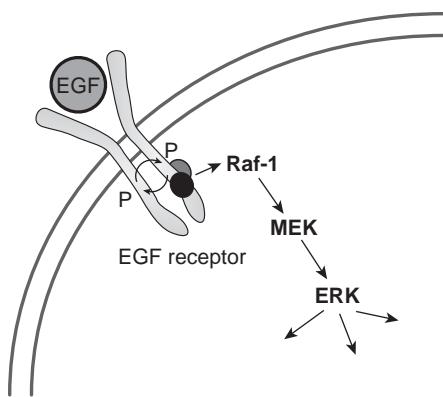
            a. G_s-coupled receptors (e.g., β-adrenergic, vasopressin V2, glucagon, dopamine D1). These receptors are functionally coupled to adenylyl cyclase, which catalyzes the conversion of adenosine triphosphate (ATP) to cyclic adenosine monophosphate (cAMP), an intracellular second messenger (*Figure 58-1*). cAMP is responsible for the downstream activation of protein


Figure 58-1. The cAMP-PKA signaling system is responsible for diverse biological effects such as increased heart rate/contractility, vasodilation, and neurotransmitter release. *Epi*, epinephrine; G_S, guanine nucleotide-binding protein; *ATP*, adenosine triphosphate; *cAMP*, cyclic adenosine monophosphate; *PKA*, protein kinase A.

Figure 58-2. The phosphoinositide signaling system is responsible for physiological responses such as salivary secretion, smooth muscle contraction, and hormone release. *ACh*, acetylcholine; G_q, guanine nucleotide-binding protein; *PLC*, phospholipase C; *IP$_3$*, inositol trisphosphate; *DAG*, diacylglycerol; *PKC*, protein kinase C; *PIP$_2$*, phosphatidylinositol bisphosphate.

kinase A (PKA), a multifunctional enzyme that alters the function of multiple substrates to ultimately produce effects such as increases in heart rate, release of glucose from the liver, decrease water loss in the kidneys, and increase neurotransmitter release.

b. **G_q-coupled receptors** (e.g., α_1-adrenergic, muscarinic M1, angiotensin AT1). Binding of endogenous ligands such as norepinephrine or acetylcholine leads to conformational change in the relevant receptor and activation of the associated G_q protein, which in turn activates a membrane-bound phospholipase C. This enzyme catalyzes the hydrolysis of membranous phosphatidylinositol bisphosphate (PIP$_2$) resulting in the production of inositol trisphosphate (IP$_3$) and diacylglycerol (DAG). The hydrophilic IP$_3$ releases stored calcium from the sarcoplasmic reticulum, whereas DAG activates protein kinase C (*Figure 58-2*). These processes are eventually responsible for biological processes such as smooth muscle contraction, aldosterone release, salivary secretion, etc.

c. **$G_{i/o}$-coupled receptors** (e.g., muscarinic M2, α2-adrenergic, opioid). The best characterized results of activating receptors coupled to $G_{i/o}$ proteins is the decrease in intracellular cAMP and opening of K^+-channels leading to hyperpolarization. The overall response of these types of events is inhibitory and leads to responses such as decreasing heart rate and inhibition of neurotransmitter release.

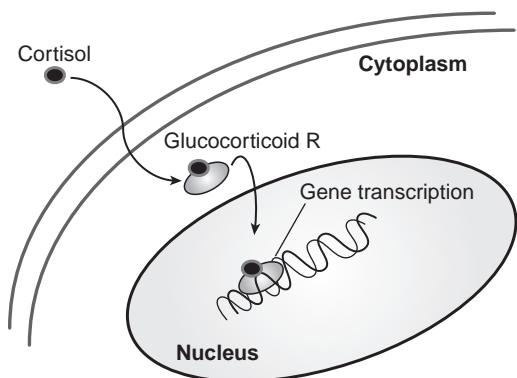
2. **Ion channels** found on the membranes of excitable cells (cardiac muscle, nerve cells, etc.) are important regulators of cellular function and serve as targets for pharmacological intervention.

a. **Ligand-gated channels** (e.g., nicotinic, GABA$_A$, glutamate). The binding of endogenous ligands (acetylcholine, GABA, etc.) on the extracellular domains allows the opening of ion-selective pores on the protein that allow for the movement of ions such as sodium, chloride, or calcium. Depending on the ion being conducted, the eventual physiological response may be skeletal muscle contraction, nerve depolarization, or hyperpolarization.

b. **Voltage-gated channels** (e.g., calcium, sodium, potassium channels). Depolarizing currents lead to opening of these channel proteins, allowing the selective movement of specific ions into (calcium, sodium) or out (potassium) of the cell. These ion fluxes lead to cell depolarization (calcium, sodium) or repolarization (potassium) in a coordinated fashion to regulated muscle contraction and nerve action potential.

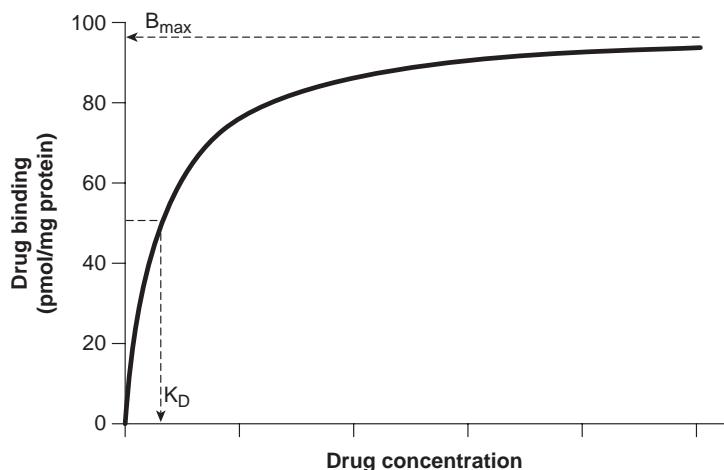
3. **Growth factor receptors** (e.g., epidermal growth factor [EGF] receptor, insulin receptor, fibroblast growth factor receptor, interleukin-2 receptors). Generally, these receptors are composed of a single transmembrane domain containing a cytoplasmic tyrosine kinase. Thus, binding of EGF to its receptor results in receptor dimerization, activation of the tyrosine kinase motif, followed by cross phosphorylation of their cytoplasmic tail regions. This tyrosine phosphorylation on specific sequences serves to produce src-homology binding domains for the docking of additional proteins that transduce the signal to the interior of the cell. Consequently, EGF receptor activation leads to recruitment of Grb/Sos to the receptor with subsequent activation of the extracellular signal-regulated kinase (ERK) pathway to promote cell growth/replication (*Figure 58-3*). Similarly, insulin binding and receptor activation promotes insulin receptor substrate 1/2 (IRS-1/IRS-2) recruitment that increases plasma membrane glucose transporter expression and enhanced glucose uptake.

Figure 58-3. The ERK-MAPK signaling pathway mediates the biological processes of growth and differentiation. *EGF*, epidermal growth factor; *MEK*, ERK-kinase; *ERK*, extracellular signal-regulated kinase.

4. **Membrane transporters**, **pumps**, **and miscellaneous receptors** (e.g., Na^+/K^+-ATPase, MDR-1 protein, natriuretic factor receptors). The natriuretic peptide family of proteins activates membrane-bound, single-transmembrane domain receptors that contain cytoplasmic guanylyl cyclase activity. Membrane-bound pumps such as the Na/K-ATPase and the MDR-1/P-glycoprotein are also targets for various therapeutic interventions even though they do not have well-characterized endogenous ligands.


B. **Intracellular receptors**

1. **Cytoplasmic receptors** may be as diverse as glucocorticoid hormone receptor, soluble guanylyl cyclase, and other enzymes or proteins that serve as targets for drugs (e.g., HMG-CoA reductase, tubulin, or calcineurin). The steroid receptors in this group (e.g., glucocorticoid receptor) have cytoplasmic localization until complexed to corticosteroids at which time they are translocated to the nucleus to function as transcription factors for gene expression (*Figure 58-4*).

2. **Nuclear receptors** include those for thyroid hormone, sex steroids, retinoids, and peroxisome proliferator activator receptors. The binding of specific hormones to their respective receptors produces a complex that serves as transcription factors to modulate gene expression. Additionally, DNA and components of the nucleosome may serve as binding sites for specific drugs.


C. **Microorganism proteins as drug targets.** Various fungal, bacterial, and viral proteins (e.g., cell wall transamidase, fungal CYP450, viral thymidine kinase) are targeted for selective pharmacological intervention to treat relevant infections. These targets are often critical to the integrity or replication of the microorganism and their modulation can result in diminished viability of the infecting agent. Drug selectivity for these targets is achieved because they are structurally the distinction from analogous mammalian targets, and this often results in complete destruction of the offending microorganism.

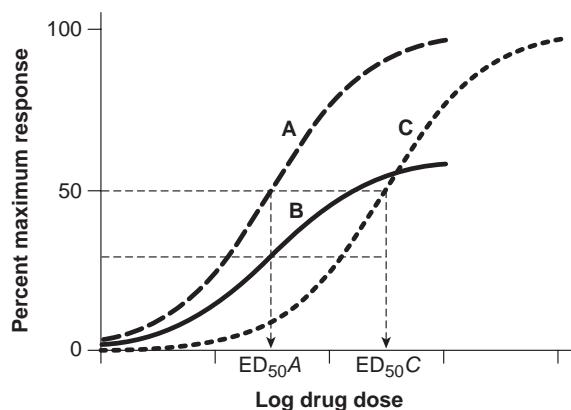
III. DRUG–RECEPTOR INTERACTIONS

A. **Drug–receptor binding**. At a fundamental level, drug molecules interact with specific receptors in order to produce the ultimate pharmacological effect. This interaction may be governed by the formation of hydrogen, ionic, or van der Waals bonds between given drug–receptor pairs. In general,

Figure 58-4. Signaling by hormones such as cortisol occurs via a cytoplasmic receptor that promotes specific gene expression after binding the ligand.

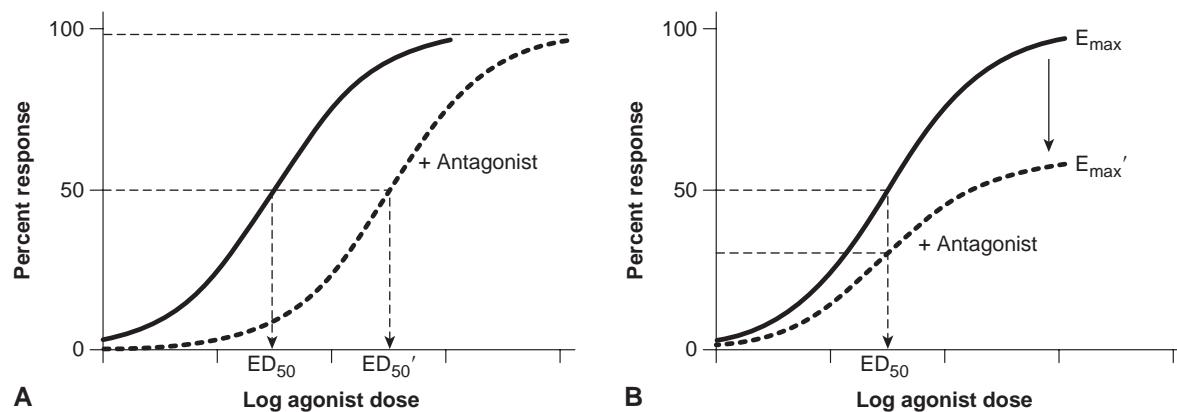
Figure 58-5. The binding of a drug to its receptor follows a rectangular hyperbolic relationship where the K_D is the concentration at which half the receptors are occupied. The B_{max} is the maximum number of binding sites (receptors) available to the drug and may be expressed in units such moles/gram tissue.

these types of bonds are relatively weak and allow for the dissociation of the drug from the receptor, and the eventual pharmacological effect is reversed as the drug concentration at the receptor decreases. The tendency of drugs to bind to receptors is determined by its affinity for the receptor site as well as its concentration at that site, according to the law of mass action. Accordingly, the number of receptors [R] occupied by a drug depends on its concentration [D] and the drug–receptor association ($k1$) and dissociation ($k2$) rate constants such that

$$[D] + [R] \underset{k2}{\overset{k1}{\rightleftharpoons}} [D - R] \qquad \text{Equation 58-1}$$


This equation suggests that the number of receptors bound by the drug at equilibrium is proportional to the concentration of the drug and is represented by a rectangular hyperbola (*Figure 58-5*). The ratio of k2 to k1 is better known as the **dissociation constant** (K_D) and represents the concentration of drug required to occupy 50% of the receptor sites in a tissue (*Figure 58-5*). The inverse of the K_D is equivalent to the **affinity** of a drug for its receptor and is proportional to the potency of the drug (below). Some drugs interact with their receptors by the formation of covalent bonds or dissociate so slowly from the receptor (very small k2) that the drug–receptor binding is irreversible or pseudo-irreversible at equilibrium. It could be expected that these types of drugs would have longer durations of action than those that are more rapidly reversible.

B. **Drugs as agonists.** Drugs that possess affinity for a specific receptor as well as intrinsic activity at that receptor are termed *agonists*. Agonists mimic the actions of the endogenous ligand (e.g., epinephrine for the β-adrenergic receptor) by modifying the conformation of the receptor in a manner that results in the initiation of intracellular signaling events and a biological response. Thus, dobutamine is able to mimic the actions of epinephrine at the β-receptor, producing increases in rate and contractility of the myocardium. For an agonist, *Equation 58-1* can be modified to

$$[D] + [R] \underset{k2}{\overset{k1}{\rightleftharpoons}} [D - R] \rightarrow \text{Response} \qquad \text{Equation 58-2}$$


The consequence of drug–receptor complex formation is a biological response that is proportional to the number of complexes formed. The application of increasing doses of an agonist will produce increasing biological response until a maximum effect is achieved. This relationship is represented by a sigmoidal dose–response curve when drug dose is plotted on a logarithmic scale (*Figure 58-6*).

1. **Full agonists** are able to produce increasing biological response with increasing dose until a maximal effect or efficacy (E_{max}) is achieved, represented by a dose–response relationship (*Figure 58-6*). From this relationship, the effective dose that produces 50% of the E_{max} (ED_{50}) can be determined as shown in *Figure 58-6*. The ED_{50} is a measure of the potency of the agonist such that drug A is more potent than drug C, even though the two have similar E_{max}s. Epinephrine is a full agonist at the β-receptor.

Figure 58-6. For the dose–response curves of three agonists, it can be seen that the A and C can be classified as full agonists because they are able to produce the maximal response possible, whereas B has a lower maximum, indicating a lower efficacy. However, agonist B has a greater potency than drug C because its ED_{50} is lower than that of C. $ED_{50}A$: dose of A producing 50% of its maximal response.

2. **Partial agonists** possess reduced intrinsic activity or efficacy, which results in reduced E_{max} relative to a full agonist (drug B versus drug A or C, *Figure 58-6*). However, a partial agonist may have greater affinity for the receptor, resulting in greater potency than a full agonist (compare drug B and C, *Figure 58-6*). Oxymetazoline (Afrin®) and buprenorphine (Buprenex®) are partial agonists at the α-adrenergic and μ-opioid receptors, respectively.

C. **Drugs as antagonists.** Drugs with affinity for a receptor but lacking intrinsic activity are called **antagonists**. These drugs are unable to alter receptor conformation in a way that leads to initiation of intracellular signal transduction processes and have their predominant pharmacological action by preventing the binding and actions of an endogenous ligand. Thus, atropine binds to the muscarinic receptor with high affinity but is unable to initiate a biological response; on the other hand, by occupying the binding site, it prevents the ability of acetylcholine to bind and produce an effect.

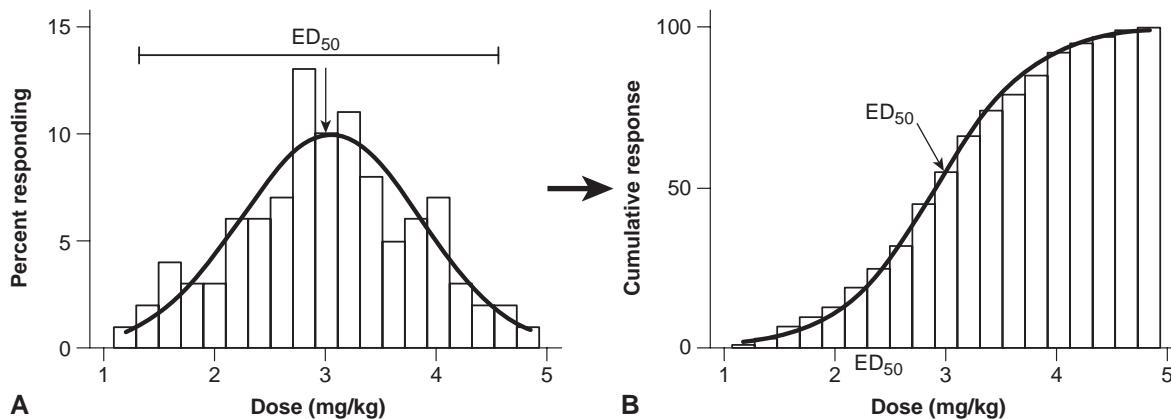
1. **Equilibrium-competitive antagonists** reversibly interact with the same binding site on the receptor as the agonist to prevent agonist binding and activation of the receptor. The reversibility of antagonist binding (*Equation 58-1*) allows the increasing doses of **agonist** to displace the antagonist to eventually produce the maximal biological response but with an apparent decrease in the affinity (increased ED_{50}). On an agonist dose–response curve, the effect of equilibrium-competitive antagonists would be to shift the agonist curve to the right without a change in the maximal response (*Figure 58-7A*). Atropine is an example of an equilibrium-competitive antagonist at the muscarinic receptor.


Figure 58-7. A. The apparent decrease in agonist potency (increase in the ED_{50} to ED_{50}'; *dashed line*) in the presence of the antagonist without a decrease in the maximal response is indicative of an equilibrium-competitive antagonist. **B.** The decrease in the maximal response of the agonist curve after antagonist treatment (*dashed line*) would suggest the actions of a nonequilibrium or irreversible antagonist.

2. **Nonequilibrium-competitive antagonists** interact with their receptors in an irreversible or pseudo-irreversible manner, resulting in a very small k2 (*Equation 58-1*). This irreversibility (usually due to covalent bonding) would reduce the number of receptors available to produce a biological response, which results in an agonist dose–response curve with reduced E_{max} and variable effect on potency (*Figure 58-7B*). Phenoxybenzamine (Dibenzyline®) is an example of nonequilibrium-competitive antagonist at the α-adrenergic receptor.

3. **Inverse agonists/antagonists** reduce the basal coupling of the receptor to the intracellular signal transduction processes, producing a negative pharmacological effect even in the *absence* of receptor agonists. β-Blockers like propranolol (Inderal®) are examples of drugs with both equilibrium-competitive antagonist and inverse agonist activity.

4. **Noncompetitive antagonists** interact with a distinct site to that occupied by the agonist to prevent the biological response initiated by the agonist. This distinct site may be on the receptor itself (tyrosine kinase domain of the EGF receptor) or a downstream signaling molecule from the receptor (calcineurin in T-cell receptor signaling). The binding of the antagonist for its site cannot be displaced by increasing doses of agonist because there is no overlap in the two sites—there is no competition between the two ligands for a common site. Thus, erlotinib (Tarceva®) is a noncompetitive antagonist of EGF at the EGF receptor and would reduce the efficacy of the agonist (E_{max}) to stimulate cell growth.

D. **Enzymes as drug receptors.** In many instances, cellular enzymes behave similarly to classical receptors in their interaction with drug molecules via ionic, hydrogen, van der Waal's, or covalent bonding. However, important differences in the behavior of enzymes warrant separate treatment.

1. **Competitive enzyme inhibitors** are drugs that bind to the active site of an enzyme in a manner that prevents substrate binding and conversion to a product. Analogous to classical drug–receptor interactions, these inhibitors would be considered competitive regardless of whether drug binding was reversible or irreversible. The inhibition of HMG-CoA reductase by simvastatin (Zocor®) would be considered competitive with respect to the substrate HMG-CoA.

   a. **Transition-state inhibitors** mimic the transition state of the enzyme substrate having the highest free energy of activation and thus a high binding affinity for the substrate/active site (e.g., captopril [Capoten®] for the angiotensin-converting enzyme).

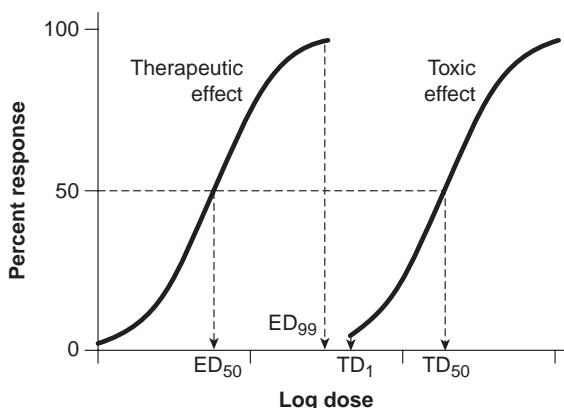
   b. **Suicide enzyme inhibitors** are drugs that are catalyzed or destroyed in the process of binding to the active enzyme site; for example, neostigmine (Prostigmin®) is metabolized to a carbamate intermediate that covalently binds to the active site of acetylcholinesterase.

2. **Allosteric modulators** bind to a distinct site from that of the substrate and thereby alter enzyme activity. Theoretically, this type of modulation can increase or decrease enzyme activity and not automatically be classified as inhibition. Allosteric modulators that inhibit enzyme activity may be considered noncompetitive inhibitors; for example, efavirenz (Sustiva®) inhibits the polymerase function of HIV reverse transcriptase.

E. **Modulation of receptor sensitivity**

1. **Desensitization** of seven transmembrane-spanning receptors generally occurs with sustained stimulation of the receptor and occurs due to reduced coupling to G proteins. Uncoupling of the receptor is due to phosphorylation of the receptor, which prevents its interaction with the G protein and also reduces the affinity of the agonist for the receptor. Myocardial β-receptors in patients with heart failure are thought to be desensitized due to sustained sympathetic nervous system stimulation.

2. **Downregulation** of the receptor is the result of prolonged receptor stimulation that leads to incorporation of the receptor into clathrin-coated pits and removal of the receptor from the plasma membrane. This process reduces agonist signaling to the intracellular compartment. Ultimately, the receptor may be transported to the lysosomal compartment for destruction or recycled back to the plasma membrane to restore cell signaling. The sustained use of β-agonists like albuterol (Ventolin®) causes the downregulation of β_2-receptors in asthmatic patients.

3. **Receptor hypersensitivity/supersensitivity** is exhibited by increased response to agonist stimulation and is most likely due to increased receptor number or enhanced coupling of the receptor to intracellular signaling processes. This phenomenon usually occurs with chronic reduction in receptor stimulation due to diminished endogenous agonists (e.g., after autonomic or motor nerve destruction). Reversal of prolonged antagonist therapy has also been associated with receptor supersensitivity (e.g., abrupt withdrawal of β-blocker therapy).


IV. PHARMACODYNAMICS IN THE CLINICAL POPULATION. Pharmaco-

logical therapy in the human patient population is fundamentally based on the principles of dose–response relationships, with higher doses producing greater effects until a maximum is reached. An inherent assumption of the dose dependency of a drug effect is that it is mediated through a specific receptor, regardless of whether the drug is an agonist or antagonist. However, the relative potencies of drugs (as indicated by the ED_{50}s) may not reflect the affinity of the drug for its receptor because this value can also be influenced by several pharmacokinetic parameters; that is, a high-affinity drug may exhibit a greater ED_{50} than a low-affinity drug if the former is poorly absorbed or more quickly inactivated by hepatic systems.

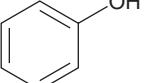
A. Quantal dose–response relationship may be developed in a patient population based on the dose required to produce a specific outcome; for example, the dose required to cause sleep or produce a 10% decrease in blood pressure. This would result in some individuals requiring very small doses, whereas others would need much higher amounts to induce the effect, the overall response following a Gaussian or normal distribution (*Figure 58-8A*). The mean of this distribution would be equivalent to the ED_{50} and 95% of patients would respond to a dose that is 2 standard deviations above or below the ED_{50} (indicated by the range shown in *Figure 58-8A*). Plotting the same data as the administered dose versus the cumulative number of patients producing the effect exhibits the recognizable dose–response curve (*Figure 58-8B*).

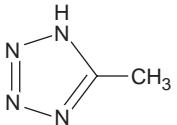
B. Graded dose–response relationship may be seen in a patient population or individuals where increasing doses of a drug results in greater pharmacological effect. This is best demonstrated by drugs that can be titrated to produce a desired outcome; for example, 10, 20, 40, and 80 mg of ator-vastatin (Lipitor®) can produce 33%, 38%, 45%, and 53% lowering in LDL cholesterol, respectively (see *Figure 10-17*).

C. Dose-dependent drug toxicity can also result in the course of pharmacological therapy and follows a similar normal distribution as demonstrated in *Figure 58-8A*—only these effects usually occur at higher doses (e.g., 1% of the population may show toxicity to the same drug at 6 mg/kg). Plotting graded dose–response curves for the therapeutic and toxic effects of drug may produce relationships as seen in *Figure 58-9*. From the graph, it can be seen that the dose-producing toxicity in 50% of the population (TD_{50}) is larger than the ED_{50}; however, the TD_1 is much closer to the ED_{99} and is an indication of the margin of safety of the drug. If the toxic effect being measured is death, then the lethal dose producing 50% death in the population is called the LD_{50}, and the ratio of the LD_{50} to the ED_{50} is called the therapeutic index. Drugs with a low margin of safety are likely to show toxicity at doses that are in the therapeutic range (e.g., warfarin [Coumadin®] and digoxin [Lanoxin®]).

Figure 58-8. **A.** The percentage of patients in a population that respond to a pharmacological intervention can be represented by a Gaussian distribution where some require only 1 mg and others need as much as 5 mg of the drug to show the desired response. This in effect is the dose–response relationship of the entire population as demonstrated by the graph (**B**) where plotting the cumulative number of responders after each dose gives the classic dose–response curve. In either graph, the dose producing an effect in 50% of the population (ED_{50}) can be determined as shown.

Figure 58-9. Drugs can have toxic or undesirable effects that follow a dose–response relationship; however, these effects often require higher doses to be observe and thus their graph appears shifted to the right of the therapeutic effect (*graph on the right*). TD_1: dose producing a toxic response in 1% of the population.

V. STRUCTURAL DETERMINANTS OF DRUG ACTION




A. **Structural specificity** is conferred by physical and chemical characteristics, or physicochemical properties, of drugs that allow for specific binding and modulation of the target receptor. These physicochemical properties of a drug are influenced by the acid–base character, water solubility, and stereochemistry, which are dependent on the chemical structure. The physicochemical properties are also important for absorption, distribution, metabolism, and excretion. This structure-to-function connection is the basis for **structure–activity relationships** (SARs) that are defined by changing the chemical structure and determining its influence on biological activity.

B. **Pharmacophore** is a term used to describe the critical organic functional groups and their spatial relationship within a drug molecule required for a specific pharmacological activity. Drugs with similar structure and the same pharmacophore typically have similar pharmacological activity but may have other ADME characteristics or potencies that distinguish them from one another.

C. A **functional group** is a specific group of atoms that have a distinctive acid–base character, contribution to water solubility, and chemical reactivity. The combination of multiple functional groups can influence the properties of adjacent functional groups and together define the physicochemical properties of the drug molecule. Common functional groups are shown in *Tables 58-1, 58-2,* and *58-3.*

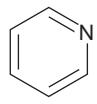
D. A **bioisostere** is a compound containing an atom or group of atoms that is spatially and electronically similar to another molecule that produces a similar biological activity. The goal of bioisosteric replacement is frequently to increase potency, decrease side effects, separate biological activities, or increase the duration of action by altering metabolism. Additionally, bioisosteric substitutions may result in a compound that is an antagonist or inhibitor of the parent molecule; for example, allopurinol (Zyloprim®) inhibits xanthine oxidase, which, through a multistep metabolic process, converts hypoxanthine to uric acid (*Figure 58-10*).

E. The **stereochemistry** of a drug molecule also contributes to the structural specificity of a drug by defining the three-dimensional spatial arrangement of the functional groups required for receptor interactions. **Stereoisomers** have the same atoms and connectivity but different arrangements in space. Stereoisomers can be divided into three main groups: enantiomers; diastereomers, including geometric isomers; and conformational isomers.

    1. **Enantiomers** are nonsuperimposable mirror images of each other because they contain at least one asymmetric, or chiral, center, usually a carbon covalently bound to four different substituents. A drug containing one chiral carbon can exist in one of two nonsuperimposable isomeric forms, although a drug with multiple chiral centers (n) has the potential to exist in one of 2^n isomeric forms that are enantiomers or diastereomers (*Figure 58-11*).

        a. Enantiomers have identical physical and chemical properties except for the direction of rotation of plane-polarized light measured in a polarimeter. One isomer will rotate plane-polarized light in a clockwise direction (**dextrorotatory**; d or +) and the other in a counterclockwise direction (**levorotatory**; l or −).

        b. An equal molar mixture of a pair of enantiomers (+ and −) is called a **racemic mixture** or **racemate**. A racemate has a net zero rotation of plane-polarized light and is therefore optically inactive. Currently, some active drugs are marketed both as a racemate (cetirizine [Zyrtec®]) and as an enantiomerically pure product (levocetirizine [Xyzal®]) (*Figure 58-11*).

Table 58-1   NEUTRAL FUNCTIONAL GROUPS


Group	Structure	Group	Structure
Alkane	$H_3C-CH_2-CH_2-CH_3$	Ketone	$H_3C-CO-CH_3$
Alkene	(H)(H_3C)C=C(CH_3)(H)	Amine (quaternary)	$(H_3CH_2C)(H_3CH_2C)N^{+}(CH_2CH_3)(CH_2CH_3)$
Aromatic	benzene ring	Ester	$H_3CH_2C-CO-OCH_2CH_3$ or $CH_3CH_2COOCH_2CH_3$
Alcohol (primary)	H_3C-OH	Amide	$H_3CH_2C-CO-NHCH_2CH_3$
Alcohol (secondary)	$H_3C-CH(OH)-CH_3$	Carbonate	$H_3CH_2CO-CO-OCH_2CH_3$
Alcohol (tertiary)	$H_3C-C(CH_3)(CH_3)-OH$	Carbamate	$H_3CH_2CO-CO-NHCH_2CH_3$
Ether	$H_3CH_2C-O-CH_2CH_3$	Urea	$H_3CH_2CHN-CO-NHCH_2CH_3$
Thioether	$H_3CH_2C-S-CH_2CH_3$	Nitro	$H_3CH_2C-N^{+}(O^{-})(=O)$ or $H_3CH_2C-NO_2$
Aldehyde	$H_3C-CO-H$	Nitrate	$H_3CH_2C-O-NO_2$
    c. Enantiomers can have large differences in potency, receptor fit, biological activity, transport, and metabolism. These differences result when the drug molecule has an asymmetric interaction with a receptor, a transport protein, or a metabolizing enzyme. The enantiomer with the desired pharmacological effect is called the **eutomer**, whereas the other isomer is the **distomer**. The distomer may not have pharmacologic activity or may be responsible for adverse effects.

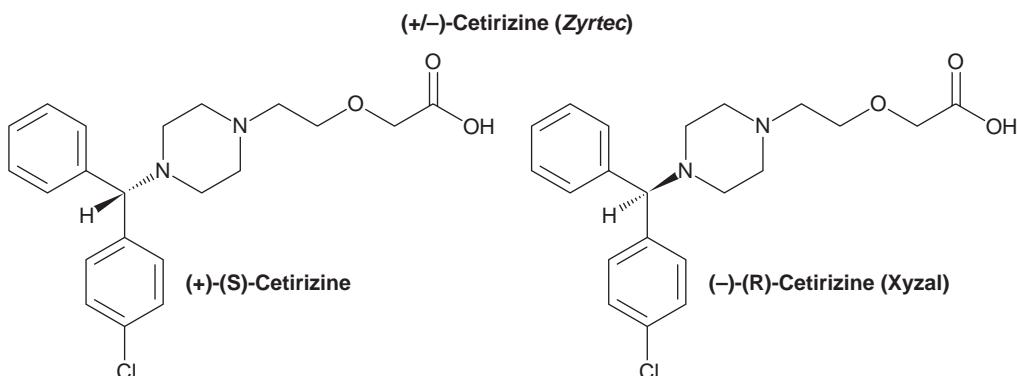
    d. Enantiomers are distinguishable in a chiral environment, including the human body, or by determining the rotation of plane-polarized light in a polarimeter. These are properties of the molecule but they do not reveal information concerning the absolute configuration around the chiral center. To determine the absolute configuration, the Cahn-Ingold-Prelog (CIP) system for assigning priority is used (R or S designation). It is important to remember that the CIP absolute configuration is applied to each chiral center and is independent of the direction of rotation of plane-polarized light for the molecule as a whole. In a pair of enantiomers, all stereocenters are opposite in their absolute configuration and therefore also in their CIP designation.

2. Diastereomers are stereoisomers that are not enantiomers. More specifically, they are stereoisomers that are not mirror images of each other or superimposable.

    a. Like enantiomers, diastereomers can be optically active. But diastereomers have some stereocenters that are identical and some that are opposite in their absolute configuration. Diastereomers

Table 58-2	ACIDIC FUNCTIONAL GROUPS

Group	Structure
Carboxylic acid	$H_3CH_2C-\overset{\overset{\displaystyle O}{\|\|}}{C}-OH$ or CH_3CH_2COOH
Imide	$H_3C-\overset{\overset{\displaystyle O}{\|\|}}{C}-\overset{\overset{\displaystyle H}{\|}}{N}-\overset{\overset{\displaystyle O}{\|\|}}{C}-CH_3$
Phenol	OH on benzene ring
Sulfonamide	$H_3CH_2C-\overset{\overset{\displaystyle O}{\|\|}}{\underset{\underset{\displaystyle O}{\|\|}}{S}}-NHCH_2CH_3$
Sulfonic acid	$H_3CH_2C-\overset{\overset{\displaystyle O}{\|\|}}{\underset{\underset{\displaystyle O}{\|\|}}{S}}-OH$
Sulfonimide	$H_3C-\overset{\overset{\displaystyle O}{\|\|}}{\underset{\underset{\displaystyle O}{\|\|}}{S}}-\overset{\overset{\displaystyle H}{\|}}{N}-\overset{\overset{\displaystyle O}{\|\|}}{C}-CH_3$
Tetrazole	tetrazole ring with CH_3
Thiol	H_3CH_2C-SH

Table 58-3	BASIC FUNCTIONAL GROUPS


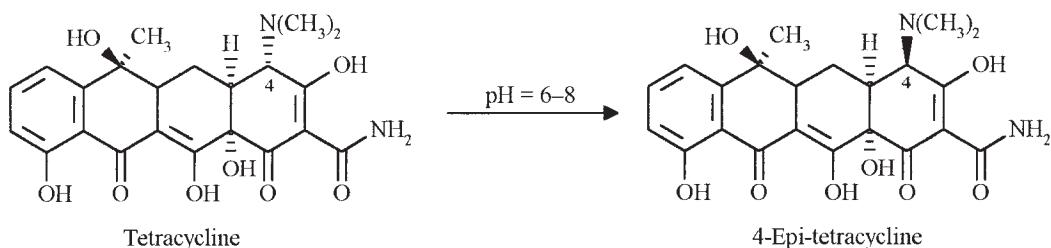
Group	Structure
Amine (primary)	$H_3CH_2C-NH_2$
Amine (secondary)	$\begin{matrix} H_3CH_2C \\ H_3CH_2C \end{matrix} NH$
Amine (tertiary)	$\begin{matrix} H_3CH_2C \\ H_3CH_2C \end{matrix} N-CH_2CH_3$
Amine (aromatic)	pyridine ring
Imine	$H_3CHC=NH$
Amidine	$H_3CH_2C-\overset{\overset{\displaystyle NH}{\|\|}}{C}-NH_2$
Guanidine	$\begin{matrix} H_3CH_2C \\ \quad\quad\quad N \\ H_3CH_2C-C-NH_2 \end{matrix}$


Figure 58-10. Bioisosteric pairs procainamide/procaine and allopurinol/hypoxanthine. The isosteric replacements are *boxed*.

possess different physicochemical properties and thus differ in properties such as solubility, volatility, and melting point. For optically active diastereomers, two or more stereocenters are required.

b. **Epimers** are a special type of diastereomers because epimers are structurally identical in all respect except for the stereochemistry of one chiral center. The process of **epimerization** (in which the stereochemistry of one chiral center is inverted) is important in drug degradation and inactivation (*Figure 58-12*).

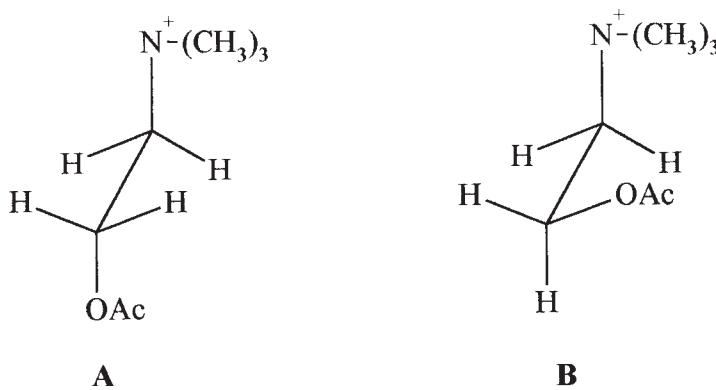
c. **Geometric isomers** are diastereomers because they are not mirror images and they have different physicochemical properties and pharmacologic activity (*Figure 58-13*). Geometric isomers are also called ***cis–trans* isomers** and result from restricted rotation around a chemical bond. This can be an alkene (double bond) or a fused ring system within a molecule that prevents interconversion between the two isomers.

3. Conformational isomers, also known as rotamers or conformers, are nonsuperimposable orientations of a molecule that results from the free rotation of atoms around a single bond. Almost every drug can exist in more than one conformation, and this ability allows many drugs to bind to multiple receptors and receptor subtypes. For example, the trans conformation of acetylcholine binds to the muscarinic receptor, whereas the gauche conformation of acetylcholine binds to the nicotinic receptor (*Figure 58-14*). It should be noted that conformational isomers are chemically indistinguishable (i.e., they have all the same physicochemical properties) from each other because the only difference between the conformers is the free rotation around a bond.

Figure 58-11. The two enantiomers of cetirizine. The chiral, or asymmetric, carbon is bonded to four different groups: a piperazine ring, a chlorinated benzene ring, an unsubstituted benzene, and a hydrogen. The structures shown are mirror images, which cannot be superimposed. A racemic mixture of cetirizine is marketed as Zyrtec, whereas the enantiomerically pure levocetirizine is marketed as Xyzal.

Figure 58-12. Epimerization of tetracycline to 4-epitetracycline. The stereochemistry of the 4-dimethylamino group is inverted; however, the stereochemistry of all other chiral centers remains unchanged.

VI. PHYSIOCHEMICAL DETERMINANTS OF DRUG ACTION. The polarity and acid–base property of a drug are two primary physiochemical characteristics of drugs.
   A. **Polarity of drugs** is a measure of their lipid and water solubility and is generally expressed as the partition coefficient.

   1. **Partition coefficient** (P) of a drug is the ratio of the solubility of the agent in an organic lipophilic solvent (usually *n*-octanol) to its solubility in water or aqueous buffer.


$$P = \frac{[\text{Drug}]_{\text{organic}}}{[\text{Drug}]_{\text{water}}}$$

The partition coefficient is often expressed as the logarithmic value, log P.

   2. **Water solubility** or hydrophilicity of a drug is dependent on two major factors: its ionic and hydrogen-bonding capacity. The presence of oxygen- and nitrogen-containing functional groups generally enhances water solubility, which is required for

   a. drug dissolution in the gastrointestinal (GI) tract,

   b. preparation of parenteral drug solutions, and

   c. ophthalmic drug solutions.

   3. **Lipid solubility** or lipophilicity is increased by the presence of nonionizable functional groups (hydrocarbon chains or ring systems) and is important in

   a. drug absorption from the GI tract,

   b. penetration of drug through biological membranes (e.g., cell membranes, blood–brain barrier),

   c. preparation of intramuscular depot injectable formulations,

   d. drug absorption via the pulmonary route,

   e. increased potency of topically applied formulations, and

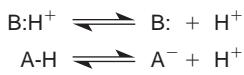
   f. increased plasma protein binding.


Figure 58-13. The presence of the double bond in diethylstilbestrol allows for the formation of *cis* and *trans* geometric isomers. The functional groups of these isomers are separated by different distances; they generally do not fit the same receptor equally well. As a result, the *trans* isomer has estrogenic activity and the *cis* isomer only has 7% the estrogenic activity of the *trans* isomer.

Figure 58-14. The *trans* (**A**) and *gauche* (**B**) conformations of acetylcholine occur as the result of rotation around the carbon–carbon single bond.

B. **Acid–base characteristic** of drugs influence their ionization in biological fluids. Using the Brønsted–Lowry definition, acids donate a proton to become ionized, whereas bases accept a proton to become ionized.

1. The **ionization constant (K_a)** indicates the relative strength of the acid or base by indicating the ratio of the unprotonated species to the protonated species (*Figure 58-15*). An acid with a K_a of 1×10^{-3} is stronger (more ionized [A^-] species) than an acid with a K_a of 1×10^{-5}, whereas a base with a K_a of 1×10^{-7} is weaker (less ionized [BH^+] species) than a base with a K_a of 1×10^{-9}.

2. The ionization constant is more commonly reported as the **pK_a** or the **negative log of the ionization constant**. The pK_a also indicates the relative strength of the acid or base. Using the aforementioned examples, an acid with a K_a of 1×10^{-3} has a pK_a of 3 and is stronger than an acid with a K_a of 1×10^{-5} (pK_a of 5), whereas a base with a K_a of 1×10^{-7} (pK_a of 7) is weaker than a base with a K_a of 1×10^{-9} (pK_a of 9).

3. **Acids** can be described as strong or weak acids based on their ability to donate a proton.

    a. **Strong acids** are completely ionized when placed in water. Strong acids include hydrochloric acid (HCl), sulfuric acid (H_2SO_4), nitric acid (HNO_3), hydrobromic acid (HBr), iodic acid (HIO_3), and perchloric acid ($HClO_4$).

    b. **Weak acids** are partially ionized when placed in water. Most organic acids contained in drugs are weak acids. The following functional groups are weak acids. The approximate pK_a range is shown in parentheses (see *Table 58.2*).

    (1) Carboxylic acid group (—COOH with a pK_a range of 4–6)

    (2) Phenolic group (Ar—OH with a pK_a range of 9–11)

    (3) Sulfonic acid group (—SO_3H with a pK_a range of 0–1)

    (4) Sulfonamide group (—SO_2NH_2 with a pK_a range of 9–10)

    (5) N-Aryl sulfonamide group (—SO_2NH—Ar with a pK_a range of 6–7)

    (6) Imide group (—CO—NH—CO— with a pK_a range of 9–10)

    (7) Thiol (R—SH with a pK_a range of 9–11)

    (8) Sulfonimide (—SO_2NH—CO— with a pK_a range of 5–6)

    (9) Tetrazole (five-member ring CHN_4 with a pK_a range of 4–6)

    c. When a weak acid, like acetic acid (pK_a = 4.76), is placed in an acid medium (high [$H+$], low pH), the equilibrium shifts to the left and suppresses ionization. This decrease in ionization conforms to Le Chatelier's principle, which states that when a stress is placed on an equilibrium reaction, the

$$B:H^+ \rightleftharpoons B: + H^+$$
$$A\text{-}H \rightleftharpoons A^- + H^+$$

$$K_a = \frac{[H+][A-]}{[AH]} \text{ or } K_a = \frac{[H+][B:]}{[BH+]}$$
$$pK_a = -\log K_a = \log \frac{1}{K_a}$$

Figure 58-15. The ionization constant (K_a) and the pK_a indicate the equilibrium between the protonated species, the unprotonated species, and the strength of the acid or base.

reaction will move in the direction that tends to relieve the stress. When the same weak acid is placed in an alkaline medium (very low [H+], high pH), the ionization increases producing more H+.

$$CH_3COOH \rightleftharpoons CH_3COO^- + H^+$$

  d. Weakly acidic drugs are less ionized in acid media than in alkaline media. When the pK_a of an acidic drug is greater than the pH of the medium in which it exists, it will be > 50% in its nonionized form and thus more likely to cross lipid cellular membranes.
4. **Bases** can be described as strong or weak bases based on their ability to accept a proton.
  a. **Strong bases** are completely ionized when placed in water. Strong bases include sodium hydroxide (NaOH), potassium hydroxide (KOH), magnesium hydroxide ($Mg(OH)_2$), calcium hydroxide ($Ca(OH)_2$), barium hydroxide ($Ba(OH)_2$), and quaternary ammonium hydroxides.
  b. **Weak bases** are partially ionized when placed in water. Most organic bases contained in drugs are weak bases. The following functional groups are weak bases. The approximate pK_a range is shown in parentheses (see *Table 58.3*).
    (1) Primary, secondary, and tertiary aliphatic amines ($R\text{-}NH_2$, $R_2\text{—}NH$, and $R_3\text{—}N$, respectively, with a pK_a range of 9–11)
    (2) Aromatic amine (aromatic ring with N included in ring with a pK_a range of 5–6)
    (3) Arylamine ($Ar\text{—}NH_2$ with a pK_a range of 4–5)
    (4) Imine ($\text{—}CH\text{=}NH$ with a pK_a range of 3–4)
    (5) Amidine ($\text{—}NH\text{—}C\text{=}N\text{—}$ with a pK_a range of 10–11)
    (6) Guanidine ($\text{—}NH\text{—}C\text{=}NH(NH_2)$ with a pK_a range of 12–13)
  c. When a weak base like ethylamine ($pK_a = 10.7$) is placed in an acid medium (high [H+], low pH), the equilibrium shifts to the left and increases the ionization (see Le Chatelier's principle in section VI.B.3.c). When the same weak base is placed in an alkaline medium (very low [H+], high pH), the ionization decreases.

$$CH_3CH_2NH_3^+ \rightleftharpoons CH_3CH_2NH_2 + H^+$$

  d. Weakly basic drugs are less ionized in alkaline media than in acid media. When the pK_a of a basic drug is less than the pH of the medium in which it exists, it will be > 50% in its nonionized form and thus more likely to cross lipid cellular membranes.
5. **Percent ionization** can be approximated by using the rule of nines. If the $|pH - pK_a| = 1$, then a 90:10 ratio (one nine in the ratio) exists. If the $|pH - pK_a| = 2$, the ratio becomes 99:1 (two nines in the ratio), and if the $|pH - pK_a| = 3$, the ratio becomes 99.9:0.1 (three nines in the ratio). The predominant form, ionized or unionized, in these ratios can be easily determined.
6. **Drug salts** are made by the combination of an acid and a base. Because most drugs are organic molecules, drug salts can be divided into two classes based on the chemical nature of the substance forming the salt.
  a. **Inorganic salts** are made by combining drug molecules (a weak base or acid) with strong inorganic acids or bases such as hydrochloric acid, sulfuric acid, potassium hydroxide, or sodium hydroxide. The salt form of the drug made from a strong inorganic and a weak organic generally has increased water solubility in comparison with the parent molecule and increased aqueous dissolution.
  b. **Organic salts** are made by combining drug molecules with either small hydrophilic organic compounds (e.g., succinic acid, citric acid) or lipophilic organic compounds (e.g., procaine). Water-soluble organic salts are used to increase dissolution and bioavailability as well as to aid in the preparation of parenteral and ophthalmic formulations. Lipid-soluble organic salts are primarily used to make depot injections.
  c. **Dissolution of salts** can alter the pH of an aqueous medium.
    (1) Salts of strong acids (e.g., HCl, H_2SO_4) and basic drugs dissociate in an aqueous medium to yield an acidic solution.
    (2) Salts of strong bases (e.g., NaOH, KOH) and acidic drugs dissociate in an aqueous medium to yield a basic solution.
    (3) Salts of weak acids and weak bases dissociate in an aqueous medium to yield an acidic, basic, or neutral solution, depending on the respective ionization constants involved.

(4) Salts of strong acids and strong bases (e.g., NaCl) do not significantly alter the pH of an aqueous medium.

7. **Amphoteric drugs** contain both acidic and basic functional groups and are capable of forming internal salts, or zwitterions, which often have dissolution problems because the ions interact with each other and not the aqueous environment.

8. A **neutralization reaction** might occur when an acidic solution of an organic salt (a solution of a salt of a strong acid and a weak base) is mixed with a basic solution (a solution of a salt of a weak acid and a strong base). The nonionized organic acid or the nonionized organic base is likely to precipitate in this case. The reaction is the basis for many drug incompatibilities, particularly when intravenous solutions are mixed.

VII. NONCLASSICAL ACTIONS OF DRUGS.

Some pharmacological agents appear to produce their therapeutic effects without interacting with a specific receptor protein, in a manner described by canonical drug–receptor characteristics. The following list is not exhaustive and may change as research explains previous "nonspecific" mechanisms; for example, inhalational anesthetics (e.g., halothane) have been shown to have specific interactions with and modulation of $GABA_A$ receptors.

A. Interaction with membranes
1. **Polyene antifungal agents** (e.g., amphotericin B [Ambisome®]) interact with fungal membrane sterols to cause pore formation and cell lysis.
2. **Alcohols**, **solvents** (e.g., ethanol, isopropyl alcohol, phenol, chlorhexidine) dissolve bacterial membranes to produce cell lysis.
3. **Certain antibiotics** (e.g., polymyxin B) interact with phospholipid components of bacterial membranes to cause cell lysis.

B. Interaction with cytoskeletal components. Microtubule disruptors (e.g., vincristine [Vincasar®], paclitaxel [Taxol®]) interact with tubulin filaments to interfere with their role in mediating cell division.

C. Interaction with DNA/RNA
1. **Alkylating agents** (e.g., nitrosoureas, nitrogen mustards) react with components such as the pyrimidine and purine bases causing cross-linking of DNA strands.
2. **DNA-intercalating agents** (e.g., actinomycin D [Dactinomycin®]) interact with adjacent G-C bases and the minor groove of the DNA double helix.
3. **DNA-cleaving agents** (e.g., bleomycin [Blenoxane®]) bind to DNA causing localized oxidative stress and DNA strand breaks.

D. Neutralizing reactions
1. **Acid–base interactions** (e.g., aluminum sulfate, calcium carbonate) react with peptic HCl to reduce symptoms of dyspepsia. The inactivation of heparin by protamine sulfate is another example of this type of neutralization.
2. **Chelators** (e.g., EDTA, dimercaprol) bind metal ions such as Ca^{2+}, Pb^{2+}, and Hg^{2+} with high affinity and enhance their removal from the body.
3. **Antibody–antigen complexes** (e.g., antivenoms, antidigoxin antibodies [Digibind®]) are administered to rapidly decrease systemic toxins or drugs via the immune system.

VIII. MAJOR SOURCES OF COMMERCIALLY VIABLE DRUGS

A. Naturally occurring drugs are usually obtained from plant or animal sources.
1. **Alkaloids** are nitrogen-containing compounds occurring in plants and possessing pharmacological activity. Most alkaloids have a basic character (e.g., morphine from opium poppy or atropine from belladonna), whereas others are neutral amides (e.g., colchicines from autumn crocus). All alkaloids end in the suffix *–ine*; however, not all drugs that end with this suffix are alkaloids (e.g., nifedipine [Procardia®] or meperidine [Demerol®]).
2. **Hormones** are endogenous chemicals released into the blood by a tissue or organ to act on more distant tissues or organs. These may be biogenic amines, peptides/proteins, or steroids.
   a. **Biogenic amines** such as epinephrine are released by the adrenal medulla to alter the function of multiple organ systems during sympathetic activation.
   b. **Steroids** such as testosterone, estradiol, cortisol, etc. are chemical derivatives of cyclopentanoperhydrophenanthrene and often obtained from animal or human sources.

    c. Peptides/proteins such as insulin, glucagon, and somatostatin are obtained from animal sources or recombinant DNA technology. Generally, peptide and protein drugs have limited oral activity and have to be administered parenterally.

3. **Glycosides** are drugs that contain a sugar moiety bound to a nonsugar or aglycone portion via glycosidic bonds and are most often from plant (e.g., digoxin) or microbial (e.g., streptomycin, doxorubicin) sources.

4. **Polysaccharides** are drugs composed of sugar polymers from human or animal sources (e.g., heparin, enoxaparin). Structural modification of naturally occurring sugars can yield additional drugs (e.g., sucralfate [Carafate®]).

5. **Antibiotics** are often fungal or other microbial products that have suppressive or lethal effects on other microorganisms (e.g., penicillin, tetracycline).

6. **Vitamins** are plant and animal products that function as essential cofactors for various metabolic processes in the body. Water-soluble vitamins include thiamine (B1), riboflavin (B2), niacin (B3), pyridoxine (B6), cyanocobalamin (B12), ascorbic acid (C), folic acid, pantothenic acid, and biotin (H). Fat-soluble vitamins include α-tocopherol (E), ergocalciferol (D), retinol (A), and phytonadione (K).

B. **Synthetic products**

1. **Small organic molecules** produced by organic synthesis to mimic the activity of naturally occurring chemicals or found to have unique pharmacological activity not previously identified.

    a. Antimicrobials (e.g., ciprofloxacin [Cipro®] or trimethoprim) are man-made chemicals that inhibit unique microbial targets such as the DNA gyrase or dihydrofolate reductase to treat susceptible infections.

    b. Receptor ligands compose the largest group of drugs and often mimic endogenous receptor ligands; for example, propranolol (Inderal®) has structural homology to epinephrine; meperidine (Demerol) mimics the structural features of endorphins at the μ-opiate receptors.

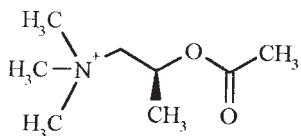
    c. Enzyme inhibitors may be targeted against microbial proteins as in section VIII.B.1.a above or mammalian enzymes; for example, aliskiren (Tekturna®) against renin, pravastatin (Pravachol®) against hepatic HMG-CoA reductase, or imatinib (Gleevec®) against c-kit tyrosine kinase.

2. **Peptides/proteins**

    a. Peptides. Eptifibatide (Integrilin®) is a synthetic cyclic peptide that mimics components of carpet viper venom to prevent platelet aggregation.

    b. Proteins. Lepirudin (Refludan®) is a recombinant, synthetic derivate of hirudin, the anticoagulant from leeches.

3. **Polysaccharides.** The synthetic pentasaccharide fondaparinux (Arixtra®) mimics the portions of heparins that interact with coagulant proteins.

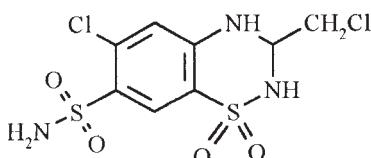
Study Questions


Directions: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. All of the following are examples of specific receptors for drug action **except**

    (A) stomach acid.
    (B) membrane proteins.
    (C) cytoplasmic proteins.
    (D) nuclear proteins.
    (E) DNA.

2. A 40-year-old teacher was prescribed lovastatin for the treatment of hypercholesterolemia. She wanted to know the mechanism of the drug before taking it. Her pharmacist explained to her that lovastatin acts by blocking the substrate-binding site of the enzyme β-hydroxy-β-methylglutaryl-coenzyme A (HMG-CoA) reductase, which catalyzes the rate-limiting step in cholesterol biosynthesis. Such drug effect is known as

    (A) addition.
    (B) synergism.
    (C) noncompetitive antagonism.
    (D) potentiation.
    (E) competitive antagonism.


3. A 70-year-old man had prolonged bleeding during an elective knee surgery. Subsequently, the patient admitted to the surgeon that he had been self-administering 81 mg aspirin daily. The consultant pharmacist explained to the patient that, although aspirin has a short plasma half-life, it can irreversibly inhibit platelet function by acetylating the nonsubstrate-binding site of the platelet cyclooxygenase, resulting in prolonged effect on platelet aggregation. This drug effect is known as

   (A) potentiation.
   (B) competitive antagonism.
   (C) synergism.
   (D) addition.
   (E) noncompetitive antagonism.

4. A 65-year-old woman with intractable pain secondary to bony metastasis of breast cancer had been receiving escalating doses of morphine sulfate intravenously. At 10 A.M., she was found to be unresponsive, her respiratory rate was 4 breaths per minute, and her pupils were pinpointed. Naloxone (Narcan), a competitive antagonist of the opiate receptor, was given intravenously and repeated once. She gradually became conscious and began to complain of pain unrelieved by morphine given at the previous dose. This is most likely because

   (A) naloxone directly aggravates the pain caused by the bony metastasis.
   (B) naloxone reduces the E_{max} for morphine.
   (C) naloxone reduces the ED_{50} for morphine.
   (D) naloxone increases the E_{max} for morphine.
   (E) naloxone increases the ED_{50} for morphine.

5. Which of the following statements regarding signal transduction is **incorrect**?

   (A) Thyroxine-bound receptors act on DNA and regulate specific transcription of genes.
   (B) Cyclic adenosine monophosphate can act as a second messenger.
   (C) The level of drug receptors at the cell surface increases with chronic stimulation by receptor agonists.
   (D) Binding of ligand to cell surface receptors can lead to synthesis of proteins.
   (E) Antacids act by interacting with small ions normally found in the gastrointestinal tract.

6. A pharmacist is consulted about selecting a drug that is relatively safe and effective for treating the patient. He searches the literature and obtains the following data that may help guide his decision. The $TD_{0.1}$ and $ED_{99.9}$ for drug A are 20 mg and 0.4 mg, respectively; whereas the $TD_{0.1}$ and $ED_{99.9}$ for drug B are 15 mg and 0.2 mg, respectively. Which of the following statements is true?

   (A) Drug A has a higher $TD_{0.1}$ and thus should be the drug of choice.
   (B) Both drugs have the same margin of safety, so more information is needed.
   (C) Drug B has a higher margin of safety and thus is preferred to drug A.
   (D) Drug A is preferred because it has a greater margin of safety than drug B.
   (E) The information obtained is irrelevant.

7. Which of the following statements concerning a drug receptor is true?

   (A) It is only found on the plasma membranes of cells.
   (B) Its expression is induced only by exogenously added drugs.
   (C) It can bind endogenous ligand to produce physiological activity.
   (D) It is mostly composed of sugars (polysaccharides).
   (E) Receptor desensitization or downregulation have no impact on the therapeutic effect of the drug.

8. Which of the following statements concerning morphine and hydromorphone (Dilaudid) is true?

   (A) Hydromorphone is a more effective analgesic because it has a smaller ED_{50} than morphine.
   (B) Morphine and hydromorphone are equally potent because they have the same E_{max}.
   (C) Morphine has a greater ED_{50} and is thus a less effective analgesic than hydromorphone.
   (D) Hydromorphone is a more potent analgesic because it has a greater E_{max} than morphine.
   (E) Hydromorphone has a smaller ED_{50} and thus is a more potent analgesic than morphine.

9. A 72-year-old man with hypertension has been taking high-dose propranolol (Inderal) for 20 years. He left home for a week and forgot to bring his medication with him. One day, he was found collapsed on the floor and was brought to the emergency room. His blood pressure was 300/180, heart rate was 180 beats per minute, and retinal hemorrhage was observed. Which of the following best explains this situation?

(A) The β-adrenergic receptors in the cardiac muscles underwent spontaneous mutation and became hyperactive.

(B) Reduction in the chronic antagonism of the β-adrenergic receptor led to downregulation of the β-adrenergic receptor.

(C) The propranolol that he had previously ingested remained in his body and acted as a receptor agonist.

(D) Long-term administration of propranolol results in desensitization of cardiac muscles to endogenous β-adrenergic stimulation.

(E) Reduction in the chronic level of receptor blockade results in supersensitivity to stimulation with endogenous catecholamines.

10. A 42-year-old man with non-small cell lung carcinoma tells his pharmacist that his doctor had prescribed erlotinib (Tarceva) for treating his cancer. The patient asked what erlotinib is and how it works. His pharmacist explains to him that it is a drug that

(A) prevents the binding of growth factors to their receptors.

(B) prevents growth factors from activating their receptors.

(C) boosts the functions of growth factor receptors.

(D) neutralizes a receptor on cancer cells by an antibody mechanism.

11. A 65-year-old woman experienced anginal pain with ST-segment elevation on electrocardiogram (ECG). She was treated with IV heparin, nitroglycerin, and atenolol (Tenormin) for acute myocardial infarction. Then 2 hrs later, when her nurse replaced her Foley bag, she noticed frank blood draining out of the Foley catheter. The physician checked the patient's partial thrombin time, which was > 150 secs. The patient was then administered protamine, which acts by

(A) promoting thrombosis.

(B) reacting with and neutralizing the effect of heparin.

(C) directly inhibiting bleeding.

(D) enhancing secretion of procoagulants.

12. Inverse agonist is a relatively new designation for drug action that a physician asks you about. Your explanation would include the fact that

(A) these agents may have biological function by altering the interaction between the receptor and G protein.

(B) there is no known drug with this type of effect.

(C) these agents can desensitize receptors to agonist stimulation.

(D) the inverse form of these drugs can stimulate physiological response.

13. A 55-year-old man with a history of heart disease was being treated with 20 mg of atorvastatin (Lipitor) but this was not adequate to bring his LDL cholesterol down to acceptable levels. So his physician increased the dose to 40 mg, which resulted in a 30% lowering in LDL. This would be an example of a

(A) quantal dose–response relationship.

(B) population dose–response relationship.

(C) cumulative dose–response relationship.

(D) graded dose–response relationship.

14. All of the following are examples of non–receptor-mediated drug effects **except**

(A) magnesium sulfate for treatment of constipation.

(B) calcium carbonate for relief of heartburn.

(C) halothane for inducing anesthesia.

(D) isopropyl alcohol used for its topical antibacterial activity.

(E) amphotericin B for fungal infections.

15. Which of the following salts will most likely yield an aqueous solution with a pH < 7?

(A) Sodium salicylate

(B) Potassium chloride

(C) Magnesium sulfate

(D) Potassium penicillin

(E) Atropine sulfate

16. All of the following functional groups are weak bases **except**

(A) aromatic amines.

(B) sulfonamide.

(C) tertiary amines.

(D) imines.

17. The dissociation constant of a drug at its receptor is most closely related to

(A) the maximal response produced by the drug.

(B) the number of spare receptors available.

(C) the affinity of the drug for the receptor.

(D) the total number of receptors available to the drug.

(E) allosterism.

18. All of the following statements about a structurally specific agonist are true **except**:

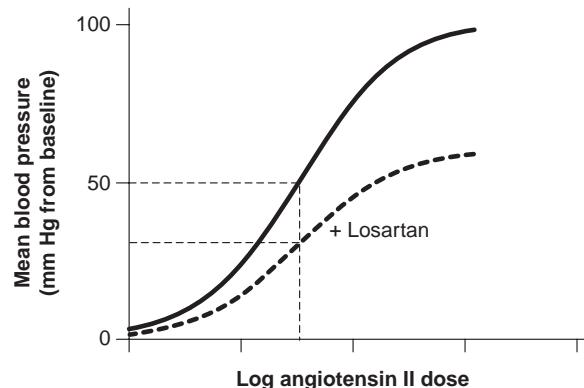
(A) Activity is determined more by its chemical structure than by its physical properties.

(B) The entire molecule is involved in binding to a specific endogenous receptor.

(C) The drug cannot act unless it is first bound to a receptor.

(D) A minor structural change in a pharmacophore can produce a loss in activity.

(E) The higher the affinity between the drug and its receptor, the greater the biological response.

19. The dextro (d) form of β-methacholine (structure shown) is approximately 500 times more active than the levo (l) enantiomer. The observed difference in pharmacological activity between the two isomers is most likely the result of differences in


(A) receptor selectivity.

(B) dissolution.

(C) distribution.

(D) interatomic distance between pharmacophore groups.

(E) solubility.

20. The compound shown in the figure can be classified as a(n)

(A) acid.

(B) base.

(C) organic salt.

(D) organic base.

(E) inorganic salt.

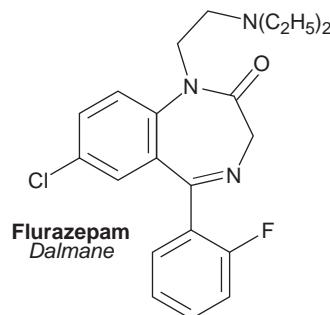
21. Which of the following acids has the highest degree of ionization in an aqueous solution?

(A) Aspirin; $pK_a = 3.5$

(B) Indomethacin; $pK_a = 4.5$

(C) Warfarin; $pK_a = 5.1$

(D) Ibuprofen; $pK_a = 5.2$

(E) Phenobarbital; $pK_a = 7.4$


22. The *solid line* on the graph in the following figure shows the change in mean blood pressure (from baseline of 90 mm Hg) with increasing bolus doses of angiotensin II in an experimental animal model. The *dashed line* is the response to the same doses of angiotensin II in the animal 2 hrs after an intravenous administration of 10 mg/kg of losartan, an antagonist of the angiotensin receptor. Based on the responses before and after the angiotensin antagonist, which of the following statements would most likely be true?

(A) Angiotensin II is a partial agonist.

(B) Losartan may interact irreversibly with the angiotensin receptor.

(C) Losartan is a partial agonist.

(D) Angiotensin II may be an inverse agonist.

(E) Angiotensin and losartan are probably working at different sites in the animal.

23. The structure–activity relationship of a drug can be altered by all of the following parameters **except**

(A) stereochemistry.

(B) specific functional groups.

(C) bioisosteric substitution.

(D) *cis–trans* conformation.

(E) the salt form of the drug.

24. Flurazepam has pK_a of 8.2. What percentage of flurazepam will be ionized at a urine pH of 5.2?

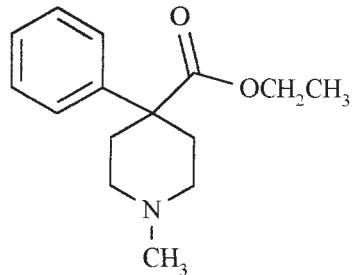
Flurazepam
Dalmane

(A) 0.1%

(B) 1%

(C) 50%

(D) 99%

(E) 99.9%


25. Which of the following isomers can only be distinguished in a chiral environment or by measuring the direction of rotation of plane-polarized light in a polarimeter?

(A) geometric isomers
(B) enantiomers
(C) diastereomers
(D) bioisosteres

26. The organic functional groups responsible for a particular pharmacological activity are called a(n)

(A) bioisostere.
(B) eutomer.
(C) epimer.
(D) pharmacophore.
(E) stereochemistry.

27. All of the following are basic functional groups **except**

(A) guanidine.
(B) primary amine.
(C) amide.
(D) amidine.
(E) tertiary amine.

28. The partition coefficient (P) of a drug is best described as

(A) the water solubility of a drug at a specific pH.
(B) the presence of nonionizable functional groups that make a drug lipid soluble.
(C) the ratio of drug solubility in a lipophilic solvent to solubility in an aqueous solvent.
(D) the presence of ionizable functional groups that make a drug water soluble.
(E) the characterization of a drug as an acid or a base.

29. An inorganic salt of imide containing drug can be made by the addition of which of the following?

(A) NaOH
(B) H_2SO_4
(C) HCl
(D) HNO_3
(E) HBr

Directions for questions 30–34: The questions and incomplete statements in this section can be correctly answered or completed by **one or more** of the suggested answers. Choose the answer, A–E.

A   if **I only** is correct
B   if **III only** is correct
C   if **I and II** are correct
D   if **II and III** are correct
E   if **I, II, and III** are correct

30. Which of the following statements may be true of drugs that are enzyme inhibitors?

I. They may be destroyed by the enzyme/receptor.
II. They can bind to a site different from that of the substrate.
III. They can form covalent bonds with their receptors.

31. Examples of strong electrolytes (i.e., completely dissociated in an aqueous solution) include

I. acetic acid.
II. pentobarbital sodium.
III. diphenhydramine hydrochloride.

32. Precipitation may occur when mixing aqueous solutions of meperidine hydrochloride with which of the following solutions?

I. Sodium bicarbonate injection
II. Atropine sulfate injection
III. Sodium chloride injection

33. Drugs classified as synthetic include which of the following?

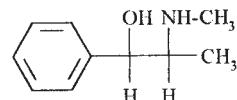
I. epinephrine
II. morphine
III. fondaparinux

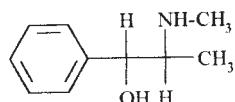
34. The excretion of a weakly acidic drug is generally more rapid in alkaline urine than in acidic urine. This process occurs because

I. a weak acid in alkaline media will exist primarily in its ionized form, which cannot be reabsorbed easily.
II. a weak acid in alkaline media will exist in its lipophilic form, which cannot be reabsorbed easily.
III. all drugs are excreted more rapidly in an alkaline urine.

Questions 35–37: Refer to the drug meperidine (Demerol; structure shown).

35. Functional groups present in the molecule shown include

I. an ester.
II. a tertiary amine.
III. a carboxylic acid.




36. Meperidine is classified as a

    I. weak acid.

    II. salt.

    III. weak base.

37. Assuming that meperidine is absorbed after oral administration and that a large percentage of the dose is excreted unchanged, the effect of alkalinization of the urine will increase its

    I. duration of action.

    II. rate of excretion.

    III. ionization in the glomerular filtrate.

38. Which of the following statements regarding digoxin (Lanoxin) would be true?

    I. It is a glycoside.

    II. It is a naturally occurring compound.

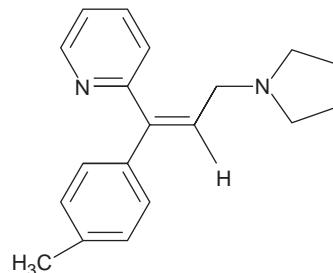
    III. It mimics the actions of an endogenous hormone.

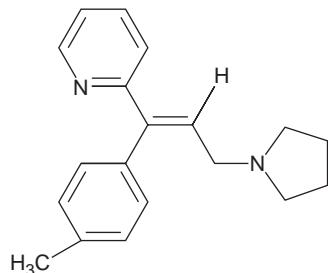
Directions for questions 39–43: The relationship of each pair of structures shown in this section is most closely associated with **one** of the following terms. The terms may be used more than once or not at all.
Choose the **best** answer, **A–E**.
    (A) Geometric isomers

    (B) Enantiomers

    (C) Diastereomers

    (D) Bioisosteres

    (E) Conformational isomers




39.

41.

42.

43.

Answers and Explanations

1. **The answer is A** *[see VII.D.1]*.
   The receptor would be a specific entity of the cell that drugs interact with to modify cell behavior. Although stomach acid is neutralized by antacids, it is not considered a specific receptor.

2. **The answer is E** *[see III.D.1]*.
   Lovastatin reversibly binds to the substrate-binding site of the enzyme HMG-CoA reductase, which catalyzes the rate-limiting step in the synthesis of cholesterol, thus lowering the cholesterol level. Therefore, lovastatin inhibits the enzyme by competitive antagonism.

3. **The answer is E** *[see III.D.2]*.
   Aspirin can covalently modify the platelet cyclooxygenase through acetylation of the enzyme other than the substrate-binding site, causing irreversible inhibition of platelet aggregation. Therefore, aspirin inhibits platelet function by noncompetitive antagonism of cyclooxygenase.

4. **The answer is E** *[see III.C.1]*.
   Naloxone is a competitive antagonist of opiate receptor. If one compares the log dose–response curve of both morphine and naloxone to that of morphine alone, the morphine–naloxone curve is shifted to the right. As a result, the ED_{50} for morphine is increased. This means that a larger than previous dose of morphine is required for achieving the same analgesic effect.

5. **The answer is C** *[see III.E.2]*.
   The level of drug receptors at the cell surface usually decreases when the target cells are chronically stimulated by receptor agonists. Downregulation of receptors may be a protective mechanism that can prevent the target cells from being overstimulated.

6. **The answer is C** *[see IV.C]*.
   The margin of safety of the two drugs can be helpful in guiding selection of a drug. Margin of safety is the ratio of $TD_{0.1}$ to $ED_{99.9}$. Thus, the margin of safety for drug A is 20 mg ÷ 0.4 mg, or 50, whereas the margin of safety for drug B is 15 mg ÷ 0.2 mg, or 75. Because drug B has a greater margin of safety than drug A, drug B is relatively safe at the dosage given to produce the desired effect.

7. **The answer is C** *[see II.A; III.C; III.E.1–2]*.
   A drug receptor, such as muscarinic cholinergic receptor that can bind atropine, normally binds endogenous acetylcholine to produce the physiological responses controlled by the parasympathetic autonomic nervous system. Receptors may be found on plasma membranes, cytoplasm, or nuclei of cells and are primarily proteinaceous in nature, although they can have sugar or lipid modifications. Receptor downregulation may lead to the phenomenon of tachyphylaxis.

8. **The answer is E** *[see III.B.1]*.
The efficacy of a drug is determined by its E_{max}, whereas its potency is measured by the ED_{50}. Hydromorphone has a smaller ED_{50} and thus is a more potent analgesic than morphine. Hydromorphone and morphine are both agonists for opiate receptors, and they have the same analgesic efficacy (i.e., they have the same E_{max}) if sufficient amounts of both drugs are used.

9. **The answer is E** *[see III.E.3]*.
A chronic level of blocking the β-adrenergic receptors by propranolol results in upregulation of the receptor level. When the patient ceased taking the drug, the cardiac muscles became supersensitive to stimulation with endogenous catecholamines. This resulted in the hypertensive crisis that caused cerebral hemorrhage and loss of consciousness.

10. **The answer is B** *[see III.C.4]*.
Erlotinib is a small molecule that inhibits the tyrosine kinase domain of the epidermal growth factor (EGF) receptor on cancer cells.

11. **The answer is B** *[see VII.D.1]*.
Protamine is a chemical antagonist of heparin that acts via an acid–base interaction.

12. **The answer is A** *[see III.C]*.
Inverse agonists stabilize the form of the receptor that is not bound to G proteins and are not agonists in the classical sense. This uncoupling of receptor and G protein may reduce basal cellular signaling even in the absence of agonists. β-Receptor antagonists are thought to have this type of activity apart from preventing the actions of catecholamines.

13. **The answer is D** *[see IV.B]*.
Increasing doses of a drug usually produces greater responses and this is described as a graded response. This would be true in an individual or a population of patients.

14. **The answer is C** *[see VII]*.
All the choices have a nonreceptor mechanism for producing their effects except for halothane that activates inhibitory receptors on neurons.

15. **The answer is E** *[see VI.B.6]*.
The solution must contain an acidic substance to have a pH < 7. Atropine sulfate is a salt of a weak base and a strong acid; therefore, its aqueous solution is acidic. Sodium salicylate and potassium penicillin are both salts of strong bases and weak acids; therefore, their aqueous solutions are alkaline. Magnesium sulfate and potassium chloride are salts of strong bases and strong acids; therefore, their aqueous solutions are neutral.

16. **The answer is B** *[see VI.B.3–4; Table 58-2; Table 58-3]*.
All these groups would accept a proton under physiological conditions except the sulfonamide, which would donate a proton instead.

17. **The answer is C** *[see III.A]*.
The dissociation constant of a drug is the concentration at which half the available receptors are bound and the inverse of this value is the affinity of the drug–receptor interaction.

18. **The answer is B** *[see V; VI]*.
The binding of a drug to its receptor usually involves only specific functional groups. These groups make up what is known as the pharmacophore of the drug molecule. Although the entire drug molecule is present at the receptor site, only a portion of it, the pharmacophore, is required for a biological response. The affinity of drug–receptor interaction does not predict whether the drug behaves as an agonist (having biological activity) or an antagonist; in fact, antagonists often have higher affinities for the receptor than agonists.

19. **The answer is A** *[see V.E.1]*.
The term *enantiomer and the d* and *l* indicate that the β-methacholine has a chiral center and exhibits optical isomerism. Because the optical isomers have different orientations in space, one orientation will give a better fit than the other and will most likely have greater biological activity than the other. Dissolution, distribution, interatomic distances, and solubility are all related to the physical and chemical properties of the two compounds, which are identical because the compounds are enantiomers.

20. **The answer is A** *[see VI.B.3; Table 58-2]*.
The aryl sulfonamide donates a proton to behave as an acid due to the electron-withdrawing action of the aromatic ring.

21. **The answer is A** *[see VI.B.2]*.
The pK_a (the negative log of the acid ionization constant) indicates the relative strength of an acidic drug. The lower the pK_a of an acidic drug, the stronger it is as an acid. A strong acid is defined as one that is completely ionized or dissociated in an aqueous solution; therefore, the stronger the acid, the greater the ionization.

22. **The answer is B** *[see III.C.2]*.
The decrease in the maximal angiotensin II effect (E_{max}) after treatment with losartan would indicate that the number of receptors available to produce drug effect has been reduced. This occurs when antagonist interacts in an irreversible manner with the receptor and leaves only a limited number of receptors through which the agonist can only produce a less than maximal response.

23. The answer is E *[see V.A–E].*

All of the choices except the salt form of the drug would influence the interaction of the drug with its receptor.

24. The answer is E *[see VI.B.5].*

Flurazepam (take note of the suffix, which helps classify the compound) is a benzodiazepine and thus a basic compound. Because the pH is less than the pK_a, flurazepam is in an acidic environment and therefore exists primarily in the ionized form. The percentage ionized can be easily calculated by using the rule of nines. The $|pH - pK_a|$ is 3, so the ratio is 99.9%:0.01% in favor of the ionized form.

25. The answer is B *[see V.E.1.a & d].*

Enantiomers are nonsuperimposable mirror images of each other that have identical physical and chemical properties except for the rotation of plane-polarized light. Enantiomers are distinguishable in a chiral environment. Geometric isomers, diastereomers, and bioisosteres each have unique physical and chemical properties.

26. The answer is D *[see V.B; V.D; V.E.1.c; V.E.2.b].*

The pharmacophore describes the critical organic functional groups and their spatial relationship within a drug molecule required for a specific pharmacological activity. A bioisostere is a compound containing an atom or group of atoms that is spatially and electronically similar to another molecule that produces a similar biological activity. A eutomer is one of a pair of enantiomers that has the desired pharmacological activity. The other isomer is the distomer that may not have pharmacological activity or may cause adverse effects. Epimers are a pair of compounds that have exactly the same stereochemistry in all positions except one.

27. The answer is C *[see VI.B.4; Table 58-1; Table 58-3].*

Primary and tertiary amines are basic because they have a free pair of electrons that can accept a proton. The quaternary amines are neutral because there are no free electrons available to accept a proton. Guanidines and amidines also have free electrons to accept a proton and therefore they are basic functional groups. Amides are neutral compounds although they appear to have a free pair of electrons like the amines, but the difference is that the electrons on the amide nitrogen are in resonance with the double bond on the carbonyl, making them unavailable to accept a proton.

28. The answer is C *[see VI.A.1].*

The partition coefficient is defined as the ratio of the solubility of an agent in an organic lipophilic solvent (i.e., *n*-octanol) to its solubility in an aqueous buffer. The functional groups present, either ionizable or nonionizable, influence the partition coefficient.

29. The answer is A *[see Table 58-2; VI.B.3.a, 4.a, & 6.a].*

The imide is a weak acid, so adding a strong base like sodium hydroxide (NaOH) or potassium hydroxide (KOH) will produce an inorganic salt. All the other choices (i.e., sulfuric acid, hydrochloric acid, nitric acid, and hydrobromic acid) are strong acids and would not produce a salt upon addition to the weak acid imide.

30. The answer is E (I, II, and III) *[see III.D].*

Suicide inhibitors are drugs that are metabolized or destroyed in the process of inhibiting enzymatic activity, whereas allosteric inhibitors target a site distinct from that for the substrate. Some drugs interact irreversibly with their enzyme target due to covalent bonding.

31. The answer is D (II, III) *[see VI.B.6].*

Almost all salts (with very few exceptions) are strong electrolytes, and the terminology *pentobarbital sodium* and *diphenhydramine hydrochloride* indicates that each compound is salt. Acetic acid is a weak acid; therefore, it is a weak electrolyte.

32. The answer is A (I) *[see VI.B].*

When meperidine hydrochloride solution is mixed with the alkaline solution of sodium bicarbonate, a neutralization reaction occurs with the possible precipitation of the water-insoluble free base meperidine. A neutralization reaction occurs when acidic solutions are mixed with basic solutions, or conversely. No reaction, in terms of acid–base, occurs when solutions are mixed with other acidic or neutral solutions or when basic solutions are mixed with other basic or neutral solutions. There should be no reaction, then, when the meperidine hydrochloride solution, which is acidic, is mixed with the acidic solution of atropine sulfate or the neutral solution of sodium chloride.

33. The answer is B (III) *[see VIII.B.3].*

Both epinephrine and morphine are naturally occurring, whereas fondaparinux is a synthetic derivative of heparin.

34. The answer is A (I) *[see VI.B].*

A weakly acidic drug will be more ionized in an alkaline urine; therefore, it will be more polar and thus more soluble in the aqueous urine. It would also be less liposoluble, less likely to undergo tubular reabsorption, and thus more likely to be excreted.

35. The answer is C (I, II) *[see VI.B; Table 58-1].*

The molecule contains a basic nitrogen, which is bonded to three carbon atoms (i.e., a tertiary amine), and an ethyl carboxylate, which is an ester group. An ester is the product of the reaction of an alcohol with a carboxylic acid that forms an alkyl carboxylate. There is no free carboxylic acid present. However, if this molecule is subjected to hydrolysis, it forms a carboxylic acid and ethyl alcohol.

36. The answer is B (III) *[see VI.B; Table 58-3]*.

Because meperidine contains a tertiary amine, it is classified as a base; because it is an organic base, it is considered weak. The nitrogen is not protonated. It is not ionic and therefore is not a salt.

37. The answer is A (I) *[see VI.B]*.

Alkalinization of the urine decreases the ionization of meperidine, making it more liposoluble and thus more likely to undergo reabsorption in the kidney tubule. This results in a decreased rate of excretion and an increased duration of action. The six-member, nonaromatic ring is a piperidine ring that is substituted at the 4-position (nitrogen is position 1) with a phenyl ring. The compound does not contain a piperazine ring or a propyl group.

38. The answer is C (I, II) *[see VIII.A]*.

The cardiac glycoside digoxin occurs naturally in foxglove and strophanthus plants but it does not substitute or mimic the actions of endogenous hormones.

39. The answer is C *[see V.E.2]*.

These molecules are isomers that have two asymmetric carbon atoms. They are not superimposable and are not mirror images; therefore, they are known as diastereomers.

40. The answer is B *[see V.E.1]*.

These molecules are isomers that have one asymmetric carbon atom. They are nonsuperimposable mirror images; therefore, they are enantiomers.

41. The answer is A *[see V.E.2.c]*.

These molecules have different spatial arrangements; however, these molecules do not have an asymmetric center. The presence of the double bond, which restricts the rotation of the groups on each carbon atom involved in the double bond, characterizes this type of isomerism as geometric.

42. The answer is D *[see V.D]*.

These molecules are neither isomers nor the same compound because one contains three oxygens, whereas the other contains two oxygens and a sulfur. Because oxygen and sulfur are in the same periodic family, they are isosteric and are known as bioisosteres.

43. The answer is E *[see V.E.3]*.

These structures are actually two views of the same compound. Rotation around the side chain single bonds connecting the ring nitrogen to the tertiary nitrogen produces these two different conformations. Thus, these are conformational isomers.

59 Nuclear Pharmacy

STEPHEN C. DRAGOTAKES, JEFFREY P. NORENBERG

I. INTRODUCTION

A. **Overview**
   1. **Nuclear pharmacy** is defined as a "patient-oriented service that embodies the scientific knowledge and professional judgment required to improve and promote health through the safe and efficacious use of radioactive drugs for diagnosis and therapy."[1]
   2. **Radiopharmaceuticals** are drugs that contain a biological moiety and a radioactive element. The biological construct targets a physiological or pathophysiological process of interest, allowing the localization of radiation that, in turn, may be imaged or used to effect therapy. Most radiopharmaceuticals are used in diagnostic medical imaging; however, they are also used in therapeutic applications, such as in the treatment of hyperthyroidism, thyroid cancer, polycythemia vera, and in the alleviation of bone pain.[2]
   3. **Nuclear pharmacy practice** entails the following:
      a. Procurement of radiopharmaceuticals
      b. Compounding of radiopharmaceuticals
      c. Performance of routine quality control procedures
      d. Dispensing of radiopharmaceuticals
      e. Distribution of radiopharmaceuticals
      f. Implementation of basic radiation protection procedures and practices
      g. Consultation with and/or education of the nuclear medicine community, patients, pharmacists, other health professionals, and the general public regarding the following:
         (1) Physical and chemical properties of radiopharmaceuticals
         (2) Pharmacokinetics and biodistribution of radiopharmaceuticals
         (3) Drug interactions and other factors that alter patterns of distribution
      h. Monitoring of patient outcomes
      i. Research and development of radiopharmaceuticals[3]
B. **Properties of radiopharmaceuticals**
   1. **Pharmacological effects.** Typically, radiopharmaceuticals lack pharmacological effects because the mass quantities range from picogram (pg) to nanogram (ng) per kilogram (kg) of administered dose.
   2. **Route of administration.** Most radiopharmaceuticals are prepared as sterile, pyrogen-free intravenous (IV) solutions or suspensions to be administered directly to the patient. Other routes of administration include intradermal, oral, interstitial, and inhalation (e.g., radioactive gases, aerosols).
   3. **Radionuclides**
      a. The radioactive component of a radiopharmaceutical is referred to as a radionuclide. Nuclides are identified as atoms having a specific number of protons and neutrons in the nucleus. A nuclide is typically identified by the chemical symbol of the element with a mass number shown as a superscript, indicating the sum of protons and neutrons (e.g., iodide-131 is indicated as ^{131}I). When the atom is radioactive, it is called a radionuclide.
      b. Radionuclides undergo spontaneous radioactive decay accompanied by the release of energy. The distribution, metabolism, and elimination of the radiopharmaceutical can be determined

by measuring this energy with imaging equipment. There are four major types of radiation emitted through this process: α, β, γ, and x-rays. α and β radiations are not useful in medical imaging and are, therefore, undesirable in diagnostic applications. Most diagnostic radiopharmaceuticals use penetrating γ-radiation, which can be easily detected and converted into imaging data.

4. **Half-lives of radiopharmaceuticals**

   a. The **physical half-life** of a radiopharmaceutical is the amount of time necessary for the radioactive atoms to decay to one-half their original number. Each radionuclide is characterized by a specific half-life that is a physical constant.

   b. The **biological half-life** of a radiopharmaceutical is the amount of time required for the body to metabolize or eliminate one-half of the administered dose of any substance through biological processes.

   c. The **effective half-life** of a radiopharmaceutical is the time required for an administered radiopharmaceutical dose to be reduced by one-half as a result of both physical decay and biological mechanisms. It is defined as $T_e = (T_p + T_b)/(T_p \times T_b)$, where T_e is the effective half-life, T_p is the physical half-life, and T_b is the biological half-life.

C. **Optimal radiopharmaceuticals**

1. **Optimal diagnostic radiopharmaceuticals**

   a. Should contain a radionuclide with a half-life short enough to minimize radiation exposure to the patient, yet long enough to allow for collection of imaging information. The optimal relationship is a physical half-life equal to approximately 67% of the biological process of interest.

   b. Should incorporate a γ-emitting radionuclide, which decays with the emission of a photon energy between 100 and 300 kiloelectron volts (keV), which is efficiently detected with current instrumentation

   c. Should contain a biological component that allows rapid localization in the organ system of interest and be metabolized or excreted from the nontarget tissues to maximize contrast and minimize the radiation absorbed dose to nontarget organs

   d. Should be readily available and cost-effective

2. **Optimal therapeutic radiopharmaceuticals**, in addition to 1.C.1.c–d, should contain α or β emitting radionuclides that can effectively deliver radiation in quantities sufficient to cause the desired therapeutic effect. Such effects include apoptosis, DNA damage, or irreparable cell damage leading to tissue effects.[4]

II. SODIUM PERTECHNETATE TECHNETIUM-99m (^{99m}Tc) GENERATOR

A. **Overview**

1. Technetium-99m (^{99m}Tc), the most commonly used radionuclide in diagnostic imaging today, is produced by the radioactive decay of molybdenum-99 (^{99}Mo).

   a. ^{99m}Tc is obtained via commercially supplied, sterile, pyrogen-free generator systems. A generator is a device used to separate a short half-life radionuclide from the longer lived parent nuclide while retaining the parent to produce more of the daughter nuclide. In this way, short half-life nuclides can be made available continuously at great distances from the sites of generator production.

   b. All of the commercially supplied generators currently use ^{99}Mo obtained from the fission of uranium-235 (^{235}U). This ^{99}Mo parent is absorbed on an alumina (Al_2O_3) ion exchange column, and the ^{99m}Tc formed from its decay is exchanged for the chloride ion (Cl^-) available in the 0.9% saline eluate solution washed through the column, as the sodium pertechnetate $Na^+(^{99m}TcO_4)^-$ forms.

2. The chemical valence state of the technetium atom within the Sodium Pertechnetate molecule, $Na^+(^{99m}TcO_4)^-$ as it is eluted from the column is +7. Typically, it must be reduced to a lower valence state before it is able to react with other compounds. Although many processes can reduce ^{99m}Tc, the stannous ion (Sn^{++}) reduction method is most commonly used in ^{99m}Tc radiopharmaceutical kits.

   a. A radiopharmaceutical kit consists of sterile, pyrogen-free vials containing a reducing agent, the compound to be labeled, and any additional adjutants necessary to affect the reaction or to stabilize the labeled product.

b. In most cases, they are lyophilized under inert atmospheres to minimize the oxidation of the reducing agent (e.g., Sn^{++}).

B. Sodium pertechnetate ^{99m}Tc *USP* (*United States Pharmacopeia*) $Na^{+99m}TcO_4^-$, as eluted from a generator in 0.9% sodium chloride (NaCl) solution, is an isotonic, sterile, nonpyrogenic, diagnostic radiopharmaceutical suitable for IV injection, oral administration, and direct instillation.

1. **Physical properties**
   a. The solution should be clear, colorless, and free of visible foreign material. The pH is 4.5–7.0.
   b. $Na^{+99m}TcO_4^-$ is itself a radiopharmaceutical, or it may be used to radiolabel all other ^{99m}Tc radiopharmaceuticals.

2. **Biodistribution**
   a. $^{99m}TcO_4^-$ is handled by the body in a fashion similar to ^{131}I—that is, it is taken up and released but not organified by the thyroid.
   b. After IV administration, $^{99m}TcO_4^-$ concentrates in the choroid plexus, thyroid gland, salivary gland, and stomach, but remains in the circulation long enough for first-pass blood-pool studies, organ perfusion, and major vessel studies.
   c. It is primarily excreted by the kidneys unchanged and is expressed in the urine 15% to 50% by 24 hrs.
   d. Between 10% and 55% of the administered dose is eliminated via feces within 3 days.

3. **Decay data**
   a. ^{99m}Tc decays by isomeric transition with a physical half-life of 6 hrs.
   b. The primary radiation emissions are 140 keV γ energy photons.

4. **Purity**
   a. *USP* radionuclidic purity requires a ^{99}Mo breakthrough limit of < 0.15 μCi/mCi of ^{99m}Tc at the time of patient administration.
   b. *USP* chemical purity requires an aluminum ion (Al^{+3}) test result of less than 10 μg/mL.

5. **Administration and dosage.** All of the following imaging studies are administered via IV, except nasolacrimal imaging, which is instilled into the lacrimal canal.
   a. Brain imaging: 10 to 20 mCi (370 to 740 megabecquerels; MBq)
   b. Thyroid imaging: 1 to 10 mCi (37 to 370 MBq)
   c. Salivary gland imaging: 1 to 5 mCi (37 to 185 MBq)
   d. Placenta localization: 1 to 3 mCi (37 to 111 MBq)
   e. Blood-pool imaging: 10 to 30 mCi (370 to 740 MBq)
   f. Urinary bladder imaging: 0.5 to 1.0 mCi (18 to 37 MBq)
   g. Nasolacrimal imaging: < 100 μCi (< 3.7 MBq)

III. RADIOPHARMACEUTICALS FOR CARDIOVASCULAR IMAGING

A. Perfusion agents for cardiac imaging. Radiopharmaceuticals are useful in cardiac imaging as agents that provide information on the regional myocardial blood perfusion. They typically are administered as part of a cardiac stress test to provide information at peak cardiac output. The patient will run on a treadmill to "stress" the heart. IV coronary vessel–dilating agents are used in place of the treadmill when the patient is not physically able to exercise. Examples of these pharmacological agents are dipyridamole, adenosine, and dobutamine. The patient will also be imaged when the heart is at "rest."

1. **Thallous chloride thallium-201 (^{201}Tl)** is a radionuclide that is produced by a cyclotron. It is used for myocardial perfusion imaging in the diagnosis of coronary artery disease and localization of myocardial infarction.
   a. **Biodistribution**
      (1) ^{201}Tl is a monovalent cation with distribution analogous to a potassium ion (K^+); myocardial uptake is by active transport via the Na^+/K^+-adenosine triphosphatase (ATPase) pump.
      (2) Biodistribution is generally proportional to organ blood flow at the time of injection, with blood clearance by myocardium, kidneys, thyroid, liver, and stomach. The remainder is distributed uniformly throughout the rest of the body.
      (3) ^{201}Tl is excreted slowly and equally in both urine and feces.

    b. Decay data
- **(1) Physical half-life**: 73 hrs
- **(2) Effective half-life**: 2.4 days
- **(3) Biological half-life**: 11 days
- **(4) Primary radiation emissions**: 68 to 80 keV x-rays and 167 and 135 keV γ energy photons.

    c. Administration and dosage. IV, 2 to 4 mCi (74 to 148 MBq)

2. **^{99m}Tc-sestamibi (^{99m}Tc-MIBI)** exists as a sterile, pyrogen-free IV injection after kit reconstitution with $Na^{+\,99m}TcO_4^{-}$ and heating at 100°C for 10 mins.

    a. Biodistribution
- **(1)** ^{99m}Tc-MIBI is a cation complex that has been found to accumulate in viable myocardium by passive diffusion into the myocyte with subsequent binding to the mitochondria within the cell.
- **(2)** The major pathway for clearance of ^{99m}Tc-sestamibi is the hepatobiliary system. This agent is excreted without any evidence of metabolism via urine and feces.

    b. Decay data
- **(1) Effective half-life**: 3 hrs (myocardium)
- **(2) Biological half-life**: 6 hrs (myocardium)

    c. Administration and dosage. IV, 10 to 30 mCi (370 to 1110 MBq)

3. **^{99m}Tc-tetrofosmin** exists as a sterile and pyrogen-free IV injection after kit reconstitution with sodium pertechnetate ^{99m}Tc injection *USP.*

    a. Description. ^{99m}Tc-tetrofosmin is a lipophilic, cationic ^{99m}Tc complex that has been found to accumulate in viable myocardium.

    b. Biodistribution. The major pathways for clearance of ^{99m}Tc-tetrofosmin are the renal system and the hepatobiliary system with 26% of the administered dose excreted in the feces and 40% excreted in the urine within 48 hrs.

    c. Physical properties. See II.A; II.B.3.

    d. Administration and dosage. IV during exercise, 5 to 8 mCi (185 to 296 MBq); during rest, 15 to 24 mCi (555 to 1443 MBq)

4. **Rubidium-82 (^{82}Rb) chloride** is a generator-produced radiopharmaceutical obtained by the decay of its accelerator-produced parent strontium (^{82}Sr; half-life is 25 days) adsorbed on a stannous oxide column.

    a. Biodistribution
- **(1)** When eluted with 0.9% NaCl at a rate of 50 mL/min, a solution of the short-lived daughter ^{82}Rb is eluted from the generator for direct IV administration.
- **(2)** After IV administration, ^{82}Rb rapidly clears from the blood and is extracted by the myocardial tissue in a manner analogous to K^{+}.
- **(3)** Myocardial activity is visualized within 1 min after administration.

    b. Decay data
- **(1) Physical half-life**: 75 secs
- **(2)** The **decay mode** is by positron emission.
- **(3)** The **primary radiation emissions** are annihilation 511 keV γ energy photons.
- **(4)** Parent ^{82}Sr and contaminant ^{85}Sr breakthrough must be closely monitored. Acceptable levels of strontium breakthrough are < 0.02 μCi ^{82}Sr/mCi ^{82}Rb and < 0.2 μCi ^{85}Sr/mCi ^{82}Rb.

    c. Administration and dosage. IV, 30 to 60 mCi (1110 to 2220 MBq)

5. **Ammonia ^{13}N** exists under a *USP* monograph as an on-site cyclotron-produced, sterile IV solution of $^{13}NH_3$, useful as a myocardial perfusion agent. After June 2012 it will be available as a FDA approved drug.

    a. Decay data
- **(1) Physical half-life**: 10 mins
- **(2) Decay mode**: positron emission resulting in the production of two 511 keV annihilation photons

    b. Biodistribution
- **(1)** After IV injection, it circulates as $^{13}NH_3$ but localizes into the myocytes via diffusion as $^{13}NH_3$. It is then metabolized to glutamine and retained by the myocytes.

(2) After IV injection, it is cleared rapidly from the blood; $< 2\%$ of the administered dose remains 5 mins postinjection.

(3) It is predominantly metabolized to ^{13}N-glutamine by different organs of the body.

(4) Between 10% and 20% is excreted via the renal system.

c. Administration and dosage. IV, 15 to 20 mCi (555 to 740 MBq)

B. Agents used to measure cardiac function. Regional myocardial wall motion

1. ^{99m}**Tc-labeled red blood cells (^{99m}Tc-RBCs)** are used for blood-pool imaging, including cardiac first-pass and gated equilibrium imaging (regional cardiac wall motion).

a. Physical properties. Autologous RBCs can be labeled by several techniques that use the Sn^{++} radiolabeling method with three general steps.

(1) The cells are treated with Sn^{++} to provide an intracellular source of the reducing agent. This step can be carried out with either in vivo or in vitro labeling procedures.

(2) The next step is the removal of excess Sn^{++} either by chemical oxidation (in vitro method) or by biological clearance (in vivo method).

(3) All of the methods include the addition of sodium pertechnetate (^{99m}TcO$_4$−). This ^{99m}Tc, while in the $^{+}7$ valence state, crosses the intact erythrocyte membrane and binds to intracellular hemoglobin (Hb) after being reduced by the available intracellular Sn^{++}.

b. Biodistribution. After IV injection, the labeling RBCs distribute within the blood pool and are well maintained in the blood pool with a biexponential whole body clearance of 2.5 to 2.7 hrs and 75 to 176 hrs (e.g., major route of excretion is via the urine).

c. Administration and dosage. IV, 10 to 20 mCi (370 to 740 MBq)

2. Pyrophosphate injection *USP* and phosphates *USP*. The major use for these agents in nuclear medicine is as convenient and stable sources of Sn^{++} for the labeling of autologous RBCs. In this application, the kits are reconstituted with normal saline and injected via IV.

IV. SKELETAL IMAGING

A. Skeletal-imaging agents

1. Overview. ^{99m}Tc-labeled bone imaging agents are useful in the detection of bone lesions that are associated with metastatic neoplasms, metabolic disorders, and infections of the bone. The imaging advantages of ^{99m}Tc, coupled with the sensitivity of bone imaging agent localization in skeletal bone hydroxyapatite, allows for detection of bone pathology before evidence is shown by conventional x-rays.

2. ^{99m}**Tc bone agents.** There are many different forms of ^{99m}Tc bone agents, with minor differences in their individual chemical structure. Currently used bone-imaging agents are based on either the P—C—P diphosphonate structure, including ^{99m}Tc-medronate disodium and ^{99m}Tc-oxidronate, or the inorganic P—O—P phosphate structure, such as ^{99m}Tc-pyrophosphate. These bone agents are S^{++} reduction method kits, which exist as sterile, pyrogen-free IV radiopharmaceuticals after reconstitution with $Na^{+99m}TcO_4{}^{-}$.

a. Physical properties

(1) All of the ^{99m}Tc bone-imaging agents are susceptible to radiological decomposition with reoxidation of the ^{99m}Tc to a higher valence state. These agents sometimes include antioxidants (e.g., ascorbic or gentisic acid) in their formulation to improve their in vitro stability.

(2) They should be stored at room temperature before and after reconstitution.

b. Biodistribution

(1) It is believed that the localization of the diphosphonates occurs by chemisorption onto the hydroxyapatite mineral matrix of skeletal bone with uptake related to bone metabolic activity and bone blood flow.

(2) For ^{99m}Tc-medronate disodium and ^{99m}Tc-oxidronate, approximately 50% of the administered dose localizes in the skeleton, and 50% is excreted by the kidneys within the first 4 to 6 hrs after IV injection.

c. Administration and dosage. IV, 10 to 20 mCi (370 to 740 MBq)

B. Bone marrow imaging. See VI.A.1; VI.A.3; VI.B.

V. LUNG IMAGING. Radiopharmaceuticals are used to evaluate both pulmonary perfusion and pulmonary ventilation to detect pulmonary embolism and to assess pulmonary function before pneumonectomy.

- **A. Pulmonary perfusion imaging**
  - **1. ^{99m}Tc-albumin aggregated (^{99m}Tc-MAA)**
    - **a. Physical properties**
      - **(1)** The ^{99m}Tc-albumin aggregated kit contains human serum albumin (HSA) that has been aggregated by heat denaturation.
      - **(2)** This Sn^{++} reduction method kit exists as a sterile, pyrogen-free suspension of radiolabeled aggregated particles after reconstitution with $Na^{+99m}TcO_4^-$.
      - **(3)** It should be stored at 2° to 8°C after reconstitution.
    - **b. Biodistribution**
      - **(1)** After IV administration of ^{99m}Tc-albumin aggregated, 80% of the radiolabeled albumin particles become trapped by capillary blockade in the pulmonary circulation.
      - **(2)** After trapping, the particles are cleared from the lungs mainly by mechanical breakup. These smaller particles are ultimately cleared from the circulation by the reticuloendothelial system.
      - **(3)** Particle size should be controlled—that is, 90% of the particles should be between 10 and 90 μm, and none should be > 150 μm, to ensure adequate trapping by the lung capillary bed but no occlusion of the large-bore vessels.
      - **(4)** Particle number should be between 200,000 and 700,000 particles per adult dose to obtain uniform imaging data without compromising capillary blood flow. Neonates should receive < 125,000 particles.
    - **c. Decay data.** Biological half-life in the lung: 2 to 3 hrs
    - **d. Administration and dosage.** IV, 1 to 4 mCi (37 to 148 MBq)
- **B. Pulmonary ventilation imaging** with radioactive gases is a routine nuclear medicine procedure that can provide valuable information about regional lung ventilation. Radiopharmaceuticals used are either radioactive gases or radioaerosols.
  - **1. Xenon-133 (^{133}Xe)** is supplied as a radioactive gas contained in glass septum vials to be administered by inhalation through a closed respiratory system or a spirometer. It is a by-product of ^{235}U fission.
    - **a. Biodistribution**
      - **(1)** ^{133}Xe is a readily diffusible gas, which is neither used nor produced by the body. It passes through membranes and freely exchanges between blood and tissue, tending to concentrate more in body fat.
      - **(2)** Inhaled ^{133}Xe distributes within the alveoli and enters the pulmonary venous circulation via the capillaries; most of the absorbed ^{133}Xe is returned and exhaled from the lungs after a single pass through the peripheral circulation.
      - **(3)** In concentrations used for diagnosis, the gas is physiologically inactive.
    - **b. Decay data**
      - **(1) Effective half-life** in the lung: 2 mins
      - **(2) Physical half-life**: 5.2 days
      - **(3) Decay mode:** β minus and γ decay
      - **(4) Primary radiation emissions:** 100 keV β energy and 81 keV γ energy photons
    - **c. Administration and dosage.** Inhalation, 2 to 30 mCi (74 to 1110 MBq)
  - **2. Radioaerosols** have become increasingly used with the advent of nebulizers that produce particles of a consistent size necessary for uniform lung distribution.
    - **a. Biodistribution**
      - **(1)** ^{99m}Tc-pentetate (^{99m}Tc-DTPA) radioaerosols of approximately 0.25 μm mass median aerodynamic diameter are useful in determining lung ventilation.
      - **(2)** After deposition of the nebulized droplets within the airways, the ^{99m}Tc-pentetate is absorbed into the pulmonary circulation.
      - **(3)** The material is subsequently excreted by the kidneys. Clearance from the lungs is sufficiently slow to allow for imaging of the lungs in multiple projections from a single administration.
    - **b. Physical properties.** See II.B.3.
    - **c. Administration and dosage.** Inhalation, 30 μCi (1110 MBq)

VI. HEPATIC IMAGING

A. **Overview.** Hepatic imaging requires the use of two different classes of radiopharmaceuticals to evaluate the two cell types responsible for hepatic function.

1. **Reticuloendothelial system imaging.** The liver, spleen, and bone marrow are evaluated with radiolabeled colloidal material, ranging in size from 0.1 to 3.0 μm. These particles are rapidly cleared from the blood by phagocytosis by the Kupffer cells or trapped in the space of Disse, which is found between the polygonal hepatocytes and the Kupffer cells.

2. **Liver spleen imaging.** Radiopharmaceuticals are useful in imaging space-occupying primary tumors and metastatic neoplasms as well as hepatic defects caused by abscesses, cysts, and trauma.

3. **Bone marrow imaging.** Images that localize in the bone marrow are useful in the evaluation of pathologies that affect bone marrow.

4. **Hepatobiliary imaging.** Hepatocyte function can be evaluated by substances meeting requirements of molecular weight, lipophilicity, and chemical structure, to be excreted by the polygonal cells into the hepatobiliary system. Hepatobiliary-imaging radiopharmaceuticals are useful in the diagnosis of cystic duct obstruction in acute cholecystitis as well as defining postcholecystectomy anatomy and physiology.

B. **Reticuloendothelial-imaging agents**

1. ^{99m}**Tc-sulfur colloid (^{99m}Tc$_2$S$_7$)** is a sterile, pyrogen-free IV radiopharmaceutical formed via a chemical reaction between ^{99m}TcO$_4^-$ and an acidified solution of sodium thiosulfate at 100°C.

   a. **Physical properties**

      (1) ^{99m}Tc$_2$S$_7$ is thought to remain in the $^+7$ valence state as the heptasulfide coprecipitate of elemental sulfur that occurs during the reaction.

      (2) The use of Na^{+99m}TcO$_4^-$ with Al^{+3} levels > 10 μg/mL can lead to the formation of particles > 5 μm, which can result in lung uptake.

      (3) Heating times should be controlled to preclude large particle formation.

   b. **Biodistribution.** After administration, 80% to 90% of the dose is phagocytized by the Kupffer cells of the liver or trapped in the space of Disse, 5% to 10% by the spleen, and the balance by the bone marrow. The blood clearance half-life is approximately 2.5 mins. Particles are not metabolized and reside in the reticuloendothelial system for a prolonged period.

   c. **Administration and dosage.** IV, liver/spleen: 1 to 8 mCi (37 to 296 MBq); bone marrow: 3 to 12 mCi (111 to 444 MBq)

C. **Hepatobiliary-imaging agents**

1. **Overview**

   a. **Iminodiacetic acid (IDA) derivatives**, which are lidocaine analogs, are useful as hepatobiliary-imaging agents because of their lipophilicity, which allows them to be selectively cleared by carrier-mediated hepatocyte metabolic pathways. Because these agents share the same excretion pathway as bilirubin, patients who have increased bilirubin levels exhibit decreased hepatic clearance and an increased renal clearance. Lack of gallbladder visualization is an abnormal finding, suggesting acute cholecystitis.

   b. **Cholecystokinetic agents**, such as sincalide and cholecystokinin, may be used to empty the contents of the gallbladder in fasting patients before injection of IDA compounds in an attempt to promote gallbladder filling and visualization. These agents can also be injected after the injection of the IDA compound to cause a visualized gallbladder to empty. Cholecystokinetic agents are used to increase the specificity and sensitivity of the imaging procedure.

   c. **Narcotic analgesics**, such as morphine, have been used to constrict the sphincter of Oddi to produce increased intraductal pressures to promote retrograde gallbladder filling.

2. ^{99m}**Tc-disofenin (^{99m}Tc-DISIDA)**

   a. **Physical properties.** See II.B.3.

   b. **Biodistribution**

      (1) ^{99m}Tc-DISIDA is rapidly cleared from the blood; 8% remains in the blood after 30 mins.

      (2) Approximately 9% of the administered activity is excreted in the urine during the first 2 hrs. The remainder of the activity is cleared through the hepatobiliary system.

      (3) Peak liver uptake is within 10 mins; peak gallbladder uptake is by 30 to 40 mins.

      (4) Gallbladder and intestinal visualization occurs within 60 mins postadministration.

c. Administration and dosage. IV, nonjaundiced patient: 1 to 5 mCi (37 to 185 MBq); IV, jaundiced patient: 3 to 8 mCi (111 to 296 MBq)

3. ^{99m}Tc-mebrofenin

  a. Physical properties. See II.B.3.

  b. Biodistribution

    (1) ^{99m}Tc-mebrofenin is rapidly cleared from the blood; 17% remains after 10 mins. Only 1% of the administered activity is excreted in the urine within the first hours; the remainder of the activity clears through the hepatobiliary system.

    (2) Peak liver uptake occurs within 10 mins; visualization of the hepatic duct and gallbladder, within 10 to 15 mins; then intestinal activity, within 30 to 60 mins.

  c. Administration and dosage. IV, nonjaundiced patient: 2 to 5 mCi (74 to 185 MBq); IV, jaundiced patient: 3 to 10 mCi (111 to 370 MBq)

VII. RENAL IMAGING

A. Overview

  1. Radiopharmaceuticals are used in renal imaging to determine renal function, renal vascular flow, and renal morphology. They are also useful for the evaluation of renal function in posttransplant patients for complications such as obstruction, infarction, leakage, tubular necrosis, and rejection.

  2. The use of radiopharmaceuticals to determine renal function or renal morphology is based on the two physiological mechanisms responsible for excretion: glomerular filtration and tubular secretion.

B. Agents cleared by glomerular filtration are useful in determining the glomerular filtration rate (GFR), renal artery perfusion, and the visualization of the collecting system.

  1. ^{99m}Tc-pentetate (^{99m}Tc-DTPA)

    a. Physical properties. See II.B.3.

    b. Biodistribution

      (1) After administration, ^{99m}Tc-pentetate rapidly distributes throughout extracellular fluid space, from which it is rapidly cleared by glomerular filtration only.

      (2) Up to 10% may be protein bound, leading to a decrease in measured GFR.

      (3) After administration, 50% of the dose is cleared by the kidneys within 2 hrs, and up to 95% is cleared by 24 hrs.

    c. Administration and dosage. IV, 10 to 20 mCi (370 to 740 MBq)

  2. Sodium iothalamate iodine-125 (^{125}I) injection is a commercially supplied, sterile, pyrogen-free injection containing 1 mg sodium iothalamate per milliliter.

    a. Biodistribution

      (1) Sodium iothalamate ^{125}I is used for determination of the GFR but not for imaging because of poor imaging emissions of ^{125}I.

      (2) Thyroid blockade with oral potassium iodide (KI) is suggested.

    b. Decay data

      (1) Physical half-life: 59 days

      (2) Decay mode: by electron capture

      (3) Primary radiation emissions: 35 keV γ energy photons and x-rays

    c. Administration and dosage. IV, 10 to 50 μCi (3.7 to 18.5 MBq)

C. Tubular secretion agents are used to evaluate renal tubular function and measure effective renal plasma flow.

  1. ^{99m}Tc-mertiatide (^{99m}Tc-MAG3)

    a. Description

      (1) Supplied as a sterile, pyrogen-free, lyophilized kit containing betiatide, precursor of mertiatide, and chelation adjutants.

      (2) After the sodium pertechnetate is added to the kit, it must be heated in a hot water bath or heating block at 100°C for 10 mins to form ^{99m}Tc-mertiatide from the betiatide precursor.

    b. Biodistribution

      (1) Mertiatide is renally excreted, 90% of the administered dose is excreted within 3 hrs postinjection.

(2) It is primarily cleared via active tubular secretion and to a small extent via glomerular filtration.

c. **Physical properties.** See II.B.3.

d. **Administration and dosage.** IV, 5 to 10 mCi (185 to 370 MBq)

D. **Renal cortical imaging agents** are used to evaluate renal anatomy because of their ability to accumulate in the kidney and provide anatomical imaging data.

1. **^{99m}Tc-succimer (^{99m}Tc-DMSA)**

a. **Physical properties**

(1) See II.B.3.

(2) ^{99m}Tc-succimer complex must be allowed to incubate for 10 mins postreconstitution and must be used within 4 hrs postincubation.

b. **Biodistribution**

(1) Within 3 to 6 hrs postadministration, 40% to 50% of the dose localizes in the renal cortex, where it is taken up by the tubular cells.

(2) Excretion into the urine is slow; 5% to 20% is excreted within the first 2 hrs, 10% to 30% by 6 hrs, and < 40% by 24 hrs.

c. **Administration and dosage.** IV, 2 to 6 mCi (74 to 222 MBq)

VIII. THYROID IMAGING

A. **Overview**

1. The basic function of the thyroid gland is the production of thyroid hormone for the regulation of metabolism. The thyroid hormones are produced within the gland through the organification of iodine obtained from the oxidation of available iodide circulating in the blood. The inability of the body to distinguish between the isotopes of iodine provides a perfect metabolic tracer for the thyroid biochemical system.

2. The function of the thyroid gland can be evaluated by the uptake of ^{131}I or ^{123}I, allowing the detection of hypothyroidism with decreased uptake and hyperthyroidism with increased uptake.

3. ^{99m}TcO$_4^-$ is a monovalent anion with an ionic radius similar to iodide. As a result, the pertechnetate ion is trapped by the thyroid gland in a fashion similar to iodide. The two species are sufficiently different in that ^{99m}TcO$_4^-$ is not organified nor incorporated into thyroid hormone, and it is subsequently released unchanged.

B. **Thyroid imaging agents**

1. **Sodium iodide iodine-123 (^{123}I)** is a radiopharmaceutical available in either solution or capsule form for oral administration. It is produced by a cyclotron.

a. **Biodistribution**

(1) Orally administered iodine is rapidly absorbed from the gastrointestinal (GI) tract; thyroid gland uptake is evident within minutes.

(2) Sodium iodide ^{123}I is considered an ideal radiopharmaceutical for iodine uptake and imaging studies because of its short half-life and useful 159 keV primary γ emissions.

b. **Decay data**

(1) **Physical half-life**: 13.2 hrs

(2) **Biological half-life**: 3.5 days

(3) **Decay mode**: by electron capture

(4) **Primary radiation emissions**: 159 keV, 27 keV, and 529 keV γ energy photons

c. **Administration and dosage.** Oral thyroid uptake: 100 to 200 μCi (3.7 to 7.4 MBq); thyroid image: 100 to 500 μCi (3.7 to 18.5 MBq)

2. **Sodium iodide ^{131}I** is used for thyroid uptake and imaging studies; however, it is now used less often because of the high radiation dose absorbed.

a. **Biodistribution**

(1) Orally administered iodine is rapidly absorbed from the GI tract; with thyroid gland, uptake is within minutes.

(2) Sodium iodide ^{131}I is not considered an ideal radioiodine radiopharmaceutical for iodine uptake and imaging studies because of its long half-life, poor imaging properties, and the high radiation dose to the thyroid from its β decay component.

(3) The radiation dose from the high-energy β particle with the imaging potential of its γ emissions make this radionuclide the agent of choice for therapeutic treatment of hyperthyroidism and thyroid cancer.

b. Decay data

(1) Physical half-life: 8.08 days

(2) Decay mode: by β decay

(3) Primary radiation emissions: 606 keV and 333 keV β energy; 364 keV, 637 keV, and 284 keV γ energy photons

c. Administration and dosage. ^{131}I is available as either a capsule or in solution for oral administration.

(1) Diagnostics

(a) Thyroid uptake: 2 to 15 μCi (0.074 to 0.555 MBq)

(b) Thyroid image: 30 to 50 μCi (1.11 to 1.85 MBq)

(c) Whole-body image: 1 to 5 mCi (37 to 185 MBq)

(2) Therapeutics

(a) Hyperthyroidism: 10 to 30 mCi (370 to 1110 MBq)

(b) Thyroid carcinoma: 50 to 200 mCi (1850 to 7400 MBq)

3. $Na^{+99m}TcO_4^-$. See II.B.

4. ^{201}Tl. Parathyroid imaging

a. Biodistribution. ^{201}Tl concentrates in the thyroid and also in parathyroid adenomas, which can be detected by a dual isotope subtraction technique of subtracting thyroid uptake counts from $Na^{+99m}TcO_4^-$ to unmask nonthyroid thallium uptake counts (*see III.A.1*).

b. Administration and dosage. IV, 2 mCi (74 MBq)

IX. BRAIN IMAGING

A. Cerebral perfusion brain-imaging agents. Radiopharmaceuticals for evaluating brain perfusion must possess a lipophilic partition coefficient sufficient to diffuse passively across the blood–brain barrier (BBB) almost completely within one pass of the cerebral circulation, as well as being sufficiently retained to permit data collection. The regional uptake of these agents is proportional to cerebral blood flow. This class of radiopharmaceuticals is useful in the diagnosis of altered regional blood perfusion in stroke.

1. ^{99m}Tc**-exametazime (**^{99m}Tc**-HMPAO)** exists as a sterile, pyrogen-free IV injection after reconstitution with sodium pertechnetate *USP*, which may be stabilized with the addition of a methylene blue/phosphate buffer stabilizing solution.

a. Description

(1) ^{99m}Tc-exametazime is a neutral, lipid-soluble complex that freely crosses the BBB. This is a relatively unstable complex, which rapidly converts to a secondary, less lipophilic complex incapable of penetrating into the brain. The in vitro addition of a methylene blue/phosphate buffer stabilizing solution after preparing the ^{99m}Tc-exametazime will stabilize the lipid-soluble complex for 4 hrs.

(2) Additional limitations on kit preparation parameters require the use of high mole fraction technetium generator eluates of < 2 hrs postelution from a generator previously eluted within 24 hrs.

b. Biodistribution

(1) ^{99m}Tc-exametazime rapidly clears from the blood, with a maximum brain uptake of 3.5% to 7.0%, and up to 2.5% remaining after 24 hrs.

(2) The activity is widely distributed throughout the body; 30% distributes to the GI tract.

(3) Within 48 hrs, 40% of the dose is excreted through the urine and 15% is eliminated via the feces.

c. Physical properties. See II.B.3.

d. Administration and dosage. IV, 10 to 20 mCi (370 to 740 MBq)

2. ^{99m}Tc**-bicisate (**^{99m}Tc**-ECD)**

a. Description

(1) ^{99m}Tc-bicisate exists as a sterile, pyrogen-free IV injection after reconstitution with sodium pertechnetate ^{99m}Tc *USP* and the addition of a phosphate buffer.

       (2) After reconstitution, a stable lipophilic ^{99m}Tc-bicisate complex is formed, which is able to cross the BBB by passive diffusion.

    b. Biodistribution

       (1) ^{99m}Tc-bicisate is rapidly cleared from blood; a maximum of 6.5% of the administered dose is localized in the brain, and 5.0% is left in the blood after 1 hr.

       (2) Once located in the brain cells, ^{99m}Tc-bicisate is metabolized by endogenous enzymes to a polar compound that is unable to diffuse out of the brain cells.

       (3) ^{99m}Tc-bicisate is primarily eliminated via the kidneys; 50% is excreted within 2 hrs, and 74% in 24 hrs. Hepatobiliary excretion accounts for approximately 12.5% of the administered dose after 48 hrs.

    c. Radionuclide properties. See II.B.3.

    d. Administration and dosage. IV, 10 to 30 mCi (370 to 1110 MBq)

B. Carrier-mediated transport (cerebral metabolism) mechanisms. These are responsible for transporting glucose across the BBB. Agents such as ^{18}F-fludeoxyglucose aid in the evaluation of cerebral function by mapping the distribution of glucose metabolism. ^{18}F-fludeoxyglucose is produced by a cyclotron.

    1. Biodistribution. Currently, there is a *USP* monograph for on-site cyclotron-produced ^{18}F-fludeoxyglucose, which is a glucose analog. ^{18}F-fludeoxyglucose concentrates in the brain, where it is phosphorylated but does not undergo subsequent metabolism because of the replacement of the hydroxyl group in the position 2 with a fluorine atom. It is then metabolically trapped for a sufficient time to allow imaging.

    2. Decay data

       a. Physical half-life: 109.7 mins

       b. Decay mode: by positron emission

       c. Primary radiation emissions: 633 keV energy positrons and 511 keV γ energy photons

    3. Administration and dosage. IV, 5 to 10 mCi (185 to 370 MBq)

C. Cerebral neurotransmitter imaging: Fluorodopa fluorine-18 (^{18}F) injection

    1. Description

       a. Cerebral neurotransmitter synthesis can be studied with fluorodopa ^{18}F injection. The intracerebral distribution of this neurotransmitter tracer can be used in the assessment of neurodegenerative diseases such as parkinsonism.

       b. Fluorodopa ^{18}F injection exists under a *USP* monograph as an on-site–produced sterile IV solution of a levodopa analog in which a portion of the molecule has been replaced with ^{18}F, a positron-emitting radionuclide.

    2. Biodistribution

       a. After IV injection, plasma activity decreases to 10% of the administered dose within 5 mins after injection.

       b. Fluorodopa ^{18}F injection is predominantly metabolized in periphery via dopa decarboxylase, and catechol-*O*-methyl transferase. To maximize brain uptake, carbidopa may be used to decrease peripheral metabolism.

       c. Rapid excretion via renal system as dopamine metabolites

    3. Radionuclide data. See IX.B.2.

    4. Administration and dosage. IV, 10 to 20 mCi (370 to 740 MBq)

D. Cerebrospinal fluid (CSF) dynamics. Radionuclide cisternography is useful in the evaluation of hydrocephalus and in detecting CSF leaks. In CSF imaging, the radiopharmaceutical **indium-111 pentetate (^{111}In-DTPA)** is introduced intrathecally into the spinal subarachnoid space, ascends through the basal cisterns, proceeds over the cerebral hemispheres, and eventually drains into the superior sagittal sinus. ^{111}In-pentetate is commercially supplied as a sterile, pyrogen-free unit dose injection. It is produced by a cyclotron.

    1. Biodistribution

       a. After intrathecal injection, this radiopharmaceutical normally ascends to the parasagittal region within 24 hrs.

       b. After absorption into the bloodstream via the arachnoid villi, the major route of elimination is by kidney; 65% of the dose is excreted within 48 hrs and 85% within 72 hrs.

    2. Decay data

       a. Physical half-life: 67 hrs

       b. CSF biological half-life: 12 hrs

     c. **Effective half-life**: 10 hrs

     d. **Decay mode**: by electron capture

     e. **Primary radiation emissions**: 171 keV and 245 keV γ energy photons

   3. **Administration and dosage.** Intrathecal, 500 μCi (18.5 MBq)

E. **Imaging dopamine transport**

   1. ^{123}I-ioflupane (^{123}I-DaTSCAN) is a cocaine analogue that has a high binding affinity for presynaptic dopamine transporters (DATs) in the brains of mammals, in particular the striatal region of the brain. A feature of Parkinson disease is a marked reduction in dopaminergic neurons in the striatal region. ^{123}I-ioflupane is indicated for detecting loss of functional dopaminergic neuron terminals in the striatum:

     • In adult patients with clinically uncertain parkinsonian syndromes, in order to help differentiate essential tremor from parkinsonian syndromes related to idiopathic Parkinson disease, multiple system atrophy, and progressive supranuclear palsy. ^{123}I-ioflupane is unable to discriminate between Parkinson disease, multiple system atrophy, and progressive supranuclear palsy.

     • In adult patients, to help differentiate probable dementia with Lewy bodies from Alzheimer disease. ^{123}I-ioflupane is unable to discriminate between dementia with Lewy bodies and Parkinson disease dementia.

   2. **Biodistribution**

   Ioflupane (^{123}I) is cleared rapidly from the blood after intravenous injection; only 5% of the administered activity remains in whole blood at 5 mins postinjection. Uptake in the brain is rapid, reaching about 7% of injected activity at 10 mins postinjection and decreasing to 3% after 5 hrs. About 30% of the whole brain activity is attributed to striatal uptake. At 48 hrs postinjection, approximately 60% of the injected radioactivity is excreted in the urine, with fecal excretion calculated at approximately 14%.

   3. **Decay data**

     a. **Physical half-life**: 13.2 hrs

     b. **Biological half-life**: 3.5 days

     c. **Decay mode**: by electron capture

     d. **Primary radiation emissions**: 159 keV, 27 keV, and 529 keV γ energy photons

X. INFECTION AND INFLAMMATION.

Evaluation of sites of infection include the use of agents that can associate with components of the natural defense mechanisms and can accumulate where they localize.

A. **Gallium (^{67}Ga) citrate**

   1. **Description**

     a. It is supplied as a sterile, pyrogen-free radiopharmaceutical with preservatives.

     b. The mechanism of localization is thought to depend on the formation of a gallium transferrin complex in the blood and on binding to transferrin receptors associated with infection and inflammation.

     c. It accumulates in areas of white blood cell (WBC) localization.

   2. **Biodistribution**

     a. After administration, the highest concentration of ^{67}Ga citrate, other than at the site of infection, is in the renal cortex. After 24 hrs, the maximum concentration shifts to bone and lymph nodes; but after 1 week, it is mainly concentrated in the liver and spleen.

     b. ^{67}Ga citrate is excreted slowly from the body; 26% is via urine, and 9% is via feces. Whole body retention is 65% after 7 days.

   3. **Radionuclide data**

     a. **Mode of production**: by cyclotron

     b. **Decay mode**: by electron capture

     c. **Physical half-life**: 78 hrs

     d. **Decay emissions**: 93 keV, 185 keV, 300 keV, and 393 keV γ photons

   4. **Administration and dosage.** IV, for infection, 3 to 8 mCi (111 to 300 MBq). A daily laxative or an enema should be used by the patient after the injection and before the images to cleanse the bowel of radioactivity that may interfere with the images and possibly lead to a false-positive result.

B. WBC labeling agents. Radiolabeled WBCs are used in the detection of a wide variety of infectious and inflammatory processes. Current use includes the diagnosis of intra-abdominal abscesses, inflammatory bowel disease, appendicitis, fever of unknown origin, and osteomyelitis. WBCs can be radiolabeled with ^{111}In-oxine or ^{99m}Tc-exametazime.

1. **^{111}In-oxyquinoline solution (^{111}In-oxine)**
   a. **Description**
      (1) ^{111}In-oxyquinoline is supplied as a sterile preservative-free, pyrogen-free, radiopharmaceutical solution for use in the radiolabeling of autologous leukocytes.
      (2) ^{111}In forms a saturated neutral lipophilic complex with oxyquinoline (1:3 ratio), which enables it to penetrate a cell membrane.
      (3) After incubation of ^{111}In-oxyquinoline with a population of autologous leukocytes, the ^{111}In is thought to become firmly bound to cytoplasmic components, thereby allowing the free oxine to be released by the cell.
   b. **Biodistribution**
      (1) After radiolabeling, the autologous leukocytes are reinjected; 30% is taken up by the spleen, and 30% is taken up by the liver, reaching a peak at 2 to 4 hrs postinjection.
      (2) Pulmonary uptake is immediately evident postinjection, but it clears, with minimal visible activity, after 4 hrs.
      (3) There is a biexponential blood clearance; 9% to 24% clears with a biological half-life of 2 to 5 hrs, and the remaining 13% to 18% clears with a biological half-life of 64 to 116 hrs.
      (4) Elimination is mainly through radioactive decay; $< 1\%$ is excreted in feces and urine during the first 24 hrs.
   c. **Radionuclide data**
      (1) **Mode of production**: by cyclotron
      (2) **Decay mode:** by electron capture
      (3) **Physical half-life**: 67 hrs
      (4) **Decay emissions**: 245 keV and 171 keV
   d. **Administration and dosage.** IV, 200 to 500 μCi (7.4 to 8.5 MBq)

2. **^{99m}Tc-HMPAO.** As a sterile and pyrogen-free IV injection after reconstitution with sodium pertechnetate, ^{99m}Tc-HMPAO may be used to radiolabel leukocytes.
   a. **Description**
      (1) ^{99m}Tc-HMPAO is a neutral, lipid-soluble complex that is able to penetrate the WBC membrane. This lipophilic complex is relatively unstable and rapidly converts to a secondary complex incapable of penetrating the WBCs.
      (2) The methylene blue/phosphate buffer–stabilized solution is not able to radiolabel cells and should not be used.
      (3) Additional limitations on kit preparation parameters require the use of high mole fraction technetium generator elutes of < 2 hrs postelution from a generator previously eluted within 24 hrs.
   b. **Biodistribution**
      (1) After IV injection, the radiolabeled cells localize in the lungs, liver, spleen, blood pool, bone marrow, and bladder.
      (2) Elimination is primarily via the liver.
   c. **Radionuclide data.** See II.B.1.b; II.B.3.a–b.
   d. **Administration and dosage.** IV, for infection, 7 to 25 mCi (260 to 925 MBq)

XI. BREAST IMAGING

A. ^{99m}Tc-sestamibi (^{99m}Tc-MIBI) exists as a sterile, pyrogen-free IV injection after kit reconstitution with $Na^{+99m}TcO_4^-$

1. **Description**
   a. ^{99m}Tc-MIBI is used for both breast and cardiac imaging.
   b. ^{99m}Tc-MIBI is indicated for planar imaging as a second line of evaluating breast lesions in patients with an abnormal mammogram or a palpable breast mass.
   c. ^{99m}Tc-MIBI may not be used to screen for breast cancer, to confirm the presence or absence of malignancy, or to replace a biopsy.

2. Biodistribution. ^{99m}Tc-MIBI is primarily excreted by the hepatobiliary system.

3. Physical properties. See II.B.3.

4. Administration and dosage. IV, 20 to 30 mCi (740 to 1110 MBq)

XII. TUMORS

A. The usefulness of radiopharmaceuticals in the detection of tumors varies in sensitivity and specificity, with differences in tumor location and type.

1. Gallium (^{67}Ga) citrate

a. Description

(1) ^{67}Ga is supplied as a sterile, pyrogen-free radiopharmaceutical with preservatives.

(2) The mechanism of localization is thought to depend on the formation of a gallium transferrin complex or binding to transferrin receptors on tumor cells.

(3) It accumulates in primary metastatic tumor sites and may detect the presence of Hodgkin disease, lymphoma, and bronchogenic carcinoma.

b. Biodistribution. See X.A.2.

c. Radionuclide data. See X.A.3.

d. Administration and dosage. IV, for tumor, 10 mCi (370 MBq)

2. ^{111}In-pentetreotide

a. Description

(1) It is supplied as a sterile, pyrogen-free kit for the preparation of ^{111}In-pentetreotide. The two-component kit consists of a reaction vial containing a lyophilized mixture of pentetreotide with stabilizer adjutants and a second vial containing an ^{111}In-chloride/ferric chloride solution.

(a) The pentetreotide molecule is a conjugate of pentetate (diethylenetriamine pentaacetic acid; DTPA) and octreotide, which is a somatostatin analog.

(b) ^{111}In-pentetreotide is prepared by adding the ^{111}In/Fe-chloride solution to the vial containing the pentetreotide. The pentetate portion of the molecule acts as a bifunctional chelate, linking the ^{111}In-radionuclide to the biologically active octreotide portion of the agent.

(2) ^{111}In-pentetreotide is indicated for localization of primary and metastatic neuroendocrine tumors expressing somatostatin receptors.

b. Biodistribution

(1) Within 1 hr after IV injection, ^{111}In-pentetreotide distributes from the plasma to extravascular space; less than one-third of the administered dose remains in the plasma 10 mins postinjection.

(2) ^{111}In-pentetreotide localizes as a function of somatostatin receptor density, with accumulation in normal pituitary, thyroid, liver, spleen, and the urinary bladder.

(3) Elimination is primarily renal; 50% of the administered dose is excreted within 6 hrs postinjection; 85% after 24 hrs, and < 90% after 48 hrs. Less than 2% of the administered dose is cleared via the feces within 72 hrs postinjection.

c. Radionuclide data

(1) Mode of production: by cyclotron

(2) Decay mode: by electron capture

(3) Physical half-life: 67 hrs

(4) Decay emissions: 245 keV and 171 keV

d. Administration and dosage. IV, 3 to 6 mCi (111 to 222 MBq)

3. Iobenguane ^{131}I injection (^{131}I-MIBG)

a. Description

(1) It is supplied as a sterile, pyrogen-free radiopharmaceutical for use as an adjunctive diagnostic agent for the localization of primary and metastatic pheochromocytomas and neuroblastomas.

(2) Iobenguane (metaiodobenzylguanidine) labeled with ^{131}I acts as a physiological analog of norepinephrine and is transported and accumulated in the adrenal medulla. This allows for the detection of neuroendocrine tumors via the specific uptake of labeled iobenguane.

(3) Because of its physiological similarities to norepinephrine, many classes of drugs that interfere with catecholamine transport and function may affect the uptake and localization of labeled iobenguane.

   b. **Biodistribution**
      (1) After IV injection, there is rapid uptake in the liver, with lesser amounts accumulating in the lungs, heart, and spleen.
      (2) Normal adrenal gland uptake is low; but for tumors such as pheochromocytomas and neuroblastomas, the uptake is relatively higher.
      (3) Elimination is renal; most of the drug is excreted mainly unchanged. Between 40% and 50% of the administered dose is excreted within 24 hrs, and 70% to 90% is excreted within 4 days postinjection.
      (4) Administration of potassium iodide 1 day before and for 10 days after administration is suggested to reduce thyroid uptake of potential radioiodine contaminants.
   c. **Physical data.** See VIII.B.2.b.
   d. **Administration and dosage.** IV, 0.5 to 1.0 mCi (18.5 to 37.0 MBq)

4. **^{201}Tl.** This agent has utility as a tumor-imaging agent because of its accumulation in the rapidly metabolizing cells of certain tumors in accordance with its mechanism of localization (see III.A.1).
   a. **Administration and dosage.** IV, 1.5 to 3.0 mCi (55 to 111 MBq)

5. **^{18}F-fludeoxyglucose *USP*.** Currently, there is a *USP* monograph for on-site cyclotron-produced ^{18}F-fludeoxyglucose, which is a glucose analog. This agent has utility as a tumor-imaging agent because of an increased demand for glucose by tumors with an advanced state of malignancy. Not only can ^{18}F-fludeoxyglucose locate and differentiate tumors, but it can also help distinguish between recurrent brain tumor and radiation necrosis in patients receiving radiation therapy (see IX.B).
   a. **Biodistribution.** ^{18}F-fludeoxyglucose concentrates in metabolically active cells, where it is phosphorylated but does not undergo subsequent metabolism because of the replacement of the hydroxyl group in the position 2 with a fluorine atom. It is then metabolically trapped for a sufficient time to allow imaging.
   b. **Administration and dosage.** IV, 5 to 25 mCi (185 to 370 MBq)

B. **Antibodies**. See XIV. D. Yttrium-90 ibritumomab tiuxetan & Indium-111 ibritumomab tiuxetan B.2. See XIV.E. Iodine I-131 tositumomab.

XIII. THERAPEUTIC AGENTS.
The therapeutic use of radiopharmaceuticals is based on the concept of selective localization of radiopharmaceuticals coupled with the lethality of the same because of the tissue damage resulting from highly ionizing particulate emissions such as β particles.

A. **Sodium iodide ^{131}I (therapeutic)**
   1. **Description**
      a. It is indicated for treatment of hyperthyroidism and thyroid carcinoma.
      b. Its therapeutic action is owing to the accumulation and retention of iodine and its isotope ^{131}I.
   2. **Biodistribution**
      a. See VIII.A; VIII.B.2.
      b. **Biological half-life in the thyroid**: euthyroid patient, 80 days; hyperthyroid patient, 5 to 40 days
   3. **Radionuclide data.** See VIII.B.2.b.
   4. **Administration and dosage.** Oral capsule or oral solution
      a. Hyperthyroidism: 10 to 30 mCi (370 to 1110 MBq)
      b. Thyroid carcinoma: 30 to 200 mCi (1110 to 7400 MBq)

B. **Strontium-89 (^{89}Sr) chloride**
   1. **Description**
      a. It is indicated for the alleviation of bone pain arising from metastatic bone disease.
      b. As a metabolic analog of calcium, ^{89}Sr concentrates selectively in areas of increased osteogenesis, thus delivering a radiation dose sufficient to provide a palliative effect.
      c. Pain relief begins 7 to 21 days after administration, with maximum relief by 6 weeks and an average duration of 6 months.
      d. Reduction in patient analgesic usage occurs in up to 75% of patients treated; complete pain relief is seen in 20% of treated patients, and no pain relief in 20% to 25% of treated patients.
      e. Bone marrow suppression effects limit ^{89}Sr use to patients with initial WBC counts > 2400 and platelet counts > 60,000.

2. **Biodistribution**
   a. After administration, ^{89}Sr clears rapidly from blood and localizes in the bone hydroxyapatite.
   b. Initial biological half-life in normal bone is 14 days; longer retention is seen in metastatic bone lesions. Between 12% and 90% of the administered dose is retained for up to 3 months after administration.
   c. Elimination is primarily renal; 66% of the administered dose clears via GFR within the first 2 days, and 33% is excreted via feces.
3. **Radionuclide data**
   a. **Mode of production**: by accelerator
   b. **Decay mode**: by β
   c. **Emission data**: 1.46 MeV maximum β energy, 100% abundance
   d. **Physical half-life**: 50.5 days
4. **Administration and dosage.** IV, 4 mCi (148 MBq), 40 to 60 μCi/kg (1.5 to 2.2 MBq/kg)

C. **Samarium-153 (^{153}Sm) lexidronam**
   1. **Description**
      a. ^{153}Sm is indicated for the relief of pain in patients who have confirmed metastatic cancer of the bone.
      b. ^{153}Sm concentrates in areas of high bone turnover and accumulates more in osteoblastic lesions than in the normal bone.
      c. The goal of ^{153}Sm therapy is for patients to be able to reduce the amount of narcotic analgesics needed to control their pain.
   2. **Biodistribution**
      a. The lesion to normal bone ratio is 5:1.
      b. The percentage of uptake of ^{153}Sm is directly proportional to the number of lesions the patient has.
      c. Less than 1% of the dose remains in the blood 5 hrs postinjection.
      d. ^{153}Sm is 100% renally excreted over 12 hrs.
      e. The onset is approximately 1 week.
   3. **Radionuclide data**
      a. **Mode of production**: by cyclotron
      b. **Decay mode**: by β and γ decay
      c. **Physical half-life**: 46.3 hrs
      d. **Decay emissions**: 640 keV, 710 keV, and 840 keV β energy and 103 keV γ energy photons
   4. **Precautions.** ^{153}Sm may cause bone marrow suppression, which should return to baseline within 8 weeks postinjection.
   5. **Administration and dosage.** IV, 1 mCi/kg (37 MBq/kg)

D. **Yttrium-90 (^{90}Y) ibritumomab tiuxetan and ^{111}In-ibritumomab tiuxetan**
   1. **Overview**
      a. ^{111}In-ibritumomab tiuxetan and ^{90}Y-ibritumomab tiuxetan are part of a therapeutic regimen used in the treatment of non-Hodgkin lymphoma (NHL) patients with relapsed refractory low-grade, follicular, or transformed B cell NHL and patients with rituximab refractory NHL.
      b. Ibritumomab tiuxetan is an immunoconjugate consisting of a monoclonal antibody ibritumomab, which is linked to the chelator tiuxetan.
      c. The ibritumomab antibody is a murine immunoglobulin G1 (IgG1) κ monoclonal antibody produced in Chinese hamster ovary (CHO) cells. The ibritumomab antibody is directed against the CD20 antigen, which is expressed on the surface of normal and malignant B lymphocytes.
      d. The linker-chelator tiuxetan provides a high-affinity chelation site for ^{111}In in the case of the imaging dose and for ^{90}Y in the case of the therapeutic dose.
      e. The therapeutic regimen is administered in two separate doses. This allows for the qualitative evaluation of the biodistribution to avoid potential toxicities such as abnormally high bone marrow localization or prolonged renal excretion. In each administration, patients must be premedicated with diphenhydramine (50 mg) and acetaminophen (50 mg) 0.5 hr before receiving the rituximab infusion required before administering the radiolabeled antibody.
         (1) Step 1 is the administration of rituximab followed by the ^{111}In-ibritumomab tiuxetan diagnostic imaging dose.

(2) Step 2 follows step 1 by 7 to 9 days and consists of a second rituximab infusion followed by the ^{90}Y-ibritumomab therapy dose.

2. Description

   a. Supplied as two separate kits to produce a single dose of ^{111}In-ibritumomab tiuxetan and a single dose of ^{90}Y-ibritumomab tiuxetan

   b. Each kit consists of four vials containing:

      (1) Ibritumomab tiuxetan in saline, 3.2 mg

      (2) Sodium acetate, 50 mM

      (3) Formulation buffer (contains human serum albumin)

      (4) One empty reaction vial

   c. Exists as a sterile, nonpyrogenic IV solution after formulation with either ^{111}In or ^{90}Y

3. Biodistribution

   a. The mean half-life for ^{90}Y-ibritumomab tiuxetan in the blood is 30 hrs.

   b. Approximately 7.8% of the administered dose is excreted in the urine over 7 days.

   c. The estimated biological half-life is 48 hrs.

4. Radionuclide data

   a. ^{111}**In.** See XIII.B.1.c.

   b. ^{90}**Y**

      (1) Mode of production: by reactor

      (2) Decay mode: by β

      (3) Physical half-life: 64.1 hrs

      (4) Decay emission: 935 mean keV, 100% emission

5. Precautions

   a. ^{90}Y-ibritumomab tiuxetan should not be administered to patients with altered biodistributions of the ^{111}In-ibritumomab tiuxetan imaging and dosimetry.

   b. ^{90}Y-ibritumomab tiuxetan should not be administered to patients with:

      (1) $\leq$ 25% lymphoma marrow involvement

      (2) Platelet count $<$ 100,000 cells/mm^3

      (3) Neutrophil count $<$ 1500 cells/mm^3

      (4) Hypocellular bone marrow

      (5) History of failed stem cell collection

   c. Ibritumomab tiuxetan is contraindicated in patients with known hypersensitivity or anaphylactic reactions to murine proteins.

   d. Patients who have previously received murine-based protein therapy should be screened for human antimouse antibodies.

   e. Infusion-related adverse events, including asthenia, chills, and nausea, are common and are usually self-limited. Tumor lysis syndrome has been reported after rituximab infusions, which are part of ^{90}Y-ibritumomab tiuxetan therapy. Patients should be monitored closely for this potentially fatal adverse event.

Study Questions

Directions for questions 1–7: Each of the questions, statements, or incomplete statements in this section can be correctly answered or completed by one of the suggested answers or phrases. Choose the best answer.

1. Which of the following emissions from the decay of radionuclides is most commonly used in nuclear medicine diagnostic imaging?

   (A) x-ray
   (B) β
   (C) α
   (D) γ
   (E) positron

2. Which of the following radionuclides is most commonly used in nuclear pharmacy practice?

   (A) gallium-67 (^{67}Ga)
   (B) thallium-201 (^{201}Tl)
   (C) technetium-99m (^{99m}Tc)
   (D) iodine-123 (^{123}I)
   (E) xenon-133 (^{133}Xe)

3. Which of the following radionuclides is produced using a generator?

   (A) technetium-99m (^{99m}Tc)
   (B) thallium-201 (^{201}Tl)
   (C) gallium-67 (^{67}Ga)
   (D) xenon-133 (^{133}Xe)
   (E) iodine-123 (^{123}I)

4. Which of the following radiopharmaceuticals can be used in skeletal imaging?

   (A) ^{99m}Tc albumin aggregated
   (B) ^{99m}Tc medronate disodium
   (C) xenon-133 gas *USP*
   (D) thallous chloride (^{201}Tl) *USP*
   (E) ^{99m}Tc disofenin

5. Which of the following radiopharmaceuticals is used in the diagnosis of acute cholecystitis?

   (A) ^{99m}Tc sulfur colloid
   (B) ^{99m}Tc medronate disodium
   (C) ^{99m}Tc albumin
   (D) ^{99m}Tc exametazime
   (E) ^{99m}Tc disofenin

6. Which of the following cyclotron-produced radiopharmaceuticals is used for assessing regional myocardial perfusion as part of an exercise stress test?

   (A) thallous chloride ^{201}Tl *USP*
   (B) sodium iodide ^{123}I
   (C) gallium citrate ^{67}Ga *USP*
   (D) ^{111}In pentetate
   (E) ^{57}Co cyanocobalamin

7. Glomerular filtration and the urinary collection system can best be evaluated using which of the following agents?

   (A) ^{99m}Tc sulfur colloid
   (B) ^{99m}Tc albumin
   (C) ^{99m}Tc sestamibi
   (D) ^{99m}Tc disofenin
   (E) ^{99m}Tc pentetate

Directions for questions 8–11: The questions and incomplete statements in this section can be correctly answered or completed by one or more of the suggested answers. Choose the answer, **A–E**.

   A   if **I only** is correct
   B   if **III only** is correct
   C   if **I and II** are correct
   D   if **II and III** are correct
   E   if **I, II, and III** are correct

8. The definition of the optimal radiopharmaceutical includes which of the following attributes?

   I.   short half-life
   II. photon with a 100–300 keV energy
   III. rapid localization in target tissue and quick clearance from nontarget tissue

9. Which of the following statements are true for sodium pertechnetate technetium-99m (^{99m}Tc) *USP*?

   I.   It is used to radiolabel all other ^{99m}Tc radiopharmaceuticals.
   II. The molybdenum-99 (^{99}Mo) breakthrough limit is < 0.15 μCi ^{99}Mo/mCi ^{99m}Tc (< 0.15 kBq/MBq).
   III. It has a physical half-life of 16 hrs.

10. Which of the following organs can be imaged with technetium-99m (^{99m}Tc) sulfur colloid?

   I.   liver
   II. spleen
   III. bone marrow

11. Which of the following radiopharmaceuticals may be used to image the thyroid gland?

    I. sodium iodide ^{131}I
    II. sodium pertechnetate ^{99m}Tc *USP*
    III. sodium iodide ^{123}I

Directions for questions 12–16: Each of the following mechanisms of localization is most closely related to one of the following radiopharmaceuticals. The mechanisms may be used more than once or not at all. Choose the best answer, **A–E**.

    A metabolic trapping
    B phagocytosis
    C capillary blockade
    D active transport
    E passive diffusion

12. thallous chloride ^{201}Tl *USP*

13. ^{99m}Tc albumin aggregated *USP*

14. ^{99m}Tc sulfur colloid

15. ^{99m}Tc exametazime

16. ^{18}F fludeoxyglucose

Answers and Explanations

1. The answer is D *[see I.B.3.b]*.
Current camera technology most efficiently detects γ radiation. α and β emissions are not useful in nuclear medicine imaging because of their harmful particulate emissions and low tissue penetration. Although x-ray emissions can be used as in the case of the mercury daughter of the thallous chloride ^{201}Tl parent, they are not efficiently detected. Annihilation radiation associated with positron decay can be imaged, but this technology is currently limited to a few specialized centers.

2. The answer is C *[see II.A.1]*.
^{99m}Tc has become the radionuclide of choice in current nuclear pharmacy practice since its introduction in the mid-1960s. ^{99m}Tc fulfills all of the requirements of the optimal radiopharmaceutical, with its physical half-life of 6 hrs, 140 keV γ energy emission, ready availability, cost, and ability to be radiolabeled to various biologically active compounds.

3. The answer is A *[see II.A.1.a]*.
^{99m}Tc is obtained via commercially supplied, sterile, pyrogen-free generator systems. A generator is a device used to separate a short half-life radionuclide from the longer lived parent nuclide, while retaining the parent to produce more of the daughter nuclide. In this way, short–half-life nuclides can be made available on a continuous basis at great distances from the sites of generator production.

4. The answer is B *[see IV.A.2]*.
The ^{99m}Tc-diphosphonate compounds are the most popular bone-imaging agents currently used in nuclear medicine imaging. They are rapidly taken up by skeletal bone; 50% of the administered dose is adsorbed onto bone hydroxyapatite and the remainder is excreted by the kidneys. The imaging advantages of the ^{99m}Tc, coupled with the sensitivity of bone agent localization in skeletal bone hydroxyapatite, allow for detection of bone pathology before evidence of pathology can be shown by conventional x-ray.

5. The answer is E *[see VI.C.1–2]*.
^{99m}Tc-disofenin is an iminodiacetic acid derivative, which is useful for hepatobiliary imaging due to its ability to be selectively cleared by a carrier-mediated hepatocyte pathway. Lack of gallbladder visualization is an abnormal finding suggestive of acute cholecystitis.

6. The answer is A *[see III.A.1]*.
Regional uptake of thallous chloride ^{201}Tl *USP* is proportional to myocardial blood supply. The injection of ^{201}Tl in concert with a treadmill exercise stress test determines myocardial perfusion at maximum cardiac output when cardiac demand outstrips supply and the distribution of ^{201}Tl is less after affected by collateral blood supply within the myocardium. Regions that do not take up ^{201}Tl are interpreted as areas of infarct or ischemia. If these focal areas of decreased uptake subsequently fill in with redistributed ^{201}Tl, they are interpreted to be areas of ischemia, in contrast with areas of infarct, which remain as diminished areas of activity.

7. **The answer is E** *[see VII.B.1].*
   ^{99m}Tc-pentetate is cleared through glomerular filtration in the same manner as inulin and can be used to determine the GFR as well as in the evaluation of obstruction of vascular supply and renal morphology.

8. **The answer is E (I, II, III)** *[see I.C].*
   The optimal radiopharmaceutical has a half-life short enough to minimize radiation exposure to the patient yet long enough to allow for collection of imaging information. It should incorporate a γ-emitting radionuclide, which decays with the emission of a photon energy between 100 and 300 keV, which is efficiently detected with current instrumentation. The radiopharmaceutical should localize rapidly in the organ system of interest and be metabolized, excreted, or both from the nontarget tissues to maximize contrast and minimize radiation-absorbed dose.

9. **The answer is C (I, II)** *[see II.A–B].*
   Sodium pertechnetate ^{99m}Tc *USP* decays by isomeric transition and has a physical half-life of 6 hrs. The emission of a γ photon has the energy of 140 keV.

10. **The answer is E (I, II, III)** *[see VI.B.1].*
    ^{99m}Tc-sulfur colloid localizes within the reticuloendothelial system, 80% to 90% of the dose is phagocytized by the Kupffer cells of the liver, 5% to 10% by the spleen, and the balance by the bone marrow.

11. **The answer is E (I, II, III)** *[see VIII.B].*
    Although all of the listed agents accumulate in the thyroid gland, only sodium iodide ^{123}I possesses ideal imaging characteristics and organification into thyroid hormone. Although the imaging properties of sodium pertechnetate ^{99m}Tc *USP* are good, the pertechnetate ion is trapped only by the thyroid and not organified, thus limiting the information provided by the image.

12. **The answer is D** *[see III.A.1].*
    Thallous chloride ^{201}Tl *USP* is a monovalent cation with distribution analogous to potassium ion (K^+). Myocardial uptake is by active transport via the Na^+/K^+-ATPase pump.

13. **The answer is C** *[see V.A.1].*
    After IV administration of ^{99m}Tc-albumin aggregated *USP*, 80% of the radiolabeled albumin particles become trapped by capillary blockade in the pulmonary circulation.

14. **The answer is B** *[see VI.B.1].*
    After the administration of ^{99m}Tc-sulfur colloid, 80% to 90% of the dose is phagocytized by the Kupffer cells of the liver, 5% to 10% by the spleen, and the balance by the bone marrow.

15. **The answer is E** *[see IX.A.1].*
    ^{99m}Tc-exametazime is used for evaluating brain perfusion. It possesses a lipophilic partition coefficient that is sufficient to diffuse passively across the BBB almost completely within one pass of the cerebral circulation, and that is sufficiently retained to permit data collection.

16. **The answer is A** *[see IX.B.1].*
    ^{18}F-fludeoxyglucose is used in evaluating cerebral function by mapping the distribution of cerebral glucose metabolism. As an analog of glucose, ^{18}F-fludeoxyglucose is transported into the brain by carrier-mediated transport mechanisms responsible for transporting glucose across the BBB. Because the presence of the fluorine atom in the position 2 prevents metabolism beyond the phosphorylation step, ^{18}F-fludeoxyglucose becomes metabolically trapped within the brain.

Medication Therapy Management

PENNY S. SHELTON, K. PAIGE D. BROWN

I. INTRODUCTION

A. **Pharmacists and patient outcomes.** Since the coining of the term *pharmaceutical care* in 1990,[1] pharmacists in all settings have taken on greater responsibility for patient outcomes. Several terms have been used to describe the pharmacist's nondispensary role in patient care: clinical or cognitive services, pharmaceutical care, and now medication therapy management (MTM). Regardless of the term used or the setting in which care is provided, pharmacy practice should be proactive and patient-centric to ensure quality patient care.

B. **Definition.** In 2005, a definition for MTM was reached by consensus among 11 national pharmacy organizations.[2] Essentially, medication therapy management services (MTMS) are a broad range of patient-specific services designed to improve quality of care and continuity of care, as well as optimize treatment outcomes.

C. **Medicare Part D and MTM.** In 2006, the Medicare Modernization Act (MMA) of 2003[3] was implemented, providing prescription drug coverage (Part D). The MMA has additional historical significance in that MTM was mandated for eligible Medicare beneficiaries. Medicare Part D services are provided by privatized prescription drug plans (PDPs). The Centers for Medicare & Medicaid Services (CMS) are responsible for requirements and regulation.

1. **Eligibility.** Although in practice MTMS encompasses a broad range of services that can benefit any patient, under Part D only patients who meet the following specific requirements are eligible for MTM:
   a. Multiple chronic conditions
   b. Multiple Part D medications
   c. Anticipated Part D medication costs of > $4000 per year
2. CMS allows the PDPs to set their own criteria for what constitutes "multiple."
3. CMS allows the PDPs to determine how MTM will be or can be provided and includes the following:
   a. Patient mailings
   b. Call centers
   c. Pharmacist-provided MTM
4. Under Part D, when the provision of MTM is allowed by the PDP to be done by a patient's pharmacist, the PDP typically "pushes" the case to the pharmacy. MTMS provided to a Medicare patient prior to the "push" (i.e., a "pull" case) are typically not covered under Part D, and therefore payment by the PDP for services rendered may not occur.

II. SCOPE OF MEDICATION THERAPY MANAGEMENT SERVICES

A. **Separation of MTM from dispensing**
1. MTMS are provided by pharmacists in several settings. MTMS are distinctive and separate from dispensing services. Pharmacists may, at the time of dispensing, identify patients who would benefit from MTM. However, MTM is more in-depth than traditional medication counseling

mandated by Omnibus Budget Reconciliation Act of 1990 (OBRA '90). MTM is more holistic, generally encompassing the patient's entire medication regimen in the context of prevention, treatment, and management of conditions and disease states.

B. Protection of patient information

    1. The provision of MTMS that includes patient interaction, documentation, and billing should ensure patient confidentiality and be compliant with the Health Insurance Portability & Accountability Act (HIPAA).

C. Comprehensive versus focused MTMS

    1. A pharmacist can design his or her practice to provide several MTMS, including comprehensive medication therapy reviews (MTRs), specific disease state management programs, and/or targeted interventions. For example, a pharmacist may identify via the provision of a comprehensive MTR that his or her patient needs additional care for his or her diabetes (i.e., disease management) or perhaps needs strategies to improve adherence (i.e., targeted intervention).

    2. Pharmacists providing disease state management services or targeted intervention programs can design their practice to include point-of-care laboratory assessment, cognitive services, product lines, and patient education. Examples of pharmacist-provided MTMS in various health care settings include but are not limited to the following:

        a. Diabetes

        b. Anticoagulation

        c. Hypertension/hyperlipidemia

        d. Adherence

    3. Regardless of whether the service is comprehensive or focused, all MTMS involve patient interaction and participation to optimize therapeutic outcomes.

D. Patients who may benefit from MTMS

    1. Complex pharmacotherapy patients

        a. Multiple medications

        b. Multiple disease states or conditions

        c. Narrow therapeutic index medications

        d. Medications requiring laboratory monitoring

    2. High risk for loss of continuity of care

        a. Multiple prescribers

        b. Recent transitions of care (e.g., hospital discharge, rehabilitation, skilled nursing facility discharge)

    3. Evidence of or high risk for medication nonadherence

        a. Irregular refill history

        b. History of failure to pick up new prescriptions

        c. Stockpiling or incorrect pill counts

        d. Financial burden (e.g., uninsured or underinsured)

        e. Low health literacy

        f. Poor transportation

        g. Patient's beliefs indicate resistance to treatment

    4. High-cost regimens

    5. Noticeable decline in the patient's health or functionality

III. ESSENTIAL COMPONENTS OF MEDICATION THERAPY MANAGEMENT

A. Patient and pharmacist relationship

    1. Pharmacists have historically been viewed as one of the most trusted professionals based on Gallup's annual *Honesty and Ethics Survey.*[4] Pharmacists are also one of the most accessible health care professionals. Patients express greater satisfaction with care when they perceive quality interactions with a health care provider.

    2. The provision of face-to-face MTMS strengthens the patient–pharmacist relationship. Although some MTMS can be provided via a phone interaction, face-to-face interaction with the pharmacist affords the ability for the pharmacist to observe visual signs and symptoms as well as changes in the patient's status and well-being.

3. For optimum patient care to occur, pharmacists need to be culturally competent and aware of the patient's level of health literacy.
   a. Cultural competency means the pharmacists are cognizant of their patients' diversity regarding beliefs, values, behaviors, and language. Barriers in these areas can lead to miscommunication and poor health outcomes.
   b. Health literacy is an individual's ability to obtain, understand, and follow directions related to his or her health care. According to the U.S. Department of Education, 9 out of 10 Americans have limitations regarding health literacy.[5] Patients with poor health literacy generally have poor health status and are more likely to have medication-related problems. The Rapid Estimate of Adult Literacy in Medicine–Revised (REALM-R) is a simple and quick tool that pharmacists can use to assess patient's health literacy.[6] Pharmacists need to adapt their counseling and MTMS based on the patient's health literacy level.
4. Successful MTM requires patient participation. Many MTM-related interventions require lifestyle or behavioral changes. Pharmacists need to assess their patients' willingness to participate and change. Pharmacists should know the stages of change delineated within the *Transtheoretical Model of Behavior Change* (*Table 60-1*).[7] Pharmacists can also use a 0-to-10 visual analog scale for assessing a patient's willingness to change. Scores ≥ 5 suggest the patient is willing to change and should be supported and encouraged.[8]

Table 60-1   EXAMPLE APPLICATION OF TRANSTHEORETICAL MODEL OF STAGES OF CHANGE[7]

Stage	Definition	Example Application (Self-Monitoring Glucose)	
Precontemplation	Patient has no interest in changing behavior or sees no need to change	Patient discharged from hospital. Prescriptions for an oral antidiabetic agent and a glucose meter are called into pharmacy. Patient picks up oral agent but refuses the meter and states, "I'm not going to check my blood sugar. I'm not sticking myself. It's unnecessary. I don't have diabetes."	
Contemplation	Patient is beginning to weigh pros and cons of change and is considering changing his or her behavior but is still somewhat ambivalent	Patient is discharged from hospital. Prescriptions for an oral antidiabetic agent and a glucose meter are called into pharmacy. Patient picks up oral agent and the glucose meter. She indicates at the time of purchase that she understands the importance of monitoring but refused a meter teaching session with the pharmacist. Three days later, the pharmacist calls to follow up with the patient and the patient states that she has not used the meter or taken it out of the box.	& Bi-Directional Movement Between Stages Occurs
Preparation	Patient is taking action or shows signs of preparing to change	Patient is discharged from hospital. Prescriptions for an oral antidiabetic agent and a glucose meter are called into pharmacy. Patient pays for both and asks for the pharmacist to explain how to use the meter. She conducts her first finger-stick in the pharmacy and asks for a follow-up appointment to meet with the pharmacist to talk about diabetes and diet.	**RELAPSE**
Action	Patient has implemented change(s)	Scenario is the same as in the aforementioned "Preparation," and when the pharmacist calls to check on the patient, she provides the pharmacist with values for twice daily blood glucoses. The pharmacist confirms the date for her follow-up appointment and tells her that she is doing a great job with monitoring and that her blood glucose values are getting better.	
Maintenance	Patient is able to maintain positive changed behavior	Patient comes in monthly for medication refills, glucose strips, and lancets. Patient maintains a log of blood glucose values and has kept follow-up appointments with physician and pharmacist. Patient has started and adheres to a regular exercise routine and a low carbohydrate diet.	

B. **Patient/caregiver interview.** Depending on the patient, it may be appropriate for the pharmacist to include a caregiver in the patient interview.

   1. Interview setting

      a. A semiprivate or private area is required for the provision of MTMS. For interviewing purposes, the more private the area, the fewer interruptions and the more likely the patient will share and retain pertinent information.

      b. The interview area should have adequate lighting and a comfortable temperature. The space should be equipped with a table and chairs. The chair for patients should have arms to assist the patient in lowering to and rising from a seated position. The space should be large enough to accommodate the pharmacist, patient, and possible caregiver. In addition, the space should be readily accessible to patients with mobility problems (e.g., wheelchair, walker).

      c. The space should be relatively quiet to facilitate conversation (e.g., ability to close a door to the space, no ringing phone). Many MTM patients are elderly and have hearing deficits. Failure to create an environment where background noise is minimized may escalate patient's frustration in communicating and adversely affect the desired outcomes.

   2. Essential technique

      a. Use open and honest communication

         (1) Introduce yourself.

         (2) Explain the purpose and process of the MTM session.

         (3) Ask for the patient's expectations, concerns, and/or issues to be addressed.

      b. Avoid using and be aware of patients' incongruent body language (i.e., mismatch in verbal and nonverbal language).

      c. Maintain good eye contact throughout the interview.

      d. Conduct the patient interview at the patient level. Avoid medical jargon.

      e. Ask purposeful questions.

      f. Use a combination of open- and closed-ended questions. Open-ended questions cannot be answered with a simple yes or no and generally begin with who, what, when, or how.

      g. Avoid rapid-fire questioning. Allow the patient time to answer a question before posing a second question.

      h. Avoid leading questions, for example, "You take your cholesterol medicine at night, right?"

      i. Use probing questions. Example: Questions asked to help elicit specific information from the patients regarding their medication therapy needs and problems.

      j. Use nondefensive phrasing. For example, patients may become defensive with "why questions." Instead of asking "Why did you not take your blood sugar medicine?" ask "What caused you to not take your blood sugar medicine?"

      k. Use active listening skills (*Table 60-2*).

      l. Communication strategies for patients with disabilities. Patients with disabilities are capable of patient-centric care and should be empowered to be active participants.

         (1) For patients with hearing deficits, remember to use a lower tone of voice and slower rate of speech. Use simpler sentences and sit directly across from the patient to facilitate lip-reading. Verbal education should be augmented with written materials. Consider providing and making available to your patient a sound amplifier.

         (2) For patients with visual deficits (e.g., presbyopia, cataracts, glaucoma, macular degeneration, color blindness), clear and concise verbal communication becomes critical. When written communication or materials are necessary, these should be printed on nonglare, off-white, or pastel-colored paper. The font should be 14 points or greater in size; and avoid the use of yellow, green, and red.

         (3) For patients with mental or cognitive deficits, the interview and education sessions may likely require the presence of a caregiver. Remember to always address the patient. Provide simple communication. Augment with simple written material.

   3. Essential components. The content gathered during a patient interview is essential to enable a comprehensive assessment. The outcome of MTMS depends on the quality of information and data that pharmacist has available. It takes a considerable amount of time to do a thorough patient interview as indicated by the following components.[9] To improve efficiency, the pharmacist may

Table 60-2 USE OF ACTIVE LISTENING SKILLS IN THE PATIENT INTERVIEW

Active Listening Skill	Explanation	Application Example
Facilitation	The interviewer uses words, body language, and/or posture to encourage the patient to continue.	Patient: "I just haven't been feeling well lately." Pharmacist: [while maintaining eye contact and leaning in toward the patient] "Tell me more."
Interpretation	The interviewer deduces there is a problem based on a statement or statements and asked the patient to address the finding.	Pharmacist: "I noticed that you have asked some questions about memory today. Do you have concerns about your memory?"
Reflection	The interviewer checks his or her understanding of what the patient has said by repeating back a statement or statements in the patient's words and gauges the patient's response.	Patient: ". . . and my doctor told me to start taking ½ tablet for my cholesterol." Pharmacist: "Your doctor told you to take a ½ tablet?" Patient: "Yes"
Clarification	The interviewer asks for more detail when he or she does not fully understand what the patient has said or implied.	Pharmacist: "You said you only take your naproxen when you need it. How often do you have to take it?" Patient: "Not often." Pharmacist: "How many times a week do you have to take it?"
Empathy	The interviewer recognizes the patient's feelings.	Patient: "I was in so much pain. I thought I was going to die." Pharmacist: "That must have been very difficult and scary for you. How is your pain today?"
Confrontation	The interviewer uses an observation, a patient behavior, or an aspect of the interview to engage the patient in addressing a problem or situation.	Situation: The patient's self-monitored blood glucose values have been consistently high. Pharmacist notices in the patient's shopping cart several food items that are high in sugar/carbohydrate. Pharmacist: [begins confronting the patient with] "Have you ever had any diet education for your diabetes?"
Silence	Silence can be used in two ways: (1) remaining silent after posing a question to enable the patient time to gather his or her thoughts and answer, and (2) remaining silent after a patient's statement can at times be used to prompt the patient to share more detail.	Patient: "My daughter took me to the emergency room last month." Pharmacist: [maintains eye contact and remains silent, encouraging the patient to continue] Patient: "They admitted me for pneumonia."

have the patient complete or provide information in advance or train a technician to assist with data collection.

a. Basic patient demographics (e.g., name, date of birth, address)
b. Chief complaint or reason for evaluation. In addition, it is helpful to ascertain what the patient/caregiver wishes to accomplish by the MTMS. In other words, what are the patient/caregiver's expectations?
c. Health care priority. Comfort, cost, or convenience
d. Past medical history, including surgeries and procedures, as well as any recent hospitalizations or emergency department visits
e. Preventative health information such as immunizations and health screenings (e.g., colonoscopy, Pap smear, mammogram, prostate examination)

     f. Family history

     g. Social history that includes caffeine, nicotine, alcohol, prescription or illicit drug abuse, exercise, diet, occupation, and support network

     h. Allergies

     i. Medication history. Prescription, over-the-counter, herbal, and home remedies

        (1) Medication name and strength

        (2) Dose and directions (as labeled vs. how taken)

           (a) For as-needed medications (PRN). Frequency of use and when last dose occurred

        (3) Indication

        (4) Duration

        (5) Perceived efficacy and side effects. If there are reported problems with efficacy or side effects, it may be helpful to inquire about other medications that have been previously tried and failed.

        (6) Prescriber

        (7) Pharmacy that filled the medication if not filled by interviewing pharmacist/pharmacy

        (8) Date last refilled (consider a pill count to help with measuring adherence)

        (9) Recent changes. Medications added or discontinued and/or dosage changes

     j. Vitals and lab values

        (1) Review of the patient's medication list prior to the appointment may be helpful to pinpoint and request the patient bring certain lab values to his or her appointment, or

        (2) Consider having the patient sign a medical release during the appointment to enable the pharmacist to obtain lab values from the patient's physician.

     k. Review of systems. The pharmacist may be the first professional to detect a health problem for which a referral may be necessary. In addition, a generalized review of systems reveals problems or conditions not commonly reported in a medical history such as falls, incontinence, and constipation. A review of systems may detect side effects that the patient did not realize may be associated with his or her medications (e.g., dry mouth).

     l. Contact information for all prescribers and insurance information (e.g., Medicare Part D PDP)

C. Medication therapy review (MTR). The MTR is conducted to determine appropriateness of therapy. The pharmacist should concentrate on necessity, safety, and efficacy of therapy. A useful outcome of the MTR is the detection/creation of a problem list (i.e., medication-related problems).

    1. Basic components of an MTR can be found within the medication appropriateness index,[10] which helps to provide a systematic approach to the MTR.

     a. Is there a justification/indication for the medication?

     b. Is there any allergy or contraindication for the medication?

     c. Is the medication or regimen being used the most efficacious?

     d. Is the dose (age/condition) appropriate?

     e. Are the directions optimized?

     f. Are necessary monitoring parameters/practices in place?

     g. Is the duration of use appropriate?

     h. Are there any therapeutic duplications?

     i. Are there any drug–drug interactions? Drug–food? Drug–disease?

     j. Are there more cost-effective therapies available?

     k. Is the patient adherent with therapy?

     l. Are there any untreated conditions?

D. Therapeutic planning. The problem list created from your systematic MTR is used to create a therapeutic plan.

    1. The plan should be patient-centric, and with MTM for Medicare Part D, the plan is referred to as the Medication Action Plan.

    2. The therapeutic plan is designed to prevent, alleviate, and eliminate medication-related problems.

    3. The plan should be written to serve as documentation for services provided.

    4. Pharmacists may choose to use a traditional SOAP or FARM format for their documentation (*Table 60-3*).

    5. Ideally, therapeutic plans should include the following:

     a. Goals for therapy

     b. The patient's status on desired outcomes

Table 60-3   COMPONENTS OF A FARM AND SOAP NOTE

FARM Note	SOAP Note
Findings **(F)**	Subjective data **(S)** and Objective data **(O)**
Assessment **(A)**	
Resolution/Recommendation **(R)**	Plan **(P)**
Monitoring **(M)** and follow-up	

      c. Recommendations for intervention

      d. Recommended monitoring parameters

      e. Desired time frame for follow-up

      f. Contingency plans for treatment may also be included in the event that treatment goals are not reached.

    6. Without appropriate follow-up, even the best of therapeutic plans are likely to fail. The success of therapeutic plans also depends on patient adherence, which is why this process should be patient-centric.

    7. The therapeutic plan required for Medicare Part D beneficiaries (i.e., MAP) should be developed in collaboration with the patient and should contain action items for which the patient is responsible.

E. Patient Medication Record (PMR). After a comprehensive MTM, patients should be provided with PMR containing list of all of their medications, doses, directions, indications, any precautions, and start/stop dates. The patients should be instructed to present their PMR to all health care providers. The pharmacist should assist the patients in updating their PMR regularly and upon changes to the patient's regimen.

F. Documentation is an essential function of the MTM process. The age-old adage "if it's not documented, then it wasn't done" remains true.

    1. Pharmacist should maintain MTM files for their patients that include their interview notes, medication therapy review workup, the therapeutic plan, and follow-up care. In addition, separate paperwork may be needed and should be maintained for billing.

    2. Since 2006, both pharmacies and pharmacists must have a national provider identifier number (NPI#) to bill for clinical services. Pharmacists can obtain their NPI# from the National Plan & Provider Enumeration System at https://nppes.cms.hhs.gov/NPPES/Welcome.do.

    3. Current procedural technology (CPT) codes are commonly used for billing by health care professionals for patient care. There are three CPT codes for MTMS (*Table 60-4*).[11] These HIPAA-compliant codes may be used when billing third-party payers for services; however, the billing codes

Table 60-4   CURRENT PROCEDURAL TECHNOLOGY (CPT) CODES FOR MEDICATION THERAPY MANAGEMENT (MTM)[11]

	Definition of CPT Codes
99605	MTM service(s) provided by pharmacist, individual, face-to-face with patient, initial 15 mins, with assessment, and intervention if provided; initial 15 mins, new patient
99606	Initial 15 mins, established patient
99607	Each additional 15 mins (list separately in addition to code for the primary service). (Use 99607 in conjunction with 99605 and 99606.)

Table 60-5	MEDICARE PART D FIVE CORE COMPONENTS OF MEDICATION THERAPY MANAGEMENT[12]

MTM Core Components

Medication therapy review (MTR)
Personal medication record (PMR)
Medication action plan (MAP)
Intervention and referral
Documentation and follow-up

do not guarantee coverage, and hence payment, for services rendered. Therefore, patients need to be informed of the fees for MTMS prior to the provision of care.

4. For Medicare Part D, the MMA and CMS mandate that MTM be provided for eligible beneficiaries, but the decision for how MTM will be provided is left to the PDPs. Some Medicare Part D PDPs have contracted with specific MTM online services, such as Mirixa and Outcomes Pharmaceutical Health Care. Pharmacists conducting MTM for beneficiaries of these PDPs must complete training on how to document and bill with these specific platforms.

G. **Medicare Part D core components for MTMS.** Pharmacists may offer many services within the framework of the essential components noted earlier. MTM through Medicare Part D requires five core components (*Table 60-5*).[12]

Study Questions

Choose the best answer for questions 1-5.

1. In the provision and billing of MTM services for a Medicare Part D patient, the pharmacist must complete:
    I. a comprehensive medication review.
    II. a personal medication record.
    III. a medication action plan.

    (A) **I** only
    (B) **III** only
    (C) **I** and **II** only
    (D) **II** and **III** only
    (E) **I, II,** and **III**

2. Mrs. Smith has recently been diagnosed with hypertension and hypercholesterolemia. She presents to your pharmacy today with new prescriptions for hydrochlorothiazide and simvastatin. When she picks up her medications, she asks to speak with the pharmacist. She asks several questions about her new regimen and inquires about how she can check her own blood pressure. According to the transtheoretical model for behavioral change, what stage is Mrs. Smith?

    (A) Precontemplation
    (B) Contemplation
    (C) Preparation
    (D) Action
    (E) Maintenance

3. Which of the following are forms of active listening interview techniques?
    I. Restoration
    II. Facilitation
    III. Silence

    (A) **I** only
    (B) **I** and **II** only
    (C) **I** and **III** only
    (D) **II** and **III** only
    (E) **I, II,** and **III**

4. The documentation of your recommendation for the patient to have a follow-up A1c obtained in 3 months should be noted in which section of a SOAP note?

    (A) Subjective
    (B) Objective
    (C) Observations
    (D) Assessment
    (E) Plan

5. Pharmacists who bill Medicare for MTM services must have a:
    I. pharmacist license.
    II. national provider identifier number.
    III. medication appropriateness index number.

    (A) **I** only
    (B) **I** and **II** only
    (C) **I** and **III** only
    (D) **II** and **III** only
    (E) **I, II,** and **III** only

Answers and Explanations

1. **The answer is E** *[see III.G; Table 60-5].*
    The provision of MTM for Medicare Part D must include the five core components of MTM. A comprehensive medication review, personal medication record for the patient, and a patient-centric medication action plan represent three of the five core components. The remaining two are intervention and referral and documentation and follow-up.

2. **The answer is C** *[see III.A.4; Table 60-1].*
    The patient is preparing to take action toward changing her personal care of her hypertension and hypercholesterolemia by seeking medical attention, picking up her new prescriptions, asking for information from the pharmacist, and showing interest in wanting to learn to self-monitor. This is the stage preparation instead of action because the patient has not yet implemented the changes in her personal care.

3. The answer is D *[see III.B.2.k; Table 60-2]*.

Facilitation and silence are well-recognized methods of utilizing active listening within a patient interview. Restoration is not one of the active listening skills. The remaining active listening skills are interpretation, reflection, clarification, empathy, and confrontation.

4. The answer is E *[see III.D.4; Table 60-3]*.

When using a SOAP format for documentation, all recommendations, including follow-up lab work, should be noted in the plan (P) section of the SOAP note. The sections of a SOAP note are subjective, objective, assessment, and plan. Observation is not a section.

5. The answer is B *[see III.F.2]*.

Since 2006 under the Medicare Modernization Act of 2003, licensed pharmacists can bill for MTMS provided to patients. Pharmacists need a national provider identifier number (NPI#).

61 Adverse Drug Reaction Reporting

BARBARA SZYMUSIAK-MUTNICK

I. INTRODUCTION. The Institute of Medicine reported in July 2006 that an estimated 1.5 million injuries occur each year as a result of medication errors and between 44,000 and 98,000 people die from medication errors annually. Other studies estimate as many as 225,000 deaths occur annually from medication errors, which makes it the third leading cause of death in the United States following heart disease and cancer. The cost of morbidity and mortality owing to drug-related adverse events in hospitalized patients was recently estimated to be at least $3.5 billion annually. There are an estimated 3 million hospital admissions each year caused by the misuse of pharmaceuticals. The suffering that patients experience because of drug-related events cannot be quantified.

Adverse drug reactions (ADRs) are a cause of significant morbidity and mortality in patients in all areas of health care today. There is wide variation in the current health care literature, but it has been estimated that from one-third to as high as one-half of ADRs are believed to be preventable.

II. DEFINITIONS. The terms *adverse drug reaction*, *adverse drug event*, *untoward drug reaction*, *drug misadventure*, *side effect*, *medication errors*, *misuse of pharmaceuticals*, and *drug-related problem* are many times used interchangeably but do not always describe the same situation.

    A. The National Coordinating Council for Medication Error Reporting and Prevention states "A medication error is any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the health care professionals, patient, or consumer. Such events may be related to professional practice, health care products, procedures, and systems, including prescribing; order communication; product labeling, packaging, and nomenclature; compounding; dispensing; distribution; administration; education; monitoring; and use."[1]

    B. The U.S. Food and Drug Administration's (FDA) definition of an **adverse event** is "Any untoward medical occurrence in a patient or clinical investigation subject administered a pharmaceutical product and which does not have to have a casual relationship with this treatment."[2]

    C. Adverse drug reaction is defined by the World Health Organization (WHO) as "one which is noxious and unintended, and which occurs at doses normally used in man for the prophylaxis, diagnosis, or therapy of disease, or for the modification of physiological function."[3]

III. TYPES OF ADVERSE DRUG REACTIONS

    A. Type A

        1. Type A reactions are extensions of the drug's known pharmacology and are responsible for the majority of ADRs.

---

[1] http://www.nccmerp.org/aboutMedErrors.html

[2] http://www.fda.gov/downloads/Drugs/GuidanceComplianceRegulatoryInformation/Guidance/UCM073087.pdf

[3] http://www.who.int/mediacentre/factsheets/fs293/en/

2. Type A reactions are usually dose dependent and predictable but can be the result of concomitant disease states, drug–drug interactions, or drug–food interactions.

3. Ways to minimize type A reactions include understanding the pharmacology of the drug being prescribed, monitoring drugs with a narrow therapeutic index, and avoiding polypharmacy when possible.

B. Type B

1. Type B reactions include idiosyncratic reactions, immunological or allergic reactions, and carcinogenic/teratogenic reactions.

2. Type B reactions are usually not the result of a known pharmacology of the drug but seem to be a function of patient susceptibility. They are rarely predictable, are usually not dose dependent, and seem to concentrate in certain body systems such as the liver, blood, skin, kidney, and nervous system.

3. Type B reactions are uncommon but are generally serious and can be life threatening.

4. Except for immediate hypersensitivity reactions, type B reactions may take as long as 5 days before the patient demonstrates hypersensitivity to a drug. There is no maximum time for the occurrence of a reaction, but most occur within 12 weeks of initiation of therapy.

IV. RECOGNITION

A. Drugs must always be considered as a possible cause of disease or symptoms that are among a patient's list of complaints. Complete drug histories, including nonprescription drugs, must be carried out.

B. Recognition is often subjective, and it is not always possible to demonstrate strong causality between the drug and the occurrence.

1. Several factors may help in assessing the determination of causality.

a. Did the patient actually ingest the drug in question?

b. Did the onset of symptoms occur after the drug was taken?

c. What is the time interval between taking the drug and the onset of symptoms?

d. Did the symptoms resolve or improve after the drug was stopped or the dose decreased?

e. Did the symptoms reoccur after the drug was reintroduced?

f. Did drug–drug interactions contribute to the symptoms?

g. Were the drugs measured in "toxic levels" in the patient's serum?

h. Has this reaction been previously seen with use of the drug?

i. What is the personal experience of the clinician with previous use of the drug and reactions secondary to the drug?

2. Nomograms have been developed to aid in the assessment of causality.

V. SURVEILLANCE PROGRAMS. Pharmacists as well as all health care professionals should take an active role in monitoring, reporting, and trending ADR information. Some of the activities involved in a concurrent and ongoing ADR surveillance program at an institutional level include the following components:

A. Pharmacy departments should take the lead in the collection of information and should submit all reviews and reports to the pharmacy and therapeutics committees for review and evaluation.

1. Encourage all health care professionals to be involved in reporting.

2. Monitor patients who are using high-risk agents.

3. Review patients who have received "antidote"-type drugs.

4. Notify prescribers of suspected ADRs, and encourage thorough documentation of the description of the reaction as well as the outcome in patients' medical records.

5. Report appropriately identified ADRs to the FDA.

6. Develop the use of pharmacy computer systems to track ADRs.

B. Evaluation of the causes of ADRs should be carried out. ADR report information should be used for educational purposes and identification of drug use and medication use processes to prevent further occurrences of such reactions. ADR reporting information should be incorporated into institutional risk management programs.

VI. REPORTING TO THE FDA. Three of the five major centers at the FDA are involved with evaluating the safety and efficacy of drugs. The largest center is the Center for Drug Evaluation and Research (CDER), which oversees both prescription and nonprescription/over-the-counter (OTC) drugs. In 2002, CDER established the Adverse Events Reporting System (AERS), a computerized database designed to support the FDA's postmarketing safety program for drugs and therapeutic biologic products. Annually, the AERS receives about 500,000 reports of adverse experiences possibly associated with drugs. The Center for Biological Evaluation and Research (CBER) ensures the safety and efficacy of blood products, vaccines, allergenics, biological therapeutics, gene therapy, medical devices and tests, xenotransplantation products, and banked human tissue and cellular products. The Center for Food Safety and Applied Nutrition (CFSAN) established the CFSAN Adverse Events Reporting System (CAERS) in 2002. The CAERS provides a monitoring system to identify potentially serious problems secondary to non–FDA-approved herbs, minerals, vitamins, dietary supplements, and other substances.

A. The national **Vaccine Adverse Event Reporting System** (VAERS) is coadministered by the FDA and the Centers for Disease Control and Prevention (CDC). More than 10 million vaccines are given to children who are younger than 1 year of age and many million more doses to adults each year. Although vaccines protect many people from dangerous diseases, they do have the potential to cause adverse effects. Approximately 15% of events reported to the VAERS are considered "more serious" and include those that require hospitalization, are life-threatening events, and cause death.

1. The National Childhood Vaccine Injury Act (NCVIA) requires health professionals to report

   a. Adverse events after the administration of vaccines specified in the act, as described in the "Reportable Events Table," within the specified period (available at http://www.vaers.hhs.gov/reportable.htm or 1-800-822-7967)

   b. Any event listed in the manufacturer's package insert as a contraindication to subsequent doses of the vaccine

2. In 1990, VAERS was set up to receive all reports of suspected adverse events caused by any U.S. licensed vaccine. Information on reporting online, by fax, or mail can be viewed at http://vaers.hhs.gov/esub/index.

3. The VAERS depends on voluntary reporting by health professionals to

   a. Identify rare adverse reactions not detected in prelicensing studies

   b. Monitor for increases in already known reactions

   c. Identify risk factors or preexisting conditions that promote reactions

   d. Identify particular vaccine lots with unusually high rates or unusual types of events

B. **MedWatch**, the FDA's Safety Information and Adverse Event Reporting Program established in 1993, is a voluntary system for health care providers using Form FDA 3500, which is available at http://www.accessdata.fda.gov/scripts/medwatch/. However, manufacturers and distributors of FDA-approved drugs, biologics, radiation-emitting devices, special nutritional products, dietary supplements, infant formulas, and devices are mandated to report problems to the FDA. The goals of the program are to increase awareness of reporting of medical-product–induced diseases and the importance of reporting, to clarify what should be reported, to make reporting as easy as possible, and to provide feedback to health professionals.

1. Importance of reporting

   a. The incidence of ADRs occurs at a high rate in health care today.

      (1) Generally, it is reported that 3% to 11% of all hospital admissions can be attributable to ADRs, although some studies report the figure to be as high as 29%.

      (2) The likelihood that a patient will experience an ADR while hospitalized is reported in the literature to be in a range from 5% to 25%.

   b. Prevention of ADRs is an important strategy in health care. It has been further noted that preventable ADRs tend to be the most costly to treat and cause the greatest degree of patient morbidity.

      (1) Future ADRs can be prevented in individual patients by careful and consistent documentation in patient records.

      (2) A program that tracks ADRs can help discover previously unidentified trends. These trends can be used within the institution to develop programs of prospective intervention to prevent reoccurrence of the reaction in the patient populations that are at similar risk.

    c. Recognition of previously undiscovered ADRs attributable to a drug is particularly true in the case of newly marketed products.

        (1) Although clinical trials are generally effective in assessing efficacy and risk to benefit ratio, inherent limitations exist in premarketing trials.

            (a) The trials are usually relatively short in duration and do not effectively mimic the exposure patients would experience if using the drug as a chronically administered agent.

            (b) Drug–drug interactions and use in patients with concomitant disease states may not be tested for in these trials.

            (c) The small size of the trials may be insufficient to detect rarely occurring adverse reactions.

            (d) Age, racial, and ethnic groups may not be participating in the same numbers as represented in the general population.

    d. Prompt recall in cases of product problems are accomplished when the MedWatch Program is used to report product problems or device defects.

2. What should be reported?

    a. ADRs that are serious, even if causality is not proven, including

        (1) A patient's death that is suspected of being a direct outcome of an ADR

        (2) A life-threatening event

        (3) An initial or prolonged hospitalization

        (4) A significant, persistent, or permanent change or disability/incapacity

        (5) A congenital anomaly (including those occurring in a fetus)

        (6) Other problems that are not listed in the manufacturer's package insert as a known side effect, especially those that may jeopardize the patient and require medical or surgical intervention.

    b. Product problems that can result in compromised safety or quality, including product contamination, mislabeling, unclear labeling, poor packaging, potency problems, and questionable stability

    c. Counterfeit or suspected counterfeit drugs

    d. Adverse events owing to blood products, allergenics, gene therapy, human tissue and cellular products, and xenotransplantation products

    e. Medication errors

    f. Adverse events with food, herbs, vitamins, cosmetics, or dietary supplements, although CAERS is the preferred reporting system

    g. Malfunctioning medical devices such as heart valves, latex gloves, dialysis machines, and ventilators and problems with nutritional products or use of a medical product that required surgical or medical intervention to prevent permanent damage to a body function or structure

3. Confidentiality of both the reporter and the patients whose cases are reported are substantially protected by the FDA. The Health Insurance Portability and Accountability Act (HIPAA) Privacy Rule is not intended to disrupt or discourage ADR reporting in any way. The rule specifically permits covered entities, such as pharmacists, physicians, or hospital representatives, to report adverse and other quality-related events. Accordingly, the HIPAA Privacy Rule permits covered entities to disclose protected health information without authorization for specified public health purposes.

4. Reporting of problems with OTC medications are required when the product has been marketed with a new drug application (NDA), including drugs formerly marketed as prescription-only drugs. OTC products marketed without an NDA do not require reporting, but reporting is strongly encouraged. Approval of the FDA is not required for the marketing of nonprescription herbs, minerals, vitamins, dietary supplements, and other substances. Because the FDA does not approve these substances, efficacy and safety do not have to be demonstrated, nor is it mandated to report problems to the FDA.

5. Reporting to manufacturers is not described in the FDA's guidelines, although a section of the MedWatch form can be checked off to inform the FDA that a copy of the report has been forwarded to the manufacturer by the reporter.

C. Information on previously reported events can be found on the FDA Web site that provides online safety information at http://www.fda.gov/medwatch/safety.htm.

VII. AMERICAN SOCIETY OF HEALTH-SYSTEMS PHARMACISTS (ASHP) GUIDELINES.
ASHP encourage reporting of serious or unexpected ADRs to the FDA, the manufacturer, or both.

VIII. THE JOINT COMMISSION.
The Joint Commission requirements for accreditation describe the need for each health care organization to monitor for adverse events involving drugs and devices in a continual, collaborative fashion.

IX. UNITED STATES PHARMACOPEIA (USP).
MEDMARX and the Medication Errors Reporting Program at the USP Institute for Safe Medication Practices (ISMP) Medication Errors Reporting Program is now reported to Quantros MEDMARX at http://www.quantros.com/medmarx.htm.

For MER information, contact ISMP at http://www.ismp.org or 1-800-324-5723.

X. FURTHER INFORMATION

A. Information about the MedWatch program can be obtained by phone at 1-800-FDA-1088 and at http://www.fda.gov/Medwatch/.

B. Information about VAERS can be obtained by phone at 1-800-822-7967 and at http://www.fda.gov/cber/vaers/vaers.htm.

C. Information about reporting to the CFSAN program can be obtained by phone at (1-888-SAFE-FOOD) or at http://www.cfsan.fda.gov.

D. Further information about the FDA's reporting systems and programs, such as CDER, can be found on the FDA's Web site (http://www.fda.gov).

Study Questions

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. The phrase "one which is noxious and unintended, and which occurs at doses normally used in man for the prophylaxis, diagnosis, or therapy of disease, or for the modification of physiological function," describes

   (A) a side effect.
   (B) an adverse drug reaction.
   (C) an adverse drug event.
   (D) a medication error.
   (E) prescribing error.

2. Type A reactions are characterized by which of the following?

   (A) Idiosyncratic reactions
   (B) A function of patient susceptibility
   (C) Caused by drug–drug interactions
   (D) Permanent medical complication
   (E) Death

3. The MedWatch form is *not* the appropriate form to report which of the following events?

   (A) A vaccine event described in the Vaccine Adverse Event Reporting System (VAERS) "Reportable Events Table"
   (B) A suspected counterfeit drug
   (C) A malfunctioning ventilator
   (D) A drug that is contained in a package with unclear labeling
   (E) An adverse reaction resulting in patient death

4. Type B adverse drug reactions are

   (A) generally serious and can be life threatening.
   (B) a result of the known pharmacology of the drug.
   (C) usually predictable.
   (D) responsible for the majority of ADRs.
   (E) usually dose dependent.

5. HIPPA rules require the following before reports are submitted to the FDA.

   (A) Written permission of the patient
   (B) Written permission of the patient's attending physician
   (C) Written permission of the patient and the patient's attending physician
   (D) Written permission from the medical records department
   (E) Reports can be submitted without authorization of the patient or health care providers

6. Reasons for close scrutiny of previously unreported ADRs in newly marketed drugs are based on all of the following concerns except:

   (A) Premarketing clinical trials may have a small number of subjects.
   (B) Groups based on age, race, and ethnicity may not be represented in the same proportion in study groups as in the general population.
   (C) ADRs that have been reported in premarketing trials are not included as part of the FDA surveillance of events in the voluntary reporting system.
   (D) Trials are relatively short in duration.
   (E) Trials may not effectively test medications that will be chronically administered agents.

Answers and Explanations

1. **The answer is B** *[see II.C]*.
   This is the definition from the WHO.

2. **The answer is C** *[see III.A.2]*.
   Type A reactions can be caused by drug–drug interactions. Idiosyncratic reactions and reactions caused by patient susceptibility are generally in the classification of type B reactions.

3. **The answer is A** *[see VI.A.1]*.
   All the others are reportable on the MedWatch form. The National Childhood Vaccine Injury Act requires the use of a VAERS form to report vaccine-related injuries.

4. **The answer is A** *[see III.A; III.B]*.
   The other answers describe type A reactions.

5. **The answer is E** *[see VI.B.3]*.
   The Health Insurance Portability and Accountability Act (HIPAA) Rule permits covered entities to disclose protected health information without authorization for specified public health purposes.

6. **The correct answer is C** *[see VI.B.c.1]*.

62 Medication Errors

ROBERT CISNEROS

I. MEDICATION ERROR PROBLEM

A. The 2000 Institute of Medicine (IOM) report *To Err Is Human* brought the problem of errors in medicine to national attention.[1]

1. An estimated 44,000 to 98,000 **deaths per year** are caused by medical errors. **Of those deaths**, approximately 7000 are the result of medication errors.

2. A call to action was given to improve patient safety.

B. In recent years, tragic medication errors have focused attention on concerns regarding patient safety.

1. A chemotherapy mix-up at a major cancer center resulted in the death of a patient from a **four-fold overdose** daily for 4 days.

2. A child accidentally received an **intravenous rather than intramuscular** dose of long-acting penicillin and died.

3. A compounding error resulted in death of a child who received a tricyclic antidepressant at a dose **10 times greater than the dose prescribed** by physician.

4. Mix-ups with heparin vials that had **similar packaging, but different concentrations**, resulted in **overdoses** causing serious injury and several infant deaths.

II. ERROR DEFINITION.

The National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP) defines a medication error as follows: "A medication error is any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the health care professional, patient, or consumer. Such events may be related to professional practice, health care products, procedures, and systems, including prescribing; order communication; product labeling, packaging, and nomenclature; compounding; dispensing; distribution; administration; education; monitoring; and use."[2]

III. TYPES OF ERRORS.

The following categories of errors have been used in numerous research studies.[3]

A. **Wrong drug error.** A drug that was not ordered for a patient was administered—for example, a patient accidentally received furosemide 40 mg orally. Possible causes: The pharmacist accidentally filled the patient's prescription for an antibiotic with furosemide; the pharmacist reached for the wrong bottle on the shelf and did not check the label carefully enough.

B. **Extra dose error.** A patient receives more doses of a drug than were ordered—for example, a patient was supposed to receive a medication with breakfast for 3 days but received it for 5 days. Possible cause: The patient's nurse was confused by the medication directions.

C. **Omission error.** A dose of a drug was not administered as ordered but was skipped—for example, a patient was supposed to receive digoxin 0.25 mg orally in the morning but did not receive the dose. Possible cause: The patient's nurse was so busy that he or she forgot to administer the dose.

---

[1]Kohn LT, Corrigan JM, Donaldson MDS, et al., eds. *To Err Is Human: Building a Safer Health System.* Washington, DC: National Academy Press; 2000.

[2]NCCMERP, "What Is a Medication Error," available at http://www.nccmerp.org/aboutMedErrors.html.

[3]Cohen MR, ed. *Medication Errors.* Washington, DC: American Pharmaceutical Association; 1999.

D. **Wrong dose or wrong strength error.** Either the wrong dose of a medicine or the wrong strength is administered—for example, the patient was supposed to receive warfarin 0.5 mg but received warfarin 5 mg instead. Possible causes: The pharmacist misread the label; the physician wrote the order as "warfarin .5 mg." Another example: A patient was supposed to receive timolol 0.25% but was given timolol 0.5%. Possible cause: The pharmacist took the wrong product off the shelf, confused by the concentrations.

E. **Wrong route error.** A patient receives a dose of a medication by a route that was not ordered by the physician—for example, a patient was supposed to receive prochlorperazine 10 mg intramuscularly but the drug was administered intravenously. Possible causes: The nurse misread the orders; the physician mistakenly wrote "IV" instead of "IM."

F. **Wrong time error.** A patient does not receive a dose of medication at the time at which it was to be administered—for example, a hospitalized patient with diabetes is scheduled to receive a dose of insulin immediately before breakfast (at 7:00 A.M.), but the dose is given 2 hrs after breakfast. Possible cause: The nurse was busy and could not give dose on time.

G. **Wrong dosage form error.** A patient receives a dose of medicine in a dosage form that was not intended—for example, nicotinic acid 500 mg tablets were ordered for a patient who instead receives nicotinic acid 500 mg slow-release capsules. Possible cause: The pharmacist did not carefully check the product or was confused by the label.

H. **Other.** Errors that do not fit into any of the other categories.

IV. COMMON ERROR HAZARDS

A. **Dangerous abbreviations**. Numerous common abbreviations and symbols have been associated with errors. Detailed lists are available from the Institute for Safe Medication Practices (ISMP) at http://www.ismp.org/tools/errorproneabbreviations.pdf and The Joint Commission at http://www .jointcommission.org/assets/1/18/official_do_not_use_list_6_111.pdf. JCAHO's accredited organizations are required to avoid using the potentially confusing abbreviations on its "do not use" list.

   1. **U, IU: unit(s).** The letter *U* can easily be misinterpreted as a number (e.g., 0 or 4), and serious harm has occurred with insulin and heparin as a result of this confusion. For example, a patient received 66 units of insulin instead of 6 units. The order, which was written for "6U" of regular insulin, was misread as 66. The word *units* should be written out in full.

   2. **QD, Q.D., qd, q.d. (daily).** These common abbreviations have been misinterpreted as "QID" or "qid" (four times daily) resulting in overdoses. The word *daily* should be written out in full.

   3. **Q.O.D, QOD, qod (every other day).** These common abbreviations have been misinterpreted as QID (four times daily), resulting in overdoses. The words *every other day* should be written out completely.

   4. **Trailing zero.** When a dose is ordered and followed with a decimal point and a zero, such as 2.0 mg or 25.0 mg, errors can occur. The decimal point may be missed and an overdose can occur. For example, warfarin 2.0 mg may be misinterpreted as 20 mg. Trailing zeros should be avoided, and the dose written without the additional zero—for example, warfarin 2 mg (instead of 2.0 mg).

   5. **Lack of leading zero.** A drug's dose may be less than 1 mg, such as for digoxin. Often the dose is written without a leading zero: digoxin .25 mg instead of digoxin 0.25 mg. Errors have occurred because the decimal point is missed—for example, warfarin .5 mg may be interpreted as warfarin 5 mg. Leading zeroes should be included, so the dose is written as digoxin 0.25 mg or warfarin 0.5mg.

   6. **MS, MSO$_4$ (morphine sulfate), MgSO$_4$ (magnesium sulfate).** The abbreviations for morphine sulfate and magnesium sulfate are quite similar and can be confused. It is recommended that *morphine sulfate* and *magnesium sulfate* be written out in full.

B. **Other confusing symbols and abbreviations.** There are numerous other hazardous symbols and abbreviations that should be used with caution when writing prescription orders and carefully examined when filling prescriptions. Examples include the following:

   1. **cc.** Stands for cubic centimeters and is often used instead of mL. This has been misinterpreted as a 0 (zero); use mL.

   2. **μg.** Used for micrograms—for example, levothyroxine 250 μg daily. The abbreviation has been mistaken for mg, and overdoses have occurred; better to use mcg or to write out the word *micrograms*.

   3. **<, >.** Symbols for less than (<) and greater than (>) have been mistaken for each other or misinterpreted as numbers. Better to write out the words *less than* or *greater than*.

4. **HCT.** This abbreviation for "hydrocortisone" has been misinterpreted as hydrochlorothiazide. Better to write out the word completely.

5. **HCl.** The abbreviation for "hydrochloric acid" has been misinterpreted as KCl (potassium chloride). Better to write out the words completely.

C. **Sound-a-like or look-a-like drug names.** The ISMP has a list of confusing drug names available at http://www.ismp.org/Tools/confuseddrugnames.pdf.

   1. Examples include the following:
      a. Amitriptyline and aminophylline
      b. Cisplatin and carboplatin
      c. K-Dur and Cardura

   2. To avoid these problems, the ISMP offers several suggestions, including the use of computerized reminders, name alert stickers, and independent checks; opening the bottle in front of the patient, who can confirm the appearance; and reporting errors.

D. **High-risk drugs.** Certain **potent drugs** have been implicated in many serious and tragic medication errors. These have been called high-risk or high-alert drugs. A list of such medications can be found at http://www.ismp.org/Tools/highalertmedications.pdf. Examples include the following:

   1. **Blood-modifying agents such as heparin and warfarin.** Errors have resulted in serious injury or death from hemorrhaging as a result of overdose (patient receiving 10 mg instead of 1 mg) or from blood clots as a result of underdose (patient receiving 0.5 mg instead of 5 mg).

   2. **Narcotics and sedatives.** Central nervous system depression and respiratory arrest have resulted from errors with these drugs, such as diazepam 25 mg given intravenously instead of 2.5 mg.

   3. **Neuromuscular paralyzing agents such as succinylcholine and vecuronium.** Accidental use or inadvertent use before adequate ventilation procedures were started has resulted in respiratory arrest and death.

   4. **Chemotherapy drugs.** These drugs are associated with potent adverse effects, affecting numerous body systems, such as the immune, neurologic, and clotting systems. Deaths have occurred as a result of errors with these products. For example, vincristine was accidentally given to a child instead of vinblastine, resulting in death. Confusion over the dosing of cyclophosphamide resulted in a fatal fourfold overdose.

V. SEVERAL SAFETY TECHNIQUES OBSERVED IN COMMUNITY PHARMACIES[4]

A. Keep work procedures organized and simplified.

B. Do not work on several prescriptions at once, just one at a time.

C. Manage interruptions, do not be pressured to rush.

D. Smell check.

E. Bar code check.

F. Use a magnifying glass when needed.

G. Enhance the design of the facility.

VI. ROOT CAUSE ANALYSIS (RCA).
This is a structured process for identifying direct and indirect factors that contributed to a medication error. The Joint Commission presents a "Framework for Conducting an RCA and Action Plan" that can be downloaded at http://www.jointcommission.org/Framework_for_Conducting_a_Root_Cause_Analysis_and_Action_Plan/.

A. Important questions to ask:

   1. What happened and why?

   2. What were the contributing factors?
      a. Age? Hours worked? Staffing?
      b. Workload? Stress? Confusing names? Location on shelf?
      c. Inadequate information? Communication?
      d. Inadequate equipment?

---

[4]Flynn EA, Barker KN, Carnahan BJ. National observational study of prescription dispensing accuracy and safety in 50 pharmacies. *J Am Pharm Assoc.* 2003;43(2):191–200.

  e. Workplace atmosphere conducive to safety?

  f. Inadequate training of pharmacist or technician?

B. Latent defect. A **weakness in a system** that does not immediately result in an error but, under the right set of circumstances, can contribute to a mistake. For example:

 1. Stocking look-alike or sound-alike drugs next to each other, contributing to a pharmacist incorrectly filling a prescription

 2. Inadequate training of employees, contributing to an error in which an automated dispensing machine was used improperly and a patient received the wrong medication

VII. NATIONAL SAFETY EFFORTS

A. The Joint Commission's current National Patient Safety Goals for Accredited Organizations can be found at http://www.jointcommission.org/mobile/standards_information/national_patient_safety _goals.aspx. Hospital goals include:

 1. Improve the accuracy of patient identification. Have two means of identifying the patient other than room number.

 2. Improve communication among caregivers. Verify and read back telephone and oral orders.

 3. Create a list of "do not use" abbreviations. Standardize the abbreviations used, and prohibit the use of those that are prone to confusion and misinterpretation.

 4. Improve the safe use of medicines.

  a. Limit the number of different concentrations available per drug product; standardize.

  b. Develop methods of identifying and reviewing sound-alike and look-alike drugs, preventing errors with them.

  c. All medications and containers should be properly labeled.

  d. Reduce the likelihood of patient harm associated with the use of anticoagulation therapy.

 5. Reduce the risk of infections.

  a. Comply with all Centers for Disease Control and Prevention (CDC) recommendations for hand washing and hygiene.

  b. Thoroughly investigate all serious adverse events and deaths associated with infection acquired in a health care setting.

 6. Keep accurate patient medication records and histories throughout the continuum of care.

  a. Ensure that a patient's medication records are complete and accurate when he or she is referred or transferred within or between organizations.

  b. Proper communication of accurate patient medication information is critical for everyone involved in the patient's care.

B. The *5 Million Lives Campaign* initiated by the Institute for Healthcare Improvement can be found at http://www.ihi.org/IHI/Programs/Campaign.

 1. Purpose: "To protect patients from **five million incidents of medical harm** over the next two years (December, 2006 to December, 2008)."

 2. Twelve interventions were identified and can be found described in more detail at the aforementioned Web site. The interventions included:

  a. Preventing **adverse drug events** through **medication reconciliation**

  b. Preventing **surgical site infections** by **appropriate care and antibiotic use**

  c. Focusing on preventing harm from **high-risk medications** such as anticoagulants, sedatives, narcotics, and insulin

  d. Reducing **methicillin-resistant *Staphylococcus aureus* (MSRA) infections** through appropriate **evidence-based practices**

C. The IOM in July 2006 released its report "Preventing Medication Errors." Several recommendations were made to improve patient safety including enhancing role of patient in medication management, improving patient education, and increasing the use of technology, such as e-prescribing. This report can be accessed at http://www.iom.edu by searching for "Preventing Medication Errors."

D. Medication error reporting. The reporting of medication errors provides critical safety feedback. The ISMP Medication Error Reporting Program (MERP) provides an online, confidential means of error reporting. According to the ISMP, the inclusion of the reporter's identity and location is optional. The information is shared with the FDA's MedWatch program as well as with the manufacturer/labeler. The Web site is located at https://www.ismp.org/orderforms/reporterrortoismp.asp.

E. The Sorry Works Coalition (http://www.sorryworks.net) is an organization of various individuals (health care professionals, lawyers, insurance executives, concerned citizens, etc.) who promote the necessity of **disclosure and apology** following error. The coalition provides training and education programs.

F. The Institute for Safe Medication Practices (http://www.ismp.org) focuses its efforts on **medication error prevention and patient safety**. The ISMP publishes four different safety newsletters, provides consulting services, and presents numerous educational programs, services, safety recommendations, and activities.

G. The National Patient Safety Foundation (http://www.npsf.org) represents **stakeholders from a broad array of disciplines**, including patients and families. The NPSF mission is focused on **improving patient safety**. It provides numerous resources, publications, and activities directed at improving the care of patients.

H. The Institute for Healthcare Improvement (IHI) has created the IHI "Open School" at http://www.ihi.org/offerings/IHIOpenSchool/Pages/default.aspx. Online modules regarding patient safety and quality assurance are available. Additional resources and material are provided. Student chapters of the Open School exist and information is provided on how to initiate these chapters.

Study Questions

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. A major result in the 2000 Institute of Medicine (IOM) report is that

   (A) pharmacists are not blamed for most medical errors.
   (B) surgeons make more mistakes than any other health professional.
   (C) pharmacists make more mistakes than any other health professional.
   (D) there is now more emphasis on error prevention.

2. A pharmacist is presented a prescription for 250 mcg of levothyroxine. Which of the following dosages would be equivalent to that amount?

   (A) 2.5 mg
   (B) 0.25 g
   (C) 0.25 mg
   (D) 25 g

3. A prescription is written for warfarin 1.0 mg. The community pharmacist accidentally dispenses 10 mg. The patient develops severe bleeding within 3 days and nearly dies. Which of the following is the most accurate assessment of this prescription?

   (A) A trailing zero is present in this prescription and could have contributed to the pharmacist's error.
   (B) This is an example of a leading zero, which contributed to the error and the patient tragedy.
   (C) Sound-alike medications contributed to this error.
   (D) This does not qualify as an error based on the National Coordinating Council for Medication Error Reporting and Prevention (NCCMERP) definition.

4. A hospital pharmacy begins stocking new intravenous mini-bags of a neuromuscular-blocking agent. The packaging is similar to a commonly used intravenous antibiotic. The addition of the new mini-bags was not widely communicated to all personnel. One weekend, several doses of this new product were accidentally dispensed in place of the intended doses of antibiotic. Several patients suffered respiratory arrest and one of the patients eventually died. What would a root cause analysis of this error find?

   (A) The only cause of this error was a pharmacist who was not paying attention. The pharmacist should be dismissed.
   (B) Poor communication practices is a latent defect in this pharmacy system and significantly contributed to the error.
   (C) The pharmacy technicians are to blame for this error, not the pharmacist, because the technicians obtained the mini-bags from stock and placed the labels on the bags. The pharmacist checked only the technician's work. The technician should be dismissed.
   (D) This is an example of an extra dose error.

5. What do the following abbreviations MS, MSO$_4$, and MgSO$_4$ have in common?

    (A) Common abbreviations for morphine sulfate
    (B) Common abbreviations for magnesium sulfate
    (C) Should not be used in the Joint Commission–accredited institutions
    (D) Approved abbreviations in most hospitals

6. A major error in a hospital pharmacy resulted in a total parenteral nutrition solution being mistaken for a cardioplegic solution for coronary bypass surgery. Which of the following is true regarding the root cause analysis that was done at the hospital after the error?

    (A) The primary objective is to find out which pharmacist made the mistake that allowed this to take place.
    (B) The result of the analysis would be the admission that an error had taken place.
    (C) All factors that could have contributed to this error would be identified and analyzed.
    (D) A root cause analysis would be inappropriate in this case.

Answers and Explanations

1. **The correct answer is D** *[see I.A.2]*.
    The IOM report revealed alarming data on deaths related to medical errors. The report contributed to increased efforts to improve patient safety.

2. **The correct answer is C** *[see III.D]*.
    Although this may seem to be an elementary question and answer, a wrong dose error such as this could easily lead to a serious injury or death to a patient.

3. **The correct answer is A** *[see IV.A.4]*.
    Warfarin 1.0 mg is an example of a trailing zero. The Joint Commission has included this in its "do not use" list of abbreviations. However, in the community setting, it is a practice that can still be frequently seen on prescriptions. When a trailing zero is observed, much caution should be exercised in interpreting the prescription.

4. **The correct answer is B** *[see VI.A.2]*.
    Poor communication was a major contributing factor to this tragic series of errors. The drug was a high-risk drug and had similar packaging as another commonly used drug. These are two major ingredients for the serious error that took place. This does not absolve the technician and pharmacist totally from any blame but emphasizes the significant role that failure of communication played within this pharmacy system. The system was as much or more to blame than any individuals. Firing the individuals does not repair the problem of poor communication in the system but only sets the stage for a similar mistake to occur again.

5. **The correct answer is C** *[see IV.A.6]*.
    These abbreviations are included in the Joint Commission's "do not use" list. Errors resulting in serious harm have occurred after mix-ups with morphine and magnesium.

6. **The correct answer is C** *[see VI.A.2]*.
    A root cause analysis is not intended to focus on blame but on all factors that could have been related to this error. Factors might have included training of pharmacist and technicians, the actual drug order, and the label. The contribution of such factors might not be discovered if the focus is on only identifying which pharmacist, technician, or other professional is to blame.

63 Federal Pharmacy Law

JAMES A. BOYD

I. FEDERAL CONTROLLED SUBSTANCES ACT

A. **Schedules of controlled substances.** Certain drugs have a potential for abuse that leads to physical or psychological dependence. As a result, the U.S. federal government has placed these drugs into Schedules (I, II, III, IV, and V) and refers to them as controlled substances. The Attorney General of the United States has the authority to add or remove a drug or substance from one of the federal Schedules, or to transfer a drug from one federal Schedule to another. The federal Schedules are updated and published annually by the federal government.

1. **Schedule I (CI; C-I).** Schedule I drugs may not be kept in a pharmacy nor dispensed pursuant to a prescription (except for properly registered facilities for investigative or research purposes). A controlled substance analogue of a drug in any Federal Schedule, commonly referred to as a "designer drug," is considered a Schedule I substance to the extent intended for human consumption. Required findings by the government for placement of a drug into Schedule I include:
   a. The drug or other substance has a high potential for abuse.
   b. The drug or other substance has no currently accepted medical use in treatment in the United States.
   c. There is a lack of accepted safety for use of the drug or other substance under medical supervision.

2. **Schedule II (CII; C-II).** Required findings for placement of a drug into Schedule II include:
   a. The drug or other substance has a high potential for abuse.
   b. The drug or other substance has a currently accepted medical use in treatment in the United States or a currently accepted medical use with severe restrictions.
   c. Abuse of the drug or other substance may lead to severe psychological or physical dependence.

3. **Schedule III (CIII; C-III).** Required findings for placement of a drug into Schedule III include:
   a. The drug or other substance has a potential for abuse less than the drugs or other substances in Schedules I and II.
   b. The drug or other substance has a currently accepted medical use in treatment in the United States.
   c. Abuse of the drug or other substance may lead to moderate or low physical dependence or high psychological dependence.

4. **Schedule IV (CIV; C-IV).** Required findings for placement of a drug into Schedule IV include:
   a. The drug or other substance has a low potential for abuse relative to the drugs or other substances in Schedule III.
   b. The drug or other substance has a currently accepted medical use in treatment in the United States.
   c. Abuse of the drug or other substance may lead to limited physical dependence or psychological dependence relative to the drugs or other substances in Schedule III.

5. **Schedule V (CV; C-V).** Required findings for placement of a drug into Schedule V include:
   a. The drug or other substance has a low potential for abuse relative to the drugs or other substances in Schedule IV.
   b. The drug or other substance has a currently accepted medical use in treatment in the United States.

    c. Abuse of the drug or other substance may lead to limited physical dependence or psychological dependence relative to the drugs or other substances in Schedule IV.

B. Registration requirements. The Federal Controlled Substances Act regulates the use of controlled substances by requiring all entities that lawfully handle them to register with the federal government, specifically, the Drug Enforcement Administration (DEA).

  1. Entities that must register

    a. Manufacturers and **wholesalers** of controlled substances must register with the DEA initially and reregister every year thereafter.

    b. Dispensers (practitioners and pharmacies) of controlled substances must register with the DEA initially and reregister every 3 years thereafter. Pharmacists, pharmacy interns, pharmacy technicians, and all other employees or agents of a pharmacy do not have to register, providing the pharmacy is properly registered and the employee or agent is acting in the usual course of employment or business.

    c. All other entities that lawfully handle any controlled substance must register with the DEA, including researchers, clinics and laboratories, and teaching institutions.

  2. Separate registration for separate activities. Every entity that engages in one of the following activities must register with the DEA. A separate registration is required for each activity, with certain exceptions (e.g., a manufacturer of a Schedule of a controlled substance is allowed to distribute that Schedule without being registered as a distributor).

    a. Manufacturing controlled substances

    b. Distributing controlled substances

    c. Dispensing controlled substances listed in Schedules II to V (e.g., practitioners, pharmacies)

    d. Conducting research with controlled substances listed in Schedules II to V

    e. Conducting instructional activities with controlled substances listed in Schedules II to V

    f. Conducting a narcotic treatment program using any narcotic drug listed in Schedules II, III, IV, or V

    g. Conducting research and instructional activities with controlled substances listed in Schedule I

    h. Conducting chemical analysis with controlled substances listed in any Schedule

    i. Importing controlled substances

    j. Exporting controlled substances

    k. Participating in maintenance or detoxification treatment and mixing, preparing, packaging, or changing the dosage form of a narcotic drug listed in Schedules II, III, IV, or V for use in maintenance or detoxification treatment by another narcotic treatment program.

  3. Separate registrations for separate locations. Each principal place of business of a registrant having more than one location must have its own registration certificate. Each pharmacy, chain pharmacy, and hospital that dispenses controlled substances must have its own registration certificate. Registration is not required for an office that is used by a registrant where controlled substances are neither stored nor dispensed.

    a. Warehouses. A warehouse where controlled substances are stored by or on behalf of a registrant is not required to register unless one of the following occurs:

      (1) Controlled substances are directly distributed from the warehouse to a registered location different from the location from which the substances were shipped.

      (2) Controlled substances are directly distributed from the warehouse to a person or entity not required to register under the Act.

  4. Registration procedure. Applications to become registered must be submitted to the DEA on the appropriate form with the required fee, information, and signature of one of the following:

    a. The individual who owns and operates the entity, if doing business as an individual.

    b. A partner of the applicant, if a partnership.

    c. An officer of the applicant, if a corporation, corporate division, association, trust, or other entity.

    d. One or more individuals who have been granted a power of attorney by an applicant. A **power of attorney** allows one to lawfully act in place of another. The power of attorney must be signed by one of the individuals listed previously in a to c and by the individual receiving the power of attorney. The power of attorney remains valid until revoked by the applicant.

5. **Registration action by the DEA.** If an application is complete, it will be accepted for filing. If it is defective, the DEA will return the application with a statement indicating the reason for its nonacceptance. The application may be corrected and resubmitted at any time.
   a. **Issuance of certificate of registration.** A certificate of registration will be issued by the DEA when it determines that the registration is required by law in order to conduct such activity (e.g., manufacturing, distributing, or dispensing a controlled substance). The certificate must be conspicuously maintained and readily retrievable at the registered location.
   b. **Denial of registration.** If the DEA determines that a registration is not required by law, it will issue an Order To Show Cause why the registration should not be denied. The applicant may request a hearing and explain why the certificate of registration should be issued. After the hearing, the DEA may deny the application or issue the certificate.
6. **Modification of registration.** A registrant may submit a letter of request to the DEA seeking to modify its registration. A modification may be sought when there is a change in the name or address that appears on the certificate, or when the pharmacy seeks DEA approval to dispense additional controlled substances (if initially authorized to only dispense a particular Schedule[s] of controlled substances).
7. **Transfer of registration.** A registration to dispense controlled substances may not be transferred to any other person or entity except when the ownership of a pharmacy is being transferred from one entity to another. In such a case, controlled substances in Schedules II to V must be properly disposed of or transferred to the new entity.
8. **Suspension or revocation of registration.** The DEA may suspend or revoke any registration. The DEA must first issue an Order To Show Cause (upon the registrant) why the registration should not be revoked or suspended. The registrant may request a hearing to explain why the registration should not be suspended or revoked. After a hearing, the DEA may suspend, revoke, or take no action on the registration.
   a. **Order of suspension or revocation.** After a registrant has received an order suspending or revoking its registration, it must take the following action:
      (1) Immediately deliver its certificate of registration and any DEA 222 order forms in its possession to the nearest office of the DEA.
      (2) As instructed by the DEA, either:
         (a) deliver all controlled substances in its possession to the nearest office of the DEA or to authorized agents of the DEA, or
         (b) place all controlled substances in its possession under seal.
   b. **Imminent danger to public health or safety.** The DEA may serve on a registrant an order of immediate suspension when it finds that there is an **imminent danger** to the **public health** or **safety**. The immediate suspension remains in effect until the conclusion of all proceedings, either administrative proceedings by the DEA or judicial proceedings. After receiving an order of immediate suspension, the registrant must take the same action as outlined previously under I.B.8.a.
9. **Exemptions from registration.** Certain individuals are exempt from registration under the Act. The following are exempt:
   a. **Military officials.** Military officials, including Public Health Service and Bureau of Prisons officials, who are authorized to prescribe, dispense, or administer, but not to procure or purchase, controlled substances in the course of their official duties, are exempt from registering with the DEA. The individual must, however, obtain a registration for such activities conducted during any separate private practice.
   b. **Law enforcement officials.** Federal and state law enforcement personnel acting in the course of enforcing any law relating to controlled substances are exempt from registration.
   c. **Civil defense officials.** Civil defense and disaster relief organization officials are exempt from registration in order to maintain and dispense controlled substances during times of proclaimed emergencies or disasters.
   d. **Agents and employees of registrants.** Agents and employees, while acting lawfully in the usual course of their business or employment, are exempt from registration when the business or employment is conducted on behalf of a person (or business) who is registered under the Act. Delivery personnel (e.g., United Parcel Service, Federal Express) are therefore not required to register. Likewise, pharmacists working for a registered pharmacy are not required to register.

10. **Termination of registration.** The registration of any person or entity will terminate when the person dies, ceases legal existence (e.g., corporate dissolution, partnership dissolution), or discontinues business or professional practice. The DEA must be notified promptly when any of these occurs. In such a case, all controlled substances in Schedules II to V must be properly disposed of.

C. **Required inventories.** The Act requires all pharmacies and hospitals (every separately registered location) to conduct an initial inventory and biennial inventory of all controlled substances in Schedules II, III, IV, and V.

1. **Initial inventory.** The initial inventory must be taken on the date the entity commences business and begins dispensing controlled substances. If the entity has no controlled substances on hand, a record of this fact must be maintained as its initial inventory.

2. **Biennial inventory.** The biennial inventory must be taken at least every 2 years from the date of the initial inventory.
    a. **Biennial date.** The biennial date may be **any** date that is within 2 years of the previous biennial (or initial) date. This date does **not** have to be reported to the DEA if it is different from the biennial date that would otherwise apply (i.e., on the exact day 2 years after the previous inventory).

3. **Inventory procedures**
    a. All inventories must be maintained in a **written**, **typewritten**, or **printed form** and be conducted at either the opening of business or the close of business on the inventory date (which must be noted on the inventory).
    b. **Separate inventory record for Schedule II controlled substances.** Because all records for Schedule II controlled substances must be maintained separately from other records, Schedule II inventories must be maintained separately from other controlled substance inventories.

4. **Inventory content.** All inventory records must contain the following:
    a. Date the inventory is taken.
    b. Each finished form of the substance (dosage form and strength).
    c. Number of units or volume of each finished form in each commercial container (e.g., 100-tablet bottle). For opened commercial containers, inventory must be taken as follows:
        (1) For Schedule II controlled substances, an exact count or measure must be taken.
        (2) For Schedule III, IV, and V controlled substances, an estimated count or measure may be taken, except that an exact count must be taken if the container holds more than 1000 tablets or capsules.
    d. For each controlled substance maintained for extemporaneous compounding, or for substances that are damaged, defective, or impure and awaiting disposal:
        (1) Name of the substance
        (2) Total quantity to the nearest metric unit weight or the total number of units of finished form
        (3) Reason the substance is being maintained and whether it is capable of use in the manufacture of any controlled substance in finished form

5. **Inventory record maintenance.** Every inventory record must be maintained at the registered location (e.g., pharmacy, hospital) for at least 2 years from the date of the inventory.
    a. Schedule II inventories must be maintained separately from all other records of the pharmacy.
    b. Schedule III to V inventory records must be maintained either separately from all other records of the pharmacy or in such a manner that the required information is readily retrievable from ordinary business records of the pharmacy. "Readily retrievable" means that the inventory records can be separated out from all other records in a reasonable time.

6. **Perpetual inventories.** The Act does not require a dispenser registrant (e.g., pharmacy, hospital) to maintain a perpetual inventory of any controlled substance.

7. **Newly controlled substances or changes in scheduling of a substance.** An inventory of a substance must be taken when, by order of the DEA, it becomes a newly controlled substance or it shifts into another Schedule. The inventory of that particular controlled substance must be taken on the effective date of the change. A complete inventory of all controlled substances is not required, nor is an inventory required when a substance moves from a controlled substance Schedule to a nonfederal Schedule.

8. **Transfer of business activity.** An inventory of controlled substances II to V must be taken at the time a pharmacy or hospital undergoes a change in ownership. The inventory must be taken on the date of transfer and serves as the final inventory of the transferor and the initial inventory of the transferee.

9. **Inventory record submission.** The Act does not require the submission of inventory records to anyone, including the DEA. The records must be maintained at the registered location for inspection and copying by authorized agents of the DEA.

D. **Obtaining controlled substances.** Schedule II controlled substances must be obtained from a supplier (wholesaler, manufacturer) by using DEA Form 222. The Act does not require the use of any special form to obtain controlled substances in Schedules III to V.

1. **DEA Form 222.** Only entities that are registered to dispense or handle Schedule II controlled substances may obtain Form 222. The forms are serially numbered and issued by the DEA with the name, address, registration number, authorized activity, and Schedules of the registrant. Each form contains an original, duplicate, and triplicate copy (Copy 1, Copy 2, and Copy 3, respectively).

   a. **Execution of Form 222.** Form 222 may be executed only on behalf of the registrant named on the form and only if the registration has not expired nor been revoked or suspended. The form must be prepared in triplicate as provided by the DEA by use of a typewriter, pen, or indelible pencil in the following manner:

      (1) Only one item may be ordered on each of the 10 numbered lines on the form. The total number of items ordered must be noted on the form in the space provided.

      (2) One item may consist of one or more commercial or bulk containers of a product. A separate item must be made for different commercial or bulk containers of a product. For each item, the form must contain the following information:

         (a) Name of the article ordered

         (b) Finished or bulk form of the product (dosage form and strength)

         (c) Number of units or volume in each commercial or bulk container (e.g., 100-tablet bottle)

         (d) Number of commercial or bulk containers ordered

         (e) If the article is not in pure form, the name and quantity per unit of the controlled substances contained in the article.

      (3) The supplier's name and address must be included on the form. Only one supplier may be listed on any one form.

      (4) Each form must include the date of the order, and no form is valid more than 60 days after its execution by the purchaser.

      (5) The form must be signed either by the person who signed the most recent application for registration or reregistration, or by a person authorized to obtain and execute order forms by a **power of attorney**.

         (a) Any purchaser may authorize one or more individuals (does not have to be an attorney-at-law), whether or not located at the registered location, to obtain and execute 222 Forms by executing a power of attorney for the individual(s).

         (b) The power of attorney must be signed by the person who signed the most recent application for registration or reregistration and by the individual(s) receiving the power of attorney. This form must be similar or identical to the DEA's "Power of Attorney for DEA Order Forms."

         (c) Once properly executed, the individual receiving the power of attorney may obtain and sign DEA Form 222 to the same extent as the individual who signed the most recent application for registration or reregistration.

         (d) The power of attorney must be filed with the executed 222 Forms of the purchaser and be retained for the same period as any order form bearing the signature of the attorney (see I.D.1.a.[8]). The power of attorney does not have to be submitted to the DEA.

      (6) Copies 1 and 2 must be submitted to the supplier. Copy 3 must be retained by the purchaser.

      (7) When the ordered Schedule II controlled substances are received by the pharmacy, the following information must be recorded on the retained Copy 3:

         (a) Number of commercial or bulk containers furnished on each item (or line)

         (b) Date on which the containers are received by the pharmacy

        (8) DEA 222 Forms must be maintained at the registered location (pharmacy or hospital) for at least 2 years from their execution. The time of execution would be the date the last entry was made on Copy 3.

    b. Cancellation by purchaser. A purchaser may cancel all or part of an order by notifying the supplier in writing. The supplier must indicate the cancellation on Copies 1 and 2 by drawing a line through the canceled items and printing the word "canceled" in the space provided for number of items shipped. Likewise, a supplier may void all or part of an order by notifying the purchaser in writing and printing the word "canceled" in the space provided for number of items shipped.

    c. Maintenance of DEA Form 222. Executed Copy 3 forms and Copies 1 and 2 of each unaccepted or defective form and the statement of refusal from the supplier must be maintained by the purchaser. They must be kept separate from all other records and be available for inspection for at least 2 years. All forms must be maintained at the registered location preprinted on the form, and not at a central location.

    d. Loss or theft of DEA Form 222. Any used or unused form stolen from or lost by a purchaser or supplier must be reported immediately to the DEA. Such notification must include the serial number of each form lost or stolen.

2. Electronic DEA Order System (CSOS). The DEA provides an electronic ordering system in addition to the DEA Form 222. Pharmacies wishing to order Schedule I and II drugs online must apply for a digital certificate for signing the order, and a digital certificate is issued for each location with a DEA registration. This requirement ensures each pharmacy location has an individual identification. The agency does not give a central registration for multiple locations (i.e., one registration serving multiple pharmacies [chains]). One registration can have more than one certificate if multiple people have power of attorney. One distinct difference with the CSOS compared to the DEA Form 222 is that the CSOS is not limited to Schedule I and Schedule II drugs. The electronic system allows registrants to orders Schedules III, IV, and V drugs and noncontrolled substances.

3. Obtaining Schedule III to V controlled substances. There is no special form for obtaining Schedule III to V controlled substances. Each registrant must, however, maintain a complete and accurate record of receipt for each such substance. The record must be maintained at either the registered location of the pharmacy or hospital, or at a central location, for 2 years. If a central location is used, the pharmacy must first notify the DEA, indicating its intention to keep central records. Central records may then be maintained unless the DEA denies the request to keep such records. An invoice or packing slip will suffice as a record of receipt, providing the following information is included:

    a. Name of the controlled substance

    b. Finished form of the substance (dosage form and strength)

    c. Number of units or volume of the finished form in each commercial container (e.g., 100-tablet bottle)

    d. Number of commercial containers of each such finished form received from other persons

    e. Date of actual receipt of each commercial container

    f. Name, address, and registration number of the person from whom the containers were received

E. Storage of controlled substances. All controlled substances in Schedules II to V must be stored in one of the following ways:

1. In a securely locked, substantially constructed cabinet

2. Dispersed throughout the stock of un-Scheduled prescription medication to prevent any theft or diversion

F. Theft or significant loss of Schedule II to V controlled substances. Every registrant must promptly notify the regional office of the DEA of the theft or significant loss of any controlled substance in Schedules II to V. This report must be done using DEA **Form 106**.

G. Disposal of controlled substances. Every disposal of a controlled substance must be accomplished by submitting DEA **Form 41** to the DEA (except for disposals pursuant to a valid prescription, discussed in the succeeding text). The form must list the controlled substances earmarked for disposal. The DEA will authorize the disposal and instruct the registrant to dispose of the controlled substances in one of the following ways:

1. By the transfer to a person or entity registered with the DEA and authorized to possess the substance. Schedule II controlled substances must be transferred by the use of the transferee's

(another pharmacy or hospital, or the wholesaler or manufacturer) DEA Form 222. A written record of the transfer of Schedule III to V controlled substances must be kept for at least 2 years and include the following information:

a. Name of the controlled substance

b. Finished form of the substance (dosage form and strength)

c. Number of units or volume of the finished form in each commercial container (e.g., 100-tablet bottle)

d. Number of commercial containers of each finished form transferred

e. Date of the transfer

f. Name, address, and registration number of the transferee

2. By the delivery to an agent of the DEA or to the nearest office of the DEA

3. By the destruction in the presence of an agent of the DEA or other authorized person

4. By any other means that the DEA determines to ensure that the substance does not become available to unauthorized persons or entities

H. **Regular disposals of controlled substances.** If a registrant (usually a hospital) regularly disposes of controlled substances in Schedules II to V, the DEA may authorize disposals without prior approval in each instance. If the DEA grants this authority, the registrant must keep records of each disposal and file periodic reports to the regional office of the DEA summarizing the disposals. The DEA may place additional conditions on such disposal, including the method of disposal and the frequency and detail of reports.

I. **Dispensing of controlled substances pursuant to a valid prescription**

1. **Persons who may issue prescriptions for controlled substances.** A controlled substance prescription may be issued only by a practitioner who is granted such authority by the state in which that practitioner is licensed. Although the Act is federal legislation, each state determines who will be authorized to dispense controlled substances. Most states allow the following individuals to prescribe: physicians, dentists, podiatrists, and veterinarians. Some states allow the following individuals, referred to as midlevel practitioners, to prescribe (usually with certain restrictions): physician's assistants, nurse practitioners, certified nurse midwives, psychiatric nurses, and mental health clinical specialists. All prescribers must be registered with the DEA or exempted from registration (see I.B.9). **Practitioner** means a physician, dentist, veterinarian, or other person licensed (midlevel practitioners) by the state to prescribe controlled substances, **and** pharmacy, hospital, or other institution licensed to distribute controlled substances. **Individual practitioner** means a physician, dentist, veterinarian, or other person licensed (midlevel practitioners) by the state to prescribe controlled substances. It is worth noting that the term "individual practitioner" is included in the definition of "practitioner." Prescribing authority granted by states is limited to professionals within the "individual practitioner" category. The statement such as "practitioner who is granted prescribing authority" means the "individual practitioner" who has been granted prescribing authority by the state because the individual practitioner is included in the definition of practitioner. "Pharmacy" is defined as a "practitioner" but, of course, does not have prescribing authority.

a. **DEA numbers and authenticity.** After registering with the DEA, all registrants are assigned a DEA number by the DEA. A practitioner's DEA number consists of nine characters. The first two characters are letters. The first letter will be either A or B. The second letter will be the first letter of the practitioner's last name. The next six characters are randomly chosen numbers. The last character is a number often referred to as the "check digit." For example, Dr. Henry Jones may have a DEA number of AJ 4357782.

(1) **Authentication of DEA number.** The DEA assigns DEA numbers with a quick method of verification built into the number. This allows a dispensing pharmacist to make a cursory review of the number for authenticity. For example, using the aforementioned DEA number, the practitioner's last name must start with a "J." Also, the following quick calculation can be made to verify that the "check digit" is correct:

(a) The digits in positions 1, 3, and 5 are added together to reach a number. In the previous example, that would be $4 + 5 + 7 = 16$.

(b) The digits in positions 2, 4, and 6 are added together, then multiplied by 2. In the previous example, that would be $(3 + 7 + 8) \times 2 = 36$.

(c) These aforementioned numbers are added together: $16 + 36 = 52$. The far-right digit becomes the check digit. The check digit must therefore be a 2. If the check digit is anything other than a 2, the number may not be a valid DEA number. In such a case, the DEA should be notified in order to verify the number.

(2) **Midlevel practitioner DEA numbers.** Midlevel practitioner DEA numbers are similar to practitioner DEA numbers except for the first character. Instead of the letter A or B, midlevel practitioners have the letter M as the first character in their DEA number. The mathematical method for verifying the authenticity of the number is the same.

(3) **DEA numbers for practitioners and midlevel practitioners who are employees of institutions.** Practitioners and midlevel practitioners who issue prescriptions in the course of their employment with an institution may issue prescriptions for all controlled substances under the institution's DEA registration. The practitioner's or midlevel practitioner's "DEA number" will be a specific internal code number issued by the institution. The code number must consist of numbers, letters, or a combination of numbers and letters and must be a suffix to the institution's DEA number, preceded by a hyphen (e.g., AP0123456-10 or AP0123456-A12).

2. **Purpose of issuance of controlled substance prescriptions.** A controlled substance prescription may be issued only in good faith for a legitimate medical purpose by a practitioner acting in the usual course of his or her professional practice. The practitioner and the dispensing pharmacist have the responsibility to ensure that a prescription is properly issued and dispensed (referred to as corresponding responsibility of the pharmacist).

   a. **Legitimate medical purpose.** Legitimate medical purpose and good faith are prerequisites for all controlled substance prescriptions. With respect to a pharmacist, these requirements will be apparent from an objective point of view. As a general rule, if, from all the surrounding facts and circumstances, a reasonably prudent pharmacist would form the opinion that a prescription was issued for a legitimate medical purpose, then the pharmacist has fulfilled his or her responsibility under the Act, and the prescription may be legally dispensed.

   b. **Usual course of professional practice.** A **practitioner–patient relationship** for the purpose of treating and caring for the patient must be present. Usually, such a relationship includes the taking and recording of an appropriate medical history, and an appropriate physical exam. This limits a practitioner's ability to prescribe outside his or her course of professional practice (e.g., a veterinarian may not prescribe a controlled substance for a human). The notion of "usual course of practice" becomes more unclear with respect to medical doctors who specialize. Such specialists often issue prescriptions "outside" their specialty. Generally, all controlled substance prescriptions from medical doctors are deemed to be "in the usual course of professional practice" as long as it is issued for a human, regardless of whether the problem being treated is within the doctor's specialty.

   c. **Restrictions on issuance of a controlled substance prescription**

      (1) A prescription may not be issued by a practitioner in order for that practitioner to obtain controlled substances for the purpose of **general dispensing** to his or her patients.

      (2) A prescription may not be issued for the dispensing of controlled substances for **detoxification** or maintenance treatment. Administration and direct dispensing of controlled substances are allowed only when conducted in properly registered treatment programs. A prescription for **methadone** is valid only when issued as an analgesic in cases of severe pain. Methadone may be dispensed in a hospital to maintain a patient's addiction as long as the patient is admitted and being treated for some other medical condition and is not administered methadone solely for detoxification purposes. The 40 mg tablets of methadone are only available to hospitals and facilities authorized for detoxification and maintenance treatment of opioid addiction. The other strengths (5 mg and 10 mg formulations) indicated for the treatment of pain are available to all authorized registrants, including retail pharmacies.

3. **Manner of issuance of a controlled substance prescription.** Schedule II controlled substance prescriptions must be written with ink or indelible pencil or typewritten (except in cases of oral emergency Schedule II prescriptions). Schedule III to V controlled substance prescriptions may be orally ordered by the practitioner. Prescriptions may be prepared by either the practitioner or

an agent of the practitioner, and communicated to the pharmacy by the practitioner or the agent. Authorization for the prescription (or refill) must, however, originate with the practitioner. Both the practitioner and dispensing pharmacist are responsible for the completeness of the prescription. All prescriptions for controlled substances must include the following information:

a. Full name and address of the patient
b. Date the prescription is issued and signed (one and the same)
c. Drug name, dosage form, and strength
d. Quantity of drug prescribed
e. Directions for use
f. Name, address, and DEA registration number of the practitioner
g. The signature of the practitioner (no preprinted or stamped signatures) as he or she would sign any legal document (all Schedule II controlled substance prescriptions must be manually signed by the practitioner)

4. **Emergency dispensing of Schedule II controlled substances**
   a. An oral Schedule II controlled substance prescription may be received from a practitioner in an emergency situation. An emergency prescription must include all of the information required for any controlled substance prescription. An emergency situation exists when **all three** of the following factors are present:
      (1) The immediate administration of the controlled substance is necessary for proper treatment of the patient.
      (2) No appropriate alternative treatment is available, including administration of a controlled substance that is not in Schedule II.
      (3) It is not reasonably possible for the practitioner to provide a written prescription to be presented to the person dispensing the controlled substance before the dispensing.
   b. **Proper dispensing.** The quantity prescribed and dispensed must be limited to the amount necessary to adequately treat the patient during the emergency period. If the practitioner is not known to the pharmacist, the pharmacist must make a reasonable good-faith effort to determine that the oral authorization came from a registered practitioner.
      (1) **Delivery of written prescription.** The practitioner who authorizes the emergency prescription must, within 7 days of the oral authorization, deliver a written prescription to the dispensing pharmacist. The prescription must contain the information required of all controlled substance prescriptions, have written on its face the words "Authorization for Emergency Dispensing," and the date of the oral authorization. The prescription may be delivered in person or by mail; if delivered by mail, it must be postmarked within the 7-day period. Upon receipt, the dispensing pharmacist must attach it to the oral emergency prescription, which was previously reduced to writing.
      (2) **Failure to deliver a written prescription.** If a practitioner fails to deliver the written prescription as required, the dispensing pharmacist must notify the regional office of the DEA. Failure by the pharmacist to notify the DEA serves to void the pharmacist's authority to dispense an oral emergency Schedule II prescription. The pharmacist will be deemed to have unlawfully dispensed a Schedule II controlled substance.

5. **Facsimile prescriptions.** Prescriptions for controlled substances III, IV, and V (and nonfederal controlled substances such as penicillin and furosemide) may be delivered to the dispensing pharmacy via facsimile machine. A facsimile prescription is deemed to be the written, signed prescription from the prescriber so long as it contains the information required of all prescriptions under federal law. The prescription must be sent directly from the prescriber or his or her authorized agent to the pharmacy.
   a. **Schedule II controlled substances.** Prescriptions for Schedule II controlled substances may be sent via facsimile to a dispensing pharmacy to facilitate dispensing of the prescription. **No drug may be released** to the patient until the original, signed prescription is presented to the dispensing pharmacist. A Schedule II controlled substance facsimile prescription **will serve** as the original, signed prescription in the following situations:
      (1) **Injectable home health prescriptions.** A facsimile Schedule II narcotic prescription calling for the compounding of a solution for direct administration to a patient in a private residence, long-term care facility, or hospice setting may serve as the original prescription.

The exception applies so long as the solution will be administered by means of parenteral, intravenous, intramuscular, subcutaneous, or intraspinal infusion.

    (2) Long-term care facility prescriptions. Any facsimile Schedule II prescription issued for a resident of a long-term care facility may serve as the original, signed prescription.

    (3) Hospice patient prescriptions. Any facsimile Schedule II narcotic prescription issued for a patient enrolled in a hospice care program certified and/or paid for by Medicare under Title XVIII or licensed by state law may serve as the original prescription. The prescriber, or his or her agent, **must** note on the prescription that the patient is a hospice patient.

6. **Electronic data transmission prescriptions for noncontrolled substances.** Prescription information that is transmitted directly from a practitioner to a pharmacy by electronic means such as via the Internet is referred to as **electronic data transmission prescription**. Electronic signatures are recognized as legally acceptable signatures of practitioners. Legend drugs, except for controlled substances, may be transmitted to pharmacies via the Internet if allowed by state law. A state may allow a practitioner and pharmacy to maintain the prescription information in electronic form without reducing it to writing, so long as they comply with state-mandated safeguards.

    a. Electronic data transmission prescriptions for controlled substances. The DEA does not yet recognize electronic data transmission prescriptions as a means of communicating prescription information for any controlled substance. Therefore, prescription information for controlled substances may not be communicated from a practitioner to a pharmacy by electronic means.

7. **Persons who may dispense controlled substance prescriptions.** A **pharmacist** acting in the usual course of his or her professional practice in a DEA-registered pharmacy (or hospital or other registered facility) may dispense a controlled substance pursuant to a prescription. A **pharmacy intern** acting under the direct supervision of his or her preceptor in a DEA-registered facility may also dispense a controlled substance pursuant to a prescription.

8. **Dispensing procedures of controlled substances pursuant to a prescription.** Once a controlled substance prescription has been lawfully issued by a practitioner and presented to a pharmacist, it may be dispensed in accordance with the following:

    a. Presentation to the pharmacist. Schedules III and IV controlled substance prescriptions are valid for 6 months from the date of issuance by the practitioner. Schedule II controlled substance prescriptions have no time limit for presentation under the Act, although they are often recognized to be valid for up to 6 months. Schedule V controlled substance prescriptions also have no set time limit for presentation under the Act. Regardless of which Schedule of controlled substance is involved, the good-faith and "legitimate medical purpose" limitation will always apply and may serve to otherwise limit the validity of a prescription.

    b. Information that must be recorded on the prescription by the dispensing pharmacist. Under the Act, a filled prescription is considered to be a lawful record of disposition for a controlled substance. As a result, every prescription for a controlled substance must contain certain information. Some of the information will already be contained in the prescription, although the dispensing pharmacist is responsible for ensuring that all of the following information is recorded (usually on the face of the prescription):

      (1) Name of the controlled substance

      (2) Finished form of the controlled substance (dosage form and strength)

      (3) Name and address of the person to whom it was dispensed

      (4) Date of dispensing

      (5) Number of units or volume dispensed (quantity)

      (6) Written or typewritten name or initials of the individual who dispensed the controlled substance

      (7) Serial number of the prescription

    c. Required information on prescription labels. Every prescription label for a controlled substance must include the following information:

      (1) Name and address of the pharmacy

      (2) Serial number assigned to the prescription

      (3) Date of the initial filling of the prescription (for refills, the date originally filled)

(4) Name of the patient

(5) Name of the prescribing practitioner

(6) Directions for use, and cautionary statements, if any

(7) For Schedule II, III, and IV controlled substances, the federal crime transfer warning must appear on the container: "Caution: Federal law prohibits the transfer of this drug to any person other than the patient for whom it was prescribed."

 d. Allowable quantities that may be dispensed. The Act contains no limitation concerning the quantity of a controlled substance that may be dispensed pursuant to a prescription. All quantities are, of course, limited to the good-faith and "legitimate medical purpose" standards.

 e. Filing controlled substance prescriptions. Written controlled substance prescriptions must be maintained at the pharmacy for a period of 2 years from the date of the original dispensing or last refill, whichever is later. They must be available for inspection and copying by employees and agents of the DEA and be filed **segregated** from all other records in one of the following ways (state law usually dictates the method to be used):

(1) Using **three separate files** as follows:

 (a) One file for Schedule II controlled substance prescriptions

 (b) One file for Schedule III, IV, and V controlled substance prescriptions

 (c) One file for un-Scheduled prescription drugs

(2) Using **two separate files** as follows:

 (a) One file for all controlled substance prescriptions (II to V), as long as Schedule III, IV, and V prescriptions have the letter "C" stamped in red ink in the lower right corner no less than 1 inch high

 (b) One file for un-Scheduled prescription drugs

(3) Using **two separate files** as follows:

 (a) One file for Schedule II controlled substance prescriptions

 (b) One file for all other controlled substances (III to V) and un-Scheduled prescription drugs, as long as Schedule III, IV, and V prescriptions have the letter "C" stamped in red ink in the lower right corner no less than 1 inch high

(4) In either **(2)** or **(3)** earlier, if a pharmacy uses an electronic record-keeping system for prescriptions (i.e., computerized records) that permits identification by prescription number and retrieval of original documents by prescriber's name, patient's name, drug dispensed, and date filled, then the requirement to mark the hard copy prescription with a red "C" is waived.

 f. Refill dispensing of controlled substances. Prescriptions for Schedule II controlled substances may not be refilled. Prescriptions for Schedules III and IV controlled substances may be refilled up to five times within 6 months from the date of issue of the prescription. Schedule V controlled substance prescriptions have no limitations for refilling under the Act; however, once again, the good-faith and "legitimate medical purpose" limitations apply here, as well as to all controlled substance refills.

(1) Refill information may be maintained either manually or by the use of a computer. The Act requires that the information be maintained one way or the other, but not both ways. If **computerized refill records** are maintained, the system must have certain capabilities and the dispensing pharmacist must follow certain procedures.

 (a) The computer must be able to provide online retrieval of the original prescription information, online retrieval of the refill history, a refill-by-refill audit trail, and an auxiliary procedure in those cases where the system experiences downtime.

 (b) The system must also allow the pharmacist who refills a prescription to document that the information he or she entered into the computer is correct.

(2) When dispensing a refill, the pharmacist must record, on the back of the original prescription or by computer, the following information:

 (a) Date of the refill

 (b) Name or initials of the refilling pharmacist

 (c) Amount of the medication dispensed (if the amount is omitted, the refill will be deemed to have been for the full face amount prescribed by the practitioner)

g. **Multiple Schedule II prescriptions prescribed on the same day to be filled sequentially.** The refill of a prescription for a controlled substance listed in Schedule II is prohibited. However, an individual practitioner may issue multiple prescriptions authorizing the patient to receive a total of up to a 90-day supply of a Schedule II controlled substance, providing each prescription is issued for a legitimate medical purpose by an individual practitioner acting in the usual course of professional practice. The individual practitioner provides written instructions on each prescription (other than the first prescription, if the prescribing practitioner intends for that prescription to be filled immediately) indicating the earliest date on which a pharmacy may fill each prescription.

h. **Partial dispensing of controlled substances.** The Act does not prohibit the partial dispensing of controlled substances in Schedules III and IV, provided that each partial filling is recorded in the same manner as refills, the total quantity dispensed in all partial fillings does not exceed the total quantity prescribed, and no partial filling occurs after 6 months from the date of issuance of the prescription. Likewise, all partial fillings of a Schedule V prescription must not exceed the total quantity prescribed.

    (1) **Partial dispensing of a Schedule II controlled substance.** The partial dispensing of a Schedule II prescription is allowed if the pharmacist is unable to supply the full quantity or the prescription is for a terminally ill patient or a patient in a long-term care facility (LTCF). Under no other circumstance may a Schedule II prescription be partially dispensed.

        (a) **Inadequate supply.** In cases of an inadequate supply, the dispensing pharmacist must note on the face of the prescription the amount dispensed. The remaining balance of the Schedule II prescription must be dispensed within 72 hrs of the first partial filling. If, for any reason, the balance is not dispensed within the 72-hr period, the pharmacist must notify the prescribing practitioner of this fact. The pharmacist may not dispense any further amounts pursuant to this prescription beyond the 72-hr period.

        (b) **Terminally ill and patients in LTCFs.** It is the pharmacist's responsibility to ensure that a patient has a medical diagnosis documenting a terminal illness or that the patient is in an LTCF. Before any partial dispensing, the pharmacist must record on the prescription whether the patient is "terminally ill" or an "LTCF patient." Any partial dispensing without one of these notations shall be deemed to be a dispensing in violation of the Act. The total amount of the Schedule II substance dispensed in all partial fillings must not exceed the total quantity prescribed. Schedule II prescriptions for a terminally ill patient or a patient in an LTCF are valid up to 60 days from the date of issuance of the prescription by the practitioner. All of the following information must be recorded, either manually on the back of the prescription or via computer (with similar capabilities required for computerized refill record keeping), when partially dispensing a Schedule II prescription for a terminally ill patient or a patient in an LTCF:

           (i) Date of the partial filling
          (ii) Quantity of drug dispensed
        (iii) Remaining quantity authorized to be dispensed
        (iv) Identification of the dispensing pharmacist

i. **Transfer of refill information for a controlled substance prescription.** Refill information concerning Schedules III, IV, and V controlled substances may be transferred to another pharmacy only once (if allowed by state law). Pharmacies electronically sharing a real-time, online database (such as chain pharmacies) may transfer refill information for these controlled substances up to the maximum number of refills permitted by law and the prescriber's authorization. The communication must be made directly between two licensed pharmacists. Both the original prescription and the transferred prescription must be maintained for 2 years from the date of the last refill. Certain information must be recorded as follows:

    (1) The **transferring pharmacist** must:

        (a) Write the word "void" on the face of the original prescription

        (b) On the back of the prescription, record the name, address, and DEA registration number of the pharmacy to which it was transferred and the name of the pharmacist receiving the information

        (c) Record the date of the transfer and the name of the transferring pharmacist

　　　　(2) The **receiving pharmacist** must:
　　　　　　(a) Write the word "transfer" on the face of the transferred prescription
　　　　　　(b) Record all of the information required for any controlled substance prescription (see I.I.3), and include the following:
　　　　　　　　(i) Date of issuance of the original prescription
　　　　　　　　(ii) Original number of refills authorized on the original prescription
　　　　　　　　(iii) Date the prescription was initially dispensed
　　　　　　　　(iv) Number of valid refills remaining and the date of the last refill
　　　　　　　　(v) Pharmacy's name, address, DEA registration number, and original prescription number from which the prescription information was transferred
　　　　　　　　(vi) Name of the transferring pharmacist

J. **Dispensing of controlled substances to a patient without a prescription.** Controlled substances that are not prescription (or legend) drugs under federal law may be dispensed to a patient at retail without a prescription. These drugs do not have on the manufacturer's label the federal statement: "Caution: Federal law prohibits dispensing without a prescription." The substances may be dispensed without a prescription in accordance with the following:

1. The dispensing must be made only by a licensed pharmacist. The actual cash transfer or delivery may be made by a nonpharmacist.
2. Not more than 8 oz of any substance containing opium, 4 oz of any other controlled substance, 48 dosage units of any substance containing opium, or 24 dosage units of any other controlled substance may be dispensed to the same purchaser in any 48-hr period.
3. The purchaser is at least 18 years old.
4. Any purchaser not known to the pharmacist must furnish suitable identification.
5. A bound record book must be maintained for 2 years from the date of the last entry. The following information must be recorded for each purchase:
　　a. Name and address of the purchaser
　　b. Name and quantity of controlled substance purchased
　　c. Date of each purchase
　　d. Name or initials of the pharmacist who dispensed the substance to the purchaser
6. All dispensing of a controlled substance without a prescription must be done in good faith and not to evade the provisions of the Act.

K. **Security considerations**
1. **Controlled substance seals.** Manufacturers must package certain controlled substances in a container with a securely affixed seal to reveal any tampering. Every bottle, multiple-dose vial, or other commercial container of any controlled substance listed in Schedule II, or of any narcotic controlled substance listed in Schedule III or IV, must be packaged with such a seal.
2. **Felony convictions.** No DEA registrant may employ an individual who has access to controlled substances if that individual had previously been convicted of a felony offense related to controlled substances.
3. **Manufacturer's label.** Every commercial container of a controlled substance must have on its label the symbol designating the Schedule in which the controlled substance is listed. The symbol must appear in the upper right corner of the label or be overprinted on the label.

L. **Record maintenance.** All records required to be maintained under the Act must be kept by the registrant for 2 years. The records may be maintained at a central location (e.g., at a chain pharmacy's regional office) after notifying the DEA. However, executed DEA 222 Forms (Copy 3), all controlled substance prescriptions, and all inventories must be maintained at the pharmacy, not centrally. All Schedule II controlled substance records must be maintained separately and readily retrievable from all other records.

M. **DEA inspections.** Inspections by the DEA of any registered facility may be conducted only in a reasonable manner and during regular business hours. Inspection may be conducted after obtaining consent of the registrant or after the DEA has obtained an administrative warrant from a judge. An application for an administrative warrant must state with specificity the nature, extent, and authority to conduct the requested inspection. The scope of an administrative inspection extends to any records required under the Act, equipment and containers used in the handling of controlled substances, and the verification of compliance with any requirement of the Act. If records are removed from the registrant by the DEA, a receipt given to the registrant will list the items taken.

N. **Long-term–care facilities (LTCFs).** An LTCF is defined as a nursing home, retirement care, mental care, or other facility or institution that provides extended health care to resident patients. LTCFs are not normally registered with the DEA, although they often maintain controlled substances that are dispensed to a patient by prescription from a pharmacy. They are not required to be registered with the DEA because the controlled substance is dispensed to the ultimate user (the patient) and is not issued by or through the LTCF. When disposing of controlled substances, LTCFs must contact the nearest DEA Diversion Field Office for disposal instructions.

1. **Emergency kits for LTCFs.** An LTCF may maintain controlled substances in emergency kits so long as state law specifically approves of such use and the state sets forth procedures that require the following:

   a. **Source of supply.** The LTCF must obtain controlled substances for the emergency kits from a DEA-registered hospital/clinic, pharmacy, or practitioner.

   b. **Security safeguards.** Access to each emergency kit in the LTCF must be restricted, and the type and quantity of controlled substances that may be placed in the emergency kit must be specifically limited.

   c. **Proper control, accountability, and record keeping.** The LTCF and the providing DEA-registered hospital/clinic, pharmacy, or practitioner must maintain complete and accurate records of the controlled substances placed in the emergency kit, including the disposition of these controlled substances, as well as take periodic physical inventories of the drugs.

   d. **Administration of controlled substances.** In emergency medical situations when medication is needed from the emergency kit, only LTCF personnel who are authorized by an individual practitioner can administer the controlled substances.

   e. **Prohibited activities.** Prohibited activities can result in the state revocation, denial, or suspension of having emergency kits containing controlled substances in an LTCF.

O. **Violations under the Act.** Penalties for violations of the Federal Controlled Substances Act depend on the Schedule of controlled substance involved, the unlawful act, **and the knowledge and intent of the violator**. It will also depend on whether it is a first offense or a subsequent offense.

1. **Civil penalty.** Generally, each violation of the Act may subject an individual to a civil penalty (fine) of up to $10,000. The government must prove that the violator was negligent with respect to compliance under the Act, as opposed to mere mistake or inadvertence.

2. **Imprisonment.** If an individual knowingly and intentionally violates the Act, he or she may be sentenced to a term of years, in addition to a civil penalty.

II. FEDERAL FOOD, DRUG, AND COSMETIC ACT (FDCA).

In 1937, sulfanilamide elixir containing deadly diethylene glycol (automobile antifreeze) was manufactured without any safety data. There were numerous deaths associated with its use, which prompted the federal government to pass the 1938 FDCA. The FDCA requires that all new drug products intended for use as labeled by the manufacturer in the United States must be proven to the federal government to be safe and effective. Such proof is submitted to the Food and Drug Administration (FDA) by use of a New Drug Application (NDA).

A. **Definition.** Under the FDCA, the term *drug* is defined as including all of the following:

1. Articles recognized in the official *United States Pharmacopeia (USP)*, official *Homeopathic Pharmacopoeia of the United States*, or official *National Formulary*, or any supplement to these

2. Articles intended for use in the diagnosis, cure, mitigation, treatment, or prevention of disease in man or other animals

3. Articles (other than food) intended to affect the structure or any function of the body of man or other animals

4. Articles intended for use as a component of any article specified in 1, 2, or 3 as mentioned previously.

B. **Legend drugs.** Legend drugs are those medications that have on their label from the manufacturer the following federally required statement: "**Rx** only." Such medications may be dispensed directly to the patient by means of a valid written or oral prescription from a practitioner or by a valid refill authorization of either. By law, these medications must bear a label with adequate directions for use, which can only be given by a licensed practitioner and, therefore, the requirement of a prescription.

A drug, intended for use by humans, is considered a legend drug (and has the aforementioned caution on its label) if any of the following apply:

1. Because of the drug's toxicity or other potential for a harmful effect, or its method of use, or collateral measures necessary to its use, it is **not safe** for use **except under the supervision** of a practitioner licensed by law to administer such drug.

2. The drug is a **new drug** for which an approved NDA limits its use to the professional supervision of a practitioner licensed by law to administer such drug. A new drug is broadly defined as being one that generally is not recognized among experts as safe and effective for use under the conditions prescribed, recommended, or suggested in the labeling. It is also defined as being a drug that, as a result of investigations to determine its safety and effectiveness for use under such conditions, has become so recognized but that has not, other than in the investigations, been used to a material extent or for a material time under such conditions. Finally, a new drug may result from a change in the dosage form, labeling, indications, or any other change in a drug product that is already being marketed. The ultimate decision of whether a drug is a new drug lies with the FDA because of its expertise in resolving technical and scientific questions.

   a. **NDA.** Every new drug marketed in the United States must be safe and effective for its intended use as labeled by the manufacturer. Proof of safety and effectiveness must be submitted to the FDA by the manufacturer via the NDA. When a new chemical entity (NCE) is identified by a manufacturer, the manufacturer must obtain an Investigational New Drug Application (IND) before conducting preclinical animal tests and clinical human investigations.

   b. **IND.** Because an NCE has not yet been approved by the FDA as a safe and effective drug, a manufacturer is required to file an IND with the FDA. The IND allows a manufacturer to conduct research with the NCE and exempts the drug from certain prohibitions of the FDCA in order to facilitate clinical investigations; thus, INDs are sometimes referred to as an Investigational New Drug Exemption. Generally, clinical investigation of an NCE is divided into three phases, with each phase involving a greater number of human subjects.

      (1) **Phase 1.** A phase 1 investigation is the initial introduction of an investigational new drug into humans to determine the metabolism, pharmacology, side effects, mechanism of action, and early evidence on effectiveness.

      (2) **Phase 2**. A phase 2 investigation includes the well-controlled, closely monitored clinical studies in order to evaluate the effectiveness of the drug for a particular indication and to further determine side effects and risks.

      (3) **Phase 3**. A phase 3 investigation includes expanded clinical trials to gather additional information concerning safety, effectiveness, and the overall benefit–risk relationship associated with the drug's use. This phase also includes gathering information to provide an adequate basis for physician labeling.

   c. **Treatment INDs (or treatment protocols).** The FDA may allow a treatment IND, which allows a researcher (physician) to use an investigational drug as treatment in serious and life-threatening diseases where no comparable or satisfactory alternative drug or other therapy is available.

C. **Over-the-counter (OTC) medications.** Certain medications may be dispensed OTC at retail distributors without a prescription. The federal government has determined that these medications may be safely and properly self-administered without the supervision of a practitioner licensed by law to administer (or prescribe) such a drug. Generally, these medications are not habit-forming and have a low toxicity or other potential for a harmful effect. These medications do not have the federal statement "**Rx** only" on their label (see II.B).

   1. OTC preparations must have **adequate directions** for use on their label, and the product must comply with the applicable FDA monograph. The FDCA requires all drugs marketed in the United States to be generally recognized as safe and effective. As a result, it convened review panels to review OTC drug effectiveness and create monographs for each therapeutic class of OTC drugs. This review is referred to as the Drug Efficacy (or Effectiveness) Study Implementation (DESI). All OTC drugs must comply with the applicable drug monograph or be considered misbranded (see II.I) and subject to FDA regulatory action.

   2. OTC preparations must have the following information on its label:
      a. Identity, in bold face, of the OTC product on the principal display panel
      b. Adequate directions for use

    c. Ingredients (including inert or inactive ingredients) in the product

    d. Net quantity of contents

    e. Expiration date of the product

    f. Lot number of the product

    g. Name and place of business of the manufacturer, packer, or distributor

    h. Disclosure of certain contents and the declaration of certain warnings, including habit-forming ingredients and warnings, pregnancy/nursing warnings, and aspirin warnings

3. Prescription drug conversion to OTC. A legend drug will convert to an OTC drug when the FDA finds that the prescription-only limitation is not necessary for the protection of the public health by reason of the drug's toxicity or other potential for harmful effect, the method of its use, or the collateral measures necessary to its use. The FDA must also find that the drug is safe and effective for use in self-medication as directed in proposed labeling.

4. Miscellaneous regulations for OTCs.

    a. Ipecac syrup. Although ipecac syrup can only be dispensed pursuant to a prescription, the FDA believes that it should be readily available OTC as an emergency treatment emetic for use in poisonings. The FDA allows the OTC sale of ipecac syrup in 1 fluid ounce containers so that it will be readily available in the household for emergency treatment of poisonings, under medical supervision, and that the drug be appropriately packaged and labeled for this purpose.

    b. Pregnancy-nursing warning. All OTC drugs intended for systemic absorption must contain a warning that if the user is pregnant or nursing a baby, she should first seek the advice of a health professional before using the product. Exceptions to this labeling requirement exist when an OTC is intended to benefit the fetus or nursing infant, and for OTC drugs that are labeled exclusively for pediatric use.

    c. Aspirin warnings. All OTC aspirin containing preparations must have a warning to keep out of children's reach and to contact a physician immediately in case of accidental overdose. Oral or rectal OTC aspirin containing preparations must also have a warning concerning Reye syndrome in children and teenagers.

    d. Chemicals and precursors. It was discovered that combination drug products containing ephedrine, pseudoephedrine, or phenylpropanolamine are the precursor materials used by illegal methamphetamine laboratories. The Comprehensive Methamphetamine Control Act of 1996 requires all retail distributors of these OTC products to fulfill certain obligations. A retail distributor includes a grocery store, general merchandise store, a pharmacy, or any other entity or person who sells these items to customers for personal use. For regulated transactions, a retailer must maintain a record of these transactions for a period of 2 years, must obtain proof of identity from customers, and must report suspicious regulated sales immediately to the DEA. The record must be maintained separately from other records of controlled substances, and the DEA suggests that the record be made in a bound log book similar to the record kept for the sale of OTC controlled substances (see I.J). The following single transactions of these products in the amounts stated are considered to be "regulated transactions."

        (1) Phenylpropanolamine (PPA). PPA is no longer in any OTC drug product.

        (2) Pseudoephedrine. Sales of combination products containing more than 24 g of pseudoephedrine. Blister pack sales of these products exceeding 24 g are **not** regulated sales.

        (3) Ephedrine. Sales of combination products containing more than 24 g of ephedrine **and all** single-entity ephedrine products regardless of the amount of ephedrine (more than 0 g).

D. Generic drugs

1. Definition. The *generic name* of a drug has been defined as its chemical name, a common name, or an official name used in an official compendium. A manufacturer seeking approval from the FDA for a drug that has already been proven to be safe and effective may file an Abbreviated New Drug Application (ANDA).

2. ANDA. A filing of an ANDA allows the approval of a drug for which exhaustive safety and efficacy studies have already been performed. A drug is considered to be the same as an approved drug when the two are identical in active ingredient(s), dosage form, strength, route of administration, indications, and conditions of use. Rigorous animal and human data to determine safety

and effectiveness are not required in the ANDA. However, information showing that the generic version of the drug is bioavailable and bioequivalent to the pioneer (original) drug is necessary. Such approved drugs are listed by the FDA in the "Approved Drug Products with Therapeutic Equivalence Evaluations," commonly referred to as the FDA Orange Book (because it comes from the FDA in an orange binder).

E. Proprietary drugs. The *proprietary name* of a drug is the name given by the manufacturer to designate the drug's source of manufacture and to differentiate it from the same or chemically similar drugs from other manufacturers. Another name for the proprietary name of a drug is its trade name.

F. Established names for drugs. The FDCA authorizes the commissioner of the FDA to designate an official name for any drug if he or she determines that such action is necessary or desirable in the interest of usefulness and simplicity. The FDCA also requires that a drug's established name appear on the label and labeling of the drug. A drug's *established name* is defined as follows:

1. It may be an **official name** designated by the commissioner of the FDA. For NCEs, the name should be simple and useful. In this regard, the FDA recognizes the United States Adopted Names Council (USAN) in deriving names for NCEs. The USAN name is considered to be an official name recognized in an official compendium. The FDA may use another name if the USAN or common or usual name is unduly complex, misleading, or is not useful for any other reason.

2. If no official name has been designated for the drug and the drug is an article recognized in an official compendium, then the **official title** contained in the compendium may be the established name.

3. If neither of the aforementioned two apply, then the **common** or **usual name** of the drug may be its established name.

G. Dispensing a prescription drug. A prescription drug may be dispensed only by a practitioner or by a pharmacist pursuant to a written or oral prescription of a practitioner, or a refill of either. The prescription label on the container dispensed to the patient must contain certain information, or it will be considered misbranded and dispensed in violation of the FDCA. This information is minimal under the FDCA and is usually supplemented by state laws, which require more information. So long as this information is in English, the dispensing pharmacist will be in compliance with the FDCA. If any of the required information is in another language, then all of the required information must be in that language. The prescription must also be packaged in a child-resistant container as required under the Poison Prevention Packaging Act (see III). The following information must appear on every prescription label:

1. Name and address of the pharmacy
2. Serial number of the prescription
3. Date the prescription is filled or the date of the prescription
4. Name of the prescriber
5. Name of the patient (if stated in the prescription)
6. Directions for use and any cautionary statements contained in the prescription

H. Drug recall. The FDCA allows the FDA to initiate regulatory actions to ensure that unsafe, unfit, or ineffective products do not reach the market, or to promptly remove those products that do reach the marketplace. The enforcement actions that may be initiated include the release of information to the general public and/or professional groups; administrative actions and inspections; the institution of recall; or seizure, injunction, or criminal prosecution.

1. **Voluntary action of the manufacturer.** After several unsuccessful attempts by the FDA to receive court-ordered recalls, the FDA recognizes that recalls are voluntary actions of the manufacturers and distributors. As a result, a recall may be undertaken at any time, or upon request of the FDA. If the FDA is unsuccessful in persuading a company to recall a product, or when the FDA determines that a recall is or will be ineffective, it may seek a court order condemning the product and allowing the product's seizure.

2. **Drug recall classification.** After the FDA has evaluated the problem(s) associated with the product and after the degree of health hazard has been determined, the FDA will assign the recall one of the following classifications:

   a. **Class I.** A situation in which there is a reasonable probability that the use of or exposure to a violative product will cause serious adverse health consequences or death

      b. Class II. A situation in which use of or exposure to a violative product may cause temporary or medically reversible adverse health consequences or where the probability of serious health consequences is remote

      c. Class III. A situation in which use of or exposure to a violative product is not likely to cause adverse health consequences

    3. Recall procedure. A recall strategy will be developed that will consider the depth of the recall (consumer level, retail level, wholesale level), the need for public warnings, and the extent of effectiveness checks for the recall. Every recalling company is responsible for notifying each of its affected direct accounts by first-class mail, mailgram, or telegram. Public notification is made by the FDA via the weekly *FDA Enforcement Report,* which publishes each recall according to its classification.

I. Adulteration and misbranding. A misbranding or adulteration of a drug is prohibited by the FDCA. Although the misbranding and adulteration provisions are mainly concerned with the manufacturing of a drug, a pharmacist may also misbrand or adulterate a drug. The purpose of the misbranding and adulteration statutes is to protect the public health of consumers who are largely unable to protect themselves where drugs are involved. The adulteration and misbranding statutes are criminal in nature and may subject a pharmacist to criminal proceedings in federal court, in addition to administrative proceedings.

    1. Adulteration. In general, the term *adulteration* refers to a change or variation from official formulary standards or from the manufacturer's standards. A drug is considered adulterated if any of the following conditions occur:

      a. If the drug consists in whole or in part of any filthy, putrid, or decomposed substance

      b. If the drug has been prepared, packed, or held under unsanitary conditions where it may have been contaminated with filth or rendered injurious to health

      c. If the drug's container is composed, in whole or in part, of any poisonous or deleterious substance that may render the contents injurious to health

      d. If the drug contains, for purposes of coloring only, a color additive that is unsafe within the meaning of the FDCA

      e. If the drug is a new animal drug, or an animal feed containing a new animal drug, that is unsafe within the meaning of the FDCA

      f. If the drug is purported to be a drug that is recognized in an official compendium, and its strength differs from, or its quality or purity falls below, the standard set forth in the compendium, unless the deviation is plainly and specifically stated on its label

      g. If the drug is not a compound recognized by name in an official compendium; if its strength differs from, or its purity or quality falls below, that which it purports or is represented to possess

      h. If the drug has been mixed or packed with another substance in order to reduce the drug's quality or strength

      i. If the drug has been substituted, wholly or partially, with another substance

      j. If the drug is an OTC drug and it is not packaged in the required tamper-resistant packaging or properly labeled in conformity with the tamper-resistant regulations (see IV)

      k. If the drug (or medical device) is an ophthalmic preparation offered or intended for ophthalmic use that is not sterile

    2. Misbranding. In general, the term *misbranding* means that a drug is sold or dispensed with a label or labeling that is in violation of the FDCA. *Label* is defined as being a display of written, printed, or graphic matter upon the immediate container of any article (or drug). *Labeling* is more broadly defined to include the label as well as other written, printed, or graphic matter upon any article or any of its containers or wrappers, or accompanying the article (or drug). A drug is considered misbranded if any of the following conditions occur:

      a. If the labeling is false or misleading in any particular

      b. If the drug is an imitation of another drug, or if it is offered for sale under the name of another drug

      c. If the drug is composed wholly or partly of insulin and it is not properly batch certified under the FDCA

      d. If the drug is composed wholly or partly of an antibiotic and it is not properly batch certified under the FDCA

    e. If the drug is dispensed by a name that is recognized in an official compendium and it is either not packaged or not labeled in conformity with the official compendium

    f. If the drug is determined by the federal government to be liable to deterioration and it is not packaged in a proper form and manner, and the label fails to bear a statement of proper precautions

    g. If the drug is dispensed in a non–child-resistant container, when a child-resistant container is otherwise required (see III)

    h. If the manufacturer fails to place on the label any of the following:

        (1) Fact that certain drugs may be habit forming

        (2) Name of each active ingredient

        (3) Name and place of business of the manufacturer, packer, or distributor

    i. If a pharmacist fails to place on a prescription container label any of the following:

        (1) Name and address of the pharmacy

        (2) Serial number of the prescription

        (3) Date of filling the prescription or the date of the prescription

        (4) Name of the prescriber

        (5) Name of the patient

        (6) Directions for use and any cautionary statements contained in the prescription

    j. If an oral contraceptive is dispensed without the required patient package insert

    k. If an intrauterine device that must be dispensed with a patient package insert is dispensed without the insert

    l. If an estrogen product is dispensed without the required patient package insert

    m. If a progestogen-containing product is dispensed without the required patient package insert

    n. If a legend drug is dispensed (or refilled) without a prescription (or refill authorization) of a licensed practitioner, it is deemed to be misbranded by the dispensing pharmacist.

    o. If the drug is an OTC drug and it is not packaged in tamper-resistant packaging or properly labeled in conformity with the tamper-resistant regulations (see IV)

    p. If the drug is an OTC drug and it is not properly labeled in conformity with the labeling requirements of the FDCA

    q. If the drug (or medical device) is an ophthalmic preparation offered or intended for ophthalmic use that is not sterile

3. Violations under the Act. Any misbranding or adulteration of a drug may subject the individual (e.g., a pharmacist) to imprisonment, a fine, or both. A pharmacy and pharmacist will be exempt from criminal sanctions in either of the following cases:

    a. Certain cases of good faith. When adulterated or misbranded products are received from a manufacturer or wholesaler in good faith by the pharmacy, the pharmacy may not be held responsible in certain situations. This exemption applies only if it is a first violation and, if requested, the pharmacy or pharmacist furnishes to the government the name and address of the person from whom the drug was received and copies of all documents pertaining to its delivery.

    b. Receipt of drug with a signed, written guaranty. A pharmacy and pharmacist will be exempt from misbranding and adulteration violations when a signed, written guaranty is received from the wholesaler or manufacturer. The guaranty must contain the name and address of the person residing in the United States from whom the drug was received in good faith and a statement that the drug is not adulterated or misbranded.

4. Seizures. Any adulterated or misbranded drug will be subject to condemnation and seizure by the U.S. government after a hearing in any district court of the United States (or territory) with proper jurisdiction. A seizure may be done without a hearing if the federal government has probable cause to believe that the violation would be dangerous to health or that the labeling of the misbranded article is fraudulent or would be materially misleading to the injury or damage of the purchaser or consumer.

5. Investigations and inspections

    a. The U.S. Secretary of Health and Human Services has the authority to conduct examinations and inspections through federal employees and by officers and employees of any state, territory, or political subdivision duly commissioned by the U.S. Secretary of Health and Human Services as an officer of the U.S. Department of Health and Human Services.

    b. Scope of investigation. An investigator may enter a pharmacy or other establishment where adulterated or misbranded drugs are held and inspect all drugs, materials, containers, and labeling. The inspection does not extend to financial data, sales data other than shipment data, pricing data, personnel data, and other records that have no bearing on adulteration and misbranding. The investigator must present appropriate credentials and a written notice to the owner, operator, or agent in charge that he or she is authorized to conduct an investigation. The inspection must be done at reasonable times, within reasonable limits, and in a reasonable manner.

    6. Current Good Manufacturing Practice (cGMP). Under the FDCA, a drug is considered adulterated if it is not manufactured "in conformity with current Good Manufacturing Practice." FDA regulations state with particularity the minimum cGMPs for methods to be used in, and the facilities or controls to be used for, the manufacture, processing, packing, or holding of a drug. The cGMPs ensure that a drug meets the requirements of the FDCA regarding safety and has the identity and strength and meets the quality and purity characteristics that it purports.

J. Registration of producers of drugs

    1. Manufacturers and businesses that distribute a drug manufactured by another but sold under their own label or trade name must register their establishment with the FDA. They also must submit a list of every drug (prescription and OTC) in commercial distribution, with updates every June and December.

    2. Pharmacies properly licensed by state law that do not manufacture or possess drugs for sale other than in the regular course of the practice of pharmacy are not required to register with the FDA. A pharmacy engaged in manufacturing or processing activities that are considered beyond the normal practice of pharmacy must register with the FDA and supply a list of every drug in commercial distribution.

        a. Scope of pharmacy practice. A pharmacy or pharmacist may not manufacture drug products. They may only compound drug preparations pursuant to a valid prescription of a practitioner for a particular patient. Large-scale manufacturing of drug products by a pharmacy or pharmacist is outside the scope of pharmacy practice and requires proper registration with the FDA and compliance with cGMPs.

K. Package inserts. The federal government has determined that prescription medication information needs to be disseminated to health professionals and, in the case of certain drugs, to the patient.

    1. Manufacturer's insert. An amendment to the FDCA required that all manufacturers provide "full disclosure" concerning prescription medication that they market. Full disclosure is accomplished by means of a package insert that is enclosed with every commercial container of a drug product. The insert should contain essential scientific information needed for the safe and effective use of the drug and should be informative and accurate. It must not be promotional in tone, false, or misleading.

    2. Patient package insert. The FDA has determined that, because of certain side effects associated with the use of particular drug products, patient package inserts must be dispensed to the patient at the time of dispensing the medications. The following products must be dispensed with a patient package insert, which is supplied with the product from the manufacturer:

        a. Oral contraceptives. Hospital inpatients or LTCF patients may receive the insert before administration of the first oral contraceptive and every 30 days thereafter, as long as the therapy continues.

        b. Intrauterine devices for human use in contraception. Every practitioner dispensing such a device must provide the patient with an informative insert.

        c. Estrogen and estrogen-containing products. Hospital inpatients or LTCF patients may receive the insert before administration of the first estrogen dose and every 30 days thereafter, as long as the therapy continues.

        d. Progestational drug products. Hospital inpatients or LTCF patients may receive the insert before administration of the first progestational drug product and every 30 days thereafter, as long as the therapy continues.

        e. Isoproterenol inhalation products require the following warning statement on the immediate container label of such a product: "Warning: Do not exceed the dose prescribed by your physician. If difficulty persists, contact your physician immediately."

        f. Miscellaneous drug products. Certain drug products were approved by the FDA with the provision that they must be dispensed along with a patient package insert that includes a

particular warning or statement of benefits and risks associated with the use of the drug. For example, isotretinoin was approved for dispensing with an insert warning about serious fetal harm when administered to pregnant women.

L. **Medication Guides**

1. The "Medication Guide" bill was signed into law in August 1996. By 2006, 95% of patients receiving a new prescription were to receive written information in nontechnical language and in a uniform format. "Medication Guides" or "MedGuides" should not be confused with the patient leaflets generated by most pharmacy computer software programs. Patient leaflets are typically part of the pharmacy software package to process prescriptions and are written and updated by a source other than the manufacturer or FDA. The language of Medication Guides is approved by the FDA, whereas patient leaflets are not approved by the FDA. The manufacturers must make Medication Guides available electronically to pharmacies. The FDA Amendments Act of 2007 includes a "risk evaluation and mitigation strategy" (REMS), giving the FDA more power to require the sponsor or manufacturer of the drug to establish procedures to increase patient safety. One of the strategies is the distribution of Medication Guides.

2. The legislation has created significant confusion and controversy within the pharmacy and health care communities. Many pharmacists assume that the patient leaflet satisfies the Medication Guide requirement, but because the language was not approved by the FDA, the agency (FDA) says the two are not substitutable. It is not clear whether one manufacturer's Medication Guide can be given to the patient when another manufacturer's equivalent generic product is dispensed. Each manufacturer is to make the Medication Guides available to pharmacies. If a pharmacy gave the wrong manufacturer's Medication Guide for a generic product, assuming the manufacturer's name is on the document, technically this could be construed as a labeling violation. Professional pharmacy organizations and other interested parties (i.e., pharmaceutical manufacturers) are working with the FDA to clarify these requirements. On the FDA web site all current medication guides may be downloaded and printed. Individuals may also request to receive notice when new medication guides are available.

M. **Prescription drug samples**

1. An **amendment** to the FDCA (Prescription Drug Marketing Act) severely restricted the distribution of drug samples by manufacturers. Under the FDCA, no person may sell, purchase, or trade, or offer to sell, purchase, or trade any drug sample. Samples may only be distributed upon written request of a practitioner. Manufacturers must maintain records of every sample distribution for a period of 3 years. Pharmacies may not receive samples from a manufacturer except in certain situations in which a practitioner requests storage of his or her samples in the pharmacy.

2. **Importation under the FDCA.** The Prescription Drug Marketing Act prohibits the import of prescription drugs once exported. Importation is allowed after notification and approval of the FDA and in cases of an emergency.

N. **Medical devices.** An amendment to the FDCA in 1976 (Medical Device Amendments) required a device manufacturer to provide reasonable assurance of the safety and effectiveness of the device. The amendment required the FDA to categorize each device on the market in 1976 into one of three classes: Class I, Class II, or Class III, depending on each device's safety and effectiveness. Generally, **Class I** devices are those that have a reasonable assurance of safety and effectiveness. **Class II** devices are those that do not have the reasonable assurance of safety and effectiveness, but there is sufficient information about the device to establish special controls to ensure its safety and effectiveness (and may be marketed with such controls). **Class III** devices are those for which information is not sufficient to provide reasonable assurance of their safety and effectiveness. Class III devices may be marketed only if they are proven to be substantially equivalent to a device on the market before 1976, by approval of a premarket application, or by reclassification into Class I or II.

1. **Medical device tracking.** Manufacturers of medical devices whose failure would be reasonably likely to have a serious adverse health consequence must track the device down the chain of distribution to the patient. Such tracking allows the manufacturer to take appropriate action with respect to recalls, defects, or other relevant information concerning the device. Every final distributor such as a pharmacy, hospital, or home health care company must report certain information to the manufacturer. Tracking information must be maintained by the manufacturer and distributor for the useful life of the device and be available for inspection by FDA personnel.

2. **Manufacturer's reports.** Every device manufacturer must report to the FDA information, when received or made aware of, that reasonably suggests that one of its marketed devices may have caused or contributed to a death or serious injury. Likewise, hospitals and other medical service facilities must provide reports on adverse reactions to, or malfunctioning of, medical devices.

3. **Adulteration and misbranding.** Medical devices may be adulterated or misbranded in the same way that drugs are adulterated or misbranded (see II.I).

III. POISON PREVENTION PACKAGING ACT (PPPA). The PPPA of 1970 requires

that drugs for human use in an oral dosage form must be packaged for the consumer in special packaging. All such federal controlled substances and drugs dispensed pursuant to a prescription must be dispensed to the consumer in special packaging. **Special packaging**, referred to as **child-resistant** containers, is defined as a container that is designed to be significantly difficult for children younger than 5 years of age to gain access to within a reasonable time. The container must not be too difficult for normal adults (ones with no overt physical or mental handicaps) to use properly and does not include packaging that all such children cannot gain access within a reasonable time. The Consumer Products Safety Commission is responsible for interpreting, establishing rules and regulations for, and enforcing the provisions of the PPPA.

A. **Exceptions.** The following medications are exempt from the special packaging requirements:

1. Sublingual dosage forms of nitroglycerin; other dosage forms intended for oral administration, such as nitroglycerin sustained-release preparations, must be packaged in child-resistant containers

2. Sublingual and chewable forms of isosorbide dinitrate in dosage strengths of 10 mg or less

3. Erythromycin ethylsuccinate granules for oral suspension and oral suspensions in packages containing not more than 8 g of the equivalent of erythromycin

4. Cyclically administered oral contraceptives in manufacturers' mnemonic (memory-aid) dispenser packages that rely solely on the activity of one or more progestogen or estrogen substances

5. Anhydrous cholestyramine in powder form

6. All unit-dose forms of potassium supplements, including individually wrapped effervescent tablets, unit-dose vials of liquid potassium, and powdered potassium in unit-dose packages, containing not more than 50 mEq of potassium per unit dose

7. Sodium fluoride drug preparations, including liquid and tablet forms, containing not more than 264 mg of sodium fluoride per package and containing no other prescription medication

8. Betamethasone tablets packaged in manufacturers' dispenser packages, containing not more than 12.6 mg betamethasone

9. Pancrelipase preparations in tablet, capsule, or powder form and containing no other prescription medication

10. Prednisone in tablet form, when dispensed in packages containing not more than 105 mg of the drug, and containing no other prescription medication

11. Mebendazole in tablet form in packages containing not more than 600 mg of the drug and no other prescription medication

12. Methylprednisolone in tablet form in packages containing not more than 84 mg of the drug and no other prescription medication

13. Colestipol in powder form in packages containing not more than 5 g of the drug and no other prescription medication

14. Erythromycin ethylsuccinate tablets in packages containing no more than the equivalent of 16 g erythromycin

15. Conjugated estrogen tablets *USP*, when dispensed in mnemonic packages containing not more than 32 mg of the drug and no other prescription medication

16. Norethindrone acetate tablets *USP*, when dispensed in mnemonic packages containing not more than 50 mg of the drug and no other prescription medication

17. Medroxyprogesterone acetate tablets

B. **Requests for a non–child-resistant container.** A prescribing practitioner may make a request in the prescription that the medication be dispensed in a non–child-resistant container. A practitioner may not, however, make a blanket request that all prescriptions issued by him or her be dispensed in non–child-resistant containers. The purchaser, or patient, may also make a request that the medication be dispensed in a non–child-resistant container. The request of the purchaser, or patient, does not

(under the PPPA) have to be in writing. The purchaser, or patient, may make a blanket request that none of his or her medications be dispensed in a child-resistant container. A dispensing pharmacist may never make the decision to use non–child-resistant containers.

C. **Reuse of child-resistant containers.** Reuse of child-resistant plastic containers are prohibited by regulation of the federal Consumer Products Safety Commission. However, the Commission has indicated that glass containers may be reused as long as a new safety closure is used.

D. **Manufacturer's packaging.** Packaging from the manufacturer that is intended to be dispensed directly to the patient must be in child-resistant plastic packaging. Bulk packaging intended to be repackaged by the pharmacist for each prescription does not have to be in special packaging from the manufacturer. Unit packaging from the manufacturer that will be dispensed directly to the consumer, or patient, must comply with the child-resistant requirements of the PPPA (unless specifically exempted; see III.A).

E. **Exemptions for easy access.** Special packaging is not required in cases where OTC medication needs to be readily available to the elderly or persons with disabilities. A manufacturer may supply a single size of a drug product in non–child-resistant packaging, as long as it also supplies the medication in packages that use the special packaging. Additionally, the package must be conspicuously labeled with the statement: "This package for households without young children." For those packages too small for this statement, the statement "Package not child-resistant" may be used.

F. **Hospitals and institutions.** As long as the medication is administered by institutional personnel and is not directly dispensed to the consumer (patient), child-resistant containers are not required.

G. **Household products and chemicals.** The special packaging requirements of the PPPA apply to household substances. *Household substance* is defined as "any substance which is customarily produced or distributed for sale for consumption or use, or customarily stored, by individuals in or about the household. . . ."

H. **Miscellaneous products requiring special packaging.** The PPPA requires that certain household substances be distributed to the consumer in special packaging. Examples of these substances include furniture polish containing petroleum distillates, drain pipe cleaners, turpentine, paint solvents, and lighter fluid.

IV. ANTI-TAMPERING ACT.
The U.S. Congress passed the Anti-Tampering Act in 1984 due to several deaths that occurred in the early 1980s from OTC medication capsules contaminated with cyanide.

A. **Violations.** Unlawful acts involving a consumer product can be broken down into one of the following listed violations. The term *consumer product* includes any food, drug, device, or cosmetic, as well as any article, product, or commodity that is customarily used by individuals for purposes of personal care or to perform services ordinarily done within a household.

1. **Tampering.** Any individual who tampers or attempts to tamper with any consumer product that affects interstate or foreign commerce, or its labeling or container, may be in violation of the statute. A violation occurs when the individual acts (or threatens to act) with reckless disregard for the risk that another person will be placed in danger of death or bodily injury. Any individual who taints any consumer product or causes its labeling or container to be materially false or misleading is in violation of the statute if done with intent to cause serious injury to the business of another.

2. **False communications.** Knowingly communicating false information that a consumer product has been tainted may be a violation. If such tainting, had it occurred, would create a risk of death or bodily injury to another person, then the false communication is deemed a violation.

3. **Conspiracy.** An agreement between two or more persons to do (or further) either of the aforementioned acts is considered a violation.

B. **OTC tamper-resistant packaging.** Certain OTC products must be packaged, by FDA regulation, in tamper-resistant packaging. Examples include contact lens solutions and other ophthalmic solutions. A **tamper-resistant package** is one having one or more indicators or barriers to entry that, if breached or missing, can reasonably be expected to provide visible evidence to consumers that tampering has occurred. To reduce tampering, the package must have **one** of the following characteristics:

1. Be distinctive by design so that the product cannot be duplicated by commonly available materials or processes or

2. Use one or more indicators or barriers to entry that employ an identifying characteristic

C. **OTC tamper-resistant labeling.** The OTC product must be labeled with a prominently placed statement alerting consumers to the specific tamper-resistant feature of the package. The statement must be placed so that it will be unaffected if the tamper-resistant feature is breached or missing.

D. **Medical devices and cosmetics.** Certain medical devices and cosmetics must be packaged in tamper-resistant packaging. The packaging requirements are similar to the requirements outlined previously for OTC drug products.

V. MAILING PRESCRIPTION MEDICATION

A. All prescription medication, including controlled substances and narcotics in Schedules II to V, may be mailed from a physician, or pharmacist pursuant to a prescription, to the patient. Flammable substances (e.g., acetone) and alcoholic beverages may not be sent to a patient through the U.S. mail.

B. The medication must be placed in a plain outer container or be securely overwrapped in plain paper. There must be no markings of any kind on the outside wrapper or container that would indicate the nature of the contents.

VI. OMNIBUS BUDGET RECONCILIATION ACT OF 1990 (OBRA '90).
Under the Constitution of the United States, the federal government has no power or authority to directly regulate the practice of pharmacy. Such power rests with each state. The federal government can, however, indirectly regulate, or affect, the practice of pharmacy by attaching conditions of participation and reimbursement for federally funded programs.

A. **Medicaid prescriptions.** With respect to prescriptions dispensed to Medicaid patients (paid in part by the federal government along with the state government), the federal government has attached certain conditions for reimbursement. Such conditions were deemed necessary to stem the always increasing cost of the Medicaid programs. It was believed that improved medication compliance by Medicaid recipients would, in the long run, reduce the cost of the programs by reducing subsequent hospitalizations and other subsequent utilization of health care. As a result, pharmacists are required to do the following in the course of dispensing a Medicaid prescription:

1. Make a reasonable good-faith effort to obtain and maintain a history of the patient, including a medication history
2. Conduct a review of every prescription for appropriateness and to screen for potential drug therapy problems
3. Make an offer to counsel each Medicaid recipient concerning the drug (if the offer is accepted, the counseling must include the drug's proper administration, common adverse or severe side effects, techniques for self-monitoring, and proper storage)

B. **Manufacturer's best price.** OBRA '90 requires manufacturers who wish to participate in the Medicaid program to offer the federal government their best price for prescription drugs. *Best price* is defined as the lowest price at which any purchaser is purchasing that drug product.

VII. HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT (HIPAA) OF 1996.
HIPAA is federal legislation that requires all health care providers, including pharmacies, to protect patient information from unauthorized use and disclosures. This is referred to as the Privacy Rule and was established as a result of the government's recognition that individually identifiable health information is readily available due to health care plans, health care clearinghouses, third-party billing practices, clinical research trials, and the transmission of health information in electronic form. Protected health information (PHI) must be confidentially maintained by a health care provider to prevent any unauthorized use or disclosure. Other covered entities, such as Organized Health Care Arrangements, health maintenance organizations (HMOs), and insurance plans, must also follow the Privacy Rule.

A. **Definitions.** Under the Privacy Rule, certain terms have specific meanings.
1. **"Covered entity"** means:
   a. A health plan (e.g., group health insurance, Medicaid, Medicare)
   b. A health care clearinghouse (e.g., billing service companies and companies that process health information received from another entity)

    c. A health care provider who transmits any health information in electronic form in connection with a transaction covered by HIPAA. *Health care* is defined as including the sale or dispensing of a drug, device, equipment, or other item in accordance with a prescription.

2. **"Individually identifiable health information"** is information created or received by a covered entity that relates to the past, present, or future physical or mental health or condition of an individual; the provision of health care to an individual; or any payment for any provision of any health care, **and** that identifies the individual **or** that provides a reasonable basis to identify the individual. The items listed in the following are deemed sufficient to identify an individual:

    a. Name

    b. Address, including all geographic subdivisions smaller than a state (e.g., street address, city, county, zip code)

    c. Dates (except year), including birth dates, admission dates, discharge dates, dates of death

    d. Telephone numbers

    e. Fax numbers

    f. E-mail addresses

    g. Social Security numbers

    h. Medical record numbers

    i. Health plan beneficiary numbers

    j. Account numbers

    k. Certificate/license numbers

    l. Vehicle identifiers and serial numbers, including license plate numbers

    m. Device identifiers

    n. Web universal resource locators (URLs)

    o. Internet protocol (IP) address numbers

    p. Biometric identifiers, including fingerprints and voice prints

    q. Full face photographic images and any comparable images

    r. Any other unique identifying number, characteristic, or code, except for codes assigned to reidentify information that has been de-identified

    s. Names of any relative, employer, or household member of the individual

3. **"Protected health information" (PHI)** is all individually identifiable health information that is transmitted or maintained in **any** form or medium, electronically or otherwise.

4. **"Notice of privacy practices for protected health information."** An individual has the right to adequate notice of the uses and disclosures of PHI that may be made by the covered entity, and of the individual's rights and the covered entity's legal duties with respect to PHI. Generally, the notice must contain information describing the individual's rights under the Privacy Rule and the covered entity's responsibilities.

    a. Header. Every notice must contain the following statement as a header or be otherwise prominently displayed: "THIS NOTICE DESCRIBES HOW MEDICAL INFORMATION ABOUT YOU MAY BE USED AND DISCLOSED AND HOW YOU CAN GET ACCESS TO THIS INFORMATION. PLEASE REVIEW IT CAREFULLY."

    b. Individual's rights. An individual has the right to request restrictions on certain uses and disclosures of PHI, the right to receive confidential communications of PHI by alternative means or at alternative locations, the right to inspect and copy his or her PHI, the right to amend his or her PHI, the right to receive an accounting of disclosures of PHI, and the right to obtain a paper copy of the notice from the covered entity.

    c. Covered entity's responsibilities. The notice must include a statement that the covered entity is required by law to maintain the privacy of PHI, a statement of its legal duties and privacy practices with respect to PHI, a statement that it must abide by the notice currently in effect, and a statement that it reserves the right to change the terms of its notice and how it will provide individuals with a revised notice.

    d. Miscellaneous contents of notice. The notice must contain a statement that individuals may complain to the covered entity and to the U.S. Department of Health and Human Services if they believe their privacy rights have been violated. The notice must state a date on which it becomes effective. The effective date must be no later than the date of the first service delivery.

    e. **Posting of notice.** A pharmacy must post the notice in a clear and prominent location where it is reasonable to expect individuals to be able to read the notice.

    f. **Written acknowledgment of notice.** Every covered entity must obtain a written acknowledgment of receipt of the notice by the individual. If one is not obtained, the covered entity must document its good-faith efforts to obtain the acknowledgment and the reason why it was not obtained.

    g. **Exceptions for inmates.** A person incarcerated in or otherwise confined to a correctional institution does not have a right to notice under the Privacy Rule, and the notice requirements do not apply to a correctional institution that is a covered entity.

5. **"Authorization"** for a covered entity to use or disclose PHI: a patient must give written authorization before a covered entity, including pharmacies and pharmacists, may use or disclose PHI. **No patient consent or authorization** is necessary when PHI use and disclosure is for **treatment, payment, or health care operations**. This allows a health care provider to consult with other covered entities (i.e., other health care providers) to provide proper patient care without being unduly hindered by the Privacy Rule. For uses and disclosures that require an authorization, the **written authorization** must be written in plain language, and a **signed copy** must be provided to the individual. The signed authorization must be maintained by the covered entity for **6 years** from the date of its creation or the date when it was last in effect, whichever is later. The written authorization must at least contain the following core elements and statements:

    a. A description of the information to be used or disclosed that identifies the information in a specific and meaningful fashion.

    b. The name or other specific identification of the person(s), or class of persons, authorized to make the requested use or disclosure.

    c. The name or other specific identification of the person(s), or class of persons, to whom the covered entity may make the requested use or disclosure.

    d. A description of each purpose of the requested use or disclosure.

    e. An expiration date or an expiration event that relates to the individual or the purpose of the use or disclosure.

    f. Signature of the individual and date. If signed by a personal representative, it must also include a description of such representative's authority to act for the individual.

    g. The written authorization must contain the following statements:

      (1) The individual's right to revoke the authorization in writing along with the exceptions to the right to revoke and a description of how the individual may revoke the authorization.

      (2) The ability or inability to condition treatment, payment, enrollment, or eligibility for benefits on the authorization, by stating either that the covered entity cannot require authorization or that if the covered entity can require authorization, the consequences to the individual of his or her refusal to sign the authorization.

      (3) The potential for the disclosed information to be redisclosed by the recipient and no longer be protected by the Privacy Rule.

6. **"Minimum necessary."** When using or disclosing PHI or when requesting PHI from another covered entity, a covered entity must make reasonable efforts to limit PHI to the **minimum necessary** to accomplish the intended purpose of the use, disclosure, or request. The minimum necessary rule **does not apply** to disclosures or requests by a health care provider for treatment, uses or disclosures made pursuant to an authorization, and uses or disclosures that are required by law. "Required by law" means a mandate in a law that compels an entity to make a use or disclosure of PHI. It includes a covered entity's compliance with state and federal laws and regulations that require the production of information; court orders and court-ordered warrants, subpoenas or summons issued by a court, a governmental or tribal inspector general, or an administrative body authorized to require the production of information and Medicare conditions of participation with respect to health care providers participating in the program.

7. **"Business associates."** A business associate of a covered entity is a person or business that performs a function or activity on behalf of the covered entity, such as claims processing, billing, utilization review, quality assurance, etc., **and** that requires the use or disclosure of individually identifiable

health information. A business associate would also include persons who provide services to the covered entity, **and** the service involves disclosure of individually identifiable health information, such as legal, actuarial, accounting, consulting, data aggregation, management, administrative, accreditation, or financial services. **Excluded** from the definition of business associates are members of the workforce of the covered entity, and functions or services that do not require disclosure of individually identifiable health information.

    a. **Business associate contracts.** Every business associate must enter into an agreement with the covered entity to ensure compliance with the Privacy Rule. Generally, the agreement must establish the required uses and disclosures of PHI by the business associate and require the return or destruction of PHI at termination of the contract.

B. Additional responsibilities of covered entities. Every covered entity must create policies and procedures for compliance with the Privacy Rule, must designate a privacy official responsible for creating such policies and procedures, must designate a contact person or office that is responsible for receiving complaints and that is able to provide further information about matters covered by the notice, and must train all members of its workforce with respect to the Privacy Rule. Every designation must be maintained by the covered entity for 6 years from the date it was last in effect. Lastly, every covered entity must have and apply appropriate sanctions against members of its workforce who fail to comply with the Privacy Rule.

C. State law privacy rules. The federal Privacy Rule is intended as the minimum requirement for privacy standards. If a state law is more stringent, then a covered entity must follow that state's privacy standards. If a state privacy law is not as stringent, the federal Privacy Rule preempts any contrary state law and a covered entity must abide by the federal Privacy Rule.

D. Penalties for violation of the Privacy Rule. Any person who violates the Privacy Rule may not be fined more than $100 for each violation up to a total of $25,000 per calendar year for all violations of an identical requirement. Additional penalties may be imposed for the following **wrongful disclosure** of individually identifiable health information:

    1. Wrongful obtainment or disclosure of PHI: fined not more than $50,000, imprisoned not more than 1 year, or both.

    2. Wrongful obtainment or disclosure of PHI under false pretenses: fined not more than $100,000, imprisoned not more than 5 years, or both.

    3. Wrongful obtainment or disclosure of PHI committed with intent to sell, transfer, or use same for commercial advantage, personal gain, or malicious harm: fined not more than $250,000, imprisoned not more than 10 years, or both.

VIII. OPIOID (NARCOTIC) ADDICTION TREATMENT PROGRAMS.

The Narcotic Addiction Treatment Program of 1974 and the Drug Addiction Treatment Act of 2000 amend the Federal Controlled Substances Act (CSA) in the treatment of drug addictions. The Narcotic Treatment Act (NTA) of 1974 required patients to begin treatment in a facility for "detoxification" and then later would receive treatment on an outpatient basis through a "maintenance" program. Facilities, physicians, and pharmacies serving in this program must have separate DEA registrations. The pharmacy for example is required to separate registrations based on detoxification, maintenance, and if the pharmacy provides compounding. There are multiple types of registrations: detoxification, maintenance, detoxification and maintenance, detoxification compounding, maintenance compounding, and detoxification and maintenance compounding. The major issue is using methadone (Schedule II) for the treatment of addictions and dividing the dosage (compounding) so patients are unaware of the tapering of the dosage.

The NTA of 1974 that established the narcotic treatment programs was the system for treating opioid addictions. The system was criticized for poor outcomes, being inflexible, and only serving a small percentage of patients, and in 2000, the Congress and the President signed into law a new regulation repealing FDA regulations and transferring the enforcement to the Substance Abuse and Mental Health Services Administration (SAMHSA). The name was changed from narcotic treatment programs to opioid treatment programs.

A. Opioid treatment programs. The narcotic treatment programs until May of 2001 required patients to start treatment in an approved facility. The Congress, recognizing that this requirement created a substantial barrier, passed the **Drug Addiction Treatment Act (DATA)**.

This new law creates a way for office-based physicians to treat addicts on an outpatient basis. "Qualifying Physicians" may prescribe and dispense Schedule III, IV, and V opioids that have been approved by the FDA for maintenance or detoxification. Currently, buprenorphine sublingual tablets (Subutex) and buprenorphine-naloxone tablets (Suboxone) are the approved drugs for this purpose.

B. **Qualifying Physicians.** "Qualifying Physicians" is defined in part as a physician board certified in addiction psychiatry or addiction medicine. The definition also defines "qualified" as a physician attending an 8-hr training in the treatment and management of opioid-dependent patients. Each qualifying physician may not treat more than 100 opioid-dependent patients. In order to prescribe to patients in this program, the physicians must obtain a special DEA number.

C. **Methadone**
   1. Methadone is a Schedule II controlled substance and is approved by the FDA for the treatment of pain. The pharmacist may dispense and compound methadone prescriptions with the standard DEA registration.
   2. When methadone or any Schedule II drug is used for the detoxification and maintenance of narcotic addiction treatment, the practitioners must obtain a separate DEA registration as a narcotic treatment program and register with the SAMHSA of the Department of Health and Human Services (HHS).

IX. FOOD AND DRUG ADMINISTRATIVE AMENDMENTS ACT (FDAAA) OF 2007.

This law was enacted in September of 2007 reauthorizing and amending many drug and device provisions that were to expire. The Act also provides new funding and more authority over drug safety. The FDAAA allows the FDA broader use of the fees generated by the Prescription Drug User Fee Act and increases the fees. The Act addresses some of the postmarket problems when approved products are removed because of safety concerns. The law gives the FDA expanded responsibilities and authority to regulate drug safety. The FDA can mandate label changes related to safety and require clinical trial reporting and postmarket studies to assess risks. The FDA under this new Act can require companies to implement risk evaluation and mitigation strategies (REMS).

The FDA under this Act has the authority to require Phase IV testing for any prescription drug. The FDA can require Phase IV studies to assess risks when the adverse event reporting or surveillance is not sufficient. The REMS provision gives the FDA the authority to require the sponsor or manufacturer of the drug to establish procedures and programs for patient safety. A REMS can require the distribution of Medication Guides, package inserts, or oral communication plan to health professions. If there is a high potential for risk, the REMS may require that the health care provider have special training or experience and/or the drug be only dispensed in specified settings and/or the patient be enrolled in a registry and agree to testing and monitoring.

The FDA did not have the authority until the passage of FDAAA to require manufacturers to modify the safety information or warnings in its labeling after the drug had been approved. The issue was that manufacturers had the label approved prior to marketing. Controversies arose between the FDA and manufacturer when new safety information was discovered and the FDA wanted the manufacturer to add more warnings on the label. FDAAA gives the FDA this power.

FDAAA requires that the FDA develop and maintain a Web site for patients and providers to have current access to labeling, safety information, and implemented REMS. Another safety provision is the development and maintenance of a surveillance system designed to detect early signs of medication risk and safety concerns.

X. RYAN HAIGHT ONLINE PHARMACY CONSUMER PROTECTION ACT OF 2008.

The law amends the CSA by adding new requirements and criminal provisions to combat the proliferation of so-called rogue Internet sites. The Act applies to all Schedules of controlled substances. As of April 13, 2009, it is illegal to deliver, distribute, or dispense a controlled substance by means of the Internet unless the online pharmacy holds a modified DEA registration that authorizes this activity. The Act contains the definition of an online pharmacy, exemptions to registration, notification requirements to the DEA to provide online services, Web site, reporting and prescription requirements, and penalties for violations.

Study Questions

Directions: Each of the numbered items or incomplete statements in this section is followed by answers or by completions of the statement. Select the **one** lettered answer or completion that is **best** in each case.

1. You have been dispensing narcotics to a patient for several months for "back" pain. You are reasonably convinced that the drug is supporting an addiction. You call the physician and she tells you that she is using the narcotic for "back" pain. Select the best answer:

   (A) Refuse to refill the narcotic since it is not a "legitimate" medical purpose.
   (B) Fill the refill because pain is a "legitimate" medical purpose.
   (C) Call the medical board and report the physician.
   (D) Suggest OTC ibuprofen.
   (E) Give the patient part of the prescription.

2. Which of the following narcotic drugs has been approved by the FDA for use in the treatment of narcotic addiction?

   (A) Morphine
   (B) Codeine
   (C) Methadone
   (D) Hydrocodone
   (E) None of the above

3. For the U.S. government to place a drug into Schedule III, which of the following findings must be made concerning the drug?

   (A) The drug or other substance has a high potential for abuse.
   (B) Abuse of the drug or other substance may lead to limited physical dependence or psychological dependence relative to the drugs or other substances in Schedule IV.
   (C) The drug or other substance has no currently accepted medical use in treatment in the United States.
   (D) Abuse of the drug or other substance may lead to moderate or low physical dependence or high psychological dependence.
   (E) There is a lack of accepted safety for use of the drug or other substance under medical supervision.

4. Under the Federal Controlled Substances Act, all of the following items must appear on a controlled substance prescription label *except* the

   (A) name, address, and DEA number of the pharmacy.
   (B) name of the patient.
   (C) name of the prescribing practitioner.
   (D) serial number assigned to the prescription.
   (E) date of the initial filling of the prescription.

5. Under the Federal Controlled Substances Act, all of the following entities must register with the DEA *except*

   (A) prescribers of controlled substances.
   (B) pharmacists who dispense controlled substances.
   (C) distributors of controlled substances.
   (D) importers of controlled substances.
   (E) universities conducting instructional activities with controlled substances listed in Schedules II to V.

6. Under the Federal Controlled Substances Act, which of the following statements concerning the emergency dispensing of a Schedule II controlled substance is true?

   (A) The practitioner who authorizes the oral prescription must, within 7 days, deliver a written prescription to the dispensing pharmacist.
   (B) The quantity prescribed and dispensed must be limited to the amount necessary to adequately treat the patient during the emergency period.
   (C) It is not reasonably possible for the practitioner to provide a written prescription to be presented to the person dispensing the controlled substance before the dispensing.
   (D) No appropriate alternative treatment is available, including administration of a controlled substance that is not in Schedule II.
   (E) All of the above statements are true.

7. Under the Federal Controlled Substances Act, the crime transfer warning, "Caution: Federal law prohibits the transfer of this drug to any person other than the patient for whom it was prescribed," must appear on the prescription container label of all controlled substances *except*

   (A) Schedule II controlled substances.
   (B) Schedule III controlled substances.
   (C) Schedule IV controlled substances.
   (D) Schedule V controlled substances.

8. Which of the following statements concerning drug recall classification is true?

  (A) A Class I recall is a situation in which the use of, or exposure to, a violative product is not likely to cause adverse health consequences.

  (B) A Class I recall is a situation in which the use of, or exposure to, a violative product may cause temporary or medically reversible adverse health consequences or in which the probability of serious health consequences is remote.

  (C) A Class I recall is a situation in which there is a reasonable probability that the use of, or exposure to, a violative product will cause serious adverse health consequences or death.

  (D) A Class II recall is a situation in which the use of, or exposure to, a violative product is not likely to cause adverse health consequences.

  (E) A Class III recall is a situation in which there is a reasonable probability that the use of, or exposure to, a violative product will cause serious adverse health consequences or death.

9. Under the Federal Food, Drug, and Cosmetic Act, all of the following statements are considered a misbranding of a drug *except* if

  (A) the labeling is false or misleading in any particular.

  (B) an oral contraceptive is dispensed without the required patient package insert.

  (C) the drug is an imitation of another drug, or if it is offered for sale under the name of another drug.

  (D) the drug consists in whole or in part of any filthy, putrid, or decomposed substance.

10. All of the following oral medications are exempt from child-resistant packaging *except*

  (A) Anhydrous cholestyramine in powder form

  (B) Nitroglycerin preparations in sustained-release form

  (C) cyclically administered oral contraceptives in manufacturers' mnemonic (memory-aid) dispenser packages that rely solely on the activity of one or more progestogen or estrogen substances

  (D) pancrelipase preparations in tablet, capsule, or powder form that contain no other prescription medication

Answers and Explanations

1. **The answer is B** *[see I.I.2]*.
"Back Pain" is a "legitimate medical purpose" making the prescription valid and the best answer is to fill the order.

2. **The answer is C** *[see VIII; VIII.A; I.I.2.c.(2)]*.
Methadone is approved by the FDA for use in the treatment of narcotic addiction. Only a properly registered narcotic treatment program may dispense methadone for maintenance or detoxification treatment. Pharmacies that are not registered may only dispense methadone for severe pain.

3. **The answer is D** *[see I.A.3]*.
To place a drug into Schedule III, the U.S. government must make the following findings concerning the drug: (1) it has a potential for abuse less than the drugs or other substances in Schedules I and II; (2) it has a currently accepted medical use in treatment in the United States; and (3) abuse of the drug may lead to moderate or low physical dependence or high psychological dependence.

4. **The answer is A** *[see I.I.8.c.(1)–(7)]*.
A pharmacy's DEA number is not required to appear on the medication container label dispensed to the patient.

5. **The answer is B** *[see I.B.2.a–k; I.B.9.d]*.
Agents and employees of DEA registrants, such as pharmacists, are exempt from registering with the DEA. Pharmacies, not the individual pharmacists, must register with the DEA.

6. **The answer is E** *[see I.I.4.a–b]*.
Emergency dispensing of an oral Schedule II controlled substance prescription must be done in strict compliance with the law. Before dispensing such a prescription, the pharmacist must make the threshold determination that ALL three factors that define an emergency situation (see I.I.4.a) are present. If any one of the three factors is absent, the prescription is not for an emergency situation, and a written prescription must be presented to the pharmacist.

7. The answer is D *[see I.I.8.c.(7)]*.
The federal crime transfer warning label is not required to appear on the prescription container label of Schedule V controlled substances.

8. The answer is C *[see II.H.2.a–c]*.
A Class I recall is a situation in which there is a reasonable probability that the use of, or exposure to, a violative product will cause serious adverse health consequences or death.

9. The answer is D *[see II.I.1, 2]*.
The Federal Food, Drug, and Cosmetic Act states that a drug is considered adulterated if it consists in whole or in part of any filthy, putrid, or decomposed substance. The terms misbranding and adulteration are often referred to in literature and case law as being the same or similar violations under the law. However, the Act sets forth specific instances of adulteration and specific instances of misbranding.

10. The answer is B *[see III.A.1]*.
Only sublingual dosage forms of nitroglycerin are exempt from child-resistant packaging.

Reviewing and Dispensing Prescription and Medication Orders

TODD A. BROWN

<div style="text-align: right">64</div>

I. DEFINITIONS

A. Prescriptions are orders for medications, nondrug products, and services that are written by a licensed or midlevel practitioner who is authorized to prescribe (see Appendix A). Pharmacists are increasingly being given prescribing privileges by enactment of **collaborative drug therapy management** (CDTM) legislation. This allows pharmacists to modify existing medications and order new medication under established protocols or guidelines agreed on by the pharmacist and physician. Prescriptions may be written, presented orally (by telephone), or presented electronically (i.e., via fax or computer network) to the pharmacist. The requirements of the prescription form include security and tamper-resistant features that vary with state regulations. The prescription serves as a vehicle for communication from the prescriber to the pharmacist about the needs of the patient. The following information should be included:

1. **Patient information**, including full name and address

2. **Date** on which the prescription was issued

3. **Name and dosage form of the product.** The name can be any of the following:
   a. Proprietary (brand)
   b. Nonproprietary (generic)
   c. Chemical

4. **Product strength.** The strength of the product is not required if only one strength is commercially available or if the product contains a combination of active ingredients. It is advisable to include the strength to reduce the chance of misinterpretation.

5. **Quantity to be dispensed.** This should include the amount and the units of measure (e.g., grams, ounces, tablets). If the amount is not specified, the directions should specify the dose to be taken and the duration of therapy so that the pharmacist can calculate the quantity required for the patient.

6. **Directions for the pharmacist.** Directions may be required for:
   a. Preparation (e.g., compounding)
   b. Labeling (i.e., information to be put on the prescription label)

7. **Directions for the patient.** These should include explicit instructions on the quantity, schedule, and duration for proper use. "As directed" should be avoided. If the directions vary, a minimum and maximum dose can be used.

8. **Refill information.** If refill information is not supplied, it is generally assumed that no refills are authorized. "As needed" (pro re nata [prn]) refills are usually interpreted as allowing for refills for 1 year unless laws or regulations restrict the amount or period in which a prescription is valid.

9. **Prescriber information.** This should include the name, office address, signature of the prescriber, the Drug Enforcement Administration (DEA) number (for controlled substances only), and the National Provider Identifier (NPI) number.

B. **Medication orders** are orders for medications by an individual authorized to prescribe and are intended for use by patients while in an institutional setting. They may be written, presented orally (by telephone), or presented electronically (i.e., via fax or computer network) to the pharmacist. The medication order generally includes the following:

1. **Patient information** (e.g., full name, identification number)
2. **Date and time** the order was written
3. **Name of the product.** The name can be any of the following:
   a. Proprietary (brand)
   b. Nonproprietary (generic)
   c. Chemical
4. **Product strength, dosage, and route of administration.** The strength of the product is not required if only one strength is commercially available or if the product contains a combination of active ingredients. It is advisable to include the strength to reduce the chance of misinterpretation. The pharmacist may decide the strength of the product dispensed after calculating the patient's dose. The dosage and route of administration should be included to reduce the chance of misinterpreting the order and to allow for correct administration to the patient.
5. **Prescriber's signature.** If the order was taken verbally, the name of the person transcribing the order should be included.
6. **Directions for the pharmacist.** These can be used for:
   a. Preparation (e.g., compounding)
   b. Labeling (i.e., information to be put on the label)
7. **Instructions for administration**, including quantity, route of administration, schedule, and duration of use

II. UNDERSTANDING THE PRESCRIPTION OR MEDICATION ORDER AND EVALUATING ITS APPROPRIATENESS

A. **Understanding the order.** A complete understanding of all information in a prescription or medication order is required. Each piece of information should be appropriate and consistent with the remaining information (i.e., the instructions for use should be appropriate for the medication being ordered). The pharmacist should determine the prescriber's intent by interpreting the following information:

1. The name and address of both the patient and the prescriber
2. The patient's disease or condition requiring treatment
3. The reason the order is indicated, relative to the medical need of the patient (e.g., an antibacterial for an infection)
4. The name of the product, the quantity prescribed, and instructions for use
5. All terminology, including units of measure (apothecary, metric, or English) and Latin abbreviations (see Appendix A for common abbreviations)

B. **Evaluating the appropriateness.** Complete information is required on the prescription or medication order to allow the pharmacist to evaluate the appropriateness. When the order is incomplete, the pharmacist must obtain the required information from either the patient or the prescriber. The following should be considered during an evaluation:

1. The patient's disease or condition requiring treatment
2. The patient's allergies or hypersensitivities
3. The pharmacological or biological action of the prescribed product
4. The prescribed route of administration
5. Whether the prescribed product might result in a drug–drug, drug–disease, or drug–food interaction
6. Whether the dose, dosage form, and dosage regimen are safe and likely to meet the needs of the patient
7. Whether the patient will have any difficulties adhering to the regimen and the potential impact on the therapeutic outcome desired
8. Whether the total quantity of medication prescribed is sufficient to allow proper completion of a course of therapy

9. Whether a physical or chemical incompatibility might result (i.e., if the product requires extemporaneous compounding)
10. Whether a licensed practitioner, acting in the course and scope of practice, issued the prescription in good faith, for a legitimate medical purpose

C. **Discovering inappropriate prescriptions or medication orders.** Pharmacists are required to review medication profiles to ensure the appropriateness of prescribed medications. This is commonly called drug utilization review (DUR). Pharmacists should not fill or process prescriptions or medication orders that they have concerns with or that are considered inappropriate but, rather, should contact the prescriber. The process of calling a prescriber to discuss concerns identified during a DUR is commonly called **therapeutic intervention**.
   1. When performing a therapeutic intervention, the following information should be provided:
      a. A brief description of the problem
      b. A reference source that documents the problem
      c. A description of the clinical significance of the problem
      d. A suggestion of a solution to the problem
   2. Documentation of the results of a therapeutic intervention is required if the prescription or medication order is changed. The name of the prescriber, date of communication, issues discussed, and resolution should be included in the documentation. This information should be kept for the same period as the prescription or medication order.
   3. If the pharmacist feels that, in his or her professional judgment, an order is inappropriate and could harm the patient, the pharmacist should not process the order. The pharmacist may also be required to explain the situation to the patient. If, after a therapeutic intervention, the pharmacist believes the order is still inappropriate, the guidelines of the institution and professional judgment should be followed.

III. PROCESSING PRESCRIPTIONS AND MEDICATION ORDERS. An environment that limits distractions and disruptions will assist in increasing the accuracy of this process. Automation and the use of pharmacy technicians allow the pharmacist to oversee these functions. The time saved allows the pharmacist greater time for patient-focused activities, such as counseling and patient education.

A. The following information should be recorded on the prescription:
   1. The prescription number (for initial filling)
   2. The original date of filling
   3. The product and quantity dispensed
   4. The pharmacist's initials
B. **Product selection.** Generic substitution statutes, as well as formulary and therapeutic substitution policies, might provide direction in product selection.
C. **Product preparation** for use by the patient. The following might be necessary:
   1. Obtaining the proper amount of medication to be dispensed
   2. Reconstitution (the addition of liquid to make a solution or suspension)
   3. Extemporaneous compounding (see Chapter 4)
   4. Assembly of the medication delivery unit
D. **Selection of the proper package or container** is required to ensure product stability, to promote patient compliance, and to comply with legal requirements.
E. **Labeling the prescribed product**
   1. The **prescription label** typically contains the following information:
      a. Name and address of the pharmacy
      b. Patient's name
      c. Original date of filling
      d. Prescription number
      e. Directions for use
      f. Product's brand name or generic name and manufacturer
      g. Product strength (if available in more than one strength)
      h. Quantity of medication dispensed

  i. Prescriber's name
  j. Expiration date of the medication
  2. Unit-dose packages contain one dose or one unit of medication. For a medication order that is dispensed in **unit-dose packages**, the label should identify the product's brand or generic name, strength, lot number, and expiration date.
  3. Auxiliary and cautionary labels ensure proper medication use, storage, and compliance and reinforce information provided during counseling.
  4. For medication in Schedules II to IV (see Chapter 63), a federal transfer warning is required.
F. Record keeping and confidentiality. The pharmacist is required to maintain **prescription files** and **records** in accordance with standards of sound practice and statutory requirements. The implementation of the **Healthcare Insurance Portability and Accountability Act** (HIPAA) has put additional requirements on all health professionals who have access to health information (see Chapter 63). State prescription monitoring programs may require pharmacists to collect and provide information regarding the use of controlled substances. A **patient profile** contains patient demographic information and a complete chronological record of all medication use and services provided in the delivery of pharmaceutical care.
  1. The patient profile should contain the following **patient information**:
    a. Patient's name
    b. Patient's address (or room number in institutional settings)
    c. Any known allergies, sensitivities, or history of idiosyncratic reactions to previous medications
    d. Birth date (i.e., to assess the appropriateness of the dose)
    e. Clinical condition(s) (to help assess the appropriateness of the medication and to prevent drug–disease interactions)
    f. Weight (to assess the appropriateness of the dose)
    g. Occupation (to detect conditions associated with a particular occupation and to help determine if the patient will be able to comply with the regimen)
    h. Nonprescription medication use (to prevent drug interactions, to assess medication effectiveness, and to detect possible adverse effects)
  2. In addition, the patient profile should contain the following information from each prescription or medication order:
    a. Name of the medication
    b. Medication strength
    c. Dosage form
    d. Quantity dispensed
    e. Directions for use
    f. Prescription number
    g. Dispensing date
    h. Number of refills authorized and remaining
    i. Prescriber's name
    j. Pharmacist's initials

IV. DISPENSING MEDICATION AND COUNSELING. The dispensing of medication requires that the pharmacist verify that patients have the necessary knowledge and ability to adhere to the prescribed treatment. This will increase the likelihood of obtaining the desired outcomes.

A. Counseling patients. The pharmacist should evaluate the patient's understanding of each medication and supply additional information when the patient's information is incorrect or insufficient. The pharmacist may need to advise patients regarding the proper dosage, appearance, and name of the medication. Information about the route of administration, instructions for use, duration of use, and the reason the product was prescribed may also be needed. In addition, the following topics might also be appropriate:
  1. Special procedures. As appropriate, the pharmacist should advise patients how to take the medication (e.g., on an empty stomach, with plenty of water) and on foods to avoid while taking the medication (e.g., alcoholic beverages, dairy products).

2. **Potential adverse effects.** The pharmacist should ensure that patients are aware of the possible adverse effects associated with a medication. Patients should understand the following:

   a. The **frequency** of an adverse effect. This will help patients recognize common adverse effects and not be overly concerned with those that are rare.

   b. The **severity** of an adverse effect. This will help patients focus on those adverse effects that are severe and not those that are inconsequential.

   c. What action should be taken to **manage** or **minimize** the adverse effect. This will help patients deal with possible adverse effects in the appropriate manner.

3. **Proper storage.** The pharmacist should counsel patients on how to store medications properly to ensure stability and potency.

4. **Over-the-counter (OTC) products.** The pharmacist should instruct patients about the use of OTC products that may not be appropriate when taking a prescribed product.

B. **Counseling health professionals.** Health professionals (i.e., in an institutional setting) may administer medications to patients. In these cases, the pharmacist should ensure that the health professional has sufficient knowledge to administer the product. Information that health professionals would need include the following:

1. The choice of a particular product
2. The proper dosage, dosage regimen, and route of administration
3. The availability of commercially made products
4. Potential adverse effects
5. Drug interactions
6. Physical incompatibilities
7. Safe handling and disposal procedures
8. Nutritional interactions or requirements
9. Drug interference with laboratory tests

V. PATIENT MONITORING.
The provision of pharmaceutical care requires a **pharmaceutical care plan**. Monitoring a patient's need for medication and the effect of the medication on the patient maximizes the effectiveness. Undesired outcomes associated with drug therapy are frequently called **drug therapy problems**.

A. **Pharmaceutical care plan.** To increase the frequency and benefits of desired outcomes, a pharmaceutical care plan should include the following:

1. **Assessment.** A review of the medical conditions and symptoms to determine the need for medication
2. **Plan.** A decision of an appropriate drug therapy based on the assessment of the patient
3. **Monitoring.** A review of the outcomes of drug therapy (i.e., goals and end points) to determine whether the patient is obtaining the desired outcomes

B. **Drug therapy problems** are evidence of less-than-optimal drug therapy. Detection requires an assessment of the need for a change in drug therapy. Possible problems include:

1. **Unnecessary drug therapy.** The medication cannot be associated with a medical condition or the presence of a condition in which nondrug therapy is more appropriate.
2. **Wrong drug.** The drug is not indicated for the condition or is not delivering the desired outcomes, or a more effective drug is available.
3. **Dose too low.** Incorrect dose, frequency, administration, or duration of therapy results in an insufficient dose of drug to the patient.
4. **Adverse drug reaction.** An allergic reaction, drug interaction, or an undesirable effect occurs from a medication.
5. **Dose too high.** Incorrect dose, frequency, or duration results in more medication than is required.
6. **Inappropriate adherence.** The patient is not taking the optimal amount of medication owing to cost, administration difficulties, alternative health beliefs, or a lack of understanding of the need for the medication.
7. **Need additional drug therapy.** Owing to an undertreated condition, synergism with concurrent drug therapy or prophylactic therapy is required.

Study Questions

Directions: Each of the questions, statements, or incomplete statements can be correctly answered or completed by **one** of the suggested answers or phrases. Choose the **best** answer.

1. Medication orders differ from prescriptions in which of the following ways? They

   (A) are intended for ambulatory use.
   (B) contain only the generic name of the medication.
   (C) are intended for institutional use.
   (D) may be transmitted electronically.
   (E) contain the quantity of medication to be dispensed.

2. If a therapeutic intervention is necessary, all of the following information should be communicated to the prescriber *except*

   (A) a declaration that "a mistake was made."
   (B) a brief description of the problem.
   (C) a reference source that documents the problem.
   (D) an alternative or suggestion to resolve the problem.
   (E) a description of the clinical significance of the problem.

3. The following information should be recorded on a prescription *except* the

   (A) prescription number.
   (B) date of filling.
   (C) expiration date.
   (D) product and quantity dispensed.
   (E) pharmacist's initials.

4. A prescription label usually contains all of the following *except* the

   (A) quantity dispensed.
   (B) lot number.
   (C) patient's diagnosis.
   (D) expiration date.
   (E) prescriber's name.

5. Auxiliary and cautionary labels should be used for all of the following purposes *except* to

   (A) substitute for verbal consultation.
   (B) ensure proper usage.
   (C) inform of storage requirements.
   (D) comply with regulatory requirements.
   (E) warn against the concomitant use of certain drugs or foods.

6. The following items are essential for a patient profile system *except*

   (A) the patient's name.
   (B) the prescriber's Drug Enforcement Administration (DEA) registration number.
   (C) the patient's allergies.
   (D) the patient's birth date.
   (E) instructions for medication use.

7. The following are drug therapy problems *except*

   (A) an adverse effect from a medication.
   (B) symptoms caused by undertreatment.
   (C) a drug–drug interaction.
   (D) an undiagnosed condition.
   (E) an allergic reaction to a medication.

Answers and Explanations

1. **The answer is C** *[see I.B]*.
   Medication orders are written for the care of inpatients. Both medication orders and prescriptions may contain the brand or generic name of the drug and may be transmitted electronically. Only prescriptions contain the quantity of medication to be dispensed.

2. **The answer is A** *[see II.C.1]*.
   Information provided to the prescriber during a therapeutic intervention should include a description of the problem, reference source, description of the clinical significance, and an alternative. Informing the prescriber that a mistake was made does not encourage cooperation and resolution of the problem.

3. **The answer is C** *[see III.A]*.
   The prescription number, date of filling, product and quantity dispensed, and pharmacist's initials should be recorded on the prescription. The expiration date of the product is not required.

4. **The answer is C** *[see III.E.1]*.
   The quantity of medication dispensed, lot number, expiration date of the product, and prescriber's name are usually included on the label. The patient's diagnosis, although listed in the patient's profile, is not included on the prescription label.

5. **The answer is A** *[see III.E.3; IV.A.1]*.
Auxiliary and cautionary labels are an adjunct to, not a replacement for, verbal consultation. Appropriate uses for such labels include ensuring proper use, storage requirements, and compliance with statutory requirements, and warning against food and drug interactions.

6. **The answer is B** *[see III.F.1–2]*.
The patient's name is required to identify each patient. Often, the address or room number is required to identify patients with similar names. The patient's allergies, birth date, and instructions for use are required to prevent drug allergies and to assess the appropriateness of the prescription or medication order.

7. **The answer is D** *[see V.B]*.
Adverse effects, undertreated conditions, allergic reactions, and drug–drug interactions are all drug therapy problems. An undiagnosed condition may lead to a drug-related problem once diagnosed; however, diagnosis is required before the need for medication can be assessed.

Common Prescription Drugs and Over-the-Counter Products

TOP OVER-THE-COUNTER (OTC) DRUGS*

	Generic Name	Trade Name	Drug Use
1	Docosanol	Abreva®	Cold sore medication
2	Ibuprofen and pseudoephedrine HCl	Advil Cold & Sinus®	Allergy and cold relief
3	Ibuprofen	Advil®	Analgesic
4	Oxymetazoline HCl	Afrin®	Nasal decongestant
5	Naproxen sodium	Aleve®	Analgesic
6	Orlistat	alli®	Weight management
7	Benzocaine, phenol	Anbesol®	Oral cavity analgesic
8	Phenazopyridine hydrochloride	Azo Standard®	UTI analgesic
9	Acetylsalicylic acid (ASA, aspirin), diphenhydramine, caffeine, calcium, phytosterols	Bayer® Aspirin	Analgesic
10	Diphenhydramine HCl, phenylephrine HCl	Benadryl® Oral	Allergy and cold relief
11	Diphenhydramine HCl, zinc acetate or camphor	Benadryl® Topical	Topical antipruritic
12	Methyl salicylate, menthol, and camphor	BENGAY®	Topical analgesic
13	Meclizine hydrochloride, cyclizine hydrochloride	Bonine®	Motion sickness medication
14	Acetylsalicylic acid (ASA, aspirin) with buffers	Bufferin®	Analgesic
15	Capsaicin	Capzasin-P	Topical analgesic
16	Menthol, camphor, alum, salicylic acid	Carmex® Lip Balm	Cold sore medication
17	Benzocaine, menthol, dextromethorphan	Cepacol®	Oral cavity analgesic
18	Benzocaine and menthol or phenol	Chloraseptic®	Oral cavity analgesic
19	Calcium citrate	Citracal®	Essential mineral
20	Loratadine and pseudoephedrine sulfate	Claritin-D®	Allergy and cold relief
21	Loratadine	Claritin®	Allergy and cold relief
22	Docusate sodium	Colace®	Stool softener
23	Zincum gluconicum	COLD-EEZE®	Cold relief
24	Salicylic acid	Compound W®	Keratolytic
25	Hydrocortisone	Cortaid®	Topical antipruritic
26	Acetaminophen, dextromethorphan HBr, phenylephrine HCl	DayQuil®	Allergy and cold relief
27	Carbamide peroxide solution	Debrox®	Ear wax removal aid
28	Dextromethorphan polistirex	Delsym®	Cough suppressant
29	Zinc oxide	Desitin®	Skin protectant
30	Brompheniramine maleate, phenylephrine hydrochloride, dextromethorphan hydrobromide, loratadine	Dimetapp®	Allergy and cold relief
31	Dimenhydrinate or meclizine HCl	Dramamine®	Motion sickness medication
32	Bisacodyl	Dulcolax®	Laxative
33		e.p.t.®	Pregnancy test
34	Acetylsalicylic acid (aspirin, ASA)	Ecotrin	Analgesic
35	Phosphorated carbohydrates	Emetrol®	Antiemetic

TOP OVER-THE-COUNTER (OTC) DRUGS* (Continued)

	Generic Name	Trade Name	Drug Use
36	Soy, black cohosh	Estroven®	Menopause support
37		Eucerin®	Skin moisturizer
38	Acetaminophen, aspirin, caffeine, diphenhydramine citrate	Excedrin® & Excedrin® PM	Analgesic laxative
39	Polycarbophil calcium	FiberCon®	
40		First Response® Ovulation Test	Ovulation test
41	Undecylenic acid	Fungi-Nail®	Antifungal, topical
42	Simethicone, calcium carbonate	Gas-X®	Antiflatulent
43	Menthol or pectin	Halls® Cough Drops	Antitussive
44	Loperamide HCl	Imodium® A-D	Antidiarrheal
45	Ammonium lactate, urea, salicylic acid	Kerasal® Foot Cream	Skin moisturizer
46	Lactase enzyme	Lactaid®	Digestive aid
47	Terbinafine hydrochloride or tolnaftate	Lamisil® AT	Antifungal
48	Clotrimazole or miconazole nitrate	Lotrimin AF®	Antifungal, topical
49	Aluminum hydroxide, magnesium hydroxide, calcium carbonate, simethicone	Maalox® & Maalox® Max	Antacid
50	Psyllium hydrophilic mucilloid	Metamucil®	Laxative
51	Pamabrom, pyrilamine maleate, acetaminophen, caffeine, ibuprofen, naproxen sodium, diphenhydramine	Midol® Products	Analgesic
52	Polyethylene glycol 3350, NF	Miralaxª	Laxative
53	Miconazole nitrate, tioconazole	Monistat® Vaginal	Vaginal antifungal
54	Ibuprofen	Motrin® IB	Analgesic
55	Guaifenesin, pseudoephedrine HCl, and dextromethorphan HBr	Mucinex® (Adult)	Expectorant
56	Aluminum hydroxide, magnesium (hydroxide and carbonate),calcium carbonate, simethicone	Mylanta®	Antacid
57	Simethicone	Mylicon® Drops	Antiflatulent
58	Pheniramine maleate, naphazoline HCl	Naphcon® A	Ophthalmic anti-allergy
59	Cromolyn sodium	Nasalcrom®	Allergy and cold relief
60	Polymyxin B sulfate, neomycin, bacitracin, pramoxine HCl	Neosporin®	Topical anti-infective
61	Nicotine transdermal	Nicoderm® CQ®	Smoking cessation aid
62	Nicotine polacrilex	Nicorette®	Smoking cessation aid
63	Permethrin	Nix®	Pediculicide
64	Ketoconazole	Nizoral® AD Shampoo	Antifungal, topical
65	Caffeine	NoDoz®	Analeptic
66	Chlorpheniramine maleate (CPH), dextromethorphan HBr (DXT), acetaminophen (APAP), doxylamine, succinate phenylephrine (PE)	NyQuil®	Cough and cold relief
67	Sodium chloride	Ocean® Nasal	Nasal decongestant
68	Benzocaine	Orabase®	Oral cavity analgesic
69	Benzocaine	Orajel®	Oral cavity anesthetic
70	Glucose oxidase, lactoperoxidase, lysozyme	OralBalance®	Oral moisturizer
71	Calcium carbonate	Os-Cal®	Essential mineral
72	Famotidine	Pepcid-AC®	Acid reducer
73	Famotidine, calcium carbonate, magnesium hydroxide	Pepcid® Complete	Acid reducer
74	Bismuth subsalicylate	Pepto Bismol®	Antidiarrheal
75	Docusate sodium and senna	Peri-Colace®	Stool softener plus laxative
76	Magnesium hydroxide	Phillips' MOM	Laxative/antacid
77	Pyrantel pamoate	Pin-X®	Anthelmintic
78	Shark liver oil, petrolatum, mineral oil, phenylephrine HCl	Preparation H® Products	Hemorrhoidal agent

Prescription Dispensing Information and Metrology

Prescriptions

PARTS OF THE PRESCRIPTION

A prescription is an order for medication for use by a patient that is issued by a physician, dentist, veterinarian, or other licensed practitioner who is authorized to prescribe medication or by their agent via a collaborative practice agreement. A prescription is usually written on a single sheet of paper that is commonly imprinted with the prescriber's name, address, and telephone number. A medication order is similar to a prescription, but it is written on the patient chart and intended for use by a patient in an institutional setting.

All prescriptions should contain accurate and appropriate information about the patient and the medication that is being prescribed. In addition, a prescription order for a **controlled substance** must contain the following information:

1. Date of issue
2. Full name and address of the patient
3. Drug name, strength, dosage form, and quantity prescribed
4. Directions for use
5. Name, address, and Drug Enforcement Agency (DEA) number of the prescriber
6. Signature of the prescriber

A written prescription order is required for substances listed in **Schedule II.** Prescriptions for controlled substances listed in **Schedule II** are **never** refillable. Any other prescription that has no indication of refills is not refillable.

Prescriptions for medications that are listed in Schedules III, IV, and V may be issued either in writing or orally to the pharmacist. If authorized by the prescriber, these prescriptions may be refilled up to five times within 6 months of the date of issue. If the prescriber wishes the patient to continue to take the medication after 6 months or five refills, a new prescription order is required.

THE PRESCRIPTION LABEL

In addition to the name of the patient, the pharmacy, and the prescriber, the prescription label should accurately identify the medication and provide directions for its use.

The label for a prescription order for a controlled substance must contain the following information:

1. Name and address of the pharmacy
2. Serial number assigned to the prescription by the pharmacy
3. Date of the initial filling
4. Name of the patient
5. Name of the prescriber
6. Directions for use
7. Cautionary statements as required by law*

AUXILIARY LABELS

Auxiliary, or cautionary, labels provide additional important information about the proper use of the medication. Examples include "Shake Well" for suspensions or emulsions; "For External Use Only" for topical lotions, solutions, or creams; and "May Cause Drowsiness" for medications that depress the central nervous system. The information contained on auxiliary labels should be brought to the attention of the patient when the medication is dispensed. The pharmacist should place only appropriate auxiliary labels on the prescription container because too many labels may confuse the patient.

BEFORE DISPENSING THE PRESCRIPTION

Double-check the accuracy of the prescription.
Provide undivided attention when filling the prescription.

1. Check the patient information (e.g., name, address, date of birth, telephone number).
2. Check the patient profile (e.g., allergies, medical conditions, other drugs, including over-the-counter medications).
3. Check the drug (e.g., correct drug name, correct spelling, appropriate drug for the patient's condition), and verify that there are no known drug interactions. **Always verify**

---

*The label of any drug that is listed as a controlled substance in Schedule II, III, or IV of the Controlled Substances Act must contain the following warning: **CAUTION: Federal law prohibits the transfer of this drug to any person other than the patient for whom it was prescribed.**

the name of the drug. Beware of drug names that look **alike (see table).**

4. Check the dosage, including the drug strength, the dosage form (e.g., capsule, liquid, modified release), the individual dose, the total daily dose, the duration of treatment, and the units (e.g., mg, mL, tsp, tbsp).

5. Check the label. Compare the drug dispensed with the prescription. Verify the National Drug Code (NDC) number. Ensure that the information is accurate, that the patient directions are accurate and easily understood, and that the auxiliary labels are appropriate.

6. **Provide patient counseling. Be sure that the patient fully understands the drug treatment as well as any precautions.**

EXAMPLES OF DRUGS WITH SIMILAR NAMES

Brand name	Celebrex	Cerebyx	Celexa
Generic name	Celecoxib capsules	Fosphenytoin sodium injection	Citalopram HCl
Manufacturer	Searle	Parke-Davis	Forest
Indication	Osteoarthritis and rheumatoid arthritis	Prevention and treatment of seizures	Major depression

Dangerous or Confusing Abbreviations

Numerous common abbreviations and symbols have been associated with errors. Detailed lists of these can be found at the websites of the Institute for Safe Medication Practices (ISMP) and Joint Commission for the Accreditation of Healthcare Organizations (JCAHO) at :

http://www.ismp.org/Tools/abbreviationslist.pdf.
http://www.jcaho.org/accredited+organizations/patient+safety/06_dnu_list.pdf.

The JCAHO has created a "Do Not Use" list of abbreviations that its accredited organizations should not allow to be used.

- **"U" or "IU" for units**: the "U" has been misinterpreted as various numbers such as zero, four; serious harm has occurred with insulin and heparin as a result of confusion. For example, a patient received 66 units of insulin instead of 6 units. The order was written for "6u" of regular insulin but was misinterpreted. The word "units" should be written out in full.

- **"QD, Q.D, qd, q.d."**: common abbreviations for daily have been misinterpreted as "QID" or "qid" and overdoses have occurred. "Daily" should be written out in full.

- **"Q.O.D, QOD, qod"**: common abbreviations for every other day have been misinterpreted as QID (four times daily). This should be written out completely as "every other day."

- **Trailing zero**: when a dose is ordered and followed with a decimal point and a zero, such as 2.0 mg or 25.0 mg, errors can occur. The decimal point may be missed and an overdose can occur. For example, Warfarin 2.0 mg may be misinterpreted as 20 mg. Trailing zeros should be avoided and the dose written without the additional zero, for example Warfarin 2 mg rather than 2.0 mg.

- **Lack of leading zero**: a drug's dose may be less than 1 mg, such as Digoxin. Often the dose may be written without a leading zero, such as Digoxin .25 mg, rather than as Digoxin 0.25 mg. Errors have occurred because the decimal point is missed. For example, Warfarin .5 mg may be interpreted as Warfarin 5 mg. Leading zeroes should be included, so the dose is written as "Digoxin 0.25 mg or Warfarin 0.5 mg."

- **MS, MSO4, MgSO$_4$: Abbreviations for morphine sulfate (MS, MSO$_4$) have been confused with Magnesium sulfate (MgSO$_4$). It is recommend to write out each name in full rather than using abbreviations: morphine sulfate or magnesium sulfate.**

In addition to the above abbreviations, there are numerous other hazardous symbols and abbreviations which should be reviewed with caution when used on prescriptions. Examples include:

- **"cc"** : Often used instead of "mL." This has been misinterpreted as a "0" (zero). Use "mL."

- **"μg"** : Used for "micrograms," for example, Levothyroxine 250 μg. daily. The symbol has been mistaken for "mg." and overdoses have occurred. Best to use "mcg." Or write out "micrograms."

- **"<" or ">"** : Symbols for " less than" (<) or "greater than" (>) have been mistaken for each other or misinterpreted as numbers. Best to write out as "less than" or "greater than."

- **"HCT"** : An abbreviation for "hydrocortisone" has been misinterpreted as "hydrochlorothiazide. " Best to write name out completely.

- **"HCl"** : An abbreviation for "hydrochloric acid" has been misinterpreted as "KCl" (potassium chloride). Best to write out name completely.

COMMON ABBREVIATIONS

Considerable variation occurs in the use of capitalization, italicization, and punctuation in abbreviations. The following list shows the abbreviations that are most often encountered by pharmacists.

A, aa., or aa	of each
a.c.	before meals
ad	to, up to
a.d.	right ear
ad lib.	at pleasure, freely
a.m.	morning
amp.	ampule
ante	before
aq.	water
a.s.	left ear
asa	aspirin
a.u.	each ear, both ears
b.i.d.	twice a day
BP	British Pharmacopoeia
BSA	body surface area
c. or c̄	with
cap. or caps.	capsule
cp	chest pain
D.A.W.	dispense as written
cc or cc.	cubic centimeter
comp.	compound, compounded
dil.	dilute
D.C., dc, or disc.	discontinue
disp.	dispense
div.	divide, to be divided
dl or dL	deciliter
d.t.d.	give of such doses
DW	distilled water
D5W	dextrose 5% in water
elix.	elixir
e.m.p.	as directed
et	and
ex aq.	in water
fl or fld	fluid
fl oz	fluid ounce
ft.	make
g or Gm	gram
gal.	gallon
GI	gastrointestinal
gr or gr.	grain
gtt or gtt.	drop, drops
H	hypodermic
h. or hr.	hour
h.s.	at bedtime
IM	intramuscular
inj.	injection
IV	intravenous
IVP	intravenous push
IVPB	intravenous piggyback
K	potassium
l or L	liter
lb.	pound
μ	Greek mu
M	mix
m^2 or M^2	square meter
mcg, mcg., or μg	microgram
mEq	milliequivalent
mg or mg.	milligram
ml or mL	milliliter
μl or μL	microliter
℥	minim
N&V	nausea and vomiting
Na	sodium
N.F.	National Formulary
No.	number
noct.	night, in the night
non rep.	do not repeat
NPO	nothing by mouth
N.S., NS, or N/S	normal saline
1/2 NS	half-strength normal saline
O	pint
o.d.	right eye, every day
o.l. or o.s.	left eye
OTC	over the counter
o.u.	each eye, both eyes
oz.	ounce
p.c.	after meals
PDR	*Physicians' Desk Reference*
p.m.	afternoon, evening
p.o.	by mouth
Ppt	precipitated
pr	for the rectum
prn or p.r.n.	as needed
pt.	pint
pulv.	powder
pv	for vaginal use
q.	every
q.d.	every day
q.h.	every hour
q. 4 hr.	every four hours
q.i.d.	four times a day
q.o.d.	every other day
q.s.	a sufficient quantity
q.s. ad	a sufficient quantity to make
R	rectal
R.L. or R/L	Ringer's lactate
℞	prescription
s. or s̄	without
Sig.	write on label
sol.	solution
S.O.B.	shortness of breath
s.o.s.	if there is need (once only)

ss. or ss	one-half	**t.i.d.**	three times a day
stat.	immediately	**tr. or tinct.**	tincture
subc, subq, or s.c.	subcutaneously	**tsp. or t.**	teaspoonful
sup. or supp	suppository	**TT**	tablet triturates
susp.	suspension	**U or u.**	unit
syr.	syrup	**u.d. or ut dict.**	as directed
tab.	tablet	**ung.**	ointment
tal.	such, such a one	**U.S.P. or USP**	United States Pharmacopoeia
tal. dos.	such doses	**w/v**	weight/volume
tbsp. or T	tablespoonful		

Metrology

THE METRIC, APOTHECARY, AND AVOIRDUPOIS SYSTEMS

Metric system

1. **Basic units**

   Mass = g or gram
   Length = m or meter
   Volume = L or liter
   1 cc (cubic centimeter) of water is approximately equal to 1 mL and weighs 1 g.

2. **Prefixes**

   kilo- 10^3, or 1000 times the basic unit
   hekto- 10^2, or 100 times the basic unit
   deka- 10^1, or 10 times the basic unit
   deci- 10^{-1}, or 0.1 times the basic unit
   centi- 10^{-2}, or 0.01 times the basic unit
   milli- 10^{-3}, or 0.001 times the basic unit
   micro- 10^{-6}, or one-millionth of the basic unit
   nano- 10^{-9}, or one-billionth of the basic unit
   pico- 10^{-12}, or one-trillionth of the basic unit

   Examples of these prefixes include milligram (mg), which equals one-thousandth of a gram, and deciliter (dL), which equals 100 mL, or 0.1 L.

Apothecary system

1. **Volume (fluids or liquid)**

   60 minims (℔) = 1 fluidrachm or fluidram (f ʒ) or (ʒ)
   8 fluidrachms (480 minims) = 1 fluid ounce (f ℥ or ℥)
   16 fluid ounces = 1 pint (pt or 0)
   2 pints (32 fluid ounces) = 1 quart (qt)
   4 quarts (8 pints) = 1 gallon (gal or C)

2. **Mass (weight)**

   20 grains (gr) = 1 scruple (Э)
   3 scruples (60 grains) = 1 drachm or dram (ʒ)
   8 drachms (480 grains) = 1 ounce (℥)
   12 ounces (5760 grains) = 1 pound (lb)

Avoirdupois system

1. **Volume**

   1 fluidrachm = 60 min.
   1 fluid ounce = 8 fl. dr.
   = 480 min.
   1 pint = 16 fl. oz.
   = 7680 min.
   1 quart = 2 pt.
   = 32 fl. oz.
   1 gallon = 4 qt.
   = 128 fl. oz.

2. **Mass (weight)**

   The grain is common to both the apothecary and the avoirdupois systems.

   437.5 grains (gr) = 1 ounce (oz)
   16 ounces (7000 grains) = 1 pound (lb)

CONVERSION

Exact equivalents

Exact equivalents are used for the conversion of specific quantities in pharmaceutical formulas and prescription compounding.

1. **Length**

   1 meter (m) = 39.37 in.
   1 inch (in) = 2.54 cm.

2. **Volume**

   1 ml = 16.23 minims (℔)
   1 ℔ = 0.06 mL
   1 f ʒ = 3.69 mL
   1 f ℥ = 29.57 mL
   1 pt = 473 mL
   1 gal (U.S.) = 3785 mL

3. Mass

$$1 \text{ g} = 15.432 \text{ gr}$$
$$1 \text{ kg} = 2.20 \text{ lb (avoir.)}$$
$$1 \text{ gr} = 0.065 \text{ g or } 65 \text{ mg}$$
$$1 \text{ oz (avoir.)} = 28.35 \text{ g}$$
$$1 \text{ ʒ (apoth.)} = 31.1 \text{ g}$$
$$1 \text{ lb (avoir.)} = 454 \text{ g}$$
$$1 \text{ lb (apoth.)} = 373.2 \text{ g}$$

4. Other equivalents

$$1 \text{ oz (avoir.)} = 437.5 \text{ gr}$$
$$1 \text{ ʒ (apoth.)} = 480 \text{ gr}$$
$$1 \text{ gal (U.S.)} = 128 \text{ fl ʒ}$$
$$1 \text{ fl ʒ (water)} = 455 \text{ gr}$$
$$1 \text{ gr (apoth.)} = 1 \text{ gr (avoir.)}$$

Approximate equivalents

Physicians may use approximate equivalents to prescribe the dose quantities using the metric and apothecary systems of weights and measures, respectively. Household units are often used to inform the patient of the size of the dose. In view of the almost universal practice of using an ordinary household teaspoon to administer medication, a teaspoon may be considered 5 mL. However, when accurate measurement of a liquid dose is required, the USP recommends the use of a calibrated oral syringe or dropper.

$$1 \text{ fluid dram} = 1 \text{ teaspoonful}$$
$$= 5 \text{ mL}$$
$$4 \text{ fluid ounces} = 120 \text{ mL}$$
$$8 \text{ fluid ounces} = 1 \text{ cup}$$
$$= 240 \text{ mL}$$
$$1 \text{ grain} = 65 \text{ mg}$$
$$1 \text{ kg} = 2.2 \text{ pounds (lb)}$$

Reference Charts For Patient Counseling

DRUGS THAT SHOULD NOT BE CRUSHED

Listed below are various slow-release as well as enteric-coated products that should not be crushed or chewed. Slow-release (sr) represents products that are controlled-release, extended-release, long-acting, or timed-release. Enteric-coated (ec) represents products that are delayed-release.

In general, capsules containing slow-release or enteric-coated particles may be opened and their contents administered on a spoonful of soft food. Instruct patients not to chew the particles, though. (Patients should, in fact, be discouraged from chewing any medication unless it is specifically formulated for that purpose.)

This list should not be considered all-inclusive. Generic and alternate brands of some products may exist. Tablets intended for sublingual or buccal administration (not included in this list) should also be administered only as intended, in an intact form.

SUGAR-FREE PRODUCTS

Listed below, by therapeutic category, is a selection of drug products that contain no sugar. When recommending these products to diabetic patients, keep in mind that many may contain sorbitol, alcohol, or other sources of carbohydrates. This list should not be considered all-inclusive. Generics and alternate brands of some products may be available. Check product labeling for a current listing of inactive ingredients.

Analgesics	Manufacturer
Actamin Maximum Strength Liquid	Cypress
Addaprin Tablet	Dover
Aminofen Tablet	Dover
Aminofen Max Tablet	Dover
Aspirtab Tablet	Dover

Back Pain-Off Tablet	Textilease Medique
Backprin Tablet	Hart Health and Safety
Buffasal Tablet	Dover
Dyspel Tablet	Dover
Febrol Liquid	Scot-Tussin
I-Prin Tablet	Textilease Medique
Medi-Seltzer Effervescent Tablet	Textilease Medique
Ms.-Aid Tablet	Textilease Medique
PMS Relief Tablet	Textilease Medique
Silapap Children's Elixir	Silarx

Antacids/Antiflatulents

Almag Chewable Tablet	Textilease Medique
Alcalak Chewable Tablet	Textilease Medique
Aldroxicon I Suspension	Textilease Medique
Aldroxicon II Suspension	Textilease Medique
Baby Gasz Drops	Lee
Dimacid Chewable Tablet	Otis Clapp & Son
Diotame Chewable Tablet	Textilease Medique
Diotame Suspension	Textilease Medique
Gas-Ban Chewable	Textilease Medique
Mallamint Chewable	Textilease Medique
Mylanta Gelcaplet	Johnson & Johnson/Merck
Neutralin Tablet	Dover
Tums E-X Chewable Tablet	GlaxoSmithKline Consumer

Antiasthmatic/Respiratory Agents

Jay-Phyl Syrup	Pharmakon

Antidiarrheals

Diarrest Tablet	Dover
Di-Gon II Tablet	Textilease Medique
Imogen Liquid	Pharmaceutical Generic

Blood Modifiers/Iron Preparations

I.L.X. B-12 Elixir	Kenwood
Irofel Liquid	Dayton
Nephro-Fer Tablet	R & D

Corticosteroids

Pediapred Solution	Celltech

DRUGS THAT MAY CAUSE PHOTOSENSITIVITY

The drugs in this table are known to cause photosensitivity in some individuals. Effects can range from itching, scaling, rash, and swelling to skin cancer, premature skin aging, skin and eye burns, cataracts, reduced immunity, blood vessel damage, and allergic reactions.

The list is not all-inclusive, and shows only representative brands of each generic. When in doubt, always check specific product labeling. Individuals should be advised to wear protective clothing and to apply sunscreens while taking the medications listed below.

Generic	Brand
Acamprosate	Campral
Acetazolamide	Diamox
Acitretin	Soriatane
Acyclovir	Zovirax
Alendronate	Fosamax
Alitretinoin	Panretin
Almotriptan	Axert
Amiloride/hydrochlorothiazide	Moduretic
Aminolevulinic acid	Levulan Kerastick
Amiodarone	Cordarone, Pacerone
Amitriptyline	Elavil
Amitriptyline/chlordiazepoxide	Limbitro
Amitriptyline/perphenazine	Triavil
Amlodipine/atorvastatin	Caduet
Amoxapine	
Anagrelide	Agrylin
Apripiprazole	Abilify
Atazanavir	Reyataz
Atenolol/chlorthalidone	Tenoretic
Atorvastatin	Lipitor
Atovaquone/proguanil	Malarone
Azatadine/pseudoephedrine	Rynatan, Trinalin
Azithromycin	Zithromax

Generic	Brand
Benazepril	Lotensin
Benazepril/hydrochlorothiazide	Lotensin HCT
Bendroflumethiazide/nadolol	Corzide
Bexarotene	Targretin
Bismuth/metronidazole/tetracycline	Helidac
Bisoprolol/hydrochlorothiazide	Ziac
Brompheniramine/dextromethorphan/phenylephrine	Alacol DM
Brompheniramine/dextromethorphan/pseudoephedrine	Bromfed-DM
Buffered aspirin/pravastatin	Pravigard PAC
Bupropion	Wallbutrin, Zyban
Candesartan/hydrochlorothiazide	Atacand HCT
Capecitabine	Xeloda
Captopril	Capoten
Captopril/hydrochlorothiazide	Capozide
Carbamazepine	Carbatrol, Tegretol, Tegretol-XR
Carbinoxamine/pseudoephedrine	Palgic-D, Palgic-DS, Pediatex-D
Carvedilol	Coreg
Celecoxib	Celebrex
Cetirizine	Zyrtec
Cetirizine/pseudoephedrine	Zyrtec-D
Cevimeline	Evoxac
Chlorhexidine gluconate	Hibistat
Chloroquine	Aralen
Chlorothiazide	Diuril
Chlorphenirmine/hydrocodone/pseudoephedrine	Tussend
Chlorpheniramine/phenylephrine/pyrilamine	Rynatan
Chlorpromazine	Thorazine
Chlorpropamide	Diabinese
Chlorthalidone	Thalitone
Chlorthalidone/clonidine	Clorpres
Cidofovir	Vislide
Ciprofloxacin	Cipro
Citalopram	Celexa
Clemastine	Tavist
Clonidine/chlorthalidone	Clorpres
Clozapine	Clozaril, Fazacio
Cromolyn sodium	Gastrocrom
Cyclobenzaprine	Flexeril
Cyproheptadine	Cyproheptadine
Dacarbazine	DTIC-Dome
Dantrolene	Dantrium
Demeclocycline	Declomycin
Desipramine	Norpramin
Diclofenac potassium	Catalfam
Diclofenac sodium	Voltaren
Diclofenac sodium/misoprostol	Arthrotec
Diflunisal	Dolobid
Dihydroergotamine	D.H.E. 45
Diltiazem	Cardizem, Tiazac
Diphenhydramine	Benadryl
Divalproex	Depakote
Doxepin	Sinequan
Doxycycline hyclate	Doryx, Periostat, Vibra-Tabs, Vibramycin

Generic	Brand
Doxycycline monohydrate	Monodox
Duloxetine	Cymbalta
Enalapril	Vasotec
Enalapril/felodipine	Lexxel
Enalapril/hydrochlorothiazide	Vaseretic
Enalaprilat	Vasotec I.V.
Epirubicin	Ellence
Eprosartan mesylate/hydrochlorothiazide	Teveten HCT
Erythromycin/sulfisoxazole	Pediazole
Estazolam	ProSom
Estradiol	Gynodiol, Estrogel
Eszopiclone	Lunesta
Ethionamide	Trecator-SC
Etodolac	Lodine
Felbamate	Felbatol
Fenofibrate	Tricor, Lofibra
Floxuridine	Sterile FUDR
Flucytosine	Ancobon
Fluorouracil	Efudex
Fluoxetine	Prozac, Sarafem
Fluphenazine	Prolixin
Flutamide	Eulexin
Fluvastatin	Lescol
Fluvoxamine	Luvox
Fosinopril	Monopril
Fosphenytoin	Cerebyx
Furosemide	Lasix
Gabapentin	Neurontin
Gatifloxacin	Tequin
Gemfibrozil	Lopid
Gemifloxacin mesylate	Factive
Gentamicin	Garamycin
Glatiramer	Copaxone
Glimepiride	Amaryl
Glipizide	Glucotrol
Glyburide	DiaBeta, Glynase, Micronase
Glyburide/metformin HCl	Glucovance
Griseofulvin	Fulvicin P/G, Grifulvin, Gris-PEG
Haloperidol	Haldol
Hexachlorophene	pHisoHex
Hydralazine/hydrochlorothiazide	Hydra-zide
Hydrochlorothiazide	HydroDIURIL, Microzide, Oretic
Hydrochlorothiazide/fosinopril	Monopril HCT
Hydrochlorothiazide/Irbesartan	Avalide
Hydrochlorothiazide/lisinopril	Prinzide, Zestoretic
Hydrochlorothiazide/losartan potassium	Hyzaar
Hydrochlorothiazide/methyldopa	Aldoril
Hydrochlorothiazide/moexipril	Uniretic
Hydrochlorothiazide/propranolol	Inderide
Hydrochlorothiazide/quinapril	Accuretic
Hydrochlorothiazide/spironolactone	Aldactazide
Hydrochlorothiazide/telmisartan	Micardis HCT
Hydrochlorothiazide/timolol	Timolide

Generic	Brand
Hydrochlorothiazide/triamterene	Dyazide, Maxzide
Hydrochlorothiazide/valsartan	Diovan HCT
Hydroflumethiazide	Hydroflumethiazide
Hydroxychloroquine	Plaquenil
Hypericum	Kira, St. John's wort
Hypericum/vitamin B_1/vitamin C/kava-kava	One-A-Day Tension & Mood
Ibuprofen	Motrin
Imatinib Mesylate	Gleevec
Imipramine	Tofranil
Imiquimod	Aldara
Indapamide	Lozol
Interferon alfa-2b, recombinant	Intron A
Interferon alfa-n3 (human leukocyte derived)	Alferon-N
Interferon beta-1a	Avonex
Interferon beta-1b	Betaseron
Irbesartan/hydrochlorothiazide	Avalide
Isoniazid/pyrazinamide/rifampin	Rifater
Isotretinoin	Accutane, Amnesteem
Itraconazole	Sporanox
Ketoprofen	Orudis, Oruvail
Lamotrigine	Lamictal
Leuprolide	Lupron
Levamisole	Levamisole
Lisinopril	Prinivil, Zestril
Lisinorpil/hydrochlorothiazide	Prinivil, Zestoretic
Lomefloxacin	Maxaquin
Loratadine	Claritin
Loratadine/pseudoephedrine	Claritin-D
Losartan	Cozaar
Losartan/hydrochlorothiazide	Hyzaar
Lovastatin	Altoprev, Mevacor
Lovastatin/niacin	Advicor
Maprotiline	Maprotiline
Mefenamic acid	Ponstel
Meloxicam	Mobic
Mesalamine	Pentasa
Methazolamide	
Methotrexate	Trexall
Methoxsalen	Uvadex, Oxsoralen, 8-MOP
Methyclothiazide	Enduron
Methyldopa/hydrochlorothiazide	Aldoril
Metolazone	Mykrox, Zaroxolyn
Minocycline	Dynacin, Minocin
Mirtazapine	Remeron
Moexipril	Univasc
Moexipril/hydrochlorothiazide	Uniretic
Moxifloxacin	Avelox
Nabumetone	Relafen
Nadolol/bendroflumethiazide	Corzide
Nalidixic acid	Nalidixic acid
Naproxen	Naprosyn, EC-Naprosyn
Naproxen sodium	Anaprox, Naprelan
Naratriptan	Amerge

Generic	Brand
Nefazodone	Serzone
Nifedipine	Adalat CC, Procardia
Nisoldipine	Sular
Norfloxacin	Noroxin
Nortriptyline	Pamelor
Ofloxacin	Floxin
Olanzapine	Zyprexa
Olanzapine/fluoxetine	Symbyax
Olmesartan medoxomil/hydrochlorothiazide	Benicar HCT
Olsalazine	Dipentum
Oxaprozin	Daypro
Oxcarbazepine	Trileptal
Oxycodone	Roxicodone
Oxytetracycline	Terramycin
Pantoprazole	Protonix
Paroxetine	Paxil
Pastinaca sativa	Parsnip
Pentosan polysulfate	Elmiron
Pentostatin	Nipent
Perphenazine	Perphenazine
Pilocarpine	Salagen
Piroxicam	Feldene
Polythiazide	Renese
Polythiazide/prazosin	Minizide
Porfimer sodium	Photofrin
Pravastatin	Pravachol
Prochlorperazine	Compazine, Compro
Promethazine	Phenergan
Protriptyline	Vivactil
Pyrazinamide	Pyrazinamide
Quetiapine	Seroquel
Quinapril	Accupril
Quinapril/hydrochlorethiazide	Accuretic
Quinidine gluconate	Quinidine
Quinidine sulfate	Quinidex
Rabeprazole sodium	Aciphex
Ramipril	Altace
Riluzole	Rilutek
Risperidone	Risperdal, Risperdal Consta
Ritonavir	Norvir
Rizatriptan	Maxalt
Ropinirole	Requip
Rosuvastatin	Crestor
Ruta graveolens	Rue
Saquinavir	Fortovase
Saquinavir mesylate	Invirase
Selegiline	Eldepryl
Sertraline	Zoloft
Sibutramine	Meridia
Sildenafil	Viagra
Simvastatin	Zocor
Simvastatin/ezetimibe	Vytorin
Somatropin	Serostim

Generic	Brand
Sotalol	Betapace, Betapace
Sulfamethoxazole/trimethoprim	Bactrim, Septra
Sulfasalazine	Azulfidine
Sulindac	Clinoril
Sumatriptan	Imitrex
Tacrolimus	Prograf, Protopic
Tazarotene	Tazorac
Telmisartan/hydrochlorothiazide	Micardis HCT
Tetracycline	Sumycin
Thalidomide	Thalomid
Thioridazine hydrochloride	Mellaril
Thiothixene	Navane
Tiagabine	Gabitril
Tolazamide	Tolazamide
Tolbutamide	Tolbutamide
Topiramate	Topamax
Tretinoin	Retin-A
Triamcinolone	Azmacort
Triamterene	Dyrenium
Triamterene/hydrochlorothiazide	Dyazide, Maxzide
Trifluoperazine	Trifluoperazine
Trimipramine	Surmontil
Trovafloxacin	Trovan
Valacyclovir	Valtrex
Valdecoxib	Bextra
Valproate	Depacon
Valproic acid	Depakene
Valsartan/hydrochlorothiazide	Diovan HCT
Vardenafil	Levitra
Venlafaxine	Effexor
Verteporfin	Visudyne
Vinblastine	Vinblastine
Voriconazole	Vfend
Zalcitabine	Hivid
Zaleplon	Sonata
Ziprasidone	Geodon
Zolmitriptan	Zomig
Zolpidem	Ambien

DRUG/ALCOHOL INTERACTIONS

Product	Interaction	Onset	Severity
ACETAMINOPHEN	ETHANOL	2	2
	Concurrent use of ACETAMINOPHEN and ETHANOL may result in an increased risk of hepatotoxicity.		
ACETOPHENAZINE	ETHANOL	1	2
	Concurrent use of ACETOPHENAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
ACITRETIN	ETHANOL	2	1
	Concurrent use of ACITRETIN and ETHANOL may result in a prolonged risk of teratogenicity.		
ALFENTANIL	ETHANOL	2	2
	Concurrent use of ALFENTANOL and ETHANOL may result in decreased therapeutic effects for alfentanil.		
ALPRAZOLAM	ETHANOL	1	2
	Concurrent use of ALPRAZOLAM and ETHANOL may result in increased sedation.		
AMITRIPTYLINE	ETHANOL	1	2
	Concurrent use of AMITRIPTYLINE and ETHANOL may result in enhanced CNS depression and impairment of motor skills.		
AMOBARBITAL	ETHANOL	1	2
	Concurrent use of AMOBARBITAL and ETHANOL may result in excessive CNS depression.		
AMOXAPINE	ETHANOL	1	2
	Concurrent use of AMOXAPINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.		
AMPRENAVIR	ETHANOL	2	1
	Concurrent use of AMPRENAVIR and ETHANOL may result in an increased risk of propylene glycol toxicity (seizures, tachycardia, lactic acidosis, renal toxicity, and hemolysis).		
APROBARBITAL	ETHANOL	1	2
	Concurrent use of APROBARBITAL and ETHANOL may result in excessive CNS depression.		
ASPIRIN	ETHANOL	1	2
	Concurrent use of ASPIRIN and ETHANOL may result in increased gastrointestinal blood loss.		
BUPROPION	ETHANOL	2	1
	Concurrent use of BUPROPION and ETHANOL may result in an increased risk of seizures.		
BUTABARBITAL	ETHANOL	1	2
	Concurrent use of BUTABARBITAL and ETHANOL may result in excessive CNS depression.		
BUTALBITAL	ETHANOL	1	2
	Concurrent use of BUTALBITAL and ETHANOL may result in excessive CNS depression.		
CALAMUS	ETHANOL	1	2
	Concurrent use of CALAMUS and ETHANOL may result in increased sedation.		
CANNABIS	ETHANOL	1	2
	Concurrent use of CANNABIS and ETHANOL may result in increased intoxication.		
CARVEDILOL, PHOSPHATE	ETHANOL	1	2
	Concurrent use of CARVEDILOL, PHOSPHATE and ETHANOL may result in faster than normal rate of release of carvedilol phosphate.		

Product	Interaction	Onset	Severity
CEFAMANDOLE	ETHANOL	2	1
	Concurrent use of CEFAMANDOLE and ETHANOL may result in disulfiram-like reactions.		
CEFMENOXINE	ETHANOL	1	1
	Concurrent use of CEFMENOXINE and ETHANOL may result in disulfiram-like reactions.		
CEFOPERAZONE	ETHANOL	2	1
	Concurrent use of CEFOPERAZONE and ETHANOL may result in disulfiram-like reactions.		
CEFOTETAN	ETHANOL	2	1
	Concurrent use of CEFOTETAN and ETHANOL may result in disulfiram-like reactions.		
CHAPARRAL	ETHANOL	1	2
	Concurrent use of CHAPARRAL and ETHANOL may result in elevated liver transaminases with or without concomitant hepatic damage.		
CHLORAL HYDRATE	ETHANOL	1	3
	Concurrent use of CHLORAL HYDRATE and ETHANOL may result in increased sedation.		
CHLORDIAZEPOXIDE	ETHANOL	1	2
	Concurrent use of CHLORDIAZEPOXIDE and ETHANOL may result in increased sedation.		
CHLORPROMAZINE	ETHANOL	1	2
	Concurrent use of CHLORPROMAZINE and ETHANOL may result in increased sedation.		
CHLORPROPAMIDE	ETHANOL	1	1
	Concurrent use of CHLORPROPAMIDE and ETHANOL may result in disulfiram-like reactions.		
CIMETIDINE	ETHANOL	1	3
	Concurrent use of CIMETIDINE and ETHANOL may result in increased ethanol concentrations.		
CISAPRIDE	ETHANOL	1	2
	Concurrent use of CISAPRIDE and ETHANOL may result in increased blood levels of ethanol.		
CITALOPRAM	ETHANOL	0	2
	Concurrent use of CITALOPRAM and ETHANOL may result in potentiation of the cognitive and motor effects of alcohol.		
CLOMIPRAMINE	ETHANOL	1	2
	Concurrent use of CLOMIPRAMINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.		
CLORAZEPATE	ETHANOL	1	2
	Concurrent use of CLORAZEPATE and ETHANOL may result in increased sedation.		
COCAINE	ETHANOL	1	2
	Concurrent use of COCAINE and ETHANOL may result in increased heart rate and blood pressure.		
CODEINE	ETHANOL	1	2
	Concurrent use of CODEINE and ETHANOL may result in increased sedation.		
COMFREY	ETHANOL	1	1
	Concurrent use of COMFREY and ETHANOL may result in elevated inner transaminases with or without concomitant hepatic damage.		
CYCLOSERINE	ETHANOL	1	1
	Concurrent use of CYCLOSERINE and ETHANOL may result in an increased risk of seizures.		

Product	Interaction	Onset	Severity
DESIPRAMINE	ETHANOL	1	2
	Concurrent use of DESIPRAMINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.		
DIAZEPAM	ETHANOL	1	2
	Concurrent use of DIAZEPAM and ETHANOL may result in increased sedation.		
DIMETHINDENE	ETHANOL	1	2
	Concurrent use of DIMETHINDENE and ETHANOL may result in increased sedation.		
DIPHENHYDRAMINE	ETHANOL	1	2
	Concurrent use of DIPHENHYDRAMINE and ETHANOL may result in increased sedation.		
DISULFIRAM	ETHANOL	1	1
	Concurrent use of DISULFIRAM and ETHANOL may result in ethanol intolerance.		
DOTHIEPIN	ETHANOL	1	2
	Concurrent use of ETHANOL and DOTHIEPIN may result in enhanced drowsiness and impairment of motor skills.		
DOXEPIN	ETHANOL	1	2
	Concurrent use of DOXEPIN and ETHANOL may result in enhanced drowsiness and impairment of motor skills.		
ESCITALOPRAM	ETHANOL	0	2
	Concurrent use of ESCITALOPRAM and ETHANOL may result in potentiation of the cognitive and motor effects of alcohol.		
ESZOPICLONE	ETHANOL	1	2
	Concurrent use of ESZOPICLONE and ETHANOL may result in impaired psychomotor functions and risk of increased sedation.		
ETEROBARB	ETHANOL	1	2
	Concurrent use of ETEROBARB and ETHANOL may result in excessive CNS depression.		
ETHOPROPAZINE	ETHANOL	1	2
	Concurrent use of ETHOPROPAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
FLUNITRAZEPAM	ETHANOL	1	2
	Concurrent use of FLUNITRAZEPAM and ETHANOL may result in excessive sedation and psychomotor impairment.		
FLUPHENAZINE	ETHANOL	1	2
	Concurrent use of FLUPHENAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
FOMEPIZOLE	ETHANOL	2	2
	Concurrent use of FOMEPIZOLE and ETHANOL may result in the reduced elimination of both drugs.		
FOSPHENYTOIN	ETHANOL	1	2
	Concurrent use of FOSPHENYTOIN and ETHANOL may result in decreased phenytoin serum concentrations, increased seizure potential, and additive CNS depressant effects.		
FURAZOLIDONE	ETHANOL	1	1
	Concurrent use of FURAZOLIDONE and ETHANOL may result in disulfiram-like reactions.		
GERMANDER	ETHANOL	2	1
	Concurrent use of GERMANDER and ETHANOL may result in elevated liver transaminases with or without concomitant hepatic damage.		
GLIPIZIDE	ETHANOL	1	1
	Concurrent use of GLIPIZIDE and ETHANOL may result in prolonged hypoglycemia and disulfiram-like reactions.		

Product	Interaction	Onset	Severity
GLICLAZIDE	ETHANOL	1	1
	Concurrent use of ETHANOL and GLICLAZIDE may result in prolonged hypoglycemia and disulfiram-like reactions.		
GLUTETHIMIDE	ETHANOL	1	2
	Concurrent use of GLUTETHIMIDE and ETHANOL may result in increased sedation.		
GLYBURIDE	ETHANOL	1	2
	Concurrent use of GLYBURIDE and ETHANOL may result in prolonged hypoglycemia and disulfiram-like reactions.		
GOSSYPOL	ETHANOL	1	2
	Concurrent use of GOSSYPOL and ETHANOL may result in delayed effects of gossypol and/or increased toxic effects of ethanol.		
GRISEOFULVIN	ETHANOL	1	1
	Concurrent use of GRISEOFULVIN and ETHANOL may result in disulfiram-like reactions.		
GUAR GUM	ETHANOL	2	2
	Concurrent use of GUAR GUM and ETHANOL may result in increased intoxication effects of ethanol.		
GUARANA	ETHANOL	1	3
	Concurrent use of GUARANA and ETHANOL may result in increased risk of ethanol intoxication.		
HYDROCODONE	ETHANOL	1	2
	Concurrent use of HYDROCODONE and ETHANOL may result in increased sedation.		
HYDROMORPHONE	ETHANOL	1	2
	Concurrent use of HYDROMORPHONE and ETHANOL may result in increased sedation.		
IMIPRAMINE	ETHANOL	1	2
	Concurrent use of IMIPRAMINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.		
INSULIN	ETHANOL	1	2
	Concurrent use of INSULIN and ETHANOL may result in increased hypoglycemia.		
INSULIN LISPRO, HUMAN	ETHANOL	1	2
	Concurrent use of INSULIN LISPRO, HUMAN and ETHANOL and may result in increased hypoglycemia.		
ISONIAZID	ETHANOL	2	1
	Concurrent use of ISONIAZID and ETHANOL may result in decreased isoniazid concentrations and disulfiram-like reactions.		
ISOTRETINOIN	ETHANOL	1	1
	Concurrent use of ISOTRETINOIN and ETHANOL may result in disulfiram-like reactions.		
KAVA	ETHANOL	1	2
	Concurrent use of KAVA and ETHANOL may result in increased CNS depression and/or increased risk of hepatotoxicity.		
KETOCONAZOLE	ETHANOL	1	1
	Concurrent use of KETOCONAZOLE and ETHANOL may result in disulfiram-like reactions (flushing, vomiting, increased respiratory rate, tachycardia).		
LOFEPRAMINE	ETHANOL	1	2
	Concurrent use of LOFEPRAMINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.		
LORAZEPAM	ETHANOL	1	2
	Concurrent use of LORAZEPAM and ETHANOL may result in increased sedation.		

Product	Interaction	Onset	Severity
MA HUANG	ETHANOL	1	1
	Concurrent use of MA HUANG and ETHANOL may result in effects on mental status.		
MATE	ETHANOL	1	3
	Concurrent use of MATE and ETHANOL may result in increased risk of ethanol intoxication.		
MEPERIDINE	ETHANOL	1	2
	Concurrent use of MEPERIDINE and ETHANOL may result in increased sedation.		
MEPHOBARBITAL	ETHANOL	1	2
	Concurrent use of MEPHOBARBITAL and ETHANOL may result in excessive CNS depression.		
MEPROBAMATE	ETHANOL	1	2
	Concurrent use of MEPROBAMATE and ETHANOL may result in increased sedation.		
MESORIDAZINE	ETHANOL	1	2
	Concurrent use of MESORIDAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
METFORMIN	ETHANOL	2	2
	Concurrent use of METFORMIN and ETHANOL may result in an increased risk of lactic acidosis.		
METHADONE	ETHANOL	1	2
	Concurrent use of METHADONE and ETHANOL may result in increased sedation.		
METHOHEXITAL	ETHANOL	1	2
	Concurrent use of METHOHEXITAL and ETHANOL may result in excessive CNS depression.		
METHOTREXATE	ETHANOL	2	2
	Concurrent use of METHOTREXATE and ETHANOL may result in increased hepatotoxicity.		
METHOTRIMEPRAZINE	ETHANOL	1	2
	Concurrent use of METHOTRIMEPRAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
METRONIDAZOLE	ETHANOL	1	1
	Concurrent use of METRONIDAZOLE and ETHANOL may result in disulfiram-like reactions (flushing, increased respiratory rate, tachycardia) or sudden death.		
MIRTAZAPINE	ETHANOL	1	2
	Concurrent use of MIRTAZAPINE and ETHANOL may result in psychomotor impairment.		
MORPHINE	ETHANOL	1	2
	Concurrent use of MORPHINE and ETHANOL may result in increased risk of respiratory depression, hypotension, profound sedation, or coma.		
MORPHINE SULFATE LIPOSOME	ETHANOL	1	1
	Concurrent use of MORPHINE SULFATE LIPOSOME and ETHANOL may result in increased risk of respiratory depression, hypotension, profound sedation, or coma.		
MOXALACTAM	ETHANOL	2	1
	Concurrent use of ETHANOL and MOXALACTAM may result in disulfiram-like reactions.		
NEFAZODONE	ETHANOL	1	3
	Concurrent use of NEFAZODONE and ETHANOL may result in an increased risk of CNS side effects.		

Product	Interaction	Onset	Severity
NIACIN	ETHANOL	0	2
	Concurrent use of NIACIN and ETHANOL may result in increased side effects of flushing and pruritus.		
NILUTAMIDE	ETHANOL	1	3
	Concurrent use of NILUTAMIDE and ETHANOL may result in an increased risk of ethanol intolerance (facial flushing, malaise, and hypotension).		
NITROGLYCERIN	ETHANOL	1	2
	Concurrent use of NITROGLYCERIN and ETHANOL may result in hypotension.		
NORTRIPTYLINE	ETHANOL	1	2
	Concurrent use of NORTRIPTYLINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.		
OLANZAPINE	ETHANOL	1	2
	Concurrent use of OLANZAPINE and ETHANOL may result in excessive CNS depression.		
OXYCODONE	ETHANOL	1	2
	Concurrent use of OXYCODONE and ETHANOL may result in increased sedation.		
OXYMORPHONE	ETHANOL	0	1
	Concurrent use of OXYMORPHONE and ETHANOL may result in increased oxymorphone plasma levels (extended-release formulation) and additive CNS/ respiratory depression.		
PARALDEHYDE	ETHANOL	2	2
	Concurrent use of PARALDEHYDE and ETHANOL may result in metabolic acidosis.		
PAROXETINE	ETHANOL	1	3
	Concurrent use of PAROXETINE and ETHANOL may increase the risk of mental and motor-skill impairment.		
PENNYROYAL	ETHANOL	1	1
	Concurrent use of PENNYROYAL and ETHANOL may result in elevated liver transaminases with or without concomitant hepatic damage.		
PENTAZOCINE	ETHANOL	1	2
	Concurrent use of PENTAZOCINE and ETHANOL may result in increased sedation.		
PERPHENAZINE	ETHANOL	1	2
	Concurrent use of PERPHENAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
PHENELZINE	ETHANOL	1	2
	Concurrent use of PHENELZINE and ETHANOL may result in hypertension urgency or emergency.		
PHENOBARBITAL	ETHANOL	1	2
	Concurrent use of PHENOBARBITAL and ETHANOL may result in excessive CNS depression.		
PHENYTOIN	ETHANOL	1	2
	Concurrent use of PHENYTOIN and ETHANOL may result in decreased phenytoin serum concentrations, increased seizure potential, and additive CNS depressant effects.		
PIPOTIAZINE	ETHANOL	1	2
	Concurrent use of PIPOTIAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
PRIMIDONE	ETHANOL	1	2
	Concurrent use of PRIMIDONE and ETHANOL may result in excessive CNS depression.		

Product	Interaction	Onset	Severity
PROCARBAZINE	ETHANOL	1	1
	Concurrent use of PROCARBAZINE and ETHANOL may result in disulfiram-like reactions and increased sedation.		
PROCHLORPERAZINE	ETHANOL	1	2
	Concurrent use of PROCHLORPERAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
PROMAZINE	ETHANOL	1	2
	Concurrent use of PROMAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
PROPIOMAZINE	ETHANOL	1	2
	Concurrent use of PROPIOMAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
PROTRIPTYLINE	ETHANOL	1	2
	Concurrent use of PROTRIPTYLINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.		
QUETIAPINE	ETHANOL	1	2
	Concurrent use of QUETIAPINE and ETHANOL may result in potentiation of the cognitive and motor effects of alcohol.		
SECOBARBITAL	ETHANOL	1	2
	Concurrent use of SECOBARBITAL and ETHANOL may result in excessive CNS depression.		
SERTRALINE	ETHANOL	1	2
	Concurrent use of SERTRALINE and ETHANOL may increase the risk of mental and motor-skill impairment.		
SULFAMETHOXAZOLE	ETHANOL	1	1
	Concurrent use of SULFAMETHOXAZOLE and ETHANOL may result in disulfiram-like reactions (flushing, sweating, palpitations, drowsiness).		
TACROLIMUS	ETHANOL	1	3
	Concurrent use of TACROLIMUS and ETHANOL may result in alcohol-related flushing and rash.		
TADALAFIL	ETHANOL	1	2
	Concurrent use of TADALAFIL and ETHANOL may result in an increased risk of hypotension and orthosiatic signs and symptoms.		
TEMAZEPAM	ETHANOL	1	2
	Concurrent use of TEMAZEPAM and ETHANOL may result in impaired psychomotor functions.		
THIETHYLPERAZINE	ETHANOL	1	2
	Concurrent use of THIETHYLPERAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
THIEOPENTAL	ETHANOL	1	2
	Concurrent use of THIEOPENTAL and ETHANOL may result in excessive CNS depression.		
THIORIDAZINE	ETHANOL	1	2
	Concurrent use of THIORIDAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.		
TIZANIDINE	ETHANOL	1	2
	Concurrent use of TIZANIDINE and ETHANOL may increase the risk of tizanidine adverse effects (excessive CNS depression).		
TOLAZAMIDE	ETHANOL	1	1
	Concurrent use of TOLAZAMIDE and ETHANOL may result in prolonged hypoglycemia and disulfiram-like reactions.		

Product	Interaction		Onset	Severity
TOLAZOLINE	ETHANOL		2	1
	Concurrent use of TOLAZOLINE and ETHANOL may result in disulfiram-like reactions.			
TOLBUTAMIDE	ETHANOL		1	1
	Concurrent use of TOLBUTAMIDE and ETHANOL may result in prolonged hypoglycemia and disulfiram-like reactions.			
TRAMADOL	ETHANOL		1	2
	Concurrent use of TRAMADOL and ETHANOL may increase the risk of excessive CNS depression.			
TRANYLCYPROMINE	ETHANOL		1	2
	Concurrent use of TRANYLCYPROMINE and ETHANOL may result in hypertensive urgency or emergency.			
TRIAZOLAM	ETHANOL		1	2
	Concurrent use of TRIAZOLAM and ETHANOL may result in increased sedation.			
TRIFLUPERAZINE	ETHANOL		1	2
	Concurrent use of TRIFLUPERAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.			
TRIFLUPROMAZINE	ETHANOL		1	2
	Concurrent use of TRIFLUPROMAZINE and ETHANOL may result in increased CNS depression and an increased risk of extrapyramidal reactions.			
TRIMETHOPRIM	ETHANOL		1	1
	Concurrent use of ETHANOL and COTRIMOXAZOLE may result in disulfiram-like reactions.			
TRIMIPRAMINE	ETHANOL		1	2
	Concurrent use of TRIMIPRAMINE and ETHANOL may result in enhanced drowsiness and impairment of motor skills.			
VALERIAN	ETHANOL		1	2
	Concurrent use of VALERIAN and ETHANOL may result in increased sedation.			
VENLAFAXINE	ETHANOL		1	3
	Concurrent use of VENLAFAXINE and ETHANOL may result in an increased risk of CNS effects.			
VERAPAMIL	ETHANOL		1	2
	Concurrent use of VERAPAMIL and ETHANOL may result in enhanced ethanol intoxication (impaired psychomotor functioning).			
WARFARIN	ETHANOL		2	2
	Concurrent use of WARFARIN and ETHANOL may result in increased or decreased international normalized ratio (INR) or prothrombin time.			
YOHIMBINE	ETHANOL		1	2
	Concurrent use of YOHIMBINE and ETHANOL may result in increased ethanol intoxication and increased anxiety and blood pressure.			
ZALEPLON	ETHANOL		1	2
	Concurrent use of ZALEPLON and ETHANOL may result in impaired psychomotor functions.			
ZOLPIDEM	ETHANOL		1	2
	Concurrent use of ZOLPIDEM and ETHANOL may result in increased sedation.			

ONSET: 0 = Unspecified
      1 = Rapid (within 24 hours)
      2 = Delayed (after 24 hours)
SEVERITY: 1 = Major (possibly life threatening or potential permanent damage)
          2 = Moderate (may exacerbate patient's condition)
          3 = Minor (little if any clinical effect)
Note: Disulfiram-like reactions include nausea, vomiting, diarrhea, flushing, tachycardia, and hypotension. Reprinted with permission from *The Drug Topics Red Book*. Montvale, NJ: Thomson Medical Economics, 2007.

DRUG/TOBACCO INTERACTIONS

Product	Interaction	Onset	Severity
ALPRAZOLAM	TOBACCO	0	2
	Concurrent use of ALPRAZOLAM and TOBACCO may result in decreased alprazolam plasma concentrations and efficacy.		
CONTRACEPTIVES, COMBINATION	TOBACCO	2	3
	Concurrent use of CONTRACEPTIVES, COMBINATION and TOBACCO may result in an increased risk of cardiovascular disease.		
ERLOTINIB	TOBACCO	0	2
	Concurrent use of ERLOTINIB and TOBACCO may result in increased erlotinib clearance and reduced serum concentrations.		
FLUVOXAMINE	TOBACCO	2	3
	Concurrent use of FLUVOXAMINE and TOBACCO may result in increased fluvoxamine metabolism.		
IMIPRAMINE	TOBACCO	2	2
	Concurrent use of IMIPRAMINE and TOBACCO may result in decreased imipramine concentrations.		
PENTAZOCINE	TOBACCO	2	2
	Concurrent use of PENTAZOCINE and TOBACCO may result in decreased pentazocine concentrations.		
PROPOXYPHENE	TOBACCO	2	2
	Concurrent use of PROPOXYPHENE and TOBACCO may result in decreased propoxyphene concentrations.		
ROPINIROLE	TOBACCO	0	2
	Concurrent use of ROPINIROLE and TOBACCO may result in decreased ropinirole plasma concentrations and efficacy.		
THEOPHYLLINE	TOBACCO	2	2
	Concurrent use of THEOPHYLLINE and TOBACCO may result in decreased theophylline concentrations.		
TOLBUTAMIDE	TOBACCO	2	2
	Concurrent use of TOLBUTAMIDE and TOBACCO may result in decreased tolbutamide concentrations.		
WARFARIN	TOBACCO	2	2
	Concurrent use of WARFARIN and TOBACCO may result in increased or decreased international normalized ratio (INR) or prothrombin time.		

ONSET: 0 = Unspecified
       1 = Rapid (within 24 hours)
       2 = Delayed (after 24 hours)
SEVERITY: 1 = Major (possibly life threatening or potential permanent damage)
         2 = Moderate (may exacerbate patient's condition)
         3 = Minor (little if any clinical effect)

USE-IN-PREGNANCY RATINGS

The U.S. Food and Drug Administration's Use-in-Pregnancy rating system weighs the degree to which available information has ruled out risk to the fetus against the drug's potential benefit to the patient. Below is a listing of drugs (by generic name) for which ratings are available.

X

CONTRAINDICATED IN PREGNANCY

Studies in animals or humans, or investigational or post-marketing reports, have demonstrated fatal risk which clearly outweighs any possible benefit to the patient.

Acetohydroxamic Acid
Acitretin
Amlodipine Besylate/Atorvastatin
    Calcium
Amprenavir
Anisindione
Atorvastatin Calcium
Bexarotene
Bicalutamide
Bosentan
Cetrorelix Acetate
Choriogonadotropin Alfa
Chorionic Gonadotropin
Clomiphene Citrate
Desogestrel/Ethinyl Estradiol
Diclofenac Sodium/Misoprostol
Dihydroergotamine Mesylate
Dutasteride
Estazolam
Estradiol
Estradiol Acetate
Estradiol Cypionate/
    Medroxyprogesterone Acetate
Estradiol Valerate
Estradiol/Levonorgestrel
Estradiol/Norethindrone Acetate
Estrogens, Conjugated
Estrogens, Conjugated, Synthetic A
Estrogens, Conjugated/
    Medroxyprogesterone Acetate
Estrogens, Esterified
Estrogens, Esterified/
    Methyltestosterone
Estropipate
Ethinyl Estradiol/Drospirenone
Ethinyl Estradiol/Ethynodiol
    Diacetate

Ethinyl Estradiol/Etonogestrel
Ethinyl Estradiol/Ferrous Fumarate/
    Norethindrone Acetate
Ethinyl Estradiol/Levonorgestrel
Ethinyl Estradiol/Norelgestromin
Ethinyl Estradiol/Norethindrone
Ethinyl Estradiol/Norethindrone
    Acetate
Ethinyl Estradiol/Norgestimate
Ethinyl Estradiol/Norgestrel
Ezelimibe/Simvastatin
Finasteride
Fluorouracil
Fluoxymesterone
Flurazepam Hydrochloride
Fluvastatin Sodium
Follitropin Alfa
Follitropin Beta
Ganirelix Acetate
Goserelin Acetate
Histrelin Acetate
Hydromorphone Hydrochloride
Interferon Alfa-2B, Recombinant/
    Ribavirin
Iodine 1 131 Tositumomab/
    Tositumomab
Isotretinoin
Leflunomide
Leuprolide Acetate
Levonorgestrel
Lovastatin
Lovastatin/Niacin
Medroxyprogesterone Acetate
Megestrol Acetate
Menotropins
Mequinol/Tretinoin
Mestranol/Norethindrone
Methotrexate Sodium
Methyltestosterone
Miglustat
Misoprostol
Nafarelin Acetate
Norethindrone
Norethindrone Acetate
Norgestrel
Oxandrolone
Oxymetholone

Pilcamycin
Pravastatin Sodium
Pravastatin Sodium/Aspirin Buffered
Raloxifene Hydrochloride
Ribavirin
Rosuvastatin Calcium
Simvastatin
Tazarotene
Testosterone
Testosterone Enanthate
Thalidomide
Tositumomab
Triptorelin Pamoate
Urofollitropin
Warfarin Sodium

D

POSITIVE EVIDENCE OF RISK

Investigational or postmarketing data show risk to the fetus. Nevertheless, potential benefits may outweigh the potential risk.

Alitretinoin
Alprazolam
Altretamine
Amiodarone Hydrochloride
Amiodipine Besylate/Benazepril
    Hydrochloride
Anastrozole
Arsenic Trioxide
Aspirin Buffered/Pravastatin Sodium
Aspirin/Dipyridamole
Atenolol
Azathioprine
Azathioprine Sodium
Benazepril Hydrochloride*
Benazepril Hydrochloride/
    Hydrochlorothiazide*
Bortezomib
Busulfan
Candesartan Cilexetil*
Candesartan Cilexetil/
    Hydrochlorothiazide*

---

*Category C or D depending on the trimester the drug is given.

Capecitabine
Captopril*
Carbamazepine
Carboplatin
Carmustine (Bcnu)
Chlorambucil
Cladribine
Clofarabine
Clonazepam
Cytarabine Liposome
Dactinomycin
Daunorubicin Citrate Liposome
Daunorubicin Hydrochloride
Demeclocycline Hydrochloride
Diazepam
Divalproex Sodium
Docetaxel
Doxorubicin Hydrochloride
Doxorubicin Hydrochloride
    Liposome
Doxycycline Calcium
Doxycycline Hyclate
Doxycycline Monohydrate
Efavirenz
Enalapril Maleate*
Enalapril Maleate/
    Hydrochlorothiazide*
Epirubicin Hydrochloride
Eprosartan Mesylate
Eriotinib
Exemestane
Felodipine/Enalapril Maleate
Floxuridine
Fludarabine Phosphate
Flutamide
Fosinopril Sodium*
Fosinopril Sodium/
    Hydrochlorothiazide*
Fosphenytoin Sodium
Fulvestrant
Gefitinib
Gemcitabine Hydrochloride
Gemtuzumab Ozogamicin
Goserelin Acetate
Ibritumomab Tiuxetan
Idarubicin Hydrochloride
Ifosfamide
Imatinib Mesylate
Irbesartan*
Irbesartan/Hydrochlorothiazide*
Irinotecan Hydrochloride
Letrozole

Lisinopril*
Lisinopril/Hydrochlorothiazide*
Lithium Carbonate
Losartan Potassium*
Losartan Potassium/
    Hydrochlorothiazide*
Mechlorethamine Hydrochloride
Melphalan
Melphalan Hydrochloride
Mephobarbital
Mercaptopurine
Methimazole
Midazolam Hydrochloride
Minocycline Hydrochloride
Mitoxantrone Hydrochloride
Moexipril Hydrochloride*
Moexipril Hydrochloride/
    Hydrochlorothiazide*
Nelarabine
Neomycin Sulfate/Polymyxin
    B Sulfate
Nicotine
Olmesartan Medoxomil
Oxaliplatin
Pamidronate Disodium
Pemetrexed
Penicillamine
Pentobarbital Sodium
Pentostatin
Perindropil Erbumine*
Phenytoin
Procarbazine Hydrochloride
Quinapril Hydrochloride*
Quinapril Hydrochloride/
    Hydrochlorothiazide*
Ramipril*
Sorafenib
Streptomycin Sulfate
Sunitinib
Tamoxifen Citrate
Telmisartan
Telmisartan/Hydrochlorothiazide
Temozolomide
Thioguanine
Tigecycline
Tobramycin
Topotecan Hydrochloride
Toremifene Citrate
Trandolapril*
Trandolapril/Verapamil
    Hydrochloride*
Tretinoin

Valproate Sodium
Valproic Acid
Valsartan*
Valsarlan/Hydrochlorothiazide*
Vinorelbine Tartrate
Voriconazole
Zoledronic Acid

C
RISK CANNOT BE RULED OUT

Human studies are lacking, and animal studies are either positive for risk or are lacking as well. However, potential benefits may outweigh the potential risk.

Abacavir Sulfate
Abacavir Sulfate/Lamivudine
Abacavir Sulfate/Lamivudine/
    Zidovudine
Abciximab
Acamprosate Calcium
Acetaminophen
Acetaminophen/Butalbital/Caffeine
Acetaminophen/Caffeine/
    Chlorpheniramine Maleate/
    Hydrocodone Bitartrate/
    Phenylephrine Hydrochloride
Acetazolamide
Acetazolamide Sodium
Acyclovir
Adapalene
Adefovir Dipivoxil
Adenosine
Alatroflaxacin Mesylate
Albendazole
Albumin (Human)
Albuterol
Albuterol Sulfate
Albuterol Sulfate/Ipratropium
    Bromide
Alclometasone Dipropionate
Aldesleukin
Alemtuzumab
Alendronate Sodium
Alendronate Sodium/Cholecalciferol
Altopurinol Sodium
Almotriptan Malate
Alpha1-Proteinase Inhibitor (Human)
Alprostadil

(Continued on next page)

---

*Category C or D depending on the trimester the drug is given.

Alteplase
Amantadine Hydrochloride
Amifostine
Aminocaproic Acid
Aminohippurate Sodium
Aminolevulinic Acid Hydrochloride
Aminosalicylic Acid
Amlodipine Besylate
Amlodipine Besylate/Benazepril
    Hydrochloride
Amoxicillin/Clarithromycin/
    Lansoprazole
Amphetamine Aspartate/
    Amphetamine Sulfate/
    Dextroamphetamine Saccharate/

LOW POTASSIUM DIET

Lexi-Drugs Online

Potassium is a mineral found in most all foods except sugar and lard. It plays a role in maintaining normal muscle activity and helps to keep body fluids in balance. Too much potassium in the blood can lead to changes in heartbeat and can lead to muscle weakness. The kidneys normally help to keep blood potassium controlled, but in kidney disease or when certain drugs are taken, dietary potassium must be limited to maintain a normal level of potassium in the blood. The following guideline includes 2–3 g of potassium per day.

Milk Group: Limit to one cup serving of milk or milk product (yogurt, cottage cheese, ice cream, pudding).

Fruit Group: Limit to two servings daily from the low potassium choices. Watch serving sizes. Avoid the high potassium choices.

Low Potassium

Apple, 1 small
Apple juice, applesauce ½ cup
Apricot, 1 medium or ½ cup canned in syrup
Blueberries, ½ cup
Cherries, canned in syrup ⅓ cup
Cranberries, cranberry juice ½ cup
Fruit cocktail, canned in syrup ½ cup
Grapes, 10 fresh
Lemon, lime 1 fresh
Mandarin orange, canned in syrup ½ cup

Nectar: apricot, pear, peach ½ cup
Peach, 1 small or ½ cup canned with syrup
Pear, 1 small or ½ cup canned with syrup
Pineapple, ½ cup raw or canned with syrup
Plums, 1 small or ½ cup canned with syrup
Tangerine, 1 small
Watermelon, ½ cup

High Potassium

Avocado
Banana
Cantaloupe
Cherries, fresh
Dried fruits
Grapefruit, fresh and juice
Honeydew melon
Kiwi
Mango
Nectarine
Orange, fresh and juice
Papaya
Prunes, prune juice
Raisins

Avoid use of the following salt substitutes due to their high potassium contents: Adolph's, Lawry's Season Salt Substitute, No Salt, Morton Season Salt Free, Nu Salt, Papa Dash, and Morton Lite Salt.

TYRAMINE CONTENT OF FOODS

Food[1]	Allowed	Minimize Intake	Not Allowed
Beverages	Decaffeinated beverages (eg, coffee, tea, soda); milk, soy milk, chocolate beverage	Caffeine-containing drinks, clear spirits, wine, bottled/canned beers	**Tap** beer
Breads/cereals	All except those containing cheese	None	Cheese bread and crackers
Dairy products	Cottage cheese, farmers or pot cheese, cream cheese, ricotta cheese, all milk, eggs, ice cream, pudding, yogurt, sour cream, processed cheese, mozzarella	None	All other cheeses (**aged** cheese, American, Camembert, cheddar, Gouda, gruyere, parmesan, provolone, romano, Roquefort, stilton)
Meat, fish, and poultry	All fresh packaged or processed (eg, hot dogs, bologna), or frozen	Pepperoni	**Aged** chicken and beef liver, dried and pickled fish, shrimp paste, summer or dry sausage, dried meats (eg, salami, cacciatore), meat extracts, liverwurst
Starches— potatoes/rice	All	None	Soybean (including paste), tofu

Food[1]	Allowed	Minimize Intake	Not Allowed
Vegetables	All fresh, frozen, canned, or dried vegetable juices except those not allowed	Chili peppers, Chinese pea pods	Sauerkraut, broad or fava bean pods (not beans)
Fruit	Fresh, frozen, or canned fruits and fruit juices	Avocado, figs	Banana peel, avocado (over-ripened)
Soups	All soups not listed to limit or avoid	None	Soups which contain **aged** cheese, **tap** beer, any made with flavor cubes or meat extract, miso soup, broad or fava bean pods (not beans)
Fats	All except fermented	None	None
Sweets	Sugar, hard candy, honey, molasses, syrups, chocolate candy	None	None
Desserts	Cakes, cookies, gelatin, pastries, sherbets, sorbets, chocolate desserts	None	None
Miscellaneous	Salt, nuts, spices, herbs, flavorings, Worcestershire sauce, Brewer's or Baker's yeast, monosodium glutamate, vitamins with Brewer's yeast	Peanuts	Soy sauce, all aged and fermented products, marmite and other concentrated yeast extracts

[a]Costs are approximate and are based on 2007 figures. Costs vary depending upon selection of format site versus individual license fees, concurrent users, number of beds in facility, or number of students enrolled. Institutional subscriptions are more expensive than individual subscriptions. It is important to have the appropriate site license.

Index

Page numbers in italic type indicate items found in the supplemental online chapters and page numbers followed by an *f* or *t* denotes figures and tables respectively.
